Evaluation of the Mercury Biomagnification Potential in Quesnel and Polley Lakes

1.0 INTRODUCTION

On August 4, 2014, the failure of a glacial lacustrine layer beneath the Perimeter Embankment of the Tailings Storage Facility (TSF) at the Mount Polley Mine, British Columbia caused a breach of the embankment and resulted in the release of construction materials, water and tailings from the TSF to Polley Lake, Hazeltine Creek and Quesnel Lake. The BC Ministry of Environment (MoE) issued a Pollution Abatement Order (PAO) with the requirement to initiate monitoring with the end goal of producing a Post-Event Environmental Impact Assessment. The objective of the impact assessment was to provide an assessment of the physical, chemical, and biological impacts of the tailings spill on terrestrial and aquatic environments.

Mount Polley Mining Corporation (MPMC) immediately developed a Rehabilitation and Remediation Strategy (the "Strategy") framework to guide rehabilitation of terrestrial and aquatic environments (Figure 1). Following this framework, MPMC began work to stabilize and contain the tailings, initiated scientific studies to identify the impacts of the tailings spill on the terrestrial and aquatic environments, and began developing strategies to rehabilitate the terrestrial and aquatic environments impacted. The first edition of the Post-Event Environmental Impact Assessment Report (PEEIAR, MPMC 2015) focused on the findings from studies conducted during the first six to eight months following the tailings spill. Post-event monitoring continued and this edition of the PEEIAR provides an update to the initial findings, with a focus on the findings from the next ten months (from March to December 2015). This edition of the PEEIAR marks completion of Phase 2 of the Strategy; the information collected from both impact assessment reports will feed into the Detailed Site Investigation and Risk Assessment and development of Remediation Options. These reports will focus on identifying the significance of contaminants from the tailings spill to human health and ecological receptors. Uncertainties identified following these investigations will be taken into consideration in MPMC's Comprehensive Environmental Monitoring Plan (CEMP). The CEMP is required under *Environmental Management Act* Permit 11678 and an assessment of impacts will be provided in the Human Health and Ecological Risk Assessment (HHERA).

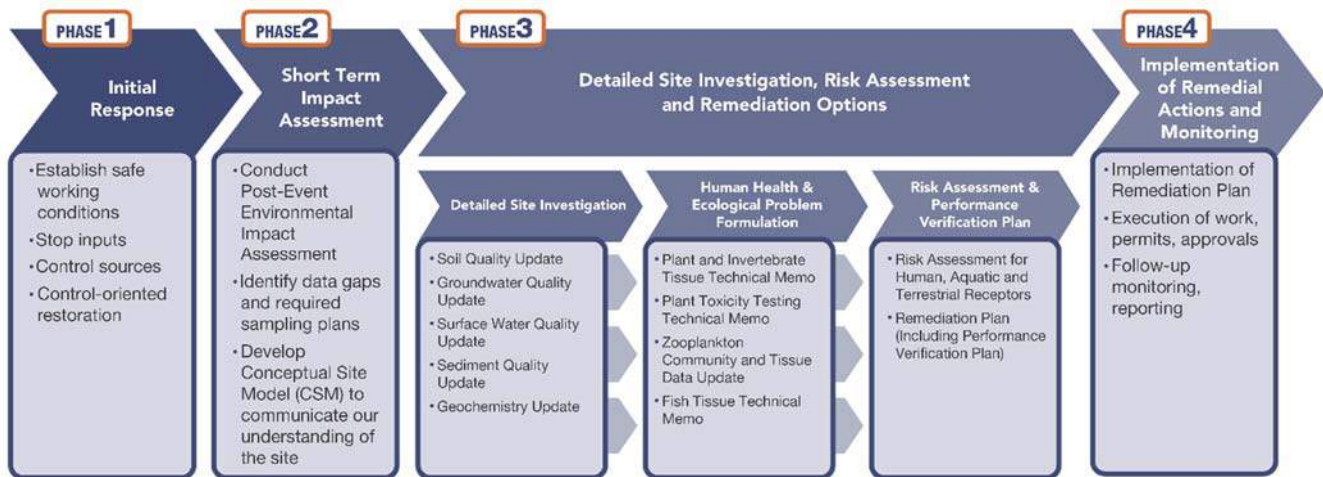

Figure 1: Rehabilitation and Remediation Strategy.

1.1 Organization of this Report

This PEEIAR is a compilation of the scientific studies that have been conducted follow the tailings spill, with particular focus on the findings from the time period between March and December 2015. A comprehensive reporting of the data collected between August 2014 and March 2015 is included in the first version of the PEEIAR (submitted to MoE in June, 2015). Readers are encouraged to review the contents of the June, 2015 report for more detail on the data collected in the first eight months following the spill.

The studies of this PEEIAR update are organized into Technical Appendices based on subject matter. Ahead of the Technical Appendices a summary of findings, by rehabilitation area, is provided (Section 3.0). The rehabilitation areas are shown on Figure 2, below. The information provided in the summary of findings is considered a high level synopsis of the significant findings from the many scientific studies conducted in response to the tailings spill. Readers are encouraged to review the Technical Appendices for detailed methods, results, figures, tables, discussion, conclusions, and references.

In this report, the term parameter of interest (POI) is used to be consistent with terminology commonly used in Environmental Assessments. The terminology, contaminant of potential concern (COPC) is used in work conducted under the CSR. For the purposes of this report, these terms are used interchangeably.

The Technical Appendices include the following scientific studies:

2.0 BACKGROUND

As described in the PEEIAR (MPMC 2015), the tailings spill resulted in a complex debris flow extending down Hazeltine Creek to Quesnel Lake, a distance of 9.4 km. The estimated amount of material (water, tailings, and construction materials) released was approximately 25 Mm³. The majority of the material released was water. The release occurred as a sequence of surges, initially as debris flow scouring out native soil and vegetation, followed by debris floods depositing tailings fines in the floodplain and the surrounding forest.

The tailings spill resulted in a thick (~2-3 m) deposit of tailings in the area referred to as the Polley Plug. The debris flow eroded Upper Hazeltine Creek resulting in a wider and deeper channel, which in turn created over steepened, unstable slopes adjacent to the Hazeltine Creek channel. Within the Hazeltine Creek Canyon, the channel was eroded down to bedrock with subsequent deposits of only thin, isolated layers of tailings. Within Lower Hazeltine Creek, the floodplain was eroded, and tailings and native material (mixed tailings) were deposited. The lower reach of Edney Creek was affected by scour and deposition from the debris flow. At the confluence of these two creeks, the Edney Creek channel was scoured resulting in a drop of approximately 2 metres in elevation providing a barrier to the free movement of fish from Quesnel Lake to Edney Creek.

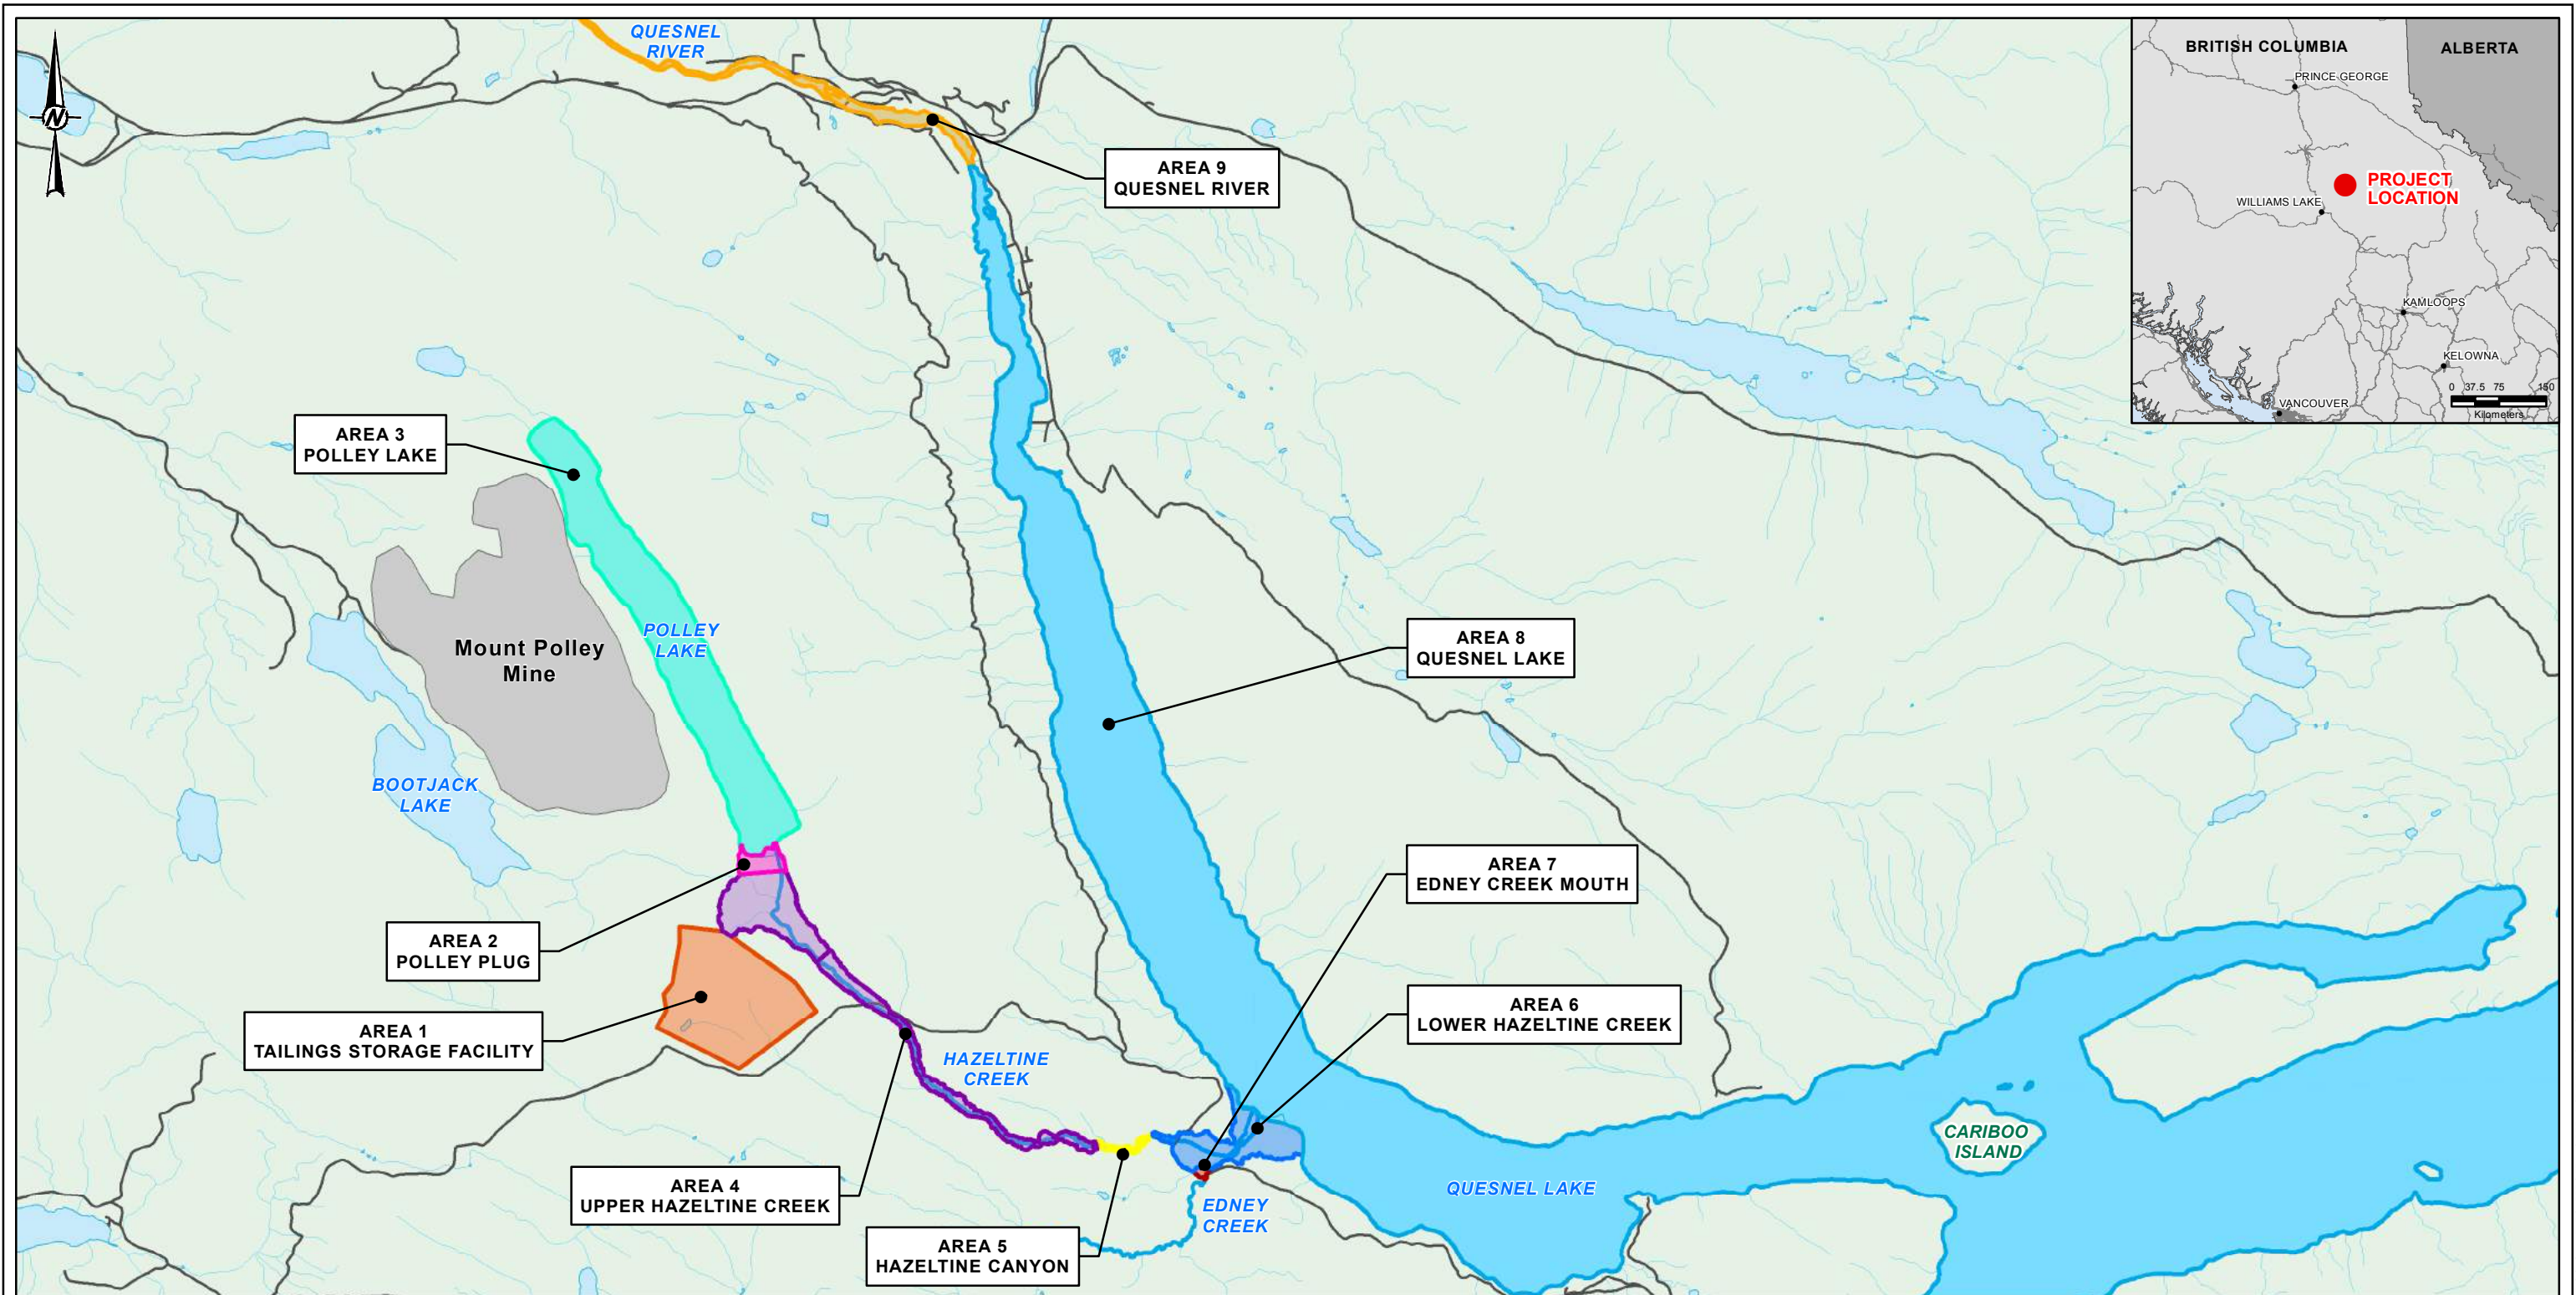

The results of chemistry studies found that the tailings and tailings-eroded native material mixture were low in organic carbon and nutrients and had concentrations of copper and, to a lesser extent, vanadium that exceeded the provincial contaminated site regulation (CSR) standards protective of soil invertebrates and plants. The geochemistry results found that the tailings were not acid-generating and had low leaching potential.

The results of monitoring the biological impacts found that the terrestrial and aquatic communities along Hazeltine Creek were lost immediately following the tailings spill. The sediment-dwelling communities in Polley Lake and in a portion of the West Basin of Quesnel Lake were covered. These effects on the local biological communities were physical and immediate. Toxicology studies using representative aquatic biota and water from Quesnel and Polley Lakes found that the more turbid samples caused an effect on one of the zooplankton test species, but that evidence did not indicate a clear metal-related toxic effect. The 2015 studies of potential toxicity to aquatic organisms from chemical exposure from spill-related related sediments deposited in Quesnel Lake were inconclusive due to the low total organic carbon (TOC) content and/or particle size differences of the tailings soil mixture compared to reference sediment. The PEEIAR assessment of biological effects to terrestrial biota, including the terrestrial riparian forest community, was limited to analysis of soil contaminants and nutrient concentrations, and mapping of areas affected by the tailings. Later studies conducted as part of the risk assessment problem formulation found that there were physical impacts to the terrestrial ecosystem where the tailings deposited on the existing forest floor (referred to as the 'halo') blocked air exchange and led to the loss of standing trees in the 'halo' area along Hazeltine Creek. However, there was no evidence for a metal-related toxic effect on the impacted trees.

3.0 SUMMARY OF FINDINGS BY AREA

To assist in design and implementation of the Rehabilitation and Remediation Strategy, nine areas potentially affected by the tailings spill were identified (Figure 2). This was done because the different areas of impact have different characteristics, different potential for impact and different study needs. The first edition of the PEEIAR found that conditions along the length of Hazeltine Creek were similar, thus Areas 4 through 7 are treated as a single area. Area 1, the TSF, was excluded as this area is part of the operating mine.

3.1 Polley Lake (and Plug)

3.1.1 Physical

Polley Lake is a long (6.17 km), narrow (0.65 km) lake situated adjacent to the Mount Polley Mine within a watershed area of 17.1 km². The estimated hydraulic residence time of the lake is approximately 16.2 years (MPMC 2015 Appendix F). Polley Lake had a mean depth of 18 m and maximum depths of 35 m in the south basin and 33 m in the north basin. The main inflow to the lake is from the Frypan Lake sub-watershed situated to the northwest. Polley Lake is a dimictic lake that mixes from the surface to the lake bottom twice each year. Thermal stratification occurs in summer; a thermocline typically forms at a depth between 5 and 15 m (Minnow 2014). Hypoxic conditions (low oxygen) generally occur at depths greater than 20 m, with dissolved oxygen (DO) concentrations less than 5 mg/L (Minnow 2014). Trophic status of the lake changed from oligotrophic/mesotrophic prior to mine development (1995/1996) to mesotrophic/eutrophic in 2012 (Minnow 2014).

Water and tailings released during the spill were deposited directly into Polley Lake. The sediment investigation indicated that tailings were heterogeneously deposited throughout Polley Lake (MPMC 2015 Appendix E). A thick deposit of tailings and other debris (known as the Plug), blocked water from flowing out of Polley Lake and into Hazeltine Creek. In addition, the wetland area that existed before the tailings spill at the outlet of Polley Lake, was inundated with tailings that have remained saturated due to the high water table associated with the lake. Reconstruction of the Hazeltine Creek channel has restored the connection to Polley Lake, and a weir installed just downstream of the lake outlet controls the volume of water flowing out of Polley Lake.

Immediately following the event, the water level in Polley Lake increased by approximately 1.7 m and turbidity was increased in the deeper waters of the lake (below the thermocline). In mid-October 2014, lake turnover occurred causing mixing of shallow and deep water in the lake; during that period turbidity and DO were uniform throughout the water column. In mid-November 2014, turbidity and DO concentrations in the lake returned to pre-event conditions and have remained consistent since (Appendix D).

3.1.2 Chemical

3.1.2.1 Surface Water Quality Update

Water quality data collected from Polley Lake by MPMC has been evaluated to assess temporal trends of POIs since the tailings spill through December 2015 (Appendix D). The water quality assessment was based on comparison of water chemistry to BC water quality guidelines (WQG), reference data, and baseline data. Immediately following the tailings spill, concentrations of copper and molybdenum were measured at concentrations greater than the BC WQGs for protection of aquatic life (MPMC 2015 Appendix F). Concentrations of those POIs in Polley Lake have been below BC WQGs throughout 2015. With respect to nutrients, total phosphorus concentrations were somewhat elevated in deep water immediately following the event, but have been within the range observed in Polley Lake prior to the event since fall turnover in November 2014. Based on the evaluation of 2015 water quality data, no POIs in surface water remain above WQGs in Polley Lake.

Metals concentrations in Polley Lake surface water will continue to be monitored as part of MPMC's routine monitoring program.

3.1.2.1.1 Free Metals in Surface Water

Between August and October 2015, Minnow deployed diffusive gradients in thin films (DGT) passive sampling devices in the south basin of Polley Lake (near-field location) to measure the amount of free and weakly complexed metals in water near the sediment-water interface (Appendix D). Labile metals are the fraction of metals that are considered to be potentially bioavailable (i.e., that can be readily transported across biological membranes of aquatic organisms). The DGT device simulates the biological membrane of an aquatic organism. Calculated concentrations of free metals in water (based on accumulation by the DGT device) were compared to concentrations of total and dissolved metals in concurrent water samples, reference concentrations from Bootjack Lake, and BC WQGs.

In Polley Lake, copper and molybdenum were measured by the DGT devices at concentrations greater than in Bootjack Lake, but lower than the BC WQGs (Figure 3). It is acknowledged that the WQGs were not derived with DGT data, so the comparison was made for information purposes only. In comparison to total and dissolved (filtered) concentrations, the DGT-labile concentrations of copper in water near the bottom of Polley Lake were lower. The 'dissolved' concentrations are measured by filtering water through a 0.45 um filter. The DGT results suggest that the free and weakly complexed fraction of these metals is lower than indicated by the filtered water samples referred to as dissolved metals in routine analysis.

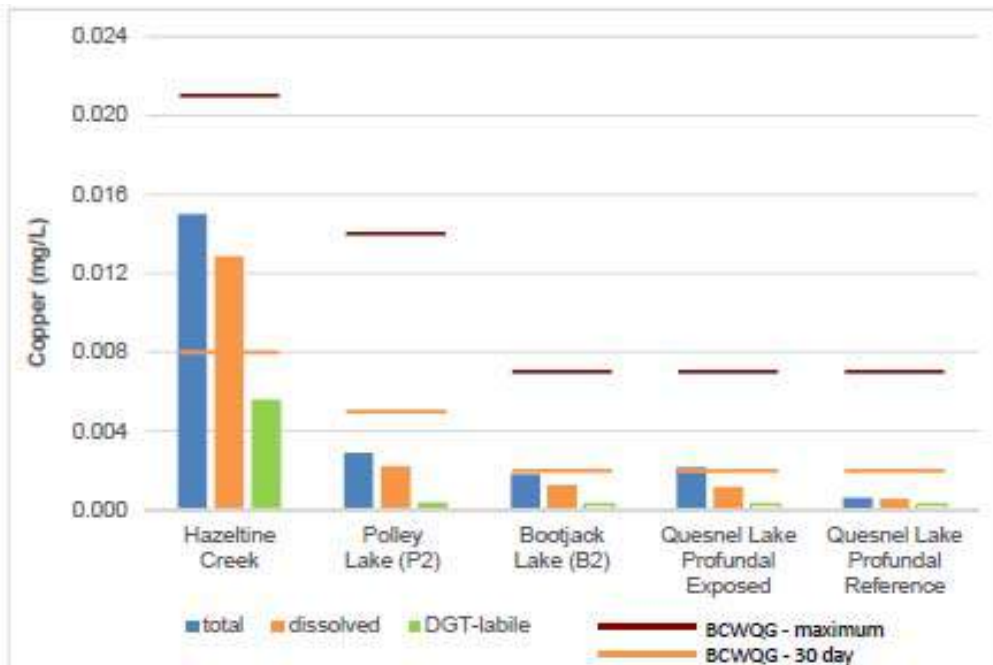

Figure 3: Total (T), Dissolved (D) and DGT-labile Concentrations of Copper in Water

Note: The open bars denote results that were less than detection limits.

3.1.2.2 *Sediment Quality Update*

Sediment quality data collected from Polley Lake by Minnow Environmental Inc. (Minnow) has been evaluated to assess changes in sediment chemistry since the tailings spill occurred (Appendix E, MPMC 2015 Appendix E). Unlike water quality, concentrations of metals in the tailings-influenced sediment are not expected to have changed substantially between sampling events in 2014 and 2015. A total of 21 sediment samples have been collected by Minnow in Polley Lake following the tailings spill. The sediment quality assessment was based on comparison of sediment chemistry to BC sediment quality guidelines (SQG), reference data and baseline data (i.e., data collected prior to the tailings spill). Baseline sediment data from Polley Lake indicated that concentrations of metals were naturally-elevated in the lake prior to the tailings spill (MPMC 2015 Appendix E).

In 2014, sediment was collected from deep and mid-depth locations throughout the lake. The 2014 chemistry data indicated that arsenic (at deep stations), copper (at mid-depth and deep stations) and iron (at mid-depth stations) were elevated in comparison to guidelines and reference/baseline concentrations. The deep station in the south basin of Polley Lake was considered to be representative of the worst case and sampled in 2015. The 2015 chemistry data indicated that arsenic and copper remained elevated in comparison to standards and reference/baseline concentrations (Appendix E). Iron was not elevated in comparison to reference/baseline at the deep station; however, the concentrations of iron at the deep station were similar between 2014 and 2015, thus the same could be assumed for the mid-depth stations where iron was elevated in 2014. Based on the evaluation of 2014 and 2015 sediment quality data, arsenic, copper and iron were identified as POIs in Polley Lake.

3.1.2.3 *Evaluation of Mercury Biomagnification Potential*

COPCs related to the tailings spill were identified for surface water (Appendix D, MPMC 2015 Appendix F), soil (Appendix B, MPMC 2015 Appendix D), and sediment (Appendix E, MPMC 2015 Appendix E). Although mercury was not identified as a COPC based on measured concentrations in these media, mercury has been identified as a stakeholder concern due to questions regarding possible methylation and subsequent biomagnification into the aquatic food web via a “reservoir effect” in Polley Lake that could potentially occur as a result of the TSF breach and the introduction of organic debris into the lakes.

The reservoir effect refers to a phenomenon of enhanced mercury mobilization sometimes observed in newly-formed reservoirs. Reservoir formation often involves flooding soils and vegetation, thus providing a new source of nutrients and organic material for bacteria that can methylate and de-methylate mercury in the flooded environment (Ullrich et al. 2001). Bacterial decomposition of this new organic material can increase the natural rate of formation of methylmercury. Methylmercury is a positively charged ion that readily binds to sulfur-based amino acids such as cysteine (Newman 2009).

Once attached to amino acids, methylmercury can be incorporated into proteins and transferred to higher trophic levels. Bacteria that methylate inorganic mercury are consumed by invertebrates, which are consumed by fish, leading to increased concentrations of methylmercury in fish tissues (CCME 2000). Stakeholder concern related to mercury is connected to the hypothesis that the deposited mixture of tailings and native organic material created conditions that promote the methylation of mercury, as occurs in a reservoir.

Golder reviewed the conditions that favour the methylation of mercury to assess whether these conditions could occur in Polley Lake and reviewed the existing monitoring data to examine if there is evidence of increased mercury concentrations as a result of the tailings spill.

3.1.2.3.1 Factors Influencing Methylation of Mercury

Azimuth (2010, 2012, and 2015) summarized environmental factors that influence mercury methylation. As outlined in Sections 4.3 to 4.5 of Azimuth (2012), key parameters that influence methylation potential are residence time, trophic status, temperature, DO, pH, dissolved organic carbon, total suspended solids, sulphate, sediment grain size, and total organic carbon in sediment. The correlation of these parameters with mercury methylation (i.e., positive or negative) is summarized in Table 3-1.

Table 3-1: Summary of Parameters and their Correlation with Mercury Methylation (Azimuth 2012) and Current (Post-event) Conditions of these Parameters in Polley Lake

Parameter	Correlation	Conditions that Favour Methylation	Polley Lake	Source for Polley Lake data
Residence time	Positive	Longer residence time	16.2 years, more likely	1
Trophic status	Positive	Highly productive systems	Moderate to high productivity; classified as mesotrophic/eutrophic, more likely	1
Water – Temperature	Positive	Warmer temperatures (weakly related)	Temperature < 10 °C at depths greater than 15 m, less likely	2
Water - Dissolved Oxygen	Negative	Low oxygen conditions	Concentrations < 5 mg/L at depths greater than 10 m, more likely	2
Water – pH	Negative	Slightly acidic waters (pH <6.5)	Median pH = 8.1, less likely	3
Water - dissolved organic carbon	Positive	Concentrations > 5 mg/L	Mean concentration = 6.2 mg/L, more likely	3
Water - total suspended solids	Positive	Higher concentrations (as transport media for mercury)	Below detection limit of 3 mg/L in most samples (n= 54); 4 samples had detected concentrations that ranged from 3.1 to 5.4 mg/L, less likely	3
Water - sulphate	Positive	Higher concentrations over environmentally relevant range (5-30 mg/L)	Mean concentration = 44.3 mg/L, more likely	3
Sediment - grain size	Negative	Fine grain sediment ⁵	Predominantly silt in the <63 µm fraction, more likely	4
Sediment - total organic carbon	Positive	Higher	Mean total organic carbon ≤ 7.7% in the <63 µm fraction, more likely	4

Abbreviations: < = less than; ≤ = less than or equal to; > = greater than; ~ = approximately; °C = degrees Celsius; m = metres; mg/L = milligrams per litre; µm = micrometres; % = percent.

² Depth profiles presented in MPMC (2015 Appendix H).

³ Appendix D. Values calculated using all Quesnel Lake samples or all Polley Lake samples collected in 2015.

⁴ Appendix E. Based on mean particle size or mean total organic carbon at exposed locations sampled in 2014 and 2015.

⁵ Condition that favours mercury methylation is described in Azimuth (2012).

In Polley Lake, some parameters indicate that mercury methylation would not be favoured (i.e., temperature, pH, and total suspended solids), whereas other parameters indicate that mercury methylation could be favoured (i.e., trophic status, DO, sulphate, and sediment characteristics). For the latter set of parameters, these conditions appear to be unrelated to the tailings spill because, with the exception of sulphate¹, pre-event and post-event conditions are comparable. Prior to the tailings spill, Polley Lake was classified as a mesotrophic/eutrophic lake with hypoxic conditions (i.e., dissolved oxygen concentrations less than 5 mg/L) generally occurring at depths greater than 20 metres (MPMC 2015 Appendix F). Pre-event sediment grain size (predominantly silt; MPMC 2015 Appendix E) and total organic carbon in sediment (mean in deep areas = 18.2%, mean in mid-depth areas = 8.4%; MPMC 2015 Appendix E) were also similar to conditions shown in Table 3-1. Overall, based on the key parameters identified in Sections 4.3 to 4.5 of Azimuth (2012) and the data presented in Table 3-1, the potential for the tailings spill to increase mercury methylation in Polley Lake is considered low.

3.1.2.3.2 Review of Existing Monitoring Data for Mercury

Water Chemistry

Water chemistry data collected between August 2014 and July 2015 are reported in Appendix D. During this time total aqueous mercury concentrations in Polley Lake samples have been below the reported detection limits of 50 ng/L (August 2014 samples), 10 ng/L (September 2014 samples), or 5 ng/L (2015 samples). Because mercury data are sparse and total aqueous mercury concentrations were below the reported detection limit in all samples, interpretation of aqueous mercury trends is limited.

In Appendix D, detection limits for samples with no detected mercury were compared to the BC water quality guideline (BC MoE 2001) of 10 ng/L, based on the assumption that the percent methylmercury in Polley Lake is 1%. Because the percent methylmercury in Polley Lake has not been measured, the aqueous mercury data cannot be directly compared to the BC water quality guideline. However, comparison to the CCME (2003) water quality guideline for inorganic mercury (26 ng/L) suggests that the potential for mercury effects is low. In water samples collected from September 2014 (i.e., detection limit of 10 ng/L) to July 2015 (i.e., a detection limit of 5 ng/L), aqueous mercury concentrations were lower than the CCME (2003) water quality guideline for inorganic mercury.

Although the above comparisons to the CCME (2003) water quality guidelines suggest that the potential for mercury effects is low, the CCME (2003) derivation document states that the water quality guidelines may not fully protect higher trophic level fish. Therefore, sediment, zooplankton tissue chemistry, and fish tissue chemistry data collected from Polley Lake were also reviewed to assess spatial and temporal trends in mercury concentrations.

Sediment Mercury Chemistry

Sediment chemistry data are reported in MPMC (2015 Appendix E) and Appendix E. Sampling in Polley Lake was conducted in 2014 at two depths: mid-depth (approximately 20 metres deep) and deep basins (approximately 29 meters deep). Sampling of both the mid-depth and deep basins were done in two areas, one located on the south side and the other on the north side of Polley Lake. Mercury concentrations were measured in the <2 mm

¹ Mean pre-event sulphate concentration was 20 mg/L (MPMC 2015 Appendix F).

fraction (deep basin samples) and the <63 µm fraction (mid-depth and deep basin samples). In 2015, sampling of the deep basin on the south side of Polley Lake was conducted and concentrations were measured for the <63 µm fraction. The deep basins had been historically sampled as a part of baseline studies for Mount Polley Mine and are summarized in MPMC (2015 Appendix E). Bootjack Lake served as a reference for Polley Lake.

In 2014 and 2015, sediment mercury concentrations in Polley Lake were lower than concentrations in Bootjack Lake (i.e., the reference lake), lower than the BC sediment quality guideline, and lower than the mean historic baseline concentration (pre-mine operation) in Polley Lake. With respect to temporal comparisons, mercury concentrations in sediment were similar in 2014 and 2015 (Appendix E).

Mercury in Zooplankton Tissue

Zooplankton tissue chemistry collected in 2015 from Polley Lake is reported in Appendix G. Tissue samples were collected in four months (May, July, August, and September) from two stations in Polley Lake; P1 (northern end of Polley Lake) and P2 (southern end of Polley Lake, closer to the outlet of Hazeltine Creek). No baseline or reference data were available for comparison.

Zooplankton mercury concentrations were similar between sampling stations (P1 and P2) in Polley Lake in 2015, with the exception of the September 2015 sampling event when P1 was higher than P2. August and September mercury tissue concentrations were higher at both stations compared to mercury concentrations in May and July. Tissue mercury concentrations in all Polley Lake samples were lower than or similar to those measured in the Quesnel Lake reference stations. Zooplankton was not sampled in 2015 in the Polley Lake reference site, Bootjack Lake.

The zooplankton data are considered preliminary at this time. Further assessment of zooplankton conditions is included in the CEMP.

Fish Tissue - Mercury

Fish tissue chemistry collected in 2014 and 2015 from Polley Lake is reported in Appendix G. Tissue chemistry comparisons were conducted spatially (i.e., exposure versus reference areas) and temporally (i.e., 2014 versus 2015 data) for site, species, and tissue type, where data were available.

In 2014 and 2015, mercury concentrations in all fish species collected from Polley Lake were either lower than or similar to concentrations in fish collected from reference locations. With respect to temporal comparisons, mercury concentrations in fish were similar in 2014 and 2015. These results are consistent with the lack of spatial and/or temporal trends observed in water chemistry, sediment chemistry, and zooplankton tissue chemistry.

This review of the available data suggests that increased mobilization of mercury in the aquatic food chain in Polley Lake as a result of the tailings spill is unlikely. There are uncertainties related to this evaluation, including that there may be additional key parameters currently unknown that influence mercury methylation. Also, the percent aqueous methylmercury in Polley Lake has not been measured but was assumed to be 1%. In order to reduce uncertainty regarding future conditions, monitoring mercury concentrations in fish tissue has been included in the CEMP. However, indications to date are that methylation and increased mobilization of mercury in Polley Lake is unlikely.

3.1.3 Biological

3.1.3.1 Sediment Toxicity

MPMC conducted a post-event toxicity testing program between August and October 2014 (MPMC 2015 Appendix E), in which surface sediment samples collected from Polley Lake were tested using a series of standard laboratory tests using sensitive invertebrate test species. The program provided an important evaluation of the bioavailability and toxicity of POIs as they are observed in site-specific samples, as well as changes to physical conditions of the sediment that may affect the capacity of sediment to support sediment dwelling organisms. The laboratory testing provided a direct measure of biological effect to individual organisms under site-relevant conditions.

The results of the 2014 post-event toxicity testing indicated no instances of significantly reduced survival or growth of either *Hyalella* or *Chironomus* test species in Polley Lake sediments relative to concurrent laboratory controls and reference samples from Bootjack Lake. One exception was a modest reduction in survival of *Chironomus dilutus* at the mid-depth area close to the south end of the lake. Further toxicity testing of Polley Lake sediment was not conducted in 2015.

3.1.3.2 Benthic Invertebrate Tissue Metal Analysis

Benthic invertebrate biomass and tissue metal analysis is provided in Appendix G. The approximate biomass of benthic invertebrates retrieved from the south basin of Polley Lake was much lower than the biomass collected from the corresponding reference area in Bootjack Lake (exposed area mean <0.17 g/m² wet weight; reference area mean >0.85 g/m² wet weight). Samples collected from Polley Lake and Bootjack Lake were composed mainly of chironomids (midge larvae) and oligochaetes.

Mean concentrations of copper, manganese, molybdenum, selenium, tin, and titanium in benthic invertebrates from Polley Lake were more variable and were significantly higher than those in the corresponding reference area (Table 3-2). Principal Components Analysis (PCA) supported these observations.

For all these metals, except selenium, concentrations were lower in benthic invertebrates compared to sediment concentrations in Polley Lake and Bootjack Lake, indicating accumulation factors of less than 1. For selenium, the concentrations in benthic invertebrates appeared to be about twice the concentration in sediment, indicating that the benthic invertebrates in Polley Lake may be accumulating selenium. The benthic invertebrates analyzed in this study were not depurated prior to analysis, so some of the metal content may be related to sediment in gut. MPMC are conducting further investigation into concentrations of selenium in biota in Polley Lake, as well as initiating further investigations into the fate and transport of selenium in Polley Lake and the significance of these measurements to benthic invertebrates and lake productivity.

Table 3-2: Summary whole benthic invertebrate and sediment chemistry results from lake sampling areas in Polley Lake, 2015

Parameter		Units	Polley Lake									
			Reference					Exposed				
			Bootjack Lake (BOL-B2)					Polley Lake (POL-P2)				
			Benthic Invertebrate Tissue		Sediment		BSAF ²	Benthic Invertebrate Tissue		Sediment		BSAF ²
Mean	t*SE	Mean	t*SE	Mean	t*SE	Mean		t*SE				
Parameters of Interest (POIs)	Arsenic	mg/kg	0.76	0.44	7.72	1.65	0.10	2.36	2.90	14.0	0.95	0.17
	Copper	mg/kg	16.7	4.4	382	59.3	0.04	97.4	84.0	823	57.2	0.12
	Iron	mg/kg	1,114	701	30,067	7,512	0.04	3,793	4,115	29,760	2,270	0.13
	Manganese	mg/kg	25.4	8.2	3,327	1,207	0.01	585	635	2,574	787	0.23
	Nickel	mg/kg	0.42	0.05	33.3	3.25	0.01	3.09	2.77	22.0	3.64	0.14
	Zinc	mg/kg	68.2	14.0	82.8	9.4	0.82	61.0	29.2	86.4	6.5	0.71
Indicator Parameters (IPs)	Barium	mg/kg	16.8	15.3	289	46.8	0.06	50.1	50.8	329	22.2	0.15
	Calcium	mg/kg	1,055	350	8,417	1,571	0.13	3,706	3,050	24,500	4,099	0.15
	Cobalt	mg/kg	0.23	0.09	13.3	1.65	0.02	2.47	2.61	23.1	2.66	0.11
	Molybdenum	mg/kg	0.49	0.21	4.32	1.22	0.11	2.74	3.04	10.1	1.56	0.27
	Phosphorus	mg/kg	7,902	129	2,537	2,182	3.12	7,250	4,167	1,200	86	6.04
	Selenium	mg/kg	2.31	0.56	2.75	0.40	0.84	7.31	2.82	4.43	1.07	1.65
	Silver	mg/kg	0.029	0.005	0.377	0.031	0.08	0.051	0.041	0.348	0.013	0.15
	Sodium	mg/kg	5,642	487	900	418	6.27	4,424	3,681	1,828	127	2.42
	Strontium	mg/kg	5.38	1.89	99.4	14.5	0.05	38.0	36.7	289	18.7	0.13
	Tin	mg/kg	0.038	0.016	0.697	0.183	0.06	0.225	0.236	2.10	0.199	0.11
	Titanium	mg/kg	6.86	1.93	461	157	0.01	224	264	1,832	238	0.12
	Vanadium	mg/kg	1.34	0.43	80.3	10.5	0.02	20.9	25.1	115	7.5	0.18

Notes:
 1. Summary statistics were calculated using method detection limit (MDL) values if data were below the MDL. Means are shown with a < symbol if all data used in their calculation were < MDL. If MDLs were variable, means were reported as < the maximum MDL.
 2. BSAF = Biota Sediment Accumulation Factor; [Mean concentration of analyte in benthic tissue (mg/kg dw)] / [Mean concentration of analyte in sediment (mg/kg dw)]
Bold font indicates mean analyte concentration in benthic invertebrates was significantly higher than in the associated reference area, p < 0.05 (using a non-parametric Mann-Whitney U test).

3.1.3.3 Benthic Invertebrate Community

Analysis of the benthic invertebrate community in Polley Lake has been conducted by Minnow to assess the initial impacts of the tailings spill and track recovery. The benthic invertebrate community assessment was based on comparison of community metrics (e.g., diversity, richness, evenness) to reference (Bootjack Lake) and baseline data. Sampling in 2014 at mid-depth locations in Polley Lake and at the deep location in the north basin indicated density (individuals per m²) and richness of invertebrates were lower in comparison to reference (Bootjack Lake), but were consistent with baseline sampling at those locations in Polley Lake. Sampling at the deep location in the south basin of Polley Lake in 2014 yielded no benthic invertebrates, indicating the benthic community was entirely covered by tailings. A follow up analysis of the benthic invertebrate community was conducted during the fall of 2015. The data report was not available for this Update Report, but will be included in the Risk Assessment and CEMP reports.

3.1.3.4 Surface Water Toxicity Testing

MPMC has conducted a post-event toxicity testing program since the tailings spill occurred, in which surface water samples collected from Polley Lake were tested using a series of standard laboratory tests using sensitive plant, invertebrate, and fish test species. The program provides an important evaluation of the potential bioavailability and toxicity of POIs as they are observed in site-specific samples. The laboratory testing provides a direct measure of biological effect to individual organisms under site-relevant conditions, and includes sensitive test species representing primary producers, primary consumers, and secondary consumers.

The results of post-event toxicity testing conducted between August 2014 and February 2015 (MPMC 2015 Appendix F) and follow-up post-event toxicity testing conducted between March and November 2015 (Appendix F) indicate that the water quality in Polley Lake did not adversely affect aquatic health. The results of toxicity testing conducted between January and November 2015 are presented in Table 3-3.

Table 3-3: Summary of Surface Water Toxicity Testing in Polley Lake (January to December 2015)

Test	Sample ID	Date	T. Cu (mg/L)	D. Cu (mg/L)	LC50 (% v/v)	IC25 (% v/v)	IC50 (% v/v)
7-d fathead minnow survival and growth	P2-Surface	06 Jan 2015	0.0024	0.0021	>100	>100	>100
	P2-Surface	14 Apr 2015	0.0025	0.0019	>100	>100	>100
7-d Rainbow Trout swim-up survival and growth	P2-Surface	06 Jan 2015	0.0024	0.0021	>100	>100	>100
	P2-Surface	14 Apr 2015	0.0025	0.0019	>100	>100	>100
	P2-Surface	25 Aug 2015	0.0033	0.0029	>100	>100	>100
	P2-Surface	12 Nov 2015	0.0036	0.0024	>100	>100	>100
7- to 8-d <i>C. dubia</i> survival and reproduction	P2-Surface	06 Jan 2015	0.0024	0.0021	>100	>100	>100
	P2-Surface	14 Apr 2015	0.0025	0.0019	>100	>100	>100
	P2-Surface	25 Aug 2015	0.0033	0.0029	>100	>100	>100
	P2-Surface	11 Nov 2015	0.0036	0.0024	>100	>100	>100

Notes: Effect concentration expressed on a volume/volume basis. LC50 = Lethal concentration causing 50% mortality. IC25/IC50 = Non-lethal concentration causing 25% or 50% reduction in growth or reproduction. Total and dissolved copper (T. Cu and D. Cu) concentrations for January to August samples are provided in Appendix B; concentrations for September to November samples are MPMC unpublished data.

3.1.3.5 Plankton Community and Tissue Metal Analysis

Sampling of plankton was conducted at two stations in Polley Lake monthly between May and September 2015 (during the open water period; Appendix G). Plankton was not sampled in Polley Lake in 2014. Plankton was also not collected from a reference lake for Polley Lake. Therefore, these data were considered to provide a preliminary indication of plankton biomass and tissue metal concentrations that can be built on in future sampling events.

- Spatial and temporal trends in phytoplankton biomass (as chlorophyll a) and zooplankton abundance throughout the open water period of 2015 were qualitatively examined by plotting the data.
- Trophic status of Polley Lake was classified as ranging from oligotrophic to mesotrophic based on nutrients, Secchi depth, and chlorophyll a concentrations measured during the 2015 period.
- Total zooplankton abundance in Polley Lake increased from May to June followed by a decline in abundance from June to August. In September, P1 had an increase in zooplankton abundance where P2 had a slight decline from August. No biomass calculations were made so it is unknown whether zooplankton biomass follows a similar seasonal pattern compared to abundance.
- Similar community composition was observed at the two stations in Polley Lake. Copepod nauplii made up the greatest proportion of total zooplankton abundance in Polley Lake between May and July whereas cyclopoid copepods were generally dominant in August and September. Cladocerans, rotifers, and calanoid copepods were generally present in smaller numbers at both stations through the open water period.
- Zooplankton tissue concentrations of arsenic, copper, mercury, and selenium were generally similar between sampling stations (P1 and P2) in Polley Lake in 2015 with the exception of the September sampling event when P1 was consistently higher than P2 for arsenic, copper, mercury, and selenium.

- Tissue concentrations of arsenic, copper, mercury, and selenium displayed an increasing trend from May to September at P1. This trend was not observed in aqueous concentrations of these parameters with the exception of copper, which also exhibited a slight increase in aqueous concentrations at both sampling locations. See Figures 4a to 4d, below.
- Zooplankton tissue selenium concentrations were at or above the BC interim dietary guideline for tissue consumption by fish (BC MoE 2014) at both stations during the sampling events in Polley Lake in 2015, as shown in Figure 4d. MPMC are continuing to monitor the zooplankton tissue selenium concentration in Polley Lake and compare results to Bootjack Lake, the reference location to determine if there are trends in concentrations over time.

The available data did not allow for evaluation of changes between 2014 and 2015 or assessment of natural variability.

Figure 4b: Concentrations of Copper Measured in Zooplankton Tissue (top) and Surface Water (bottom) Collected from Polley Lake, 2015.

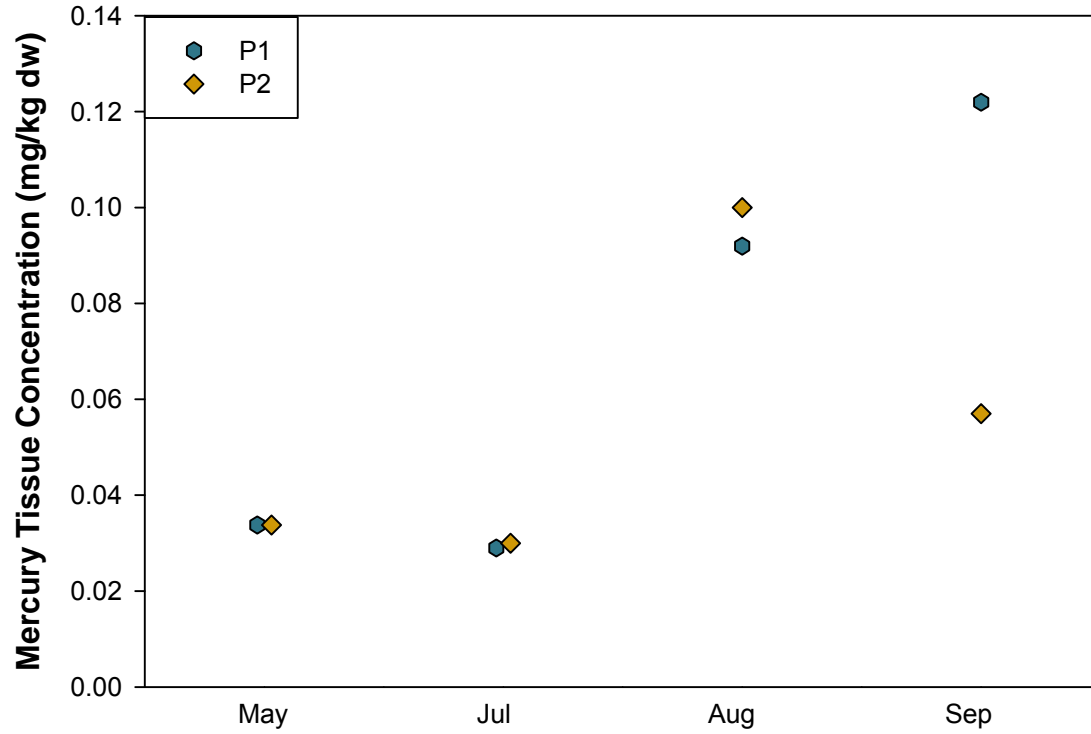

Figure 4c-Concentrations of Mercury Measured in Zooplankton Tissue Collected from Polley Lake, 2015.

Figure 4d: Concentrations of Selenium Measured in Zooplankton Tissue (top) and Surface Water (bottom) Collected from Polley Lake, 2015.

3.1.3.6 *Fish Productivity*

The primary effect of the event on the Rainbow Trout of Polley Lake was the disruption to rearing habitat in Hazeltine Creek and the potential loss of a year-class of Rainbow Trout and the blockage of access to Hazeltine Creek for spawning in 2015 and 2016 (Appendix G). Post-event toxicity testing indicated that Polley Lake water did not affect survival or growth of fish, survival or growth of daphnid zooplankton, or growth of plant test species. Rainbow Trout and Longnose Sucker length and weight data suggest that feeding efficiency was not affected. A summary of Rainbow Trout tissue metal concentrations and potential impacts on fish productivity is discussed below.

3.1.3.7 *Fish Tissue Metal Analysis*

Multiple stakeholders collected fish tissue samples following the release of tailings. Golder consolidated the data from these multiple sources into a single dataset to facilitate data review. The details of the methods for review are provided in Appendix H, Fish Tissue. As discussed in detail in Appendix H, there are several limitations to this data set and this evaluation is considered to be preliminary at this time. See discussion of selenium data below. Additional monitoring to investigate these selenium concentrations will be conducted, as required.

3.1.3.7.1 *Comparison to Tissue Guidelines*

Tissue guidelines are available for arsenic, mercury and selenium (See Appendix H). The proportion of samples above tissue guidelines is reported by species (including all species for which data are available) and tissue type. The primary comparison for arsenic and mercury is for muscle tissue because this sample type is the most frequently consumed portion of the fish. However, liver and kidney may be consumed by some populations, and therefore, Golder has conservatively retained those comparisons in this data summary. General observations regarding the number of exceedances of these guideline values are as follows.

- There were no arsenic guideline exceedances observed for Polley Lake fish.
- There were no mercury guideline exceedances observed for Polley Lake fish.
- Some selenium guideline exceedances were observed for Polley Lake fish. These guideline exceedances are considered to be suspect at this time. In particular, the selenium tissue results for Frypan Creek-Polley Lake Rainbow Trout are unusually high for the ovary tissue in comparison to the muscle tissue. The data are also considered somewhat suspect as the selenium concentrations in surface water have been below the water quality guideline for the protection of fish and egg productivity.
- Given the unexpected and unusual tissue data, further investigation regarding data quality is currently underway. In the meantime, the selenium concentrations in fish tissue from Frypan Creek-Polley Lake are considered to be suspect.

These exceedances are outlined in Table 3-4 for human health protection and Table 3-5 for environmental protection.

Table 3-4: Summary of Selenium Tissue Exceedances for the Protection of Human Health in Polley Lake. These data should be interpreted with caution as data quality concerns are investigated further

Guideline	Year	Species	Location	Number and Type
Low Fish Intake (75 mg/kg dw) Recreational Fishers	2014	Rainbow Trout	Polley Lake (exposure)	3 of 15 liver
	2015	Rainbow Trout	Polley Lake (exposure)	3 of 8 liver
Moderate Fish Intake (14.5 mg/kg dw) General Population	2014	Rainbow Trout	Polley Lake (exposure)	14 of 15 liver
	2015	Rainbow Trout	Polley Lake (exposure)	8 of 8 ovary, 8 of 8 kidney, 8 of 8 liver
High Fish Intake (7.3 mg/kg dw) First Nation Subsistence	2014	Longnose Sucker	Polley Lake (exposure)	3 of 16 whole body
		Rainbow Trout	Polley Lake (exposure)	1 of 2 ovary, 14 of 15 liver
	2015	Rainbow Trout	Polley Lake (exposure)	8 of 8 ovary, 8 of 8 kidney, 8 of 8 liver
	2016	Rainbow trout	Polley Lake (exposure)	3 of 8 ovary

Table 3-5: Summary of Selenium Tissue Exceedances for Environmental Protection in Polley Lake

Year	Species	Location	Number and Type
2014	Longnose Sucker	Polley Lake (exposure)	1 of 1 muscle
	Rainbow Trout	Polley Lake (exposure)	1 of 15 muscle and 1 of 2 ovary
	Longnose Sucker	Polley Lake (exposure)	16 of 16 whole-body
	Rainbow Trout	Polley Lake (exposure)	1 of 3 whole-body
	Rainbow Trout	Polley Lake (exposure)	5 of 8 muscle and 8 of 8 ovary
2016	Rainbow Trout	Polley Lake (exposure)	3 of 8 ovary

3.1.3.7.2 Risk Assessment and Toxicological Context

Fish tissue chemistry data were reviewed in further detail for selected combinations of metals and fish species and/or sample types to provide early context for how the data will be integrated into the HHERA. Fish tissue

chemistry data would typically be used to develop a realistic, worst-case exposure estimate for each receptor being evaluated. This receptor-specific evaluation means that different parts of the fish tissue chemistry data set would be used for each receptor, depending on a variety of factors such as fish ecology, variability in the data, and the strength of association between the chemistry data and the underlying assessment endpoint. Ultimately, fish tissue can be used as part of the following three measurement endpoints:

- Consumption of fish by humans --- Increased metals concentrations in muscle samples from large bodied fish caught for recreation or sustenance can contribute to risks to human receptors. Further input is needed from the Williams Lake Indian Band and Soda Creek First Nation regarding appropriate fish tissue to consider for local consumption.
- Bioaccumulation by fish – Increased accumulation of metals in fish tissue can cause adverse effects to the fish themselves.
- Consumption of fish by ecological receptors – Increased metals concentrations in whole-body samples from smaller fish can contribute to risks to piscivorous fish and wildlife. Increased metals concentrations in muscle or organ samples can also contribute to increased risk to higher trophic level wildlife such as bears or raptors which might preferentially feed on these parts of this fish instead of consuming the whole body.

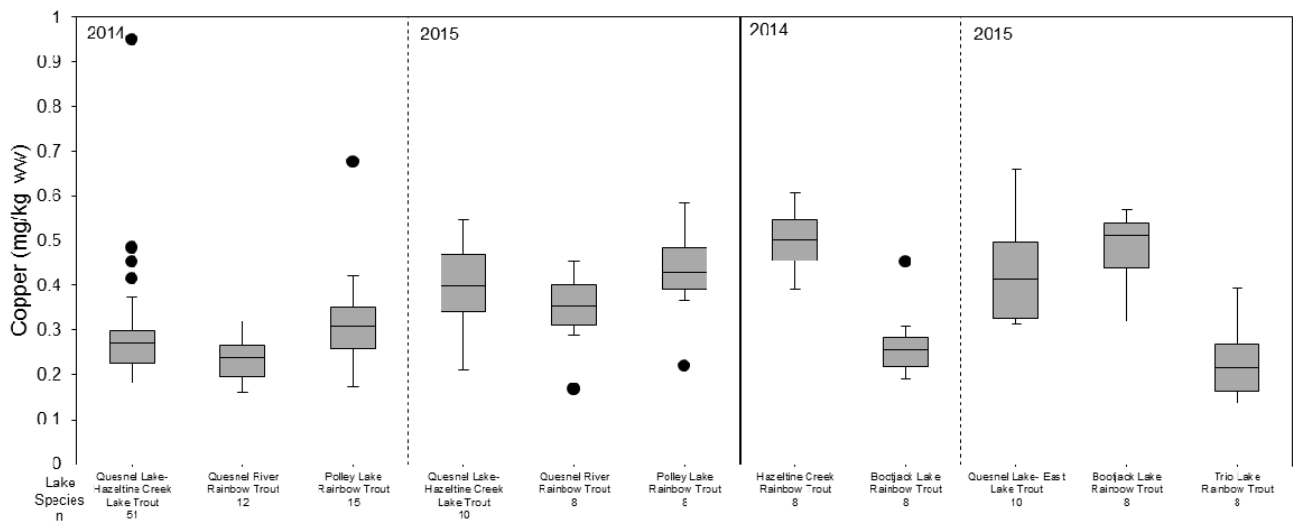

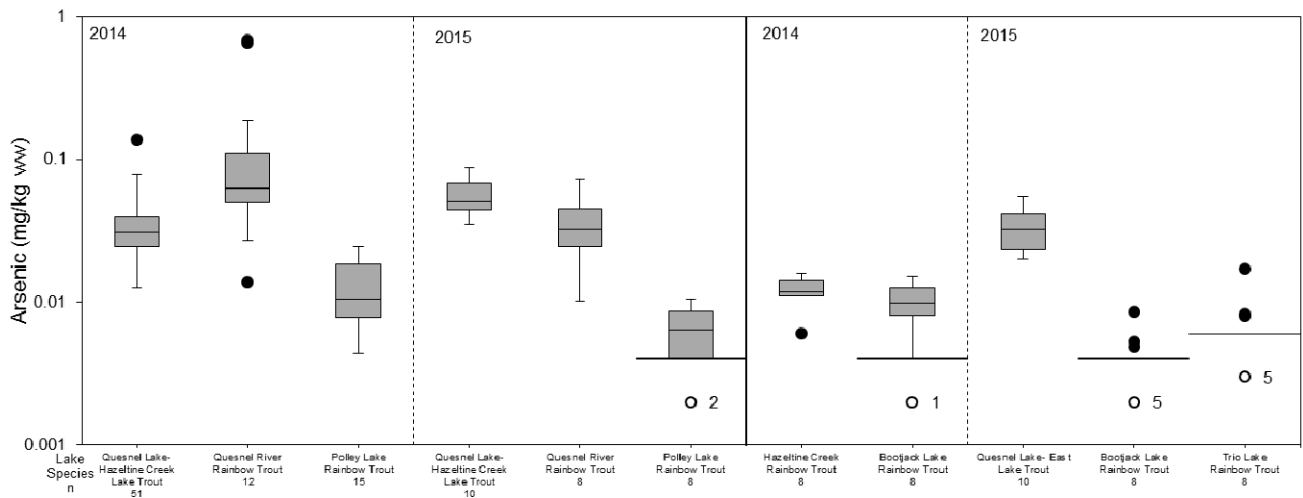

For Polley Lake, Rainbow Trout are an isolated population. A fence prevents them from moving into Hazeltine Creek while restoration work, including the addition of habitat improvements, continues for Hazeltine Creek. Therefore, Rainbow Trout are representative of conditions of Polley Lake. Rainbow Trout are also consumed by humans and wildlife, so they fulfill all three objectives. Rainbow Trout data from Polley Lake were compared to Bootjack Lake and Trio Lake for reference purposes.

Consumption of Fish by Humans

Figure 5 (below) provides a summary of the box plots for specific metals in the muscle samples from large-bodied fish species. As described above, Lake Trout, Rainbow Trout, and juvenile Sockeye Salmon were identified as a reasonable surrogate for the preliminary consideration of this pathway. Individual box plots with pair-wise comparisons for different sites, species, and years are provided in Appendix I, Attachment 2.

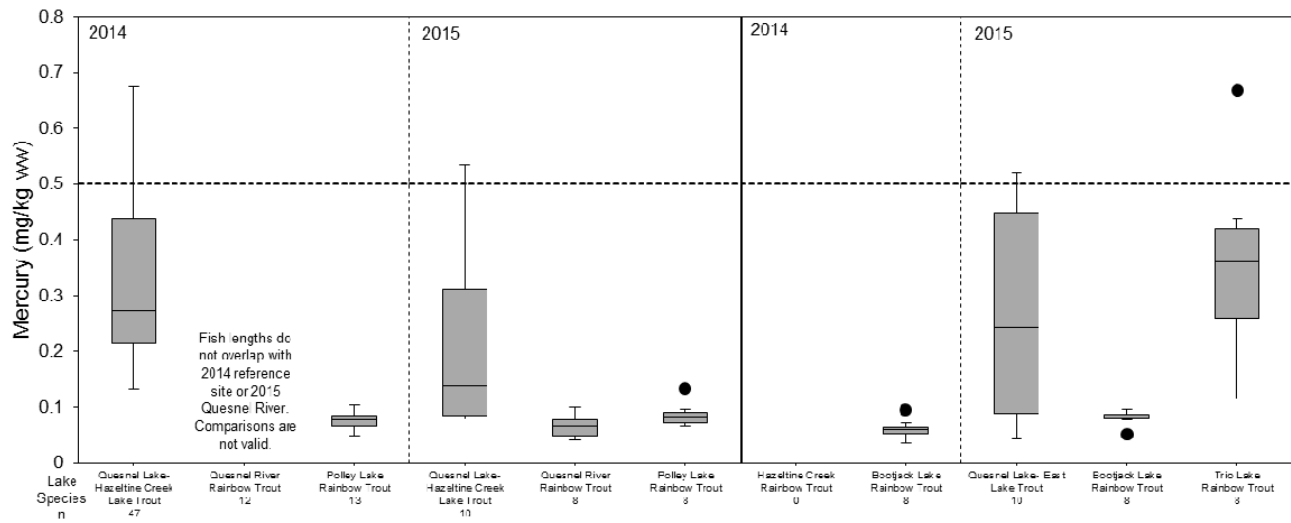

PEEIAR UPDATE REPORT - MOUNT POLLEY MINE

PEEIAR UPDATE REPORT - MOUNT POLLEY MINE

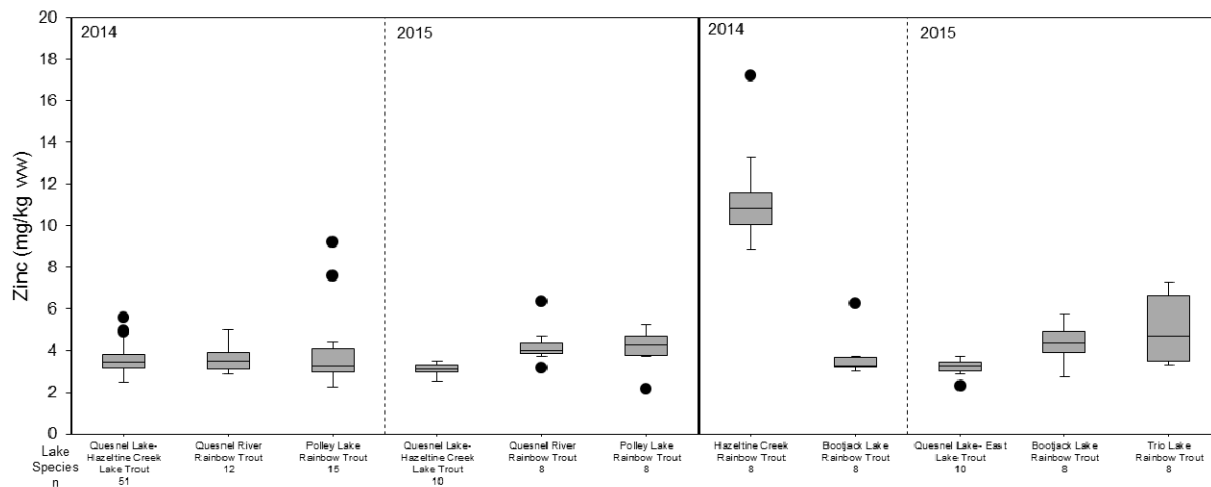

Figure 5: Summary of Available Muscle Chemistry Data for Select Fish Species and Sampling Sites (2014, 2015).

Note: Cadmium and vanadium are not presented because most values were below detection limit with the exception of four samples for cadmium, and one sample for vanadium. Box plots are censored at the detection limit (DL = solid horizontal line). Concentrations below the DL are plotted as an open symbol at half the DL. Extreme values are plotted as individual values. mg/kg ww = milligrams per kilogram wet weight; mg/kg dw = milligrams per kilogram dry weight; n = sample size; dashed vertical lines (- - -) indicate the separation of years; solid vertical lines (-) indicate the separation of exposure and reference; dashed horizontal lines (- - -) indicate guidelines from CFIA (mercury) or BC MoE (selenium).

The purpose of Figure 5 is to highlight whether there are obvious changes in metal accumulation between reference and exposed sites, or between years that would indicate that there has been a change in tissue concentrations. In brief, results are summarized as follows:

- Arsenic concentrations in muscle samples were variable among reference and the exposed sites. Samples from Polley Lake Rainbow Trout appeared to be similar to Bootjack and Trio Lake Rainbow Trout, as well as Rainbow Trout collected from Hazeltine Creek prior to the release of tailings. All measured concentrations were less than the Canadian Food Inspection Agency (CFIA) preliminary tissue guideline.
- Copper concentrations in muscle samples were similar between Polley Lake and Bootjack Lake.
- Mercury concentrations in muscle samples appeared to be similar between exposed sites and reference sites.
- Selenium concentrations in Rainbow Trout muscle collected in 2015 from Frypan Creek (tributary to Polley Lake) were frequently higher than the tissue guideline for environmental protection, and appear to be elevated relative to the applicable references sites (i.e., Bootjack Lake, Trio Lake). The selenium concentrations measured in Frypan Creek Rainbow Trout muscle did not exceed the screening value for First Nation subsistence fish consumers. Readers are reminded that these selenium data are considered to be anomalous and are undergoing further quality checks (see below). Selenium concentrations in Polley Lake Rainbow Trout muscle appear similar to those observed in Hazeltine Creek Rainbow Trout, which were collected prior to the release of tailings.

- Zinc concentrations in muscle tissue appeared to be generally consistent between exposed and reference sites, and were also lower than the median concentrations measured in Hazeltine Creek Rainbow Trout, which were collected prior to the release of tailings.
- The selenium concentrations in Frypan Creek-Polley Lake Rainbow Trout ovary tissue exceeded thresholds for productivity and are higher than what would be expected based on the muscle tissue data. Selenium concentrations in Rainbow Trout ovary tissue collected from Polley Lake (Frypan Creek) in 2015 showed a substantial increase relative to ovary concentrations in Rainbow Trout collected from Hazeltine Creek or Bootjack Lake in 2014 (Figure 6). A similar increase was noted in Rainbow Trout kidney and muscle samples (Figure 5) for the same individual fish. These concentrations were considered potentially anomalous based on the magnitude of the increase and the lack of a similar magnitude of increase in water or fish dietary concentrations. The anomalous data was contained in a single certificate of analysis, and therefore, the analytical laboratory was requested to provide further validation. A summary of the validation conducted to date is included in Appendix H. The concentrations measured in Rainbow Trout ovary tissue were lower in 2016, though concentrations ranged above and below the guidelines for protection of productivity in fish and birds, and the guideline for subsistence consumers of fish. MPMC are conducting additional studies of selenium concentrations in Polley Lake biota and are seeking feedback from the Williams Lake and Soda Creek First Nations regarding current or traditional consumption of Rainbow Trout and other fish tissues.

Figure 6: Summary of Available Ovary Chemistry Data for Rainbow Trout from Relevant Sampling Sites.

Note: Boxplots are censored at the detection limit (DL = solid horizontal line). Concentrations below the DL are plotted as an open symbol at half the DL. Extreme values are plotted as individual values. mg/kg ww = milligrams per kilogram wet weight; mg/kg dw = milligrams per kilogram dry weight; n = sample size; dashed vertical lines (- - -) indicate the separation of years; solid vertical lines (-) indicate the separation of exposure and reference; dashed horizontal lines (- - -) indicate guidelines from CFIA or BCMoE.

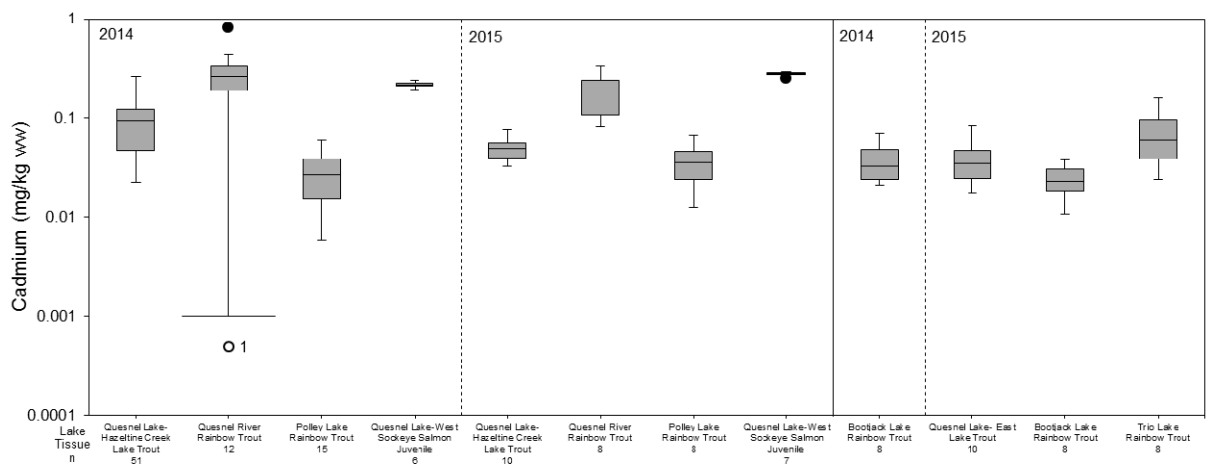

Bioaccumulation by Fish

Figure 7 (liver), below, provides summaries of the available fish tissue chemistry data for liver samples presented as censored box plots for the specific metals identified. Individual censored box plots showing comparisons of exposure and reference sites, species, and years are provided in Appendix H, Attachment 2. The purpose of the five summary figures presented herein is to highlight changes in metal concentrations between reference and exposed sites, or between years in tissues that have been associated with metal accumulation. In brief, results are summarized as follows:

- For arsenic, copper, and zinc, liver (Figure 7) and kidney concentrations were generally consistent between the Polley Lake compared to Bootjack and Trio Lakes.
- Mercury concentrations in fish liver were consistently low for both Polley Lake and Bootjack Lake.
- Concentrations of vanadium may have been higher in Polley Lake Rainbow Trout liver in 2015 compared to reference, which were generally below the detection limit.
- Selenium concentrations in the liver samples collected from Rainbow Trout in Polley Lake, Frypan Creek and Bootjack Lake in 2014 appeared to be greater than Bootjack samples collected in 2015. The concentrations of selenium in liver samples appeared to decrease in Bootjack Lake between 2014 and 2015 (Figure 7). As noted above, additional data quality confirmation is on-going to confirm the 2015 Polley Lake Rainbow Trout data.

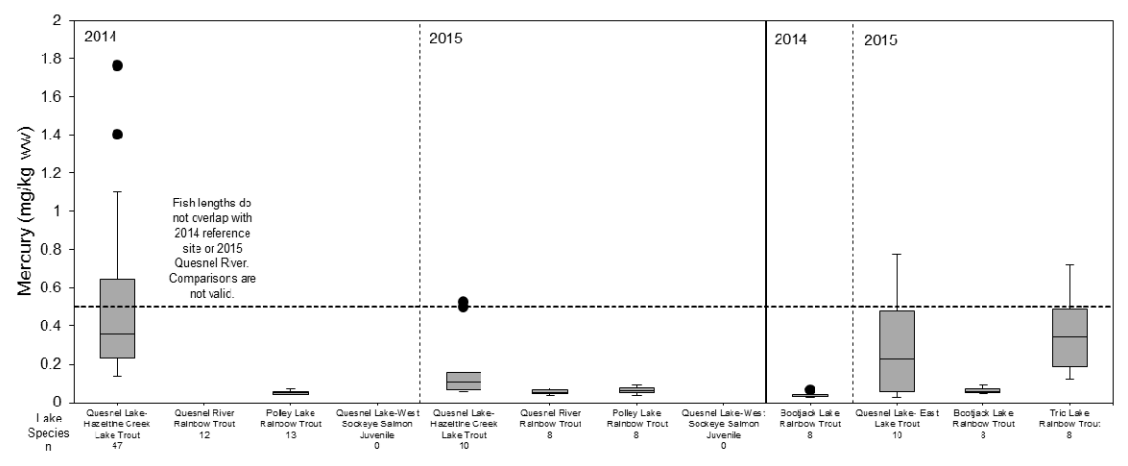

PEEIAR UPDATE REPORT - MOUNT POLLEY MINE

PEEIAR UPDATE REPORT - MOUNT POLLEY MINE

Figure 7: Summary of Available Liver Chemistry Data for Select Fish Species and Sampling Sites (2014, 2015).

Box plots are censored at the detection limit (DL = solid horizontal line). Concentrations below the DL are plotted as an open symbol at half the DL. Extreme values are plotted as individual values. mg/kg ww = milligrams per kilogram wet weight; mg/kg dw = milligrams per kilogram dry weight; n = sample size; dashed vertical lines (- - -) indicate the separation of years; solid vertical lines (-) indicate the separation of exposure and reference; dashed horizontal lines (- - -) indicate guidelines from CFIA (mercury) or BC MoE (selenium).

Consumption by Piscivores

The fish assemblage in Polley Lake is limited. Whole body fish samples were not collected.

3.2 Hazeltine and Edney Creeks

3.2.1 Physical

Hazeltine Creek flows from Polley Lake to the West Basin of Quesnel Lake, a distance of approximately 9.2 km. Prior to the tailings spill, Hazeltine Creek flowed into Edney Creek just upstream of the discharge to Quesnel Lake. Edney Creek drains the watershed south of the Mount Polley Mine, and is understood to be a larger drainage than Hazeltine Creek and to provide more significant fish habitat as pertains to fish communities migrating to and from Quesnel Lake.

Water and tailings released during the spill created a debris flow that eroded material along the Hazeltine Creek channel and surrounding area (referred to as the floodplain). The debris flow formed a wider and deeper channel along the entire length of Hazeltine Creek by removing sediments from the channel, and native soil and forest from the floodplain. The floodplain accounts for 57% (136 ha) of the total terrestrial area affected by the debris flow. An additional 100 hectares of forest surrounding the floodplain (referred to as the halo) was inundated by tailings and remobilized sediment and the forest floor was buried to varying depths. Figure 8 shows the extent of erosion and tailings inundation in Lower Hazeltine Creek.

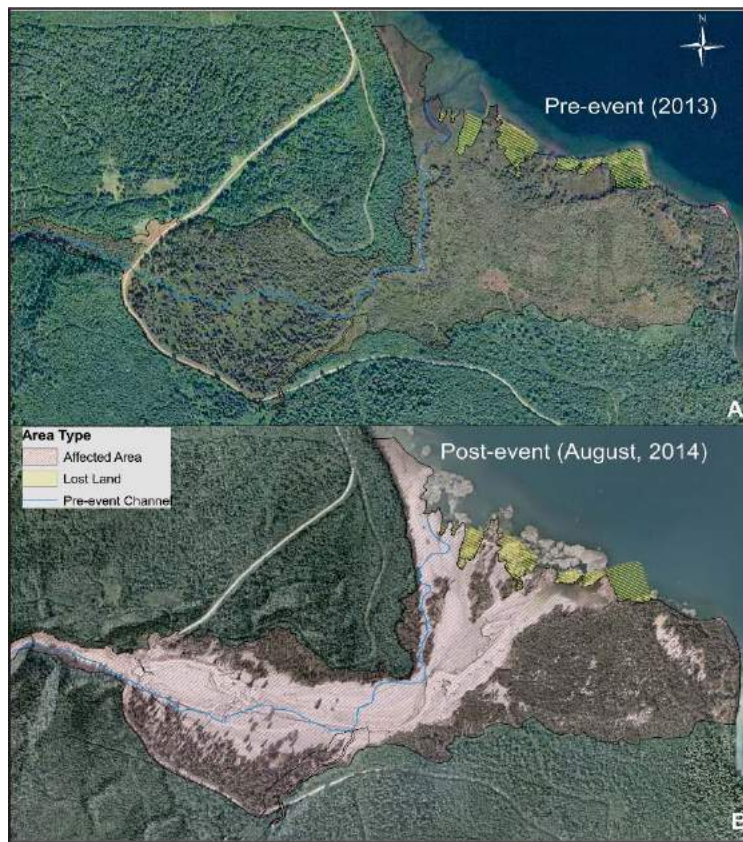

Figure 8: Pre-event and post-event view of Hazeltine Creek delta.

The lower portion of Edney Creek was also eroded away by the debris flow and fish passage into upper Edney Creek was cut off. Early rehabilitation efforts were able to restore the connection between Edney Creek and Quesnel Lake, and isolate Edney Creek from continuous impact by tailings deposited along Hazeltine Creek. While the lower portion of Edney Creek was impacted by the physical effects of the debris flow, Edney Creek water quality is determined by a watershed that was not influenced by the event and thus impacts on Edney Creek water quality were not assessed. As such, analyses of impacts to people, and terrestrial and aquatic wildlife are focused on conditions along Hazeltine Creek.

The Hazeltine Creek corridor (inclusive of the channel, floodplain, and halo) includes both terrestrial and aquatic habitats that have been impacted by the tailings spill. The impacts to these habitats and the communities within each are discussed separately below.

Terrestrial Habitat

Within the floodplain, the physical impact of the tailings spill included uprooting and transport of trees and other forest biota down the Hazeltine Creek corridor, leaving the floodplain largely absent of original vegetation. The force of the debris flow diminished at the edges of the floodplain, such that the trees in the “halo” zone were not uprooted, but the forest floor was covered by a layer of tailings and left absent of understory vegetation. The nature of the physical impact within the halo zone was less obvious than within the floodplain. The deposition of tailings and water within the halo filled the pores in the forest floor and mineral soil, blocking exchange of oxygen (O₂) and carbon dioxide (CO₂) involved in root and microbial metabolism and respiration. Many trees in the halo area appeared moribund in the spring and early summer of 2015, likely because the depth, fine texture, and saturation of the tailings created anaerobic conditions in the rooting zone. Under anoxic conditions, anaerobic and facultative soil microbes can use alternative electron acceptors such as sulfate, nitrate, ferric iron, manganese oxide, and carbon dioxide to produce energy. Field observations of an anaerobic (‘rotten egg’) odour, supported by quantitative measures (refer to Appendix I), in holes excavated in the tailings indicated at least some microbes were using sulfate as an alternative electron acceptor to oxygen. By contrast, the obligate aerobic tree roots, mycorrhizal fungal symbionts, and associated soil food web invertebrate organisms had died in the anoxic soils. These organisms require approximately 5% oxygen and use oxygen as their electron acceptor.

The pattern of tree mortality observed within the halo zone indicated tree death was caused by the anaerobic environment of the tree roots and not metal toxicity. Primarily, the foliage of trees was observed to have died uniformly through the crown, suggestive of sudden death caused by oxygen starvation to tree roots. The dying trees observed in July 2015, were reportedly still green until May 2015, after which the foliage rapidly turned brown. It is likely the tree roots had started to die immediately when the tailings inundated the floodplain, but foliage did not turn brown until the following spring after the winter dormancy had broken. As soils warmed in the spring of 2015, the foliage would have transpired while dead roots were incapable of acquiring and transporting water to the crown via the xylem. The browning of the foliage hence occurred rapidly in spring, over a period of approximately 1 to 2 months. Further summary of the impacts to the forest community within the halo area is provided in Appendix I.

Aquatic Habitat

Like within the floodplain, the sediments and aquatic community associated with Hazeltine Creek were scoured during the debris flow and transported downstream. As the debris flow receded, the remaining creek channel was composed of exposed and eroding underlying native materials and tailings, with turbid waters flowing into Quesnel Lake. After providing for safe worker access and controlling the residual source inputs from the TSF, construction began on an armoured creek channel capable of resisting erosion and providing for future fish habitat. Pockets of tailings and tailings dam materials were removed from the footprint of the constructed channel and from the footprint of any fill materials placed in the floodplain. A significant interim feature of sediment control during these works was treatment of the entirety of Hazeltine Creek flow in two sequential sediment ponds located in the lower

Hazeltine Creek floodplain. The sediment ponds provided beneficial suspended solids removal. Construction of the armoured Hazeltine Creek channel was completed in May 2015. Further work is planned to add habitat features for aquatic life along the length of the channel.

Prior to and during construction, turbidity concentrations in Hazeltine Creek were elevated above the short and long-term BC WQGs. Clear-flow conditions ensued upon completion of the channel construction. A progressive decline in turbidity levels continued throughout 2015 with levels measured closer to BC WQGs by the end of the year. Turbidity and total suspended solids remain POIs as they can be elevated above BC WQGs during occasionally turbid flow events when the creek is subject to erosion (See Appendix D). Fish access to Hazeltine Creek is currently blocked until construction is complete and appropriate habitat has been established.

3.2.2 Chemical

3.2.2.1 Soil Quality Update

Soil quality data collected from along Hazeltine Creek by SNC and Golder has been evaluated to characterize the chemical and physical composition of the deposited tailings. The soil quality assessment was based on comparison of soil chemistry to Contaminated Sites Regulation (CSR) standards and reference data. Copper and vanadium were found to exceed the most conservative applicable CSR standards and were greater than reference concentrations. The soil quality assessment found that metals concentrations between the two types of tailings observed (grey fine grained and red-black sand) were not significantly different. With regards to nutrients, average nutrient concentrations were up to 12 times less and concentrations of TOC were up to 34 times less in tailings compared to reference and native soil (Appendix B).

Based on the evaluation of 2014 and 2015 soil quality data, copper and vanadium were identified as POIs in tailings deposited along Hazeltine Creek. The bioavailability of these metals to terrestrial life has been assessed further, as discussed below.

3.2.2.2 Groundwater Quality Update

Limited groundwater quality data collected in the summer of 2015 from along Hazeltine Creek by Golder has been evaluated to provide field confirmation of the geochemistry findings that the tailings have a low potential for leaching of metals. Further investigation is planned for the summer of 2016 to confirm the potential for dissolved metal transport from the tailings to shallow groundwater that would largely discharge to Hazeltine Creek.

The groundwater quality assessment was based on comparison of groundwater chemistry to CSR standards and reference data. No exceedances of standards were observed in groundwater samples collected in 2015 and the average concentrations of metals in groundwater samples from along the creek were similar to reference concentrations (Appendix C). Based on the evaluation of 2015 groundwater quality data, no POIs were retained.

The additional groundwater investigation to be conducted in 2016 has been broadened in response to stakeholder concerns, and includes characterization of the hydrogeological regime near Hazeltine Creek.

3.2.2.3 Surface Water Quality Update

Water quality data collected from Hazeltine Creek by MPMC has been evaluated to assess temporal trends of POIs since the tailings spill through December 2015 (Appendix D). The water quality assessment was based on comparison of water chemistry to BC WQGs, reference data, and baseline data. Baseline water quality data indicates that concentrations of copper were naturally-elevated in Hazeltine Creek prior to the tailings spill. The water quality assessment identified exceedances of total metal WQGs in Hazeltine Creek in the first half of 2015, mainly during turbid flow periods typically associated with elevated concentrations of particulate matter. Clear-flow conditions ensued upon completion of channel construction, and typically resulted in lower concentrations of particulate matter and subsequently lower concentrations of total forms of metals.

The majority of metals identified as POIs in the first half of 2015 decreased to concentrations below guideline levels by mid-summer and remained stable through December 2015, with a few noted exceptions (e.g., beryllium, chromium, and cobalt in Hazeltine Creek at the Horsefly-Likely Forest Service Road (the “Ditch Road”) bridge). By December 2015, only total and dissolved copper consistently exceeded BC WQGs for the protection of aquatic life. Copper therefore remains the primary POI in Hazeltine Creek based on the 2015 data. When the creek is subject to erosion (primarily runoff and high flow events) resulting in turbid flow events, some other metals may also exceed guidelines. The water quality data from June through December 2015 is considered representative of post creek construction conditions within Hazeltine Creek. The immediate impacts of the tailings spill to Polley Lake and the creek, as well as impacts during construction of the creek channel, had subsided during this period.

Discharge of treated effluent to Hazeltine Creek, as authorized by BC MoE in the amendment to Permit 11678 (November 29, 2015), was initiated on December 1, 2015. Concomitant with the initiation of the authorized discharge, selenium concentrations increased at two stations in Hazeltine Creek located close to and downstream from the discharge location. The most sensitive receptors to selenium are egg laying vertebrates. Although these receptors have been either excluded (fish) or are limited in number (aquatic feeding birds), selenium was also monitored as a POI in Hazeltine Creek. Concentrations of selenium in water appear to have decreased in the first quarter of 2016 by 1 to 2 times compared to the concentrations reported in December 2015 following the initial discharge of treated effluent to the creek.

Metals concentrations in Hazeltine Creek surface water will continue to be monitored as part of MPMC’s routine monitoring program.

Free Metals in Surface Water

Between August and October 2015, Minnow deployed diffusive gradients in thin films (DGT) passive sampling devices in pools within the Hazeltine Creek canyon to measure the amount of free and weakly complexed metals from water near the sediment-water interface (Appendix D). Calculated concentrations of free metals in water (based on accumulation by the DGT device) were compared to concentrations of total and dissolved metals in concurrent water samples, and BC WQGs. Further background discussion of the DGT data is provided in the Polley Lake section above.

In Hazeltine Creek, copper was measured by the DGT devices at concentrations greater than other waterbodies, but lower than the applicable BC WQGs (Figure 3 above; Appendix D). It is acknowledged that the WQG were not developed based on DGT data so the comparison was made for information purposes only. In comparison to total and dissolved (filtered) concentrations, the DGT-labile concentrations of copper in water in Hazeltine Creek were lower.

3.2.2.4 Sediment Quality Update

Sediment quality data collected by Minnow from Hazeltine Creek has been evaluated to assess changes in sediment chemistry since the tailings spill occurred and following reconstruction of the creek channel (Appendix E). The sediment quality assessment was based on comparison of sediment chemistry to BC sediment quality guidelines (SQG), reference data, and baseline data. Baseline sediment data indicates that concentrations of metals were naturally-elevated in Hazeltine Creek prior to the tailings spill.

In 2014 prior to reconstruction of the creek channel, sediment was collected from locations in the upper, mid, and lower sections of the creek. The 2014 chemistry data indicated that copper and iron were elevated in comparison to guidelines and reference/baseline concentrations. Reconstruction of Hazeltine Creek included removal of tailings and laying of clean rock. Two sedimentation ponds were installed at the end of the creek, just upstream of Quesnel Lake, to contain particulate material that entered the creek during construction activities or through erosion from upland areas. In 2015 following reconstruction of the creek, sediment within the sedimentation pond was collected to represent sediment that might be present within the creek. The 2015 chemistry data indicated that copper and iron were elevated in comparison to standards and reference/baseline concentrations. Arsenic concentrations were higher in 2015 than in 2014. Based on the evaluation of 2015 sediment quality data, arsenic, copper, and iron remain POIs in Hazeltine Creek. Mercury and selenium have been added as POIs due to stakeholder concerns.

3.2.2.5 Geochemistry

Geochemistry investigations conducted by SRK Consulting (SRK) have continued since the release of the PEEIAR to geochemically characterize tailings material released during the tailings spill (Appendix A, MPMC 2015 Appendix C). The investigations have included tests to determine the potential for acid generation (acid-base accounting), as well as assessment of tailings composition, mineralogy, and leaching under subaerial (humidity cell and column tests) and subaqueous (sequential extractions) conditions.

Preliminary investigations (MPMC 2015 Appendix C) found that when compared to average concentrations in similar rock types, the only enriched elements in the tailings were copper and selenium. Only a portion (approximately 33%) of the copper is associated with sulphide, with the remainder (approximately 67%) associated with silicate minerals. This non-sulphide fraction is relatively insoluble and would have a low potential for leaching under both subaerial and subaqueous conditions. The sulphide fraction would also have low potential for leaching under subaerial conditions because the tailings were determined to be neutral or slightly alkaline with negligible potential to cause acid rock drainage (ARD). The ARD potential is negligible owing to low sulphur content and high buffering potential from calcite in the tailings. The portion of non-sulphide selenium is lower than copper (approximately 13%), and potential for leaching is also expected to be low for selenium.

Updated results provided by SRK (Appendix A) corroborate the initial findings. Results of kinetic leaching reported for 32 weeks of the 40 week long tests (humidity cells and column tests) indicate leaching rates have reduced over time and at 32 weeks showed a progressive decrease, which is likely to continue to the end of the tests. Based on the information from the geochemical tests to date the following conclusions can be drawn with respect to the potential for leaching from the tailings deposited along Hazeltine Creek under subaerial conditions:

- The results indicate that a significant amount of copper (up to 66%) is associated with the non-sulphide portion (likely chlorite) of the tailings and is considered to be non-reactive. This is based on previous studies and the results provided in this report that required acidic conditions to leach copper associated with the non-sulphide fraction.
- Kinetic testing confirmed that leaching considerations are under neutral to alkaline conditions and continue to support the previous assessment that ARD is not expected in these materials. Based on 32 weeks of testing, leaching rates are beginning to stabilize and general downward trends are expected to continue as the testing progresses. Variability in leaching rates is also being established and water contact chemistry predictions (i.e. geochemical source terms) should be possible after 40 weeks of testing.
- For any tailings materials with water flow paths longer than half a metre, mineral solubility controls for copper are expected. Longer flow paths in the fine grained materials may also be conducive to lower rates of oxygen diffusion and therefore conditions that support selenium reduction to its more insoluble forms such as selenite and elemental selenium.
- Testing is on-going and the current assessment of tailings reactivity and leaching rates will be updated once testing passes 40 weeks.

3.2.3 Biological

3.2.3.1 Terrestrial Ecosystem Assessment

As discussed above, in the summer of 2015, a study was conducted to describe and quantify the differences in terrestrial habitat quality between the halo and reference/background areas (Appendix I). Secondly, the study was conducted to determine the cause of mortality for trees in the halo area. The study considered forest floor and mineral soil properties, forest stand attributes (e.g., tree species composition, site index, height, age, basal area, stems per hectare, and stand structure), vegetation attributes (e.g., species cover, richness, and diversity), evidence of wildlife use, and wildlife attributes (e.g., snag density and size, and coarse woody debris cover and diameter).

The results of the study indicated that roots of trees within the halo were in a state of decay and were visibly disappearing from the soil horizons. Abundance and richness of the plant community were significantly lower in the halo than reference. Over forty plant species were either eliminated or reduced by over 80% in the halo compared to reference. Species gained in the halo plots tended to be “weedy” species, characteristic of disturbed areas (e.g., fireweed, dandelion, great mullein, hawksweed, white clover). Species lost tended to be characteristic of mature forests (e.g., wild ginger, rattlesnake plantain, one-side wintergreen). Cover of all plant layers were also significantly reduced due to the decline of the trees and burial of the plant community.

As discussed in the summary of physical impacts, the results available from the field program indicate that the pattern of tree mortality in the halo was caused by the anaerobic conditions in the tree rooting zone created by the deposit of fine, saturated tailings material over the forest floor. This deposit immediately blocked soil pores and reduced oxygen reaching the roots of the trees. Water trapped within the fine particles created a perched water table that continued to restrict oxygen reaching the roots. Health of the soil and microbial community also declined in response to the restricting layer of water or deposited material.

Further work is being conducted to determine if metals concentrations in soil and tailings will inhibit re-establishment of the forest community.

3.2.3.2 Terrestrial Plant and Soil Invertebrate Tissue Metals Analysis

Sampling of edible plants (berries, spruce, willow, and rye grass) and soil invertebrates (ants, beetles, worms, and slugs) was conducted in 2015 within the terrestrial area impacted by the tailings spill (i.e., Hazeltine Creek floodplain and halo) (Appendix J). The purpose of the program was to evaluate whether concentrations of soil POIs had increased in plants or soil invertebrates as a result of the tailings deposition. Plant and invertebrate sample results were compared to reference sample results and baseline data (plants only) to determine if tissue concentrations of POIs were increased and to evaluate the potential exposure to higher trophic level receptors. Each tissue sample was collected with a co-located soil sample to calculate tissue:soil ratios (i.e., bioaccumulation factors [BAFs]).

Concentrations of several metals were occasionally found to be greater in plant or invertebrate samples from the floodplain or halo in comparison to reference or baseline. BAFs calculated for copper and vanadium (POIs in soil) were below one indicating there is no relationship between copper or vanadium concentrations in soil and plants or soil and invertebrates.

A limitation of these datasets were the small number of samples, particularly for soil invertebrates. Additional sampling of plants and soil invertebrates along Hazeltine Creek will be conducted in 2016.

3.2.3.3 Surface Water Toxicity Testing

Toxicity testing was conducted on water samples collected in Hazeltine Creek prior to and following the December 1, 2015 discharge of treated mine effluent to Hazeltine Creek (authorized by BC MoE in the amendment to Permit 11678 dated November 29, 2015). Surface water samples from Hazeltine Creek were tested using a series of standard laboratory tests using sensitive invertebrate and fish test species. Neither short-term nor long-term exposure to Hazeltine Creek water, collected before or after the start of discharging treated water, resulted in adverse effects to aquatic life. The results of toxicity testing conducted between November and December 2015 are presented in Table 3-6. No toxicity was observed for any of the tests conducted, indicating that the creek water was not toxic to sensitive fish and invertebrate species tested during sensitive life stages.

Table 3-6: Summary of Surface Water Toxicity Testing in Hazeltine Creek (November to December 2015)

Test	Sample ID	Date	T. Cu (mg/L)	D. Cu (mg/L)	LC50 (% v/v)	IC25 (% v/v)	IC50 (% v/v)
96-h Rainbow Trout LC50	HAC-12	02 Nov 2015	-	-	>100	-	-
48-h <i>D. magna</i> LC50	HAC-12	02 Nov 2015	-	-	>100	-	-
7-d Rainbow Trout swim-up survival and growth	HAC-12	30 Dec 2015	0.013	0.01	>100	>100	>100
	HAC-12	12 Nov 2015	0.0099	0.0077	>100	>100	>100
7- to 8-d <i>C. dubia</i> survival and reproduction	HAC-12	30 Dec 2015	0.0099	0.0077	>100	>100	>100

Notes: Effect concentration expressed on a volume/volume basis. LC50 = Lethal concentration causing 50% mortality. IC25/IC50 = Non-lethal concentration causing 25% or 50% reduction in growth or reproduction. Total and dissolved copper (T. Cu and D. Cu) concentrations for November and December samples are MPMC unpublished data.

3.2.3.4 Sediment Toxicity

Additional testing, including sediment bioassays, community, and benthic invertebrate tissue samples were not conducted in 2015 as the creek was under construction and was not considered to be fish habitat.

3.2.3.5 Benthic Invertebrate Tissue Metals Analysis

Benthic invertebrate samples collected from upper Hazeltine Creek were dominated by a high abundance of black fly larvae, while a more diverse benthic invertebrate assemblage, composed mainly of caddisflies and mayflies, was evident at the lower Hazeltine Creek sampling area. Benthic invertebrate samples collected from Edney Creek were composed of a diverse mix of organisms, including mayflies, stoneflies and caddisflies.

The mean concentrations of several metals were significantly higher in benthic invertebrates from both upper and lower sampling areas of Hazeltine Creek than those in the corresponding reference area (Edney Creek; Table 3-7; Appendix G). PCA results confirmed the distinction between the two exposed areas and reference (Appendix G).

PEEIAR UPDATE REPORT - MOUNT POLLEY MINE

Notes:

- Summary statistics were calculated using maximum method detection limit (MDL) values if data were below the MDL. Means are shown as < the maximum reported MDL if all data used in their calculation were < MDL. If MDLs were variable, means were reported as < the maximum MDL.
- BCF = Bioconcentration Factor; [Mean concentration of analyte in benthic tissue (mg/kg dw)] / [Mean dissolved concentration of analyte in water (mg/L)]. Mean water concentrations calculated using all available data.
- Results are based on a single sampling event, therefore data from this single sample are displayed.

Mean analyte concentration in benthic invertebrates was significantly higher than in the associated reference area (EDC, 2015), p < 0.05 (using a non-parametric Mann-Whitney U test).

Mean analyte concentration in benthic invertebrates was significantly lower than in the associated reference area (EDC, 2015) and pre-event data (2010, if available), p < 0.05 (using a non-parametric Mann-Whitney U test).

Mean analyte concentration in benthic invertebrates was significantly higher than in the associated reference area (EDC, 2015) and pre-event data (2010, if available), p < 0.05 (using a non-parametric Mann-Whitney U test).

Mean benthic invertebrate metal concentrations in Edney Creek show low concentrations, including concentrations of selenium below the dietary guideline of 4 ug/g for environmental protection. Prior to the tailings spill, mean concentrations of several metals, including selenium, were higher in upper and lower areas of Hazeltine Creek compared to samples taken in 2015. Concentrations of selenium in invertebrates collected in 2010 in upper and lower Hazeltine Creek were 10.9 ug/g dw and 3.5 ug/g dw, respectively, compared to 4.9 ug/g dw and 2.7 ug/g dw, respectively, in 2015. These data may indicate high natural variability for selenium in this area. Analyses of 10 samples of glacial sands, silts and varved clays (glaciolacustrine-glaciofluvial sediments) from along Hazeltine Creek yielded selenium values ranging from 0.3 to 4.8 ppm, while tailings (2013) averaged 1.14 ppm selenium. The 10 Hazeltine Creek glacial sediment samples had higher average cadmium and antimony than the average values in the 2013 tailings for these elements. (C.D.Anglin, pers comm, 2016) Post-event benthic invertebrate concentrations of copper and vanadium in the upper and lower Hazeltine Creek were higher than pre-event conditions. It is unknown at this time if the observed increase in concentrations of metals in benthic invertebrates is related to sediment particulates in the gut content of the benthic invertebrates or if these concentrations have been absorbed into tissues. Evaluation of fish tissue concentrations may help in this matter, as sediment bound metals would be more efficiently excreted. Further assessment of the metal concentrations in benthic invertebrates and the significance to predator species is underway.

3.2.3.6 Benthic Invertebrate Community

No benthic invertebrate community sampling was conducted in Hazeltine Creek in 2014 due to the absence of appropriate erosional habitat following the tailings spill (i.e., substrates were entirely fine materials derived from the tailings and scoured creek bed). Benthic invertebrate sampling was undertaken in 2015 following reconstruction of the creek channel to track recovery. The data were not available at the time of writing this report. These data will be included in the Risk Assessment report due later this year (2016).

3.3 Quesnel Lake

3.3.1 Physical

Quesnel Lake is a large, deep fjord lake reaching from the Cariboo Mountains into the Interior Plateau of BC. The lake has a surface area of 266 km² and is comprised of West, East, and North Arms. The average and maximum depths of the lake are 157 and 511 m, making Quesnel Lake one of the deepest fjord-type lakes in the world (Laval et al. 2008). The West Basin is a relatively shallow (113 m maximum depth) portion of the West Arm that is separated from the rest of the lake by a shallow sill approximately 35 m deep, near Cariboo Island, and is considered the area between Cariboo Island and the Quesnel River (Laval et al. 2008). The West Basin has vertical mixing that is typical of temperate lakes, with thermal stratification for most of the year interrupted by brief turnover periods in the spring and the fall when vertical density gradients are lowest. A thermocline typically forms at a mean depth of 12.4 m (Nidle et al. 1994). In the deeper portions of the lake, seasonal turnover events only occur in the upper 100 to 200 m of the water column due to changes in temperature-density relationships with increased pressure at greater depths. Nutrient data collected since the mid-1990 indicate that the trophic status of the lake is oligotrophic (Nidle et al. 1994).

Hazeltine Creek enters the West Basin of Quesnel Lake. It is estimated the tailings spill resulted in the discharge of about 18.6 million m³ of mixed tailings, soil and water into Quesnel Lake (MPMC 2015 Appendix B). The majority of the discharged material settled in the West Basin at depths >100 m below surface (MPMC 2015 Appendix B). The area of this major deposit was estimated to be approximately 1.81 km² with thickness of the deposit ranging up to about 10 m. On the underwater lake side-slope from the mouth of Hazeltine Creek, native material was eroded by underwater debris flow; deposition of tailings material on the side-slope was considered negligible. Along the side-slope from the mouth of Hazeltine Creek and in the deep portion of the West Basin, the immediate physical impact to the lake bottom included the loss of habitat and displacement of the benthic community. No significant deposition of material was measure in the main body of the lake (MPMC 2015 Appendix B), but up to 40% of material that remained in suspension was predicted to disperse into the main body of the lake at low concentration.

Turbidity monitoring in Quesnel Lake following the tailings spill revealed within the West Basin a turbidity plume in the water column at depths >20 m below surface and below the thermocline. The turbidity plume persisted until late November 2014 when lake turnover occurred and the water column mixed. By January 2015, the turbidity in Quesnel Lake had decreased to below that prescribed by the BC WQGs (MPMC 2015 Appendix F). Throughout 2015, levels of turbidity and total suspended solids were low in the far-field areas of Quesnel Lake as well as in the West Basin, and generally remained below guidelines (Appendix D). Exceptions to this were instances between March and May 2015, where higher levels of turbidity were recorded in the near-field area at the mouth of Hazeltine Creek during turbid flow periods in Hazeltine Creek.

3.3.2 Chemical

3.3.2.1 Surface Water Quality Update

Water quality data collected from Quesnel Lake by MPMC has been evaluated to assess temporal trends of POIs since the tailings spill through December 2015 (Appendix D). The water quality assessment was based on comparison of water chemistry to BC WQGs and reference data. During the period immediately following the tailings spill, copper was identified as the primary POI within the West Basin of Quesnel Lake. Total copper was below applicable BC WQGs in the near-field, mid-field and far-field stations in Quesnel Lake throughout most of 2015. Exceptions to this were instances where total concentrations were above the BC WQG between March and May in the near-field area close to the mouth of Hazeltine Creek and to a lesser extent at the western mid-field station further away from the mouth. These higher total concentrations coincided with turbid flow periods in Hazeltine Creek and dissolved concentrations did not exceed BC WQGs. Other metals monitored at the Quesnel Lake stations in 2015 were below applicable BC WQGs. With respect to nutrients, phosphorus data collected throughout 2015 suggested that event-related changes with respect to the potential for a change in lake trophic status were not evident in Quesnel Lake. Based on the evaluation of 2015 water quality data, no POIs in surface water remain above WQGs in Quesnel Lake.

Metals concentrations in Quesnel Lake surface water will continue to be monitored as part of MPMC's routine monitoring program.

3.3.2.2 *Free Metals in Surface Water*

Between August and October 2015, Minnow deployed diffusive gradients in thin films (DGT) passive sampling devices in a profundal area of Quesnel Lake near the mouth of Hazeltine Creek to measure labile (free and weakly complexed) metals from water near the sediment-water interface (Appendix D). Calculated concentrations of free metals in water (based on accumulation by the DGT device) were compared to concentrations of total and dissolved metals (determined by filtering through a 0.45 µm filter) in concurrent water samples, reference concentrations from a reference profundal area of Quesnel Lake, and BC WQGs. We note that WQG were not derived using DGT data, so the comparison is for information purposes only.

In Quesnel Lake, DGT-detectable parameters were measured by the DGT devices at concentrations similar to reference concentrations and lower than the applicable BC WQGs (Figure 3 above). In comparison to total and filtered concentrations, the DGT-labile concentrations in water near the bottom of Quesnel Lake were lower. These data show that the proportion of free and weakly complexed metals is low.

3.3.2.3 *Sediment Quality Update*

Sediment quality data collected from Quesnel Lake by Minnow has been evaluated to assess changes in sediment chemistry since the tailings spill occurred. Unlike water quality, concentrations of metals in the tailings-influenced sediment are not expected to have changed substantially between sampling events in 2014 and 2015. The sediment quality assessment was based on comparison of sediment chemistry to BC SQGs and reference data. Reference sediment data from areas of Quesnel Lake unlikely to be impacted by the tailings spill indicated that concentrations of metals were naturally elevated in the lake prior to the tailings spill (MPMC 2015 Appendix E).

Sediment has been collected from littoral and profundal areas in the lake, and at various distances from the mouth of Hazeltine Creek. The 2014 chemistry data indicated that several metals including arsenic and copper were elevated in comparison to guidelines and reference concentrations. Concentrations of metals were observed to decrease with distance from the mouth of Hazeltine Creek, while total organic carbon (TOC) was observed to increase. Sediment chemistry in 2015 was similar to 2014 and exhibited the same spatial pattern of decreasing copper concentrations and increasing TOC with distance from Hazeltine Creek mouth.

3.3.2.3.1 *Evaluation of Mercury Biomagnification Potential*

Golder reviewed the conditions that favour the methylation of mercury to assess whether these conditions occur in Quesnel Lake and reviewed the existing monitoring data to examine the evidence (if any) of increased mercury concentrations as a result of the tailings spill.

Factors Influencing Methylation of Mercury

Azimuth (2010, 2012, 2015) summarized environmental factors that influence mercury methylation. As outlined in Sections 4.3 to 4.5 of Azimuth (2012), key parameters that influence methylation potential are residence time, trophic status, temperature, DO, pH, dissolved organic carbon, total suspended solids, sulphate, sediment grain size, and total organic carbon in sediment. The correlation of these parameters with mercury methylation (i.e., positive or negative) is summarized in Table 3-8 below.

As summarized in Table 3-8 below, conditions in Quesnel Lake generally do not favour mercury methylation. Quesnel Lake is oligotrophic, cold, well oxygenated, slightly basic, and relatively low in concentrations of dissolved organic carbon, total suspended solids, and sulphate. Sediment grain size and TOC are also not favourable for mercury methylation.

Table 3-8: Summary of Parameters and their Correlation with Mercury Methylation (Azimuth 2012) and Current (Post-event) Conditions of these Parameters in Quesnel Lake

Parameter	Correlation	Conditions that Favour Methylation	Quesnel Lake	Source for Quesnel Lake data
Residence time	Positive	Longer residence time	10 years (entire lake); 3 months (West Basin); less likely	1,6
Trophic status	Positive	Highly productive systems	Low productivity; classified as oligotrophic; less likely	1
Water - Temperature	Positive	Warmer temperatures (weakly related)	Temperature < 10 °C at depths greater than 40 m; less likely	2
Water - Dissolved Oxygen	Negative	Low oxygen conditions	Concentrations > 5 mg/L at all depths; less likely	2
Water - pH	Negative	Slightly acidic waters (pH <6.5)	Median pH = 7.95; less likely	3
Water - dissolved organic carbon	Positive	Concentrations > 5 mg/L	Mean concentration = 2.2 mg/L; less likely	3
Water - total suspended solids	Positive	Higher concentrations (as transport media for mercury)	Below detection limit of 3 mg/L in most samples (n= 198); 13 samples had detected concentrations that ranged from 3 to 54.1 mg/L.; less likely	3
Water - sulphate	Positive	Higher concentrations over environmentally relevant range (5-30 mg/L)	Mean concentration = 6.6 mg/L; less likely	3
Sediment - grain size	Negative	Fine grain sediment ⁵	In the <63 µm fraction, predominantly silt in profundal samples and predominantly sand in littoral samples.; less likely in littoral, more likely in profundal	4
Sediment - total organic carbon	Positive	Higher	Mean total organic carbon ≤ 2.3% in the <63 µm fraction; less likely	4

Abbreviations: < = less than; ≤ = less than or equal to; > = greater than; ~ = approximately; °C = degrees Celsius; m = metres; mg/L = milligrams per litre; µm = micrometres; % = percent.

Review of Existing Monitoring Data for Mercury

Water Chemistry

Water chemistry data collected between August 2014 and July 2015 are reported in Appendix D. Between August 2014 and July 2015, with the exception of one water sample, total aqueous mercury concentrations in Quesnel Lake samples have been below the reported detection limits of 50 ng/L (August 2014 samples), 10 ng/L (late August and September 2014 samples), or 5 ng/L (2015 samples). The single sample with a detected concentration (11 ng/L) was collected from station QUL-96 in September 2014. Water samples collected on the same day from nearby station QUL-2 were below the detection limit of 10 ng/L. Because mercury data are sparse and total aqueous mercury concentrations were below the reported detection limit in all but one sample, interpretation of aqueous mercury trends is limited.

The single measured aqueous mercury concentration and the detection limits for samples with no detected mercury were compared to the BC Water Quality Guideline (BC MoE 2001) of 10 ng/L, based on the assumption that the percent methylmercury in Quesnel Lake is 1%. Because the percent methylmercury in Quesnel Lake has not been measured the aqueous mercury data cannot be directly compared to the BC water quality guideline. However, comparison to the CCME (2003) water quality guidelines for inorganic mercury suggest that the potential for mercury effects is low. In water samples collected from late August 2014 (i.e., detection limit of 10 ng/L) to July 2015 (i.e., detection limit of 5 ng/L), aqueous mercury concentrations were lower than the CCME (2003) water quality guideline for inorganic mercury (26 ng/L).

Although the above comparison to the CCME (2003) water quality guideline suggests that the potential for mercury effects is low, CCME (2003) states that the water quality guideline may not fully protect higher trophic levels. Therefore, sediment, zooplankton tissue chemistry, and fish tissue chemistry data collected from Quesnel Lake were also reviewed to assess spatial and temporal trends in mercury concentrations.

Sediment Mercury

Sediment chemistry data are reported in MPMC (2015 Appendix E) and Appendix E. Sampling in Quesnel Lake was conducted in 2014 and 2015 at two depths: littoral (1 to 2 metres deep) and profundal (approximately 80 to 100 metres deep). In 2014, both the littoral and profundal sampling in Quesnel Lake included two reference areas and four exposed areas. For each sampling location, concentrations were measured in the <2 mm fraction and the <63 µm fraction. In 2015, both the littoral and profundal sampling included one reference area and one exposed area. Concentrations were measured in the <63 µm fraction only. Baseline sediment chemistry data were not available for Quesnel Lake (MPMC 2015 Appendix E).

In littoral and profundal sediment samples collected in 2014 and 2015, concentrations of mercury in exposed areas were generally higher than concentrations in reference areas. However, mercury concentrations in exposed areas were lower than the BC working sediment quality guideline. In 2014 and 2015, mean sediment mercury concentrations in exposed areas were either lower than or similar to the mean baseline concentration in Hazeltine Creek.

With respect to temporal comparisons, sediment mercury concentrations in 2015 were generally higher than concentrations measured in 2014 post-event. Mean sediment mercury concentrations appeared to be higher in 2015 relative to 2014 both in exposed areas (31 to 42%) and reference areas (16 to 19%).

Zooplankton Tissue Mercury

Zooplankton tissue chemistry collected in 2014 and 2015 from Quesnel Lake is reported in Appendix G. Tissue samples were collected from three stations in Quesnel Lake: one exposed station called Hazeltine (in the West Arm west of Cariboo Island) and two reference stations, Horsefly (near the Horsefly River) and Junction (in the Main Basin where the east and north arms meet).

Zooplankton tissue metals concentrations were variable at all three stations, with no consistent spatial or temporal trends.

Fish Tissue Mercury

Fish tissue chemistry collected in 2014 and 2015 from Quesnel Lake is reported in Appendix H. Tissue chemistry comparisons were conducted spatially (i.e., exposure versus reference areas) and temporally (i.e., 2014 versus 2015 data) for site, species, and tissue type, where data were available.

The following observations were made with respect to spatial comparisons in Quesnel Lake:

- For five of the sampled fish species with sufficient tissue mercury data to compare between exposed and reference areas (i.e., Lake Trout, Largescale Sucker, Northern Pikeminnow, Redside Shiner, and juvenile Sockeye Salmon), mercury concentrations in fish collected from exposed locations appeared to be similar to concentrations in fish collected from reference locations.
- Two species exhibited potential differences between exposed and reference areas:
 - Kokanee collected in 2014 from Quesnel Lake near Quesnel River (exposure) had higher mercury concentrations in ovary relative to Kokanee collected from Quesnel Lake North Arm (reference), although concentrations in liver and muscle samples were similar.
 - Peamouth Chub collected in 2015 from Quesnel Lake Hazeltine Creek Confluence (exposure) had higher mercury concentrations in whole body relative to fish collected from Quesnel Lake North Arm (reference). There is uncertainty in this comparison because it was not possible to confirm that similar length distributions were sampled in the two waterbodies due to a lack of fish length data.

With respect to temporal comparisons in Quesnel Lake, mercury concentrations in tissue appeared to be similar.

Overall, the spatial and temporal comparisons indicate that fish tissue mercury concentrations in Quesnel Lake are comparable to concentrations measured in reference locations and that concentrations have not increased since the tailings spill. These results are consistent with the lack of spatial and temporal trends observed in water chemistry, sediment chemistry, and zooplankton tissue chemistry. These data are considered to be preliminary at this time. Further monitoring of fish tissues will be conducted as part of the CEMP.

3.3.3 Biological

3.3.3.1 Sediment Toxicity Testing

MPMC conducted a post-event toxicity testing program between August and October 2014 (MPMC 2015 Appendix E), in which surface sediment samples collected from Quesnel Lake were tested using a series of standard laboratory tests using sensitive invertebrate test species. The program provided an important evaluation of the bioavailability and toxicity of POIs as they are observed in site-specific samples, as well as changes to physical conditions of the sediment that may affect the capacity of sediment to support sediment dwelling organisms. The laboratory testing provided a direct measure of biological effect to individual organisms under site-relevant conditions.

The results of post-event toxicity testing conducted in 2014 indicated effects to the survival and growth of test organisms in tailings-affected sediments collected in Quesnel Lake. Sediments collected from Quesnel Lake exhibited physical differences from sediments generally present in aquatic environments, and from sediment collected from reference areas and from the same locations pre-event. Physical differences included uniform particle size, relatively high density, and relatively low TOC content. Chemical differences included elevated metal concentrations. Effects were not clearly correlated with either physical or chemical characteristics of sediment following the series of tests conducted in 2014.

Additional testing was conducted in 2015 to elucidate the respective roles of the physical and chemical factors, as well as to confirm the general patterns of toxicity observed in Quesnel Lake sediments in the 2014 testing program. This additional investigation of toxicity of Quesnel Lake impacted sediments indicated no effect to the survival of either invertebrate test organism, which differed from 2014. In contrast, effects on growth of both invertebrate test organisms (*C. tentans* and *H. azteca*) were confirmed in 2015, with growth apparently being the more sensitive test endpoint in the impacted sediment tested. Effects on growth were not seen with the addition of TOC to concentrations similar to reference conditions, and comparisons of exposed sediments to a clay control indicated either no difference from the clay control (*C. dilutus*) or slightly greater growth than the clay control (*H. azteca*). This is consistent with previous findings that *C. dilutus* is intolerant of sediment with TOC lower than approximately 1% despite feeding of the test organisms (Suedel and Rodgers 1994). The consistent positive response to TOC amendment in both exposed sediment and reference clay (uncontaminated but with high fines content) suggests that the response to TOC was through provision of food resources rather than through additional metal binding capacity. Strong positive relationships were observed between growth of both organisms and TOC whereas there were no strong relationships with copper. These observations are consistent with geochemical investigations, which indicated that leaching of tailings-associated metals is low (Appendix A, MPMC 2015 Appendix C) and physical characteristics of the sediment may lead to slower rates of sediment recolonization in the profundal zone.

3.3.3.2 Benthic Invertebrate Biomass and Tissue Metal Analysis

3.3.3.2.1 Quesnel Lake Littoral

Benthic invertebrate biomass and tissue metal analysis is provided in Appendix G. The approximate biomass of benthic invertebrate subsamples retrieved from exposed and reference littoral areas of Quesnel Lake were similar (Table 3-9). Quesnel Lake littoral benthic invertebrate samples were composed mainly of chironomids, mayflies, leeches, amphipods, and pea clams.

Table 3-9: Summary whole benthic invertebrate and sediment chemistry results from lake sampling areas in Quesnel Lake, 2015¹

Notes:
 1. Summary statistics were calculated using method detection limit (MDL) values if data were below the MDL. Means are shown with a < symbol if all data used in their calculation were < MDL. If MDLs were variable, means were reported as < the maximum MDL.
 2. BSAF = Biota Sediment Accumulation Factor; [Mean concentration of analyte in benthic tissue (mg/kg dw)] / [Mean concentration of analyte in sediment (mg/kg dw)]
Bold font indicates mean analyte concentration in benthic invertebrates was significantly lower than in the associated reference area, p < 0.05 (using a non-parametric Mann-Whitney U test).

Mean concentrations of metals in benthic invertebrates from the littoral far-field area of Quesnel Lake did not differ from the reference area (Table 3-9), including copper. PCA results supported this finding, with very little distinction between the exposed and reference area results.

Biota-to-sediment accumulation factors (BSAFs) for the Quesnel Lake littoral exposed area (Quesnel Lake LFF) were similar to those at the reference area. Copper concentrations in sediment were below the sensitive sediment standard in the littoral exposed area. Although the BSAF for selenium in invertebrates collected from the littoral zone was greater than 1.0, it was similar to reference and concentrations of selenium in invertebrates were less than the wildlife dietary guideline of 4 ug/g dw.

3.3.3.2 Quesnel Lake Profundal

The approximate biomass of benthic invertebrates retrieved from the profundal exposed area of Quesnel Lake was lower than the approximate biomass of benthic invertebrate subsamples retrieved from the corresponding profundal reference area (exposed mean <0.09 g/m² wet weight; reference mean >0.34 g/m² wet weight; Appendix G). Samples collected from both profundal areas of Quesnel Lake were composed mainly of chironomids.

Copper was the only metal with a mean benthic invertebrate concentration in the profundal near-field area of Quesnel Lake that was significantly greater than the reference area mean (Table 3-9 above). A higher concentration of copper in benthic invertebrates was expected, as the sediment concentrations were significantly higher in copper in near field profundal compared to reference. However, the biota-to-sediment accumulation (BSAF) for the relationship of copper in invertebrates to copper in sediment was less than 1.0 and had a negative slope (Appendix G, Figure 3). The concentration of copper in benthic invertebrates collected from the near-field exposed area appeared to be greater than reference by approximately three times compared to a 16x difference in sediment concentrations of copper. These data show that copper is not a biomagnifying metal.

For selenium, the mean benthic invertebrate concentrations for near field profundal was slightly greater than the dietary guideline (4.6 ug/g vs 4 ug/g), but significantly less than reference. The mean benthic invertebrate concentration of selenium was 8.1 ug/g in the reference samples. These preliminary data may indicate that Quesnel Lake selenium concentrations in invertebrates varies above and below the guideline naturally or from other sources. Further investigation into the concentrations of metals in benthic invertebrates in Quesnel Lake exposed and reference sites is planned as part of the CEMP.

3.3.3.3 Benthic Invertebrate Community

Analysis of the benthic invertebrate community in Quesnel Lake has been conducted by Minnow to assess the initial impacts of the tailings spill and track recovery (MPMC 2015 Appendix E). The benthic invertebrate community assessment was based on comparison of community metrics (e.g., diversity, richness, evenness) to reference areas in Quesnel Lake. Sampling in 2014 at littoral areas in Quesnel Lake, at various distances from the Hazeltine Creek mouth (near-field, far-field and far-far-field) indicated that richness and density were lower at near-field locations compared to reference. Metrics for far-field and far-far-field littoral locations indicated those communities were similar to reference. Samples from profundal areas exhibited greater difference from reference, with lower richness and density at both near and far field locations; several samples yielded no benthic

invertebrates, indicating the benthic community was entirely covered and/or displaced by tailings. Additional samples of benthic community diversity and abundance were collected from Quesnel Lake in the fall of 2015. Although the data were not ready at the time of preparing this report, based on the biomass data provided above, there appear to no longer be a difference in biomass in the Quesnel Lake littoral zone. A difference in biomass continues to exist in the profundal zone. The data were not ready at the time of preparing this report. These data will be included in the Risk Assessment report that will be submitted later this year (2016).

3.3.3.4 Surface Water Toxicity Testing

MPMC has conducted a post-event toxicity testing program since the tailings spill occurred, in which surface water samples collected from Quesnel Lake were tested using a series of standard laboratory tests using sensitive plant, invertebrate, and fish test species. The program provides an important evaluation of the bioavailability and toxicity of POIs as they are observed in site-specific samples. The laboratory testing provides a direct measure of biological effect to individual organisms under site-relevant conditions, and includes sensitive test species representing primary producers, primary consumers, and secondary consumers.

The results of post-event toxicity testing conducted between August 2014 and February 2015 (MPMC 2015 Appendix F) indicated that receiving environment waters in Quesnel Lake were not acutely toxic (i.e., lethal) to sensitive plant, invertebrate, and fish species, nor chronically toxic (i.e., sub-lethal, longer term effects) to sensitive plant and fish species. Reproductive test responses in *Ceriodaphnia* were observed in three samples. The responses were inferred to be related to suspended matter in the samples, as filtered samples from the same locations did not elicit toxicity.

In subsequent sub-lethal toxicity tests with water samples collected from Quesnel Lake between March and December 2015, no impacts on survival and growth of fish were observed, and no impacts on survival of invertebrates were observed (Appendix F). The only observed effects were on reproduction of invertebrates in a subset of the unfiltered samples collected in Quesnel Lake close to the Hazeltine Creek mouth in January and March 2015. Again, no effects were reported in the corresponding filtered samples. Dissolved copper concentrations were not different between filtered and unfiltered samples. All measured parameters were below corresponding BC WQGs, supporting our interpretation that exposure to suspended particulate matter in the unfiltered samples may have resulted in the reproduction responses. The results of toxicity testing conducted between March and December 2015 are presented in Table 3-10.

Table 3-10: Summary of Surface Water Toxicity Testing in Quesnel Lake (March to December 2015)

Test	Sample ID	Date	T. Cu (mg/L)	D. Cu (mg/L)	LC50 (% v/v)	IC25 (% v/v)	IC50 (% v/v)
7-d fathead minnow survival and growth	QUL-66-0m	15 Jan 2015	0.0043	0.0019	>100	83.2 (46.7-100)	>100

7- to 8-d <i>C. dubia</i> survival and reproduction	QUL-66-0m	15 Jan 2015	0.0043	0.0019	>100	11.1 (7.2-29.1)	>100
	QUL-66-0m (Filtered)		-	0.0019	>100	>100	>100
	QUL-66-85m		0.0049	0.002	>100	8.3 (2.3-23.0)	>100
	QUL-66-85m (Filtered)		-	0.002	>100	>100	>100
	QUL-66-0M	02 Mar 2015	-	-	>100	74.2 (5.7-NC)	>100
	QUL-66-0M (Filtered)		-	-	>100	>100	>100
	QUL-55a-0M		25 Aug 2015	0.00095	0.00055	>100	>100

Notes: Samples were not filtered, unless indicated otherwise. Effect concentration expressed on a volume/volume basis; in instances where an effect was observed, 95% confidence limits were not always calculable (NC). LC50 = Lethal concentration causing 50% mortality. IC25/IC50 = Non-lethal concentration causing 25% or 50% reduction in growth or reproduction. Total and dissolved copper (T. Cu and D. Cu) concentrations for January to August samples are provided in Appendix B.

3.3.3.5 Plankton Community and Tissue Metal Analysis

Sampling of plankton was conducted weekly in 2014 in the months immediately following the tailings spill (September to November; MPMC 2015 Appendix H) and then monthly between May and September 2015 (Appendix G). Plankton communities exhibit inherent variability related to temperature, daylight, depth sampled etc. Because the same months were not sampled in both 2014 and 2015 the data between years are not directly comparable. Due to differences in resolution of taxonomic identification as well as units, the zooplankton abundance and biomass data were not compared to pre-event data presented in Hume et al. (2005) and MacLellan et al. (1993). Thus, the update report focuses on characterizing the plankton community observed between May and September 2015.

In 2015, plankton communities were sampled at three stations in Quesnel Lake (one near field exposure station and two far field reference stations) during the open water period from May to September. Spatial and temporal trends in phytoplankton biomass (as chlorophyll a), and zooplankton abundance and biomass were qualitatively examined by plotting the data. Trophic status of Quesnel Lake was determined through comparison of chlorophyll a, nutrient concentrations, and water transparency (Secchi depths). The evaluation of trophic status indicated that Quesnel Lake is oligotrophic (nutrient-poor, unproductive system). Chlorophyll a in Quesnel Lake was low and seasonally variable, and chlorophyll a concentrations generally increased through the open water period from May to September.

The zooplankton tissue results are presented in Figures 9a to 9d, below. A brief summary of the findings for Quesnel Lake sampling is as follows:

- Phytoplankton biomass (as chlorophyll *a*) in Quesnel Lake was below 1.0 µg/L in all sampling events, but varied seasonally. Chlorophyll *a* concentrations generally increased through the open water period from May to September. Overall, Quesnel Lake is classified as oligotrophic based on several classification systems, which use nutrients (total phosphorus and total nitrogen), Secchi depths, and chlorophyll *a* concentrations to evaluate trophic status.
- Total zooplankton biomass and abundance in Quesnel Lake during the open water period of 2015 was generally higher than values observed during post-event sampling in fall of 2014. Seasonal variability was observed through the open water period of 2015 with a generally increasing trend in biomass and a generally decreasing trend in abundance observed from May to September 2015.
- Zooplankton biomass and abundance in Quesnel Lake were generally dominated by either cyclopoid copepods or cladocerans. Seasonal differences were observed throughout the open water period of 2015 with cyclopoid copepods generally dominant in spring and early-summer and cladocerans dominant in late-summer and fall. Limited spatial variability was observed among stations with similar trends observed at the Hazeltine, Horsefly, and Junction stations through the open water period in 2015.
- Zooplankton tissue concentrations of copper, selenium, mercury, and arsenic were plotted by sampling period for each station in Quesnel Lake to qualitative evaluate trends in these parameters in comparison to aqueous concentrations of these parameters at comparable water quality sampling locations.
 - An increasing trend in arsenic concentrations was observed in zooplankton tissue from all three stations; however, this trend was not observed in aqueous arsenic concentrations at comparable water sampling stations. In 2015, aqueous arsenic concentrations were generally similar at all three stations and all concentrations were below the BC WQG. The trends in tissue concentrations do not reflect what is observed in arsenic concentrations in surface water collected from nearby locations.
 - No consistent trends were observed in zooplankton copper concentrations measured in sampling events from 2014 and 2015. Tissue concentrations of copper were generally higher at Hazeltine compared to the other two stations. In 2014, tissue concentrations of copper appeared to increase from October to November; however, this same increasing trend was not observed to continue in 2015. One elevated copper concentration was observed at Hazeltine in May 2015. Given that copper does not biomagnify in freshwater systems (Cardwell et al. 2013) and aqueous copper concentrations in May 2015 were similar to or lower than aqueous concentrations during other sampling events that did not result in comparable copper concentrations in tissue, this elevated value appears to be anomalous.
 - Zooplankton tissue mercury concentrations were variable at all three stations, with no consistent spatial or temporal trends. In 2015, tissue concentrations of mercury at Hazeltine and Junction increased between May and September to values within the range observed at Junction in September 2014. Aqueous mercury data are sparse and aqueous concentrations were below the reported detection limit in all samples and interpretation of aqueous mercury trends is therefore limited.
 - Zooplankton tissue selenium concentrations appeared to exhibit a generally increasing trend at all stations throughout the 2015 sampling period with the exception of the August 2015 sampling event when lower concentrations were observed. Over the open-water period of 2015, aqueous selenium concentrations exhibited a slight decreasing trend.

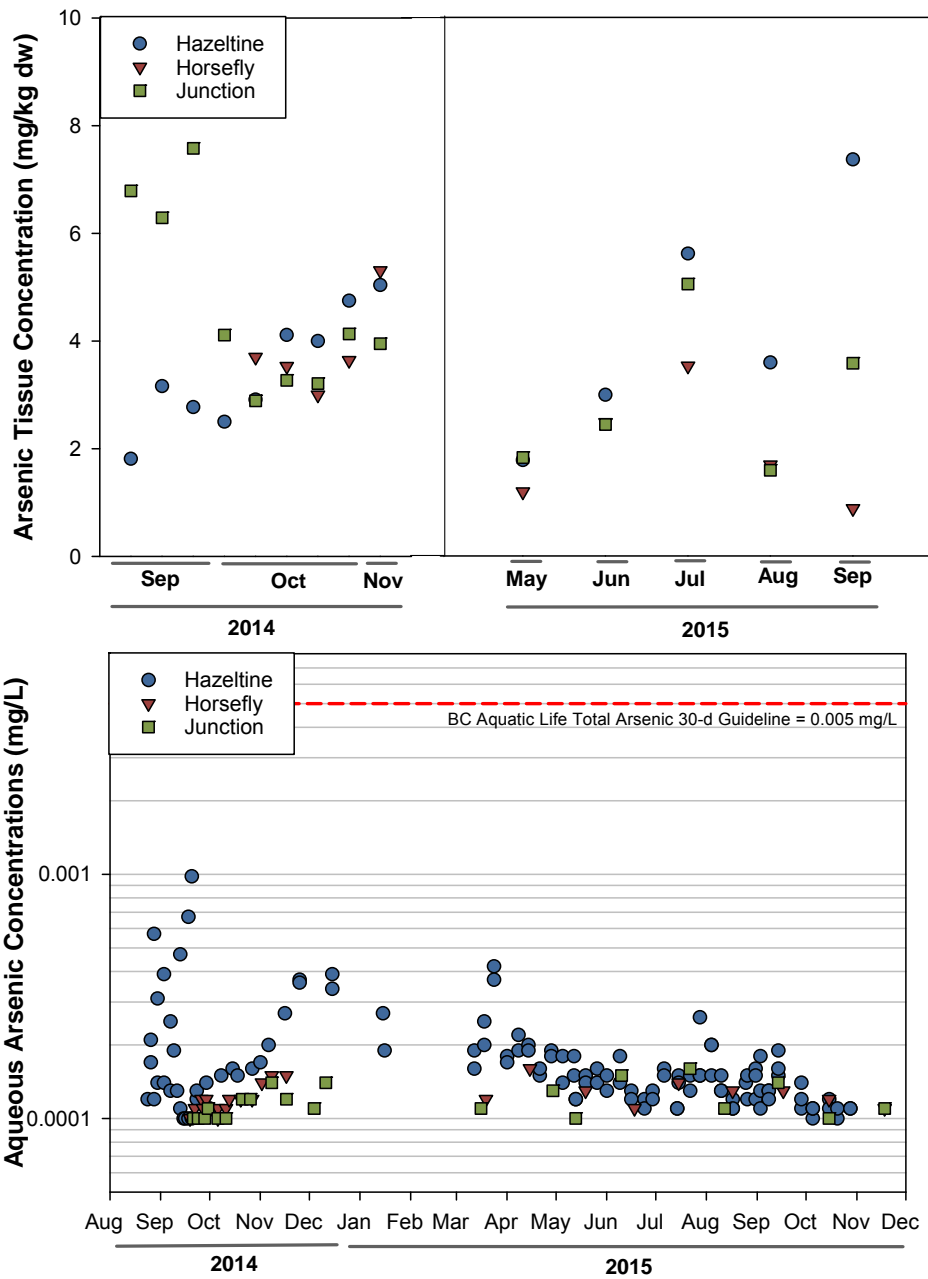

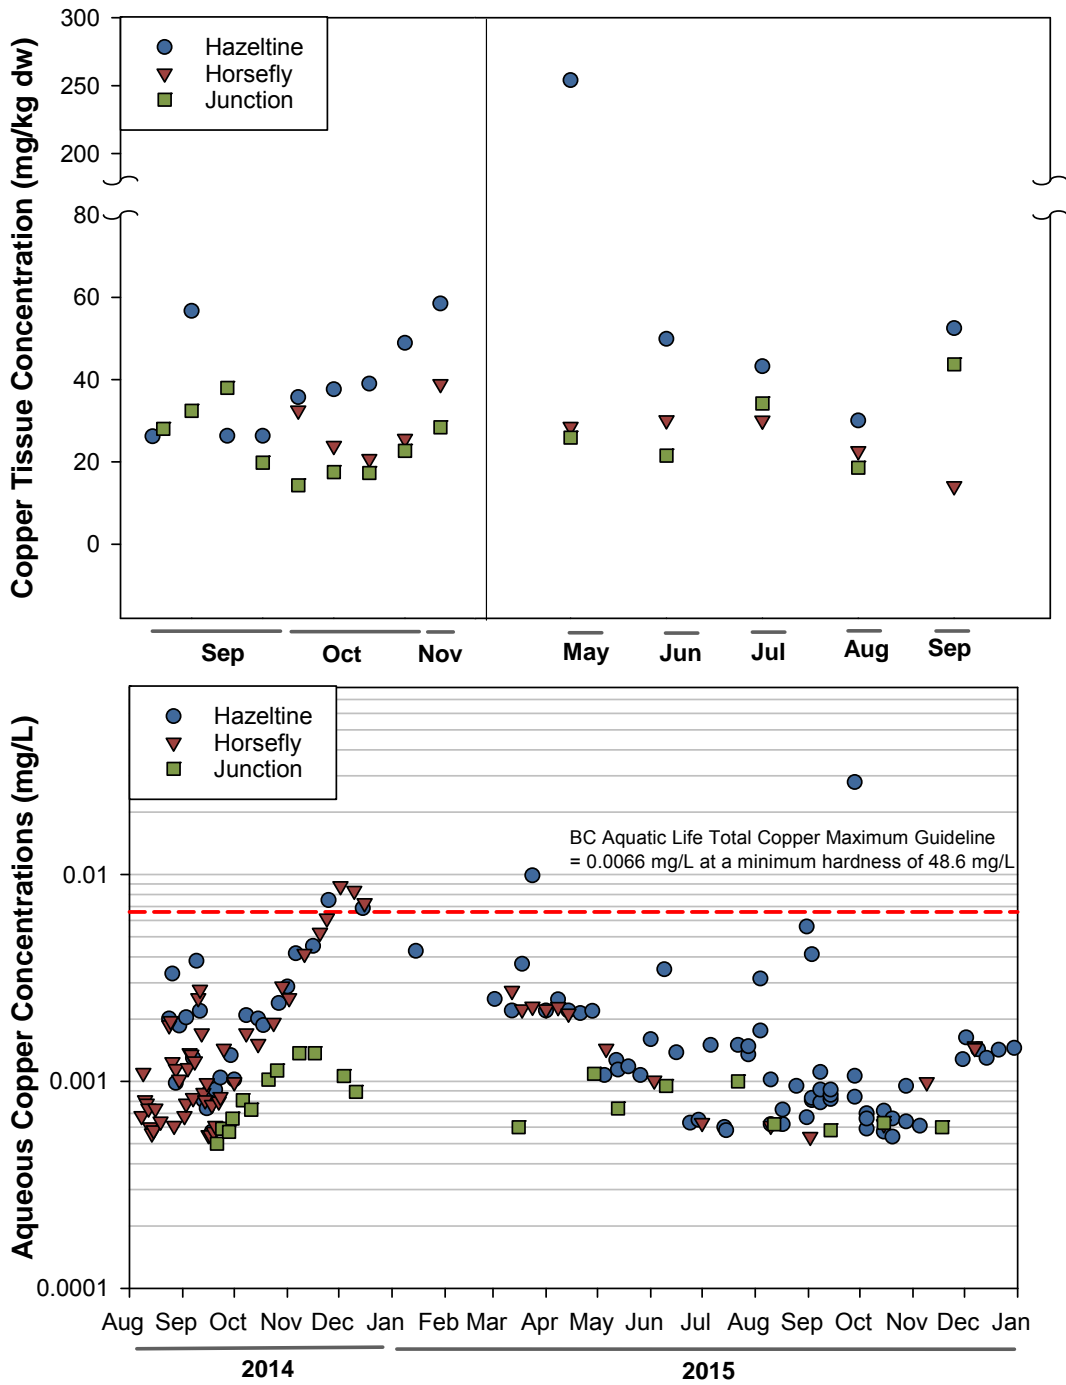

Figure 9a: Concentrations of Arsenic in Zooplankton Tissue and Surface Water Collected from Quesnel Lake in Fall 2014 and 2015.

Note: Potentially anomalous value observed in Hazeltine in May 2015.

Figure 9b: Concentrations of Copper in Zooplankton Tissue and Surface Water Collected from Quesnel Lake in Fall 2014 and 2015.

Note: Open symbols represent non-detect values.

Figure 9c: Concentrations of Mercury in Zooplankton Tissue and Surface Water Collected from Quesnel Lake in Fall 2014 and 2015.

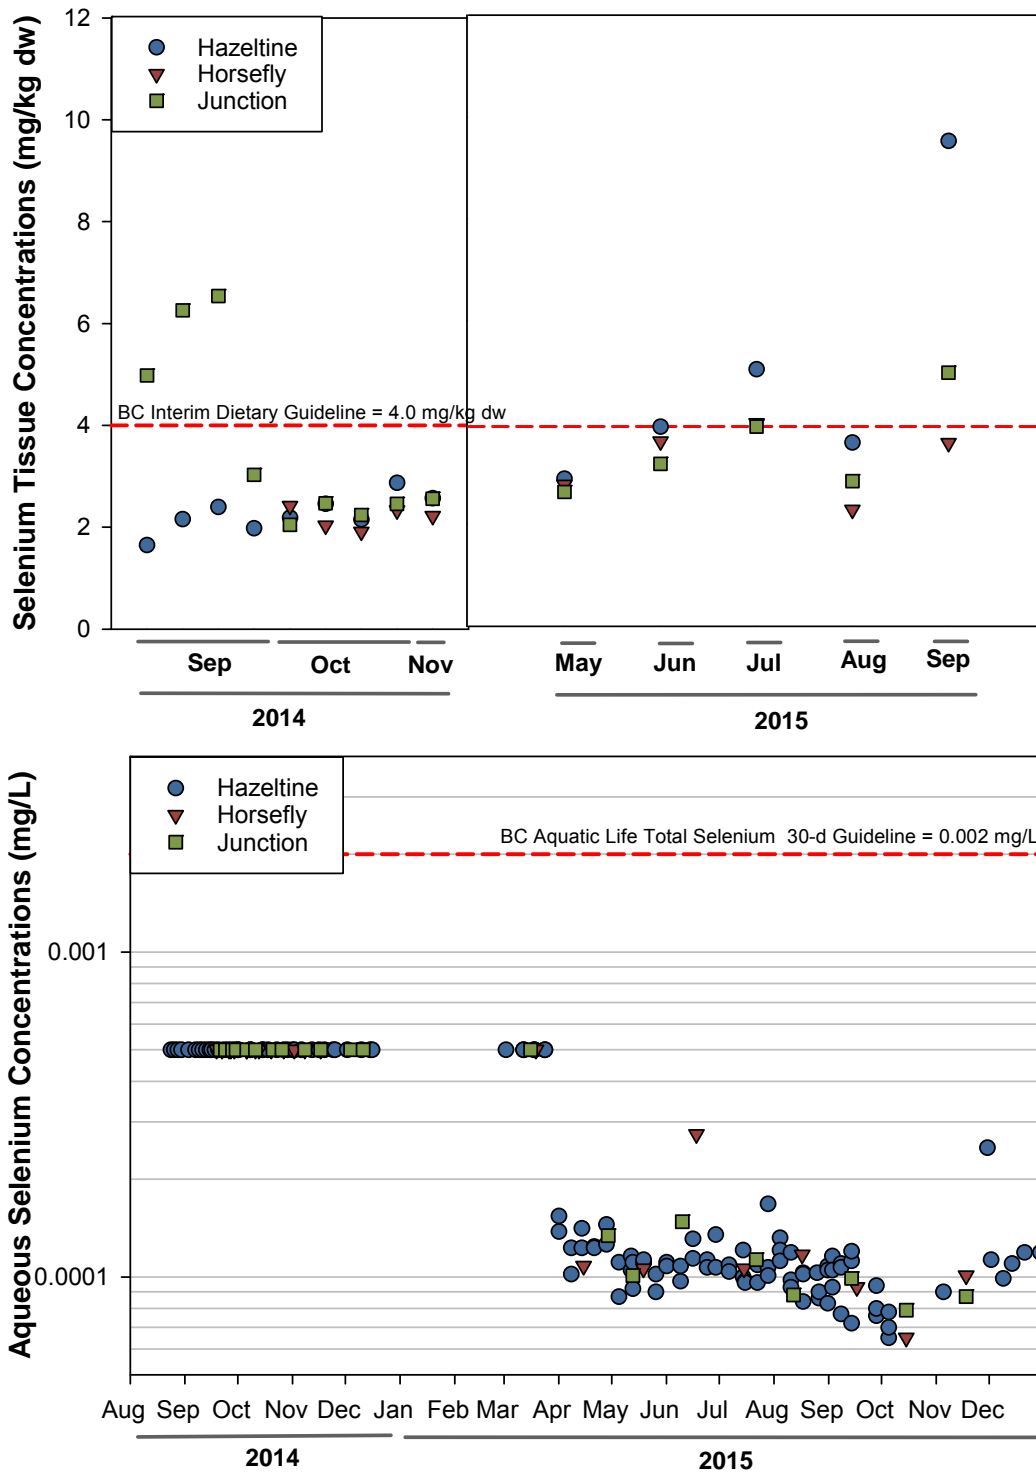

Figure 9d: Concentrations of Selenium in Zooplankton Tissue and Surface Water Collected from Quesnel Lake in Fall 2014 and 2015.

3.3.3.6 Fish Productivity

Post-event toxicity testing indicated that Quesnel Lake water did not affect survival or growth of fish, survival or growth of daphnid zooplankton, or growth of plant test species. The literature indicates that the direction of change in primary productivity as a result of introduction of suspended sediments to a lake depends on whether the phytoplankton are light limited or nutrient limited. The information available suggest that there was an influx of phosphorus into Quesnel Lake. Although changes in phytoplankton and zooplankton biomass were not observed, juvenile Sockeye Salmon collected west of Cariboo Island in 2014 were larger than those from the lake east of Cariboo Island. Juvenile Sockeye Salmon collected west of Cariboo Island in 2015 were similar in size to fish collected in other parts of the lake pre-event and in 2015. The absence of an observed increase in either phytoplankton or zooplankton abundance may reflect grazing/predation, which may in turn be reflected in the larger and possibly more numerous juvenile Sockeye observed in DFO's data compared to previous years.

3.3.3.7 Fish Tissue Metal Concentrations

Multiple stakeholders collected fish tissue samples following the release of tailings. Golder consolidated the data from these multiple sources into a single dataset to facilitate data review. The methods used to present the data are discussed in detail in Appendix H. The following section summarizes the observations made for Quesnel Lake.

3.3.3.7.1 Comparison to Tissue Guideline

- There were no arsenic guideline exceedances observed for Quesnel Lake fish.
There were mercury guideline exceedances observed for Quesnel Lake fish, as outlined in Table 3-11, below:

Table 3-11: Summary of mercury guideline exceedances in fish sampled from Quesnel Lake (2014-2015)

Table with 4 columns: Year, Species, Location, and Number and Type. It details mercury guideline exceedances for Burbot and Lake Trout in 2014 and 2015 across various locations in Quesnel Lake.

Selenium concentrations that exceed the BC MoE screening values for the protection of First Nation subsistence consumers and the general population are outlined in Table 3-12, below. The screening value for the protection of First Nation subsistence consumers of 7.3 ug/g dw was based on a fish ingestion rate of 220 g/day (Health Canada, 2004). The screening value for the protection of the general population of 17.5 ug/g dw was based on a fish ingestion rate of 111 g/day (Health Canada, 2004). Exceedances were noted for both exposed and reference sites. Selenium concentrations in Quesnel Lake fish that exceed the BC MoE guideline for Environmental Protection are outlined in Table 3-13, below.

Table 3-12: Exceedances of MoE selenium screening values in fish tissues collected from exposed and reference sites in Quesnel Lake

Guideline	Year	Species	Location	Number and Type
Low Fish Intake (75 mg/kg dw) Recreational Fishers	2014	Rainbow Trout	Quesnel Lake near Quesnel River (exposure)	1 of 2 liver
		Rainbow Trout	Quesnel River (exposure)	1 of 12 liver
	2015	Kokanee	Quesnel Lake near Quesnel River (exposure)	1 of 8 liver
Moderate Fish Intake (14.5 mg/kg dw) General Population	2014	Burbot	Quesnel Lake Hazeltine Creek (exposure)	2 of 12 liver
		Kokanee	Quesnel Lake near Quesnel River (exposure)	10 of 10 liver
		Kokanee	Quesnel Lake North Arm (reference)	10 of 10 liver
		Lake Trout	Quesnel Lake Hazeltine Creek (exposure)	1 of 51 liver
		Rainbow Trout	Quesnel Lake near Quesnel River (exposure)	2 of 2 liver
		Rainbow Trout	Quesnel River (exposure)	2 of 3 ovary, 8 of 12 liver, 1 of 12 muscle

Guideline	Year	Species	Location	Number and Type
High Fish Intake (7.3 mg/kg dw) First Nation Subsistence	2015	Kokanee	Quesnel Lake near Quesnel River (exposure)	8 of 8 liver
		Rainbow Trout	Quesnel River (exposure)	6 of 8 liver
		Sockeye Salmon (juvenile)	Quesnel Lake East (reference)	1 of 3 liver
		Sockeye Salmon (juvenile)	Quesnel Lake North Arm (reference)	1 of 3 liver
		Sockeye Salmon (juvenile)	Quesnel Lake Middle (exposure)	1 of 4 liver
		Sockeye Salmon (juvenile)	Quesnel Lake West (exposure)	1 of 7 liver
	2014	Burbot	Quesnel Lake Hazeltine Creek (exposure)	1 of 8 ovary, 2 of 12 liver
		Kokanee	Quesnel Lake Quesnel River (exposure)	10 of 10 liver
		Kokanee	Quesnel Lake North Arm (reference)	10 of 10 liver
		Lake Trout	Quesnel Lake Hazeltine Creek (exposure)	36 of 51 liver
Mountain Whitefish		Quesnel Lake Hazeltine Creek (exposure)	3 of 3 ovary, 3 of 4 liver	
Rainbow Trout		Quesnel Lake near Quesnel River (exposure)	2 of 2 liver	
Rainbow Trout		Quesnel River (exposure)	3 of 3 ovary, 10 of 12 liver, and 1 of 12 muscle	
Sockeye Salmon (juvenile)		Quesnel Lake North Arm (reference)	3 of 3 liver	
Sockeye Salmon (juvenile)		Quesnel Lake Middle (exposure)	1 of 3 liver	
Sockeye Salmon (juvenile)		Quesnel Lake West (exposure)	6 of 6 liver	

Guideline	Year	Species	Location	Number and Type
	2015	Burbot	Quesnel Lake Hazeltine Creek (exposure)	1 of 1 ovary
		Kokanee	Quesnel Lake Quesnel River (exposure)	8 of 8 liver
		Lake Trout	Quesnel Lake Hazeltine Creek (exposure)	2 of 9 kidney, 1 of 10 liver
		Lake Trout	Quesnel Lake East (reference)	3 of 10 kidney, 2 of 10 liver
		Rainbow Trout	Quesnel River (exposure)	1 of 1 ovary, 7 of 8 kidney, 8 of 8 liver
		Sockeye Salmon (juvenile)	Quesnel Lake North Arm (reference)	3 of 3 liver
		Sockeye Salmon (juvenile)	Quesnel Lake Middle (exposure)	4 of 4 liver
		Sockeye Salmon (juvenile)	Quesnel Lake West (exposure)	7 of 7 liver
		Sockeye Salmon (juvenile)	Quesnel Lake East (reference)	3 of 3 liver

Table 3-13: Summary of Selenium Tissue Exceedances for Environmental Protection

Year	Species	Location	Type and Number
2014	Rainbow Trout	Quesnel Lake near Quesnel River (exposure)	1 of 2 muscle
	Northern Pikeminnow	Quesnel Lake Hazeltine Creek Confluence (exposure)	2 of 36 whole-body
	Northern Pikeminnow	Quesnel Lake Horsefly River Confluence (exposure)	1 of 10 whole-body
	Northern Pikeminnow	Quesnel Lake North Arm (reference)	1 of 31 whole-body
2015	Largescale Sucker	Quesnel Lake Hazeltine Creek Confluence (exposure)	1 of 8 muscle
	Peamouth Chub	Quesnel Lake Hazeltine Creek Confluence (exposure)	1 of 8 whole-body

Notes: Quesnel Lake Horsefly River confluence was previously classified as “exposure” by DFO and this classification was retained.

3.3.3.7.2 Risk Assessment and Toxicological Context

For Quesnel Lake, Golder selected a subset of fish species for which there are adequate data (e.g., at least 8 samples in both exposure and reference sites; sampled in both years) and focused on species that represent small-bodied fish that are more likely to reflect local conditions and large bodied fish that likely reflect exposure in a larger area and are valued for human consumption. The following species were selected:

- Peamouth Chub and juvenile Sockeye Salmon were selected as a representative small-bodied fish that are expected to occupy a smaller home range (relative to large-bodied fish such as Lake Trout or Rainbow Trout) and would be consumed by piscivorous fish. Definitive data regarding Peamouth Chub home range size are not currently available, but literature supports this assumption (e.g., Environment Canada 1995). There is also an adequate number of Peamouth Chub samples from both exposed and reference sites in both years. Juvenile Sockeye Salmon were also considered to occupy a smaller home range, although they move from their spawning habitats out into the open lakes as they mature.
- Lake Trout and Rainbow Trout were selected as representative larger-bodied fish that are likely to be consumed by humans (and potentially, by large piscivorous wildlife). There are also adequate numbers of Lake Trout and Rainbow Trout samples from both exposed and reference sites in both years.
- Adult Sockeye Salmon were excluded because the duration and frequency of their time in impacted areas is limited to migration back to their natal streams. Feeding during this time is expected to be minimal. Juvenile Sockeye Salmon are included because they would be residents within the study area and are of concern to many stakeholders.

The primary focus of the comparison was between locations that shared a similar ecology. Fish samples from exposed sites in Quesnel Lake were compared to reference sites in Quesnel Lake.

Human Consumption of Fish

Figure 5 in the Polley Lake section above, provides a summary of the available box plots for specific metals in the muscle samples from large-bodied fish species. As described above, Lake Trout, Rainbow Trout and juvenile Sockeye Salmon were identified as a reasonable surrogate for the preliminary consideration of this pathway. Individual box plots with pair-wise comparisons for different sites, species and years are provided in Appendix H. The purpose of this figure is to highlight whether there are obvious changes in metal accumulation between reference and exposed sites, or between years that would indicate that there has been a change in metal concentrations in muscle tissue that is frequently consumed by people. In brief, results are summarized as follows:

- Arsenic concentrations in muscle samples were similar among reference and the exposed sites. The box plots for Rainbow Trout and Lake Trout caught in exposed sites in Quesnel Lake overlapped with the box plots for Lake Trout collected from the reference sites in Quesnel Lake, indicating that there was not a significant increase in fish tissue concentrations observed. All measured concentrations were less than the preliminary tissue guideline.
- Copper, selenium and zinc concentrations in muscle samples were similar among reference and exposed sites. There was one muscle sample from a Rainbow Trout collected at Quesnel River in 2014 that exceeded the BC screening value for selenium for the protection of subsistence fish consumers. Concentrations were below the screening value in 2015.

- Mercury concentrations in muscle samples appeared to be similarly variable between exposed sites and reference sites. About 10% Lake Trout muscle samples from both exposed and reference areas of Quesnel Lake had tissue concentrations that exceeded the muscle preliminary tissue guideline for the protection of human health in both years.

Bioaccumulation by Fish

Figures 6 and 7 (liver and ovary) in the Polley Lake section above, provide summaries of the available fish tissue chemistry data for organ-specific samples presented as censored box plots for the specific metals identified. Individual censored box plots showing comparisons of exposure and reference sites, species and years are provided in Appendix H, Attachment 2. The purpose of the summary figures presented herein is to highlight changes in metal concentrations between reference and exposed sites, or between years in tissues that have been associated with metal accumulation. In brief, results are summarized as follows:

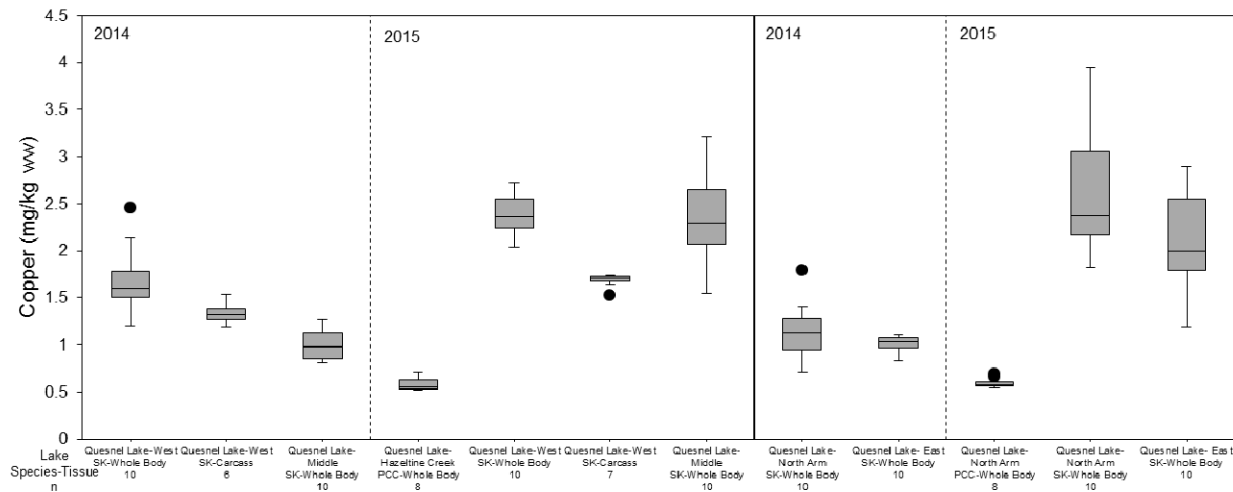

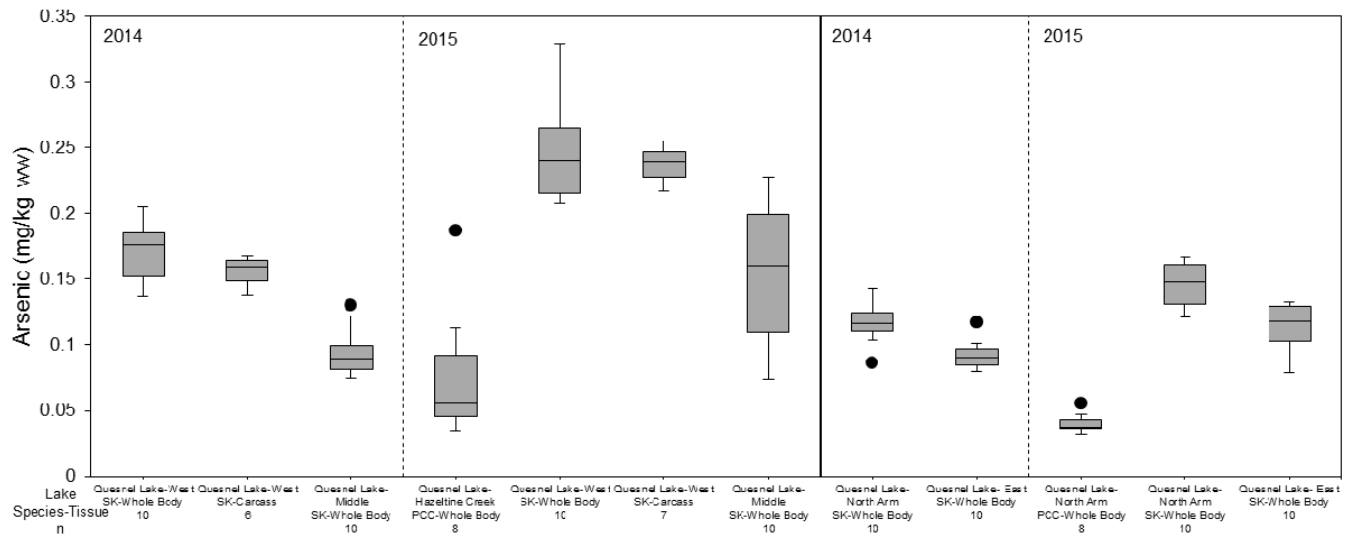

- For arsenic and copper, liver concentrations were generally consistent between the exposed and reference sites. One potential exception is juvenile Sockeye Salmon from Quesnel Lake (West) which tended to have higher liver arsenic and copper concentrations than those observed in other species. There are no juvenile Sockeye Salmon liver samples from reference sites, and therefore, it is not clear whether this is a species-specific difference (i.e., Sockeye accumulate more arsenic in their liver than Rainbow Trout) or a potential site-specific influence. For arsenic in kidney samples, there may be an increased concentration at the Quesnel River exposed site compared to Quesnel Lake – East. However the Lake Trout collected from Quesnel Lake at Hazeltine were similarly low compared to Quesnel Lake – East.
- Mercury concentrations in fish liver were variable for both the reference sites and exposed sites. Some of these concentrations exceeded the fish tissue guidelines as outlined above. Liver tissue is not commonly consumed, but Golder would welcome input on this from the Williams Lake Indian Band and Soda Creek First Nation.
- Selenium concentrations in liver were similar between exposed and reference samples in Quesnel Lake and concentrations exceeded the guideline for environmental protection in some samples.
- Vanadium concentrations were generally not detected in fish from either exposed or reference in Quesnel Lake.
- Zinc concentrations in Lake Trout liver and kidney were low in both reference and exposed areas of Quesnel Lake.

Consumption by Piscivores

A summary of the box plots for specific metals in the available whole body Peamouth Chub and juvenile Sockeye Salmon samples is provided in Appendix H and Figure 10 below. Peamouth Chub and juvenile Sockeye Salmon were considered reasonable surrogates for the preliminary consideration of potential risks to piscivorous wildlife. The purpose of this summary figure is to highlight whether there are obvious changes in metal accumulation between reference and exposed sites, or between years that would indicate that this pathway is operable.

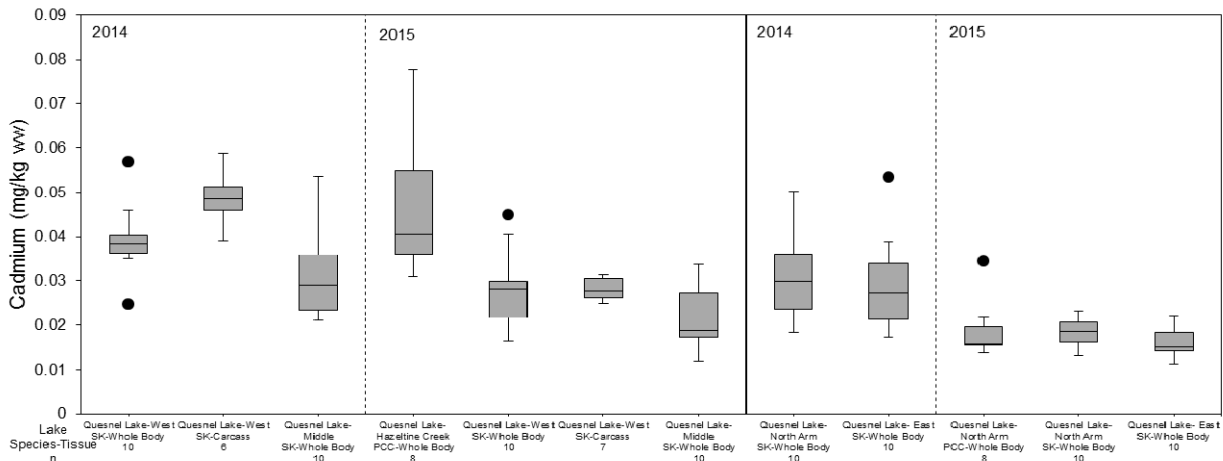

PEEIAR UPDATE REPORT - MOUNT POLLEY MINE

PEEIAR UPDATE REPORT - MOUNT POLLEY MINE

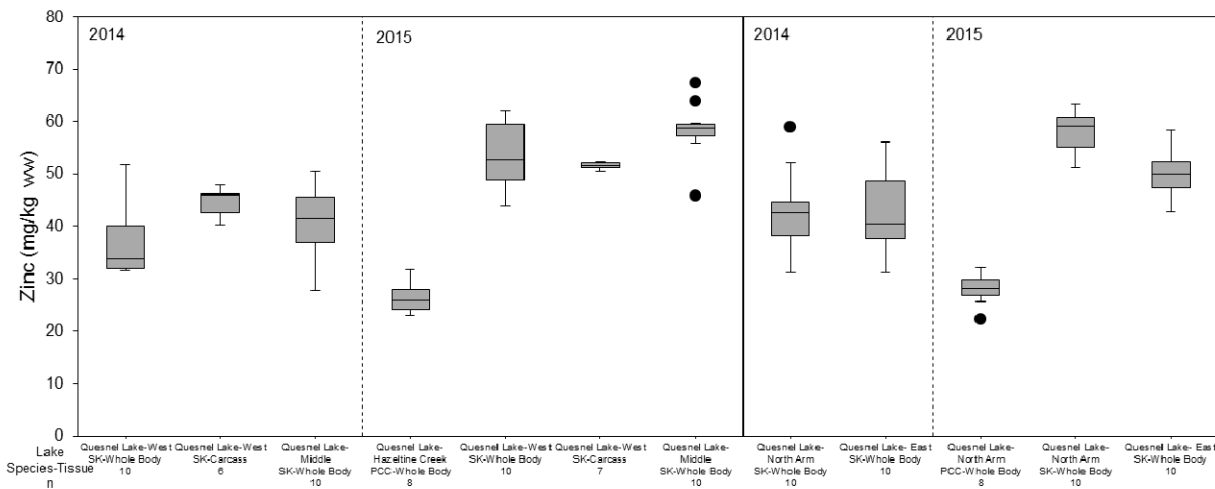

Figure 10: Summary of Available Whole Body and Carcass Chemistry Data for Sockeye Salmon and Peamouth Chub from Relevant Sampling Sites (2014, 2015).

Note: Boxplots are censored at the detection limit (DL = solid horizontal line). Concentrations below the DL are plotted as an open symbol at half the DL. Extreme values are plotted as individual values. mg/kg ww = milligrams per kilogram wet weight; mg/kg dw = milligrams per kilogram dry weight; n = sample size. Dashed vertical lines (---) indicate the separation of years. Solid vertical lines (-) indicate the separation of exposure and reference; dashed horizontal lines (---) indicate guidelines from CFIA (mercury) or BC MoE (selenium).

Cadmium, mercury and selenium concentrations may be elevated in whole body Peamouth Chub samples collected from Quesnel Lake at Hazeltine Creek relative to Quesnel Lake in the North Arm, based on the lack of overlap in their box plots. Conversely, the box plots overlapped for zinc and copper, indicating that the concentrations were similar between exposed and reference fish. This comparison is limited to one exposed site (Quesnel Lake – Hazeltine Creek) compared to one reference site (Quesnel Lake – North Arm).

For juvenile Sockeye Salmon, arsenic concentrations may be higher in whole body samples from exposed compared to reference and also higher in 2015 compared to 2014. For mercury, a difference in fish length did not allow a comparison between exposed and reference fish. There were no apparent spatial or temporal trends in the whole body concentrations of copper, cadmium, selenium and zinc in juvenile Sockeye Salmon. MPMC will continue to monitor fish tissue metal concentrations under the CEMP.

3.4 Quesnel River

3.4.1 Physical

Quesnel River is the major drainage from Quesnel Lake and is located at the north end of the lake's West Basin. The river is located approximately 13 km north of where Hazeltine Creek discharges into Quesnel Lake. Modelling predicted that by summer 2015, between 15% and 20% of the original amount of suspended material in Quesnel Lake from the tailings spill would have been discharged into Quesnel River (MPMC 2015 Appendix B). That amount of material represents 12% or less of the river's annual sediment load.

Following the tailings spill, turbidity concentrations in Quesnel River were generally below the long-term BC WQG, with the exception of measurements from late November 2014 to late January 2015 following the fall turnover of Quesnel Lake and mixing of the deep turbid water. Daily average and in situ turbidity concentrations in Quesnel River have shown an overall progressive decrease over time throughout 2015.

3.4.2 Chemical

Surface Water Quality Update

Water quality data collected from Quesnel River by MPMC has been evaluated to assess temporal trends of POI since the tailings spill through December 2015 (Appendix D). The water quality assessment was based on comparison of water chemistry to BC WQGs. For a period of time following the fall turnover of Quesnel Lake, concentrations of total copper in Quesnel River exceeded the short-term BC WQG. However, water quality in Quesnel River since January 2015 has not exhibited any concentrations of metals greater than guidelines or standards. Based on the evaluation of 2015 water quality data, no POIs remain in Quesnel River.

Sediment Quality Update

The Quesnel River is erosional and no areas of sediment deposition were identified during sampling and therefore impact characterization did not include sediment.

3.4.3 Biological

3.4.3.1 *Benthic Invertebrate Biomass and Tissue Metal Concentrations*

Benthic invertebrate samples collected from the Quesnel River and the corresponding reference area (Cariboo River) were more diverse than those collected from Hazeltine Creek, and were composed mainly of stoneflies, mayflies, caddisflies, and snails.

Benthic invertebrates from the Quesnel River did not have significantly different mean concentrations of any of the contaminants relative to those from the reference river (upper Cariboo River; Appendix E). PCA results supported this finding, with very little to no distinction present between the exposed and reference.

3.4.3.2 *Surface Water Toxicity Testing*

MPMC has conducted a post-event toxicity testing program since the tailings spill occurred, in which surface water samples collected from Quesnel River were tested using a battery of standard laboratory tests using sensitive plant, invertebrate, and fish test species. The program provides an important evaluation of the bioavailability and toxicity of POIs as they are observed in site-specific samples. The laboratory testing provides a direct measure of biological effect to individual organisms under site-relevant conditions, and includes sensitive test species representing primary producers, primary consumers, and secondary consumers.

The results of post-event toxicity testing conducted between August 2014 and February 2015 (MPMC 2015 Appendix F) indicated that receiving environment waters in Quesnel River were not acutely toxic (i.e., lethal) to sensitive plant, invertebrate, and fish species, nor chronically toxic (i.e., sub-lethal, longer term effects) to sensitive plant and fish species.

In subsequent sub-lethal toxicity tests with water samples collected from Quesnel River between March and December 2015, no impacts on survival and growth of fish were observed, and no impacts on survival of invertebrates were observed (Appendix F). One unfiltered sample collected from Quesnel River in March 2015 showed a slight (IC25% = 95.9) reproductive test response. This response was not associated with elevated water chemistry (i.e., concentrations of all parameters in this sample were below applicable BC WQGs), nor did the response align with fish toxicity testing results reported for the same sample. The results of toxicity testing conducted between January and December 2015 are presented in Table 3-14 .

Table 3-14: Summary of Surface Water Toxicity Testing in Quesnel River (January to December 2015)

Test	Sample ID	Date	T. Cu (mg/L)	D. Cu (mg/L)	LC50 (% v/v)	IC25 (% v/v)	IC50 (% v/v)
7-d fathead minnow survival and growth	QUR-1	07 Jan 2015	0.004	0.0016	>100	>100	>100

	QUR-1	24 Aug 2015	0.00067	<0.00050	>100	>100	>100
	QUR-1	12 Nov 2015	0.00082	<0.00050	>100	>100	>100

Notes: Samples were not filtered, unless indicated otherwise. Effect concentration expressed on a volume/volume basis; in instances where an effect was observed, 95% confidence limits were not always calculable (NC). LC50 = Lethal concentration causing 50% mortality. IC25/IC50 = Non-lethal concentration causing 25% or 50% reduction in growth or reproduction. Total and dissolved copper (T. Cu and D. Cu) concentrations for January to August samples are provided in Appendix B; concentrations for September to November samples are MPMC unpublished data.

4.0 OVERALL SUMMARY OF IMPACTS FROM TAILINGS SPILL

To date, the post-event studies continue to indicate that the tailings spill has resulted in physical impact to Polley Lake, Hazeltine Creek and valley, the mouth of Edney Creek, the benthic environment in the West Basin of Quesnel Lake, and the communities in these environments. Observations of potential chemical and biological impacts have been made:

- Soil and sediment data show that there are some metals that exceed guidelines and/or standards.
- Geochemistry investigations continue to indicate that the tailings are not acid-generating and have low leaching potential. A preliminary groundwater investigation involving limited sampling of shallow groundwater from within the tailings deposited in Hazeltine Creek valley had concentrations of metals that were below groundwater standards. Further investigation is planned for the summer of 2016.
- Surface water data has shown a decreasing trend in the concentrations of total metals and turbidity that were associated with the tailings spill. Concentrations of all contaminants that were initially elevated are now below water quality guidelines, with the exception of copper in Hazeltine Creek.
- Surface water has been tested using a series of toxicity tests and found to be not toxic to various aquatic test species. Some turbid samples appeared to impact on performance of one of the aquatic insects. However, zooplankton samples have not shown a decreasing trend in biomass in Quesnel Lake.
- Sediment toxicity testing was conducted and found to be associated with low toxicity. The sediment substrate, low in TOC and particle size, was found to hinder performance of benthic invertebrates in standard tests. The changed environment may also slow the progress of natural re-colonization in the profundal zone.
- Benthic invertebrate biomass measurements indicate lower populations in Polley Lake and the deeper (profundal) areas of the West Arm of Quesnel Lake.
- Benthic invertebrate biomass was similar to reference in the littoral areas of Quesnel Lake, Quesnel River and Edney Creek.
- Benthic invertebrate tissue concentrations indicate higher concentrations of metals, including selenium in Polley Lake compared to Bootjack Lake. Copper concentrations were higher in the deeper (profundal) areas of the West Arm of Quesnel Lake compared to reference. Concentrations of copper and vanadium in benthic invertebrates were higher in Hazeltine Creek following the tailings spill, but the concentrations of selenium were higher prior to the breach than after, and higher than 2015 measurements for Polley Lake. Concentrations of metals in Edney Creek benthic invertebrates were not different from reference.
- Available data for evaluating fish productivity for Polley Lake indicates that it is currently similar to reference conditions. Further investigation into potential impacts of selenium tissue concentrations in Rainbow Trout to productivity are in-progress. Fish productivity in the West Arm of Quesnel Lake was found to be similar to reference conditions.
- Concentrations of metals in fish were generally found to be variable and, with a few exceptions, the concentrations observed at exposed sites were similar to reference sites. Selenium in Polley Lake Rainbow Trout ovary tissue in 2015 was one of the few metal/tissue combinations that suggest a significant increase in metal accumulation may be present; however, this data set is considered anomalous relative to the preponderance of available selenium tissue data and was not duplicated by data collected in the spring of 2016. Notwithstanding the potential for anomalous data in a subset of the available ovary data, Golder recommends further evaluation of long-term trends in selenium concentrations and their potential for adverse effects to aquatic populations in a site-specific risk assessment and monitoring of selenium concentrations in Polley Lake biota as part of the CEMP.

5.0 NEXT STEPS

The next steps in the Rehabilitation and Remediation Strategy is conducting the Human Health and Ecological Risk Assessment (HHERA) and this work is currently underway. Supplementary investigations conducted during the summer of 2016 will provide additional data for the risk assessment and reduce uncertainty regarding environmental conditions. MPMC is moving ahead with further remediation of the affected areas on the mine site and in Hazeltine Creek and have also developed their CEMP, required under Permit 11678. The CEMP contains a detailed plan to monitor potential impacts associated with on-going operations and to provide confirmation that conditions associated with the tailings spill measured during these earlier investigations are either representative of conditions in the future, or that conditions will continue to improve over time.

6.0 CLOSURE

We trust that this report meets your needs at this time. If you have any questions regarding this work, please do not hesitate to call Trish Miller.

Executive Summary

A geochemical characterization program was developed and carried out by SRK Consulting (Canada) Inc. on spilled tailings from the Mount Polley Mine (MPM) dam failure that occurred on August 4, 2014, approximately 55 km north-east of Williams Lake, BC. Initial results were provided in SRK (2015), with results pending for analysis of the non-sulphide fraction of the spilled tailings and laboratory kinetic testing (humidity cells and columns). This report provides the pending results, although kinetic testing is on-going.

Copper and selenium were the main focus of continued investigations as they were identified to be enriched in the initial study and possibly have potential for leaching. However, all parameters with guidelines for the protection of freshwater aquatic life in British Columbia are being monitored.

The non-sulphide copper analysis (i.e. a 2.5% sulphuric acid leach) indicated that up to 66% of the solid phase copper in the tailings materials is associated with the non-sulphide portion of the tailings. As extremely acidic conditions are required to leach this form of copper, it is considered to be non-reactive in the Hazeltine Creek environment because pH conditions are neutral and there is a low risk of acid rock drainage potential from the tailings.

Kinetic testing results have been reported for 32 weeks as of the date of this report. Results support the assessment that ARD is not expected from the tailings and leaching will be under neutral to alkaline conditions. Leaching rates are beginning to stabilize and general downward trends are expected to continue as the testing progresses. Variability in leaching rates is also being established and the necessary components for providing contact water chemistry predictions (i.e. geochemical source terms) will be available after testing passes 40 weeks.

One of the considerations for water chemistry prediction will be flow paths as copper and selenium leaching rate differences were noted between the humidity cells and columns. Mineral solubility limits for calcite (calcium carbonate) and tenorite (copper oxide) were reached in the columns but not in the humidity cells, with the formation of secondary copper minerals expected to limit concentrations of copper. Selenium is not expected to have a mineral solubility control under fully oxygenated conditions, but the longer water flow paths in fine grained materials may also be conducive to lower rates of oxygen diffusion and, therefore, conditions that support selenium reduction to more insoluble forms such as selenite and elemental selenium.

Kinetic testing is on-going and the current assessment of tailings reactivity and leaching rates will be updated once testing passes 40 weeks.

1 Introduction

SRK was retained by the Mount Polley Mining Corporation (MPMC) to develop and execute a plan to geochemically characterize tailings materials that were released as a result of the tailings dam failure on August 4, 2014 from the Mount Polley Mine (MPM), located approximately 55 km north-east of Williams Lake, BC. The plan included a review of existing operational data, development of a geochemical conceptual model to guide sampling design, and a sampling and analysis plan.

The majority of geochemical characterization work has been completed with interpretation of results previously reported by SRK (2015). The work presented in this report that was not previously reported includes characterization of the non-sulphide component of the tailings and laboratory kinetic testing results (i.e. humidity cells and water unsaturated columns). This report is a supporting document to the initial work and provides updates to the conclusions provided in the SRK (2015) report on the metal leaching and acid rock drainage (MLARD) potential of exposed tailings along Hazeltine Creek.

2 Background

Geochemical characterization, including acid-base accounting (ABA) tests, trace element analyses, mineralogical analyses, and sequential extractions were undertaken on representative samples of tailings that spilled into Hazeltine Creek, and Quesnel and Polley Lakes from the MPM. The characterization approach was based on SRK's sampling plan (SRK 2014) and the geochemical conceptual models presented along with complete details on the sampling and analytical methods used, field observations and analytical results are provided in SRK (2015). For ease of reference, relevant sections have been reproduced in this report.

Two types of tailings-bearing materials were observed along Hazeltine Creek. They were classified in the field as 'grey tailings' and 'magnetite sands'. Grey tailings were dominantly grey in colour and had a finer texture (silty sand) than the magnetite sands. Magnetite sands were speckled pinkish-orange and black. They were strongly magnetic and sandier than the grey tailings. The grey tailings tended to be most abundant along the embankments and upper benches of the creek, whereas the magnetite sands were commonly present in low-lying areas near the creek. With the exception of the area near the tailings dam failure and Polley Lake, the tailings were deposited in relatively thin 'skiffs' (e.g. 10 to 20 cm deep). The thickest observed tailings deposits (e.g. around 1 metre deep) were in the immediate vicinity of the tailings dam failure and Polley Lake (SRK 2015).

The main geochemical finding was that the MPM tailings are not potentially ARD generating, which is consistent with historical understanding of the tailings and the low sulphur nature of the ore deposit. Any leaching would be expected to occur under neutral to basic pH conditions only, which tends to support low mineral and element specific solubility. The only elements that were noted to be enriched when compared to typical crustal rocks (basalt) were copper and selenium. Both of these elements were expected to be associated with sulphide minerals and require oxidation to be leached. The potential for reductive dissolution processes to leach elements from

natural oxidation components of the spilled tailings that settled in Quesnel and Polley Lakes was assessed and found to be low.

The main questions/tasks remaining after the initial characterization report were:

- Confirm if copper is partially deported to non-sulphide minerals (also referred to by MPM as copper 'oxide').
- Characterize leaching rates of the spilled tailings.

Establishing the proportion of copper and other elements associated with the non-sulphide fraction is important as they are not likely to readily leach from the tailings at neutral pH. Leaching rates of the tailings have been assumed to be low, but need to be demonstrated and are an important consideration for assessing potential water chemistry changes arising from the tailings in the receiving environment.

3 Methods

3.1 Non-Sulphide Copper Analysis

Approximately 25% (17 out of 69) of the Hazeltine Creek tailings materials collected in the field between September 8, 2014 and September 19, 2014 were submitted for determination of copper and other elements associated with the non-sulphide fraction. Samples were selected to capture the range of sulphur, total inorganic carbon (TIC), copper, and selenium content in the Hazeltine Creek samples based on previous results (SRK 2015).

Determination of non-sulphide copper was performed by ALS Environmental based on a similar method routinely used by MPM on-site as follows:

- Leach dried samples with 2.5% sulphuric acid (H_2SO_4).
- Mix the acidic slurry using a vortex shaker and then on a shaker table for 90 minutes.
- Collect supernatant after settling, filter and submit for ICP-MS multi-element scans (35 elements including sulphur and low level selenium).

The main difference from the MPM method is that ICP-MS was used instead of atomic absorption spectroscopy. Two samples were randomly selected to serve as duplicates for QA/QC purposes.

3.2 Kinetic Testing

3.2.1 General

The kinetic testing program consists of six standard laboratory humidity cells (HCs), three column leach tests, two blanks (a HC and a column), and one HC duplicate (Table 3-1). Samples were selected to represent the median and upper range of geochemical variability identified during the initial characterization work.

The intent of the program is to establish weathering rates under atmospheric conditions using humidity cell testing and then use column tests to evaluate the effect of longer water flow paths. Longer flows paths are more likely to represent field conditions and to assess potential attenuation processes such as formation of secondary minerals and surface sorption.

Geochemical composition and mineralogy characteristics were obtained during the initial characterization work and results are summarized in Section 4.3 for ease of reference.

Table 3-1: Composite preparation requirements and sample labelling.

Kinetic Test ID	Tailings Type	Original Sample IDs (SRK 2015)
HC-1/COL-1; HC-1D	Magnetite Sand	Composite of ST11-02-02, ST12-02 and ST11-02-1

3.2.2 Humidity Cells

The HCs were set up according to the methods described in the 1991 Mine Environment Neutral Drainage Program’s Acid Rock Drainage Prediction Manual (MEND 1991). A photograph of the set-up is provided in Figure 3-1.

Figure 3-1: Set-up of tailings humidity cells at ALS Environmental. For scale, the diameter of the clear plastic cells is 20 cm.

The two major sample mixture/tailings types identified in the field, (1) magnetite sands tailings and (2) grey tailings, were both tested. The duplicate cell (HC-1D) is a split from HC-1. The blank cell (HC-7) was constructed using the exact same material and adhesives as the other cells and is operating according to the same procedures.

Weekly analyses of leachate included volume recovered, pH, and conductivity.

The following parameters were measured weekly for the first four weeks and then every two weeks thereafter:

- Acidity, alkalinity
- Oxidation-reduction potential (ORP)
- Sulphate
- Nitrate, nitrite, ammonia
- Bromide, chloride, fluoride
- Orthophosphate, total phosphorus
- 35 element scan by ICP-MS
- Low level mercury

The tests were initiated on March 6, 2015, and have yielded 32 weeks of data at the time the data were interpreted for this report. While these tests typically run for a minimum of 40 weeks, release rates are now stable and initial interpretations are provided herein. All tests are continuing.

3.2.3 Columns

The column tests, including the blank, were constructed from plexiglass (acrylic) with an 8.2 cm inner diameter and a perforated base supporting two layers of nylon screen (400 mesh). The columns were filled as follows:

- Column 1 (magnetite sand): 4.3 kg to a height of 45 cm
- Column 2 (magnetite sand): 4.5 kg to a height of 36 cm
- Column 3 (grey tailings): 1.5 kg to a height of 16 cm

ALS Environmental confirmed that heavier Column 2 had a lower height than Column 1, which is attributed to greater compaction compared to the other columns.

Each of the samples is being trickle leached. Columns 1 and 2 have about 90 mL added daily until 500 mL has been added in a work week (5 days). For Column 3, only 30 mL of water can be added in a day to avoid pooling on the surface and, as a result, only 150 mL is added in a week. Collection of leachate from the magnetite sands is performed weekly, whereas collection of leachate from the grey tailings column requires up to three weeks due to the fine grained nature of these materials resulting in slow infiltration rates. Laboratory analysis of leachate includes the

same parameters as the humidity cells (Section 3.2.2). A photograph of the set-up is provided in Figure 3-2.

The tests were initiated on April 21, 2015. The magnetite sands samples have yielded 25 weeks of data, and the grey tailings 8 weeks of data at the time the data were interpreted for this report.

Figure 3-2: Column set-up at ALS Environmental. For scale, the diameter of the columns is 8 cm and the height of materials in column 1 (far left) is 45 cm.

4 Results

4.1 Quality Assurance and Quality Control

Various quality control and quality assurance (QA/QC) measures were included in the program. Duplicate comparisons were done for the non-sulphide copper analysis and kinetic tests. For the kinetic tests only, ion balance calculations and blank sample analysis were also done. Results were as follows:

- Duplicates – samples were assessed with a relative percent difference (RPD) target of 25% (set by SRK) when results were greater than ten times the limit of detection. RPD was calculated using the equation below, where 'x' is the concentration of the original sample and 'y' is the concentration from the duplicate sample:

$$\text{RPD}(\%) = \frac{x - y}{(x + y)/2} \times 100$$

- The RPD criterion does not apply at concentrations near the LOD because RPD is expected to frequently be greater than 25% due to reduced analytical accuracy at very low concentrations. This applied to silver and boron. All other parameters with guidelines for the protection of freshwater aquatic life in British Columbia (BC FAL guidelines) were within the criterion. Results for non-sulphide copper analysis for provided in Appendix A and duplicate humidity cell results are included in Appendix C.
- Ion balance – samples were assessed with an RPD target of $\pm 15\%$ (set by SRK) when major anions and cations were greater than ten times analytical detection limits. For all sampling dates the ion balance was within $\pm 15\%$.
- Blanks – samples were assessed with a target of ten times the detection limit (set by SRK). None of the samples exceeded this criterion.

SRK's overall conclusion is that data quality is acceptable.

4.2 Non-Sulphide Copper Analysis

Results of sulphuric acid leaching to determine the amount of non-sulphide copper and selenium are provided in Table 4-1. Analytical results are provided in Appendix A.

The main finding was that a significant portion of the copper in the tailings is associated with the non-sulphide fraction, ranging from 29% to 66% with an average of 46%. This finding is consistent with previous understanding of the non-sulphide copper fraction representing between 20% and 70% (Taplin 2002; Henry 2009) and mineral processing of the MPM ore, as sulphide flotation would preferentially remove sulphides and leave behind a higher portion of non-sulphide minerals.

Selenium was much lower in the non-sulphide fraction, ranging from 4% to 23%, with an average of 13% of the total fraction.

Table 4-1: Non-sulphide analysis results for copper and selenium.

Sample ID	Sample Type	Non-Sulphide		% of Total

4.3 Kinetic Testing

4.3.1 General

Geochemical properties of the humidity cells were provided in SRK (2015), but for ease of reference key properties are provided in Table 4-2 and complete results are provided in Appendix B. Copper, selenium and sulphur concentrations for kinetic test samples and the entire dataset are compared in Figure 4-1 and Figure 4-2.

Table 4-2: Geochemical properties of kinetic tests.

Kinetic Test	Tailings Type	TIC kg CaCO ₃ /t	Total S %	S ²⁻ %	AP kg CaCO ₃ /t	TIC/AP ratio	Cu mg/kg	Se mg/kg
HC-1/COL-1	Magnetite Sand	25	0.26	0.27	8.4	3.0	1200	1.5
HC-1D	Magnetite Sand	-	0.27	0.27	8.4	-	1200	1.7

4.3.2 Humidity Cells

At the time of this report, data for 32 weeks had been received. Charts of humidity cells results for all parameters that have BC FAL guidelines are provided in Appendix C and a summary of leaching rates (loadings) are provided in Appendix D. Charts for pH and sulphate are provided in Figure 4-3 for ease of reference as these parameters are used to understand oxidation and leaching rates. Copper and selenium charts are also provided in Figure 4-3 as these are the two main elements noted to be of leaching concern by SRK (2015).

Humidity cell results for all parameters except pH are presented as loading rates in units of mg/kg/week. The laboratory data provides results as concentrations (i.e. mg/L), but given the known weight of each sample and a measured volume of water leached through the cells on a weekly basis, concentrations are converted to loadings.

Leachates from all humidity cell tests have shown alkaline pHs, just slightly above 8.0, and are dominated by sulphate, alkalinity (predicted to be bicarbonate), calcium and lesser amounts of magnesium, potassium and sodium. Release rates for major cations and trace elements have just begun to stabilize and are trending slightly down. Initially elevated sulphate was observed for most tests in the first few weeks of testing, which is typical of these tests reflecting flushing of oxidation products accumulated prior to testing.

The majority of tests are leaching at generally similar rates, with the exception of HC-4 (grey tailings). Copper is leaching at the highest rate in this test (HC-4) whereas selenium is leaching at the lowest rate for this sample. This is not consistent with the solid phase content of copper (Figure 4-4) nor with the significant correlation previously established by SRK (2015) between copper and selenium in the tailings. The solid phase correlation would indicate that selenium should also be leaching at the highest rate in HC-4, but instead it is leaching at the lowest rate (Figure 4-5). The tests are all yielding alkaline leachates (around pH 8), which typically supports low solubility of copper and with no pH difference between the tests. Other parameters that appear to be inconsistent in HC-4 are the relatively elevated nitrate, nitrite and iron (Appendix C). Investigations are on-going to understand the leaching behaviour in HC-4.

4.3.3 Columns

At the time of reporting, 25 weeks of data had been received for the magnetite sand samples and only 8 weeks for the grey tailings sample. Concentration charts for columns for all parameters with BC FAL guidelines are provided in Appendix E and stable loading rates are provided in Appendix D. Results for pH, sulphate, copper and selenium are provided in Figure 4-6, for the same reason as described in Section 4.3.2.

Loading rates (i.e. mg/kg/week) are also being used to show leaching results as described in Section 4.3.2. The one difference between the columns and the humidity cells is that in the columns water initially took several weeks to travel through the materials and be collected. Column 3 (COL-3; grey tailings) still takes several weeks to collect enough leachate for analysis. As a result, the rates for columns are calculated based on how long water took to travel through the column and be collected. For the magnetite sand columns (COL-1 and COL-2), this is now the same as humidity cells (i.e. one week) but the grey tailings column divides the rate by three weeks.

Column leachates are alkaline, with pHs just slightly above 8.0 and are dominated by sulphate, alkalinity (predicted to be bicarbonate), calcium and lesser amounts of magnesium, potassium and sodium, which is similar to the humidity cells. A comparison of humidity cell and column leachates is provided in Section 4.3.4. Release rates for major cations and trace elements have generally just begun to stabilize for the magnetite sands columns (COL-1 and COL-2), but have still not stabilized in the grey tailings column (COL-3). Generally all parameters are either stable or trending down slightly. Initially, elevated sulphate release was observed for most tests in the first few weeks probably reflecting flushing of oxidation products accumulated prior to testing.

With only three samples, correlations are not particularly meaningful, but the differences in rates are consistent with solid phase content where highest sulphate, copper and selenium rates also contain highest solid phase content of these parameters.

4.3.4 Kinetic Test Comparison

A comparison between humidity cells and columns for pH, sulphate, copper and selenium provides the basis to understand how the different test configurations impact leaching rates in order to better predict how tailings materials in the field might react and impact water chemistry. The comparison also included mineral saturation indices (SI) for calcite (CaCO_3), malachite ($\text{Cu}_2\text{CO}_3(\text{OH})_2$) and tenorite (CuO) using the equilibrium modelling software package PHREEQC (version 2.17.4137) (Parkhurst and Appelo, 1999). A number of secondary minerals were reviewed in the calculations but the above three were chosen as they illustrate the influence of longer flow paths (calcite) and also potential controls on copper solubility (malachite and tenorite). Ferrihydrite (an iron oxyhydroxide) is also likely at saturation in the tests and is an important secondary mineral for attenuating metals, but concentrations were always below detection and therefore SI calculations were not possible. In the SI calculation, the most recent chemistry from each of the tests was used and equilibrated with the atmosphere. The comparison is provided in Table 4-3.

The pH conditions were essentially the same for both tests at around pH 8.0. Sulphate was lower in HC-1, as compared to its column pair, higher for HC-2 and essentially the same (i.e. less than 15% RPD) for HC-3. Copper release rates were essentially the same in paired sample 1, but lower in the other two paired column tests. Selenium release rates were always lower in the column tests, by approximately an order of magnitude in paired samples two and three. The columns have been running for a shorter period of time and rates are expected to continue decreasing for the columns and therefore differences will potentially become more pronounced.

Saturation indices showed that flow path was impacting mineral solubility in the magnetite sand tests. When interpreting SIs, positive values indicate that the mineral is predicted to precipitate, whereas negative numbers indicate that the mineral would not precipitate. For both of the magnetite sand tailings samples, calcite and tenorite were below saturation in the humidity cells, but above saturation in the column tests indicating that the longer flow path would likely lead to calcite and tenorite precipitation. Malachite was at or just below saturation. The grey tailings sample had nearly identical saturation indices in both the humidity cell and column test. While the flow path is about half of the distance as the magnetite sands samples, calcite was already saturated in the humidity cell test and did not need a longer flow path to reach mineral equilibrium. The grey tailings are taking nearly three times as long to allow water to pass through the column, which appears to be support mineral equilibrium to be reached over a shorter flow path. Implications of these results are discussed in Section 5.3.

Table 4-3: Comparison of humidity cell and column leaching rates and mineral equilibria.

Tailings Type	Test	Date Started	pH avg	SO ₄ mg/kg/wk	Cu mg/kg/wk	Se mg/kg/wk	Saturation Indices		
							Calcite	Malachite	Tenorite

5 Discussion

5.1 Overview

The overall geochemical characterization program outlined by SRK (2015) was developed to provide information on the potential for leaching from the spilled tailings. The non-sulphide copper analysis results can be broadly applied to both subaerial and subaqueous leaching, whereas the kinetic tests are specifically for subaerial weathering of the spilled tailings along Hazeltine Creek. Both of these are discussed further below.

Previous interpretations by SRK (2015) indicated that the risk of ARD in the spilled tailings was low. The kinetic tests continue to support that ARD is a low risk and contact water from the Hazeltine Creek tailings will be under neutral pH conditions. As a result, the focus of the discussion below is on neutral metal leaching.

5.2 Non-sulphide Copper

The tailings at Mount Polley are expected to be depleted in sulphide minerals relative to ore due to metal recovery during ore processing (i.e. sulphide flotation) and as a result, the non-sulphide fraction is expected to be enriched in the tailings compared to typical ore. This was confirmed in the spilled tailings collected in this study, with non-sulphide copper representing up to 66% of the total copper present, with the remaining copper (44%) associated with the sulphide fraction. This is also consistent with previous findings reported by SRK (2015).

The mineral form of this non-sulphide copper is likely the silicate chlorite (a common rock-forming, iron magnesium aluminum silicate mineral) based on previous mineralogical characterization work (SRK 2015). In terms of environmental significance, previous work (Taplin 2002; Henry 2009) and this study have shown that the non-sulphide fraction is relatively insoluble and copper leaching from this fraction can be considered a low leaching risk regardless of whether it is in a subaerial or subaqueous environment.

The non-sulphide fraction also contained a small portion of selenium, with an average of 14% and a maximum value of 23% calculated. While this may lower leaching rates expected if selenium was only associated with the sulphide fraction, the tailings would still contain over 1 mg/kg of 'reactive' selenium and be considered enriched when compared to typical crustal averages.

5.3 Tailings Weathering Rates

Weathering rates for subaerial tailings situated along Hazeltine Creek are being established, with testing now past half way of the recommended 40 weeks. As sample selection included materials that represented median and upper 95th percentile materials in terms of sulphur, copper and selenium concentration, leaching variability is also being established.

Any future use of laboratory leaching rates for predicting contact water chemistry (i.e. geochemical source terms) will need to consider a number of factors such as the surface area of the tailings, site temperature and the length of the water flow path through the tailings (Day et al, 2014). Particle size and water contact factors do not need to be considered as for tailings specifically, testing is performed on as-received materials and water contact is also expected to be much higher than more coarse grained material such as waste rock. For water chemistry predictions that involve coarse waste rock, differences in water contact can be significant.

The influence of flow path on the test materials can already be seen in the preliminary results presented in this report. The longer flow paths in the columns containing magnetite sands samples resulted in calcite saturation, as well as tenorite and increases in malachite saturation, whereas these minerals were not saturated in the humidity cell tests (Table 4-3). As discussed in SRK (2015), the presence of secondary copper minerals will tend to keep the concentration of copper at a 'ceiling' concentration, which is supported by measured concentrations at other copper porphyry sites at neutral pH (Day and Rees, 2006). For locations along Hazeltine Creek where the tailings settled in thin layers (i.e. less than 0.5 metres), dilution from precipitation is expected to be high and concentrations could be even lower than predicted by mineral solubility limits.

Selenium is not expected to be influenced by a mineral solubility control at neutral pH and fully oxygenated conditions, but there was a difference in leaching rates between the columns and humidity cells that was not observed with the sulphate leaching rates. Sulphate in the humidity cells and columns is considered a conservative tracer as concentrations are not high enough for mineral precipitation of sulphate minerals that could have a significant control on concentrations (i.e. precipitation of gypsum) and extremely low redox conditions are needed to reduce sulphate to sulphide. Selenium does not need to have very low reducing conditions to transition from its oxidized form selenate to selenite or even elemental selenium (MEND 2015). More reduced forms of selenium will be preferentially removed from solution as selenite has a much higher sorption affinity for mineral surfaces than selenate and elemental selenium will precipitate. As a result, the difference observed for selenium leaching rates between the humidity cells and columns may be a function of redox differences. Continued monitoring of the tests will help confirm this interpretation.

6 Conclusions

The results and interpretations presented in this report are a continuation of the geochemical characterization studies undertaken on representative samples of tailings that spilled into Hazeltine Creek in August 2014 from the MPM dam failure. The continued studies have included non-sulphide copper association, humidity cells and column testing.

The results indicate that a significant amount of copper (up to 66%) is associated with the non-sulphide portion (likely chlorite) of the tailings and is considered to be non-reactive. This is based on previous studies and the results provided in this report that required acidic conditions to leach copper associated with the non-sulphide fraction.

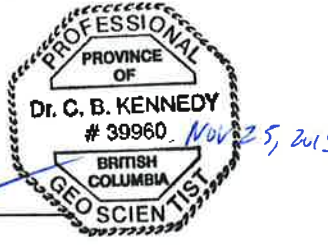

Kinetic testing confirmed that leaching considerations are under neutral to alkaline conditions and continue to support the previous assessment that ARD is not expected in these materials. Based on 32 weeks of testing, leaching rates are beginning to stabilize and general downward trends are expected to continue as the testing progresses. Variability in leaching rates is also being established and water contact chemistry predictions (i.e. geochemical source terms) should be possible after 40 weeks of testing.

For any tailings materials with water flow paths longer than half a metre, mineral solubility controls for copper are expected. Longer flow paths in the fine grained materials may also be conducive to lower rates of oxygen diffusion and therefore conditions that support selenium reduction to its more insoluble forms such as selenite and elemental selenium.

Testing is on-going and the current assessment of tailings reactivity and leaching rates will be updated once testing passes 40 weeks.

APPENDIX B

Soil Quality

Factual Report for Soil Investigation, Hazeltine Creek Floodplain

Prepared by:

Andrew Bruemmer, P.Eng., Trish Miller, M.Sc., CSAP and Reidar Zapf-Gilje, P.Eng., Ph.D., CSAP

Golder Associates Ltd.

DATE January 26, 2016**REFERENCE No.** 1411734-112-TM-Rev0-11000**TO** Colleen Hughes
Mount Polley Mining Corporation**FROM** Andrew Bruemmer, Reidar Zapf-Gilje, Trish Miller**EMAIL** Andrew_Bruemmer@golder.com;
Reidar_Zapf-Gilje@golder.com;
Trish_Miller@golder.com**FACTUAL REPORT FOR SOIL INVESTIGATION, HAZELTINE CREEK FLOODPLAIN****1.0 INTRODUCTION**

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with this factual report that presents the results of the soil investigation work completed within the Hazeltine Creek floodplain, adjacent to the Mount Polley mine, located near Likely, BC (the Site). The soil investigation at the Site was completed as part of the Detailed Site Investigation (DSI) to address potential contamination following the failure of the Tailings Storage Facility (TSF) at the Mount Polley Mine (the Site) on August 4, 2014. The results of the soil investigation presented in this factual report detail work completed in July and August, 2015.

1.1 Background

Following the failure of the TSF at the Site, a Soil Quality Impact Assessment (SQIA) was prepared by SNC Lavalin Inc. (SNC). This document was submitted to the BC Ministry of Environment (MoE) as part of the Post-Event Environmental Impact Assessment Report (PEEIAR) in June 2015 (Golder 2015a). The soil characterization work completed by SNC focused on the Hazeltine Creek study area, which extends approximately 9 km from the eastern edge of the TSF to the western shoreline of Quesnel Lake. The study area was approximately 1 km at its widest point, in the lower portion of Hazeltine Creek near Quesnel Lake. The study area was further divided to align with the remediation areas that were identified by Golder as part of the PEEIAR.

SNC's soil characterization program was developed based on preliminary field observations that defined the extent of the tailings deposition and established eighteen (18) transects at approximately 500 m intervals along Hazeltine Creek. At each transect location the extent of tailings deposition was documented and representative samples of tailings and native soils were collected across the width of the transect. Local reference soil samples were also collected from undisturbed locations in the forest beyond the area impacted by tailings from the debris flow.

Soils samples collected as part of the SQIA were submitted to an accredited laboratory (ALS Environmental, in Burnaby, BC) for analysis of a combination of Potential Contaminants of Concern (PCOCs), including total metals, light and heavy extractable petroleum hydrocarbons (LEPH/HEPH), polycyclic aromatic hydrocarbons (PAHs), glycols, volatile organic compounds (VOCs) and xanthanates. The preliminary list of PCOCs was based on a review of reagents and products used as part of the milling process at the mine. Additional analyses were also completed for soil nutrient and salinity parameters, and selected physical tests such as grain size and bulk density.

The analytical laboratory results identified concentrations of copper and vanadium in multiple tailings samples that exceeded the applicable CSR park land use (PL) standards. A single arsenic exceedance was also noted in the tailings samples, though the concentration was considered isolated. Copper and vanadium concentrations in native soil samples (i.e., native soil underlying deposited tailings material – referred to as “native”) and local reference samples (from areas beyond the tailings deposits flow – referred to as “local reference”) were less than applicable CSR PL standards, though concentrations of chromium, manganese, nickel, and selenium exceeded CSR PL standards for selected local reference samples. Concentrations of PCOCs associated with mine processing reagents were less than laboratory detection limits.

Laboratory pH results indicated that tailings samples were basic (i.e., pH greater than 7). Native soil samples were approximately neutral, while local reference soil samples were somewhat acidic. Available nutrient concentrations in tailings samples were generally lower than in native and/or local reference soil samples.

The results of SNC's soil assessment provided a preliminary understanding of Site conditions following the failure of the TSF. The results also provided the basis for the soil investigation described in this factual report.

1.2 Objectives and Scope of Work

The overall objective of the soil investigation was to collect sufficient soil quality data to support the completion of a Detailed Site Investigation (DSI) and Human Health and Ecological Risk Assessment (HHERA) for the Site. The DSI and HHERA are required under the CSR, as part of the overall rehabilitation of the Site.

Specifically, the objectives were to increase the sampling density within the areas affected by the debris flow and to delineate the vertical and lateral extent of soil contamination at the Site.

In order to meet the objectives of the assessment, Golder developed a scope of work that included the following tasks:

- Review of previous soil quality data collected as part of the SQIA completed by SNC;
- Identification of data gaps and finalization of soil characterization program;
- Collection of soil samples from deposited tailings and surrounding native soils and submission of selected samples to an analytical laboratory for analysis of Contaminants of Concern (COCs);
- Documentation of rehabilitation works within the Hazeltine Creek Channel, to monitor movement and excavation of deposited tailings and to assess the validity of previous soil quality data collected by SNC;
- Comparison of laboratory results to applicable regulatory criteria;
- Calculation of statistical parameters, to assist the interpretation of the laboratory results and to improve the overall understanding of soil quality at the Site; and
- Preparation of a technical memorandum (this memorandum), presenting the results of the previous and current soil investigation.

A summary of the applicable regulatory framework for the assessment is provided in Section 2.0, below. The sampling methods are described in Section 3.0.

2.0 REGULATORY FRAMEWORK

The Contaminated Sites Regulation (CSR; BC Reg. 375/96, O.C. 1480/96 and M271/2004, as updated [includes amendments up to BC Reg. 4/2014, updated to January 31, 2014]) is the principal document for the evaluation of the environmental quality of soil at the Site. The standards listed in the CSR provide numerical concentrations for the evaluation of soil quality and the identification of remediation requirements. The CSR soil standards are divided into six categories based on land use: Agricultural (AL), Urban Park (PL), Wildland (WL), Residential (RL), Commercial (CL), and Industrial (IL).

Wildland is considered to be the applicable land use at the Site and is defined in the CSR, as follows:

“The use of land for the primary purpose of supporting natural ecosystems, including the use of land for ecological reserves, national or provincial parks, protected wetlands or woodlands, native forests, tundra and alpine meadows, but does not include uses defined as urban park land use.”

Although there are no wildlands standards specified in the CSR, Section 11 of the CSR states that where the use of land is for wildlands, the urban park land use standards would apply in the soil at a depth of less than 3 metres and the commercial land use standards would apply to substances in the soil at a depth of 3 metres or more.

The CSR includes standards for the protection of human health (including intake of contaminated soil) and environmental protection in consideration of environmental receptors. The following site-specific factors were considered applicable for comparison to analytical soil results:

- Human health protection for groundwater used for drinking water;
- Human health protection for intake of contaminated soil;
- Environmental protection for toxicity to soil invertebrates and plants; and
- Environmental protection for groundwater flow to freshwater surface water used by aquatic life.

The site-specific factors for groundwater used for livestock or irrigation water were not considered applicable as there are not considered to be agricultural land uses in the vicinity of the Site.

Further to the generic and numerical CSR soil standards, the BC MoE has developed methods for determining background soil quality, which are summarized in the MoE’s “*Protocol 4 for Contaminated Sites – Determining Background Soil Quality*” (Protocol 4, dated October, 2010). Protocol 4 provides regional background soil quality estimates for metals in BC. Based on the regional outlines specified in Protocol 4, the Site is located within Region 5 – Cariboo. Protocol #4 specifies background concentration of 150 µg/g for chromium, 150 µg/g for nickel, and 4.0 µg/g for selenium. These background concentrations are considered applicable to the Site and are also higher than the most conservative applicable CSR standards at the Site. Therefore, the background concentrations were considered applicable for screening the soil results collected at the Site. Background concentrations for other metals parameters were not retained for further consideration, as the established concentrations are less than applicable CSR soil standards.

3.0 APPROACH AND METHODS

The approach and rationale for the soil investigation are presented in “*Sampling and Analysis Plan – Mount Polley Mine Detailed Site Investigation and Human Health and Ecological Risk Assessment and Confirmation of Remediation Report*” (Golder, July, 2015).

In summary, seven of eighteen representative sections established by SNC were retained by Golder for further assessment. The seven sections were retained based on identified data gaps and to increase the sampling density in selected areas of the Site. The locations of the representative sections are shown on Figure 1; the sections that were retained include: ST01, ST02, ST06, and ST10 (Lower Hazeltine Creek); ST14 and ST15 (Hazeltine Canyon); and ST18 (Upper Hazeltine Creek/Polley Plug). Additional samples were collected from Terrestrial Ecological Risk Assessment (TERA) plots, to support the completion of the risk assessment. The selection and locations of TERA plots are summarized in detail in the Problem Formulation for the ERA.

This factual report combines the data from SNC’s report with the new data from this DSI investigation, and presents the combined data on figures, in tables and statistics.

3.1 Soil Investigation

The purpose of the investigation work was to characterize the quality of soil at the Site and to delineate the vertical and lateral extent of soil contamination. For the purposes of this report, the term “soil” refers to the three following material types that were sampled during investigation work:

- Tailings. Samples were classified as tailings based on visual observations and chemistry results (refer to Section 3.3.1, below);
- Native soils underlying deposited tailings (native); and
- Native background soils (local reference).

Soil quality was characterized using the following methods:

- Laboratory analyses of selected parameters including metals, plant available nutrients, total organic carbon and inorganic carbon; and
- Collection of field parameters including dissolved oxygen content (DO), pH, oxidation-reduction potential (ORP) and specific conductivity during sample preparation and collection.

Delineation of contaminated soil was achieved by:

- Comparing the laboratory chemistry results to applicable CSR soil standards, regional background concentrations, and local reference concentrations;
- Documenting field observations, including visual evidence of tailings deposition; and
- Reviewing aerial photographs collected following the event.

Soil samples were collected between July 28 and August 25, 2015 by Golder field staff, with support from Soda Creek First Nation field assistants and MPMC Environmental Department staff. Soil sampling was conducted using either hand shovels or augers, depending on the stability and thickness of the substrate. Where the tailings layer was thick, it was also typically saturated making hand digging impractical so a hand auger was used. Pits were terminated when the underlying native forest floor was reached. At TERA plot locations, samples of the tailings and forest floor layers were also collected, if possible.

The depth and a description of tailings and forest layers were recorded on test pits and auger hole logs. Standard soil samplings methods were followed throughout the investigation work; the soil sampling methods are included in Attachment #1. The observations made at each of the sampling locations were documented on test pits and auger hole logs are included in Attachment #2

The sampling locations and exceedances are shown plans and cross-sections on Figures A-2 through A-14. Detailed results and stratigraphy for the representative cross-sections investigated as part of this DSI are shown on figures included in Attachment #3.

3.2 Laboratory Analysis

ALS Laboratory Group (ALS) of Burnaby, BC performed chemical analyses of soil samples collected during the characterization work. Environmental samples were transported to the laboratory in coolers with ice packs and chain-of-custody forms. The laboratory methods used by ALS to complete the analyses followed BC CSR approved methods.

Copies of the analytical reports, and the corresponding Chain of Custody forms, are presented in Attachment #4.

3.3 Statistical Analyses

Summary statistics, including minimum and maximum values, mean, median, 90th and 95th percentiles, and 95% Upper Confidence Limit on the Mean (UCLM) were calculated for the soil sample sets in order to support the data interpretation. The statistics were calculated using Microsoft Excel, with the exception of 95% UCLM values, which were calculated using ProUCL.

The summary statistics were calculated using soil sample results from Golder's 2015 soil investigation, as well as results collected as part of SNC's SQIA completed in 2014.

3.3.1 Sample Population

Prior to establishing a sample population for statistical analysis, sample locations, field observations, and analytical results were reviewed to identify characteristics unique to each type of material.

Based on the results provided by SNC, tailings samples were characterized as having high concentrations of copper and vanadium, and low levels of nutrients. By comparison, native under tailings and local reference soils showed concentrations of copper and vanadium that were generally less than the applicable CSR standards. Nutrient levels were also higher in native soils.

Some of the samples which were initially classified as native based on field observations were, upon closer scrutiny, determined to be representative tailings material. Such samples were encountered in areas where significant mixing of tailings and native soil occurred. Therefore, if a sample initially classified as native showed the following characteristics, it was re-classified as a tailings sample:

- The sample was collected at a location where mixing of tailings and native soil occurred;
- The sample contained concentrations of copper and vanadium above the 95th percentile of native samples; and
- The sample contained concentrations of copper and vanadium above the maximum concentration in local reference samples.

The following samples were reclassified as tailings samples: SS15-10 (AH layer), Willow Stake Soil-5, Willow Stake Soil-2, P2 – B layer, Willow Stake Soil-3.

Similarly, selected samples initially classified as tailings were reclassified as native because they were located in an area of Hazeltine Creek where mixing occurred following the TSF failure and where the channel had been rehabilitated. This re-classification was based on field observations, sample location, activity that has occurred since the TSF failure, and chemistry results.

Tailings chemistry data collected by SNC as part of the SQIA indicated that tailings samples contained concentrations of copper greater than the most conservative applicable soil standard of 150 mg/kg. By comparison, copper concentrations of native soil underlying tailings were less than 150 mg/kg.

Therefore, samples initially classified as tailings were re-classified as native if they had the following attributes:

- The sample was collected in area of the creek that had been rehabilitated; and
- The copper concentration was less than 150 mg/kg,

The following samples were reclassified as native: Rye grass soil-2, rye grass soil-6, and rye grass soil-8.

3.4 Soil Excavations

Rehabilitation works, including construction of a new channel within Hazeltine Creek, have been ongoing since the October 2014. Channel construction and armoring was completed in May, 2015.

Golder reviewed information provided by MPMC that summarized volumes of excavated material that were displaced during the channel reconstruction and sediment control works in areas adjacent to the creek. The soil volumes were reviewed to develop an understanding of the current Site conditions. The excavation volumes presented in this factual memorandum are considered preliminary, as it is expected that rehabilitation work will continue in the future.

3.5 Quality Assurance and Quality Control Procedures

To document that the sampling and analytical data were interpretable, meaningful and reproducible, the Golder quality assurance and quality control (QA/QC) program was followed. This involved using QA/QC measures in both the collection (field program) and analysis (laboratory) of environmental samples.

The following discussion includes a brief summary of the QA/QC measures implemented by Golder during the field program and during our review of the data, as well as the QA/QC measures implemented by the analytical laboratory.

Quality control measures use in sample collection and shipment included the following:

- Sampling methods were consistent with established Golder protocols and provincial/federal requirements;
- Field notes were recorded during the investigation and have been stored in the project file;
- UTM coordinates of sample locations were recorded in the field using a hand-held GPS; and
- Samples were kept cool and subsequently transported to the laboratory using Golder chain-of-custody procedures.

The quality assurance measures for the field program included:

- Submission of blind field duplicate samples. A blind field duplicate sample is a second sample of soil from the same location that is submitted to the analytical lab under a separate label such that the lab has no prior knowledge that it is a duplicate. A field duplicate analysis rate of 10% was established as the QA objective for the field program.
- For duplicate samples, either the relative percent difference (RPD) or difference factor (DF) was used to evaluate the sample result variability, depending on the magnitude of the concentrations. The RPD is a measure of the variability between two outcomes from the same procedure is calculated by

$$absolute\left(\frac{(x_1 - x_2)}{average(x_1, x_2)}\right) \times 100$$

where x_1 is the original sample result and x_2 is the blind field duplicate result. In general, Golder's Data Quality Objective (DQO) outlines an RPD of less than 35% on average, or a maximum of 50%, depending on the parameter, the concentration and associated laboratory data quality objective. A RPD greater than 30% may reflect "in bottle" variability or variation in the test process. RPD is calculated when sample results are equal to or greater than five times the laboratory method detection limit. DF is the absolute difference between the two values divided by the method detection limit and is calculated when sample results are less than five times the method detection limit but not less than the method detection limit. In general, DF should be less than 2.

The following criteria were considered acceptable for laboratory QA/QC samples:

- For organic and inorganic analytes, analytical duplicates should exhibit less than 35% RPD on average, and no more than 50% for a specific analyte;
- Analytical results for reference materials or spiked standards should be within 10% of certified values for inorganic elements or 30% of certified values for organic compounds;
- Analytical blanks should be less than the detection limits used for the specific analysis;
- Certification by the Canadian Association for Laboratory Accreditation Inc. (CALA) for analytical methods used for this program; and
- Reports from the laboratory were internally reviewed prior to submission to Golder. If internal QA/QC problems are encountered, the field samples and internal QA/QC samples are re-analysed.

4.0 RESULTS

This section of the factual report presents the results of the soil investigation, including stratigraphy, field and analytical results, statistical analyses, and results of QA/QC analyses.

4.1 Stratigraphy

Representative photographs of the Site stratigraphy are included in Attachment #4, at the end of this report.

As documented in the PEEIAR, tailings samples consisted of a grey layer of fine-grained material overlying a red-black layer of sandy material. The deposited tailings overlaid native, organic forest soil and/or till.

The stratigraphy observed along the length of Hazeltine Creek can be summarized as follows:

- The thickest deposits of tailings were observed in the vicinity of Polley Lake Plug (i.e., the depositional area immediately downstream of the TSF failure location and at the outlet of Polley Lake), where tailings were observed to be greater than 3 m thick in certain locations. The layer of fine-grained tailings material was observed to be up to 1 m thick. At the time of the soil investigation work, tailings material within the plug area had not been removed as part of the rehabilitation efforts at the Site;
- The thickness of tailings material within Upper Hazeltine Creek was less than observed at the Polley Plug, but thicknesses of up to 2.5 m (at ST15) were observed during soil sampling work. Tailings material was being excavated as part of rehabilitation efforts at the time of the soil investigation;
- Measurable deposits of tailings material were not observed within Hazeltine Canyon, as material within the canyon was scoured to bedrock and deposited within Lower Hazeltine Creek; and
- A mixture of native till and tailings deposition was observed in Lower Hazeltine Creek and at the mouth of Edney Creek. The soil mixture is considered to be consisted with the scouring and deposition that occurred following the event.

4.2 Field Analyses

The following field data were collected for soils: temperature, DO, specific conductivity, total dissolved solids (TDS), salinity, pH, and ORP.

The field pH measurements observed by Golder were consistent with the observations made by SNC: local reference soils were slightly acidic, native soils were approximately neutral, and tailings samples were slightly basic.

The results of field analyses are presented in Table 1.

4.3 Analytical Results

Soil quality results are presented for tailings, native soils under tailings, and local reference soils in Tables 2, 3, and 4, respectively, at the end of this report. Results were screened against applicable BC CSR PL soil standards from Schedules 4, 5 and 10. The analytical results presented below do not include soil samples collected by SNC.

4.3.1 Tailings Samples

Tailings samples were collected and submitted to the laboratory for analysis of metals, plant available nutrients, and total carbon analysis as part of the soil characterization work completed by Golder.

The results were consistent with the sampling work completed by SNC, as concentrations of copper exceeded applicable CSR PL soil standards for all samples that were analyzed. Vanadium also frequently exceeded applicable CSR PL soil standards in 37 of 126 samples that were analyzed. A single arsenic result (15.1 mg/kg) was marginally above CSR PL standard of 15 mg/kg. When rounding this concentration, the result is considered to meet the standard. Nutrient and total carbon concentrations in the tailings were low, compared to local reference and native under tailings samples (refer to Section 4.5, below).

Copper and vanadium exceedances were observed in tailings samples collected in both the scour zone and the forested halo zone. As discussed in Section 4.1, deposited tailings consisted of a fine, grey layer of material, overlying a coarse, red-black layer of sandy material. The magnitude of the vanadium and copper concentrations was generally similar within the two separate layers of tailings material.

Remaining metal parameters were less than the applicable CSR PL soil standards.

4.3.2 Native Soils underlying Tailings

Native, under tailings soil samples were collected as part of the soil characterization work completed by Golder. Selected samples were submitted to the laboratory for analysis of metals, pH, and plant available nutrients.

Analytical laboratory results were generally less than the applicable CSR PL standards though exceedances of arsenic, cadmium, chromium, and copper were noted.

4.3.3 Local Reference Soils

Local reference soil samples were collected and submitted to the laboratory analysis of metals, plant available nutrients, and total carbon, as part of the soil characterization work completed by Golder.

The laboratory results for metals were less than the applicable CSR PL soil standards, with the exception of one chromium result, which exceeded the CSR standard of 60 mg/kg. However, the magnitude of the concentration (60.9 mg/kg) was less than the regional background concentration for chromium (150 mg/kg), outlined in BC MoE Protocol 4.

The results of local reference oil sample analyses were combined with background results collected by SNC, in order to develop local reference concentrations for the Site. The reference concentrations are described in Section 4.4.2, below.

4.4 Statistical Analyses

As indicated in Section 3.3, the summary statistics were calculated using data collected by SNC in 2014, as well as additional data collected by Golder in 2015. The results of the statistical analyses for tailings, native under tailings, and local reference samples, are summarized in the following sections.

4.4.1 Tailings Samples

The summary statistics for tailings samples that were analyzed as part of the DSI are shown in Table 5, at the end of this technical memorandum. The statistical analyses for tailings samples can be summarized as follows:

- The upper 90th percentiles of metal parameters in tailings samples were less than the most conservative applicable CSR soil standard, with the exception of copper and vanadium;
- The upper 90th percentile for copper (1,070 mg/kg) was nearly an order of magnitude greater than the applicable ecological soil standard of 150 mg/kg. The 90th percentile was, however, more than an order of magnitude lower than the applicable soil standard for protection of human health (15,000 mg/kg);
- The upper 90th percentile for vanadium (229 mg/kg) was approximately 10 percent higher than the applicable CSR soil standard (200 mg/kg);
- The 95% UCLM for copper (830 mg/kg) was greater than the applicable ecological soil standard of 150 mg/kg;
- The 95% UCLM for vanadium (189 mg/kg) was less than the applicable CSR soil standard of 200 mg/kg; and
- The maximum concentration of arsenic (16.5 mg/kg) was greater than the applicable CSR soil standard of 15 mg/kg, but the 90th percentile and 95% UCLM concentrations were less than the applicable CSR standard.

Summary statistics for remaining parameters were less than applicable CSR standards.

4.4.2 Native Under Tailings Soils

The summary statistics for native, under tailings soil samples are shown on Table 5, at the end of this technical memorandum. The statistical analyses for native, under tailings soil samples can be summarized as follows:

The maximum concentrations for metal parameters that were analyzed were less than the most conservative applicable CSR standard, with the exception of arsenic, copper, and chromium. However, the upper 90th percentiles for these parameters were less than the most conservative applicable CSR standard.

4.4.3 Local Reference Soils

The summary statistics for local reference samples that were analyzed as part of the DSI are shown on Table 6, at the end of this technical memorandum.

The upper 95th percentile of the reference soil sample set was considered the local reference concentration (consistent with BC MoE Protocol #4) for comparison to tailings and native under tailings soil samples. The calculated local reference concentrations, shown on Table 6 at the end of this report, were less than applicable CSR PL standards and were less than CSR Protocol #4 Regional Background Concentrations.

4.5 Summary of Data Results

Tailings and native under tailings samples were screened against the applicable CSR PL standards, regional background concentrations, and local reference concentrations. The screening was completed in order to develop a list of contaminants of concern (COCs) at the Site. The summary below is considered factual.

4.5.1 Tailings

Nutrient and total carbon concentrations in tailings samples were consistent with previous results collected at the Site and were lower than native and local reference concentrations. The average concentrations of total available nitrogen and total carbon in tailings were calculated to be 5.9 mg/kg and 1.2 mg/kg, respectively. By comparison, average concentrations of total available nitrogen and total carbon in local reference soils were 10.9 mg/kg and 12.6 mg/kg, respectively).

The upper 90th percentile concentrations of the following metals (with an applicable CSR standard) were greater than local reference concentrations for:

- Arsenic, copper, molybdenum, selenium, strontium and vanadium.

BC MoE Protocol #4 provides regional background concentrations for the six metals identified above with the exception of strontium. The upper 90th percentiles for the parameters were also greater than the regional background concentrations, with the exception of selenium.

The upper 90th percentile concentrations of the following metals (without an applicable CSR standard) were greater than local reference concentrations:

- Boron, calcium, phosphorus, sodium, sulphur, titanium, zirconium.

A summary of the screening of regulated CSR metal parameters against local reference, regional background, and CSR standards is provided in Table 7, below.

Table 7: Summary of Screening in Tailings

COPC	Number of Exceedances of CSR MCS	Max	Mean	95% UCLM	90 th Per.	Local Ref. ¹	Regional Bkgd. ²	CSR Standard (MCS) ³
Arsenic	2 / 126	[16.5]	11	11.1	12.6	11.9	10	15
Copper	126 / 126	[1560]	[805]	[829.7]	[1070]	75	65	150
Molybdenum	0 / 126	7.3	4.3	4.46	5.4	1.6	1	10
Selenium	0 / 126	1.7	1.0	1.03	1.2	0.61	4	3
Strontium	0 / 85	212	141	146.6	180	144	-	47000
Vanadium	37 / 126	[289]	186	189.2	[222]	113	100	200

Notes:

Concentrations shown are in mg/kg, unless otherwise noted.

mg/kg = milligrams/kilogram; UCLM = upper confidence limit of the mean; MCS = Most Conservative Standard; Ref. = Reference; Bkgd. = Background

1. Local reference (LB) is interpreted to be the 95th percentile of reference sample results. This interpretation is consistent with BC MoE Protocol #4. For sample results less than detection limit, half the detection limit was used in the calculation.

2. Regional background (RB) data based on values outlined in BC MoE Protocol 4.

3. The MCS protective of human and ecological health was used.

[Concentration] = Exceeds the most conservative CSR Standard

Concentration = Exceeds the regional background values outlined in BC MoE Protocol 4

4.5.2 Native under Tailings

The upper 90th percentile concentrations of the following metals (with an applicable CSR standard) were greater than local reference concentrations:

- Arsenic, copper, molybdenum, and selenium.

The upper 90th percentile concentrations of the following metals (without an applicable CSR standard) were also greater than local reference concentrations:

- Calcium, sodium, sulphur, and zirconium.

A summary of the screening of native under tailings soil samples, against local reference, regional background, and CSR standards is provided in Table 8.

Table 8: Summary of Screening for Native Under Tailings Samples

COPC	Number of Exceedances of CSR MCS	Max	Mean	95% UCLM	90 th Per.	Local Ref. ¹	Regional Bkgd. ²	CSR Standard (MCS) ³
Arsenic	3 / 68	[16.4]	7.7	8.40	12	11.9	10	15
Copper	7 / 68	[366]	85	103	149	75	65	150
Molybdenum	0 / 68	3.5	1.1	1.26	2	1.6	1	10
Selenium	1 / 68	[8.9]	0.5	0.79	0.7	0.61	4	3
Strontium	0 / 39	223	83.1	95.1	123	144	-	47000
Vanadium	0 / 68	121	70.4	75	94	113	100	200

Notes:

Concentrations shown are in mg/kg, unless otherwise noted.

mg/kg = milligrams/kilogram; UCLM = upper confidence limit of the mean; MCS = Most Conservative Standard; Ref. = Reference; Bkgd. = Background

1. Local reference (LB) is interpreted to be the 95th percentile of reference sample results. This interpretation is consistent with BC MoE Protocol #4. For sample results less than detection limit, half the detection limit was used in the calculation.

2. Regional background (RB) data based on values outlined in BC MoE Protocol 4.

3. The MCS protective of human and ecological health was used.

[Concentration] = Exceeds the most conservative CSR Standard

Concentration = Exceeds the regional background values outlined in BC MoE Protocol 4

4.6 Soil Excavation

The following information provides a summary of the excavation work that was completed within the Hazeltine Creek drainage as part of the channel construction. It is expected that additional information, including surveyed extents, will be available as part of the final phase of rehabilitation work.

- Upper Hazeltine Creek (from Polley Lake to Gavin Lake Road Bridge): tailings material was removed during the channel construction and taken to the TSF. Based on information available at the time of this report, approximately 269,000 m³ has been relocated to the TSF. Additional tailings material has been excavated from the reach of the drainage; however, the material is currently stockpiled in the vicinity of the Polley Plug and has not been accounted for in the overall volume of displaced material;
- Middle Hazeltine Creek: this reach of the drainage was primarily affected by erosion, and not deposition, processes. Tailings material was not removed from this portion of the drainage; and
- Lower Hazeltine Creek: deposited material, consisting of a mixture of tailings and sediment, has been excavated and stockpiled adjacent to the re-constructed channel. Approximately 6,000 m³ of material have been excavated from Lower Hazeltine Creek.

4.7 Results of QA/QC Analyses

The QA/QC analyses included a comparison of field duplicate samples that were collected in the field as well as a review of laboratory data. A summary of the results is provided in the following sections.

4.7.1 Results of Field Duplicates

Field duplicate samples were collected at a rate of 23% for metals analyses and 16% for plant available nutrients. The duplicate sampling frequency meets Golder's internal objective of 10%.

Field duplicates were tabulated and reviewed for RPD and DF values; the results are presented in Table 9, at the end of this report. The RPD and DF values that were calculated were generally below Golder's internal DQOs of 35% and 2.0, respectively, though selected RPD values were greater than 35%. The maximum RPD was 114% for a cadmium sample collected from the tailings layer.

Where calculated RPD values exceeded the DQO of 35%, further evaluation of the data was completed. For example, the cadmium concentrations associated with the RPD of 114% were approximately 4 times less than the applicable standard. Therefore, the uncertainty associated with the RPD is not considered to affect the overall interpretation of the results. The elevated RPD values for other metals parameters were evaluated in the same manner as the cadmium concentrations described above.

4.7.2 Laboratory Program

Laboratory hold times were met for parameters that were analyzed. All laboratory DQOs were met.

The data is considered reproducible and suitable for the assessment of soil quality.

4.7.3 Summary of QA/QC Review

Based on the results of the field duplicate analyses and the laboratory QA/QC review, the soil samples collected as part of the investigation generally meet the DQOs established as part of this investigation. Although the RPDs for certain paired analyses exceeded Golder's DQOs (as listed above), the data is considered reliable as the results do not affect the overall conceptual understanding of the Site.

In conclusion, the data quality review indicates that the data is sufficiently accurate and reproducible, and can be relied upon for completion of remediation works and/or risk assessment for the Site.

5.0 CONCLUSIONS

Golder Associates Ltd. completed a soil investigation on behalf of MPMC, in support of the DSI completed following the failure of the TSF at the Mount Polley Mine. The objectives of the soil investigation were to increase the sampling density within the areas affected by the debris flow and to delineate the vertical and lateral extent of soil contamination at the Site.

Based on the scope of work that was completed as part of the soil investigation, these objectives have been met. The results of the soil investigation will be used as part of the overall DSI for the Site in order to develop a current understanding of the Site conditions.

6.0 STATEMENT OF LIMITATIONS

This report was prepared for the exclusive use of MPMC. The report is based on data and information collected during investigations conducted by Golder Associates Ltd. personnel. It is based solely on the conditions of the subject property at the time of the site investigation conducted in August, 2015, as described in this technical memorandum. The data presented in this memorandum represent soil conditions encountered at the sampling locations tested during this time period. Soil conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors. Golder Associates Ltd. makes no warranty, expressed or implied, and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

The findings and conclusions documented in this report have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this report, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this report. All third parties relying on this report do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder's report or other work product. Golder is not responsible for any unauthorized use or modifications of this report.

MPMC may rely on the information contained in this report subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this report, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein. With respect to regulatory compliance issues, regulatory statutes are subject to interpretation. These interpretations and the regulations themselves may change over time, thus MPMC should review these issues.

If new information is discovered during future work Golder should be requested to re-evaluate the conclusions of this report and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this report is affected by any change of site conditions, purpose, development plans or significant delay from the date of this report in initiating or completing the project.

7.0 CLOSURE

We trust that this Technical Memorandum provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at (604) 296-4200.

Notes:
 MPMC = Mount Polley Mining Corporation
 m bgs = metres below ground surface; mg/L = milligram per litre
 µs/cm = microsiemens per centimetre; g/L = grams per litre
 ppt. = parts per thousand; mV = millivolts

Table 2 - Results of Soil Analyses (Tailings Samples)
MPMC - Detailed Site Investigation
Mount Polley Mine, BC

Table with 18 columns for samples and 17 columns for parameters. The table is divided into sections: Physical Parameters, Grain Size, Plant Available Nutrients, Organic/Inorganic Carbon, and Strong Acid Leachable - Total Metals. Each cell contains numerical values or chemical symbols.

Notes:
MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation
m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; mg/kg = milligram per kilogram; < = below detection limit; - = no data

- a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent

Legend for symbols used in the table: underline, double underline, round brackets, square brackets, braces brackets.

Table 2 - Results of Soil Analyses (Tailings Samples)
MPMC - Detailed Site Investigation
Mount Polley Mine, BC

Table with 20 columns for sample IDs (ST01-05 to ST18-05) and multiple rows for parameters such as pH, Organic Carbon, Moisture, Grain Size, Plant Available Nutrients, Organic/Inorganic Carbon, and various metals (Aluminum, Arsenic, Barium, etc.). Includes BC CSR Standards and background levels.

Notes:
MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation
m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; mg/kg = milligram per kilogram; < = below detection limit; '-' = no data
a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent

Legend table mapping symbols to guideline types:
underline: exceeds BC CSR DW guideline
double underline: exceeds BC CSR ICS guideline
round brackets: exceeds BC CSR TSIP guideline
square brackets: exceeds BC CSR GWtoFSW guideline
braces brackets: exceeds BC CSR Generic guideline

Table 2 - Results of Soil Analyses (Tailings Samples)
MPMC - Detailed Site Investigation
Mount Polley Mine, BC

Table with columns for Sample ID, Easting Northing, Units, BC CSR Standards (Human Health, Ecological Health, Generic, Background), and 20 soil analysis locations (ST01-03 to ST06-03). Rows include Physical Parameters (pH, TOC, etc.), Grain Size, Plant Available Nutrients, Organic/Inorganic Carbon, and Strong Acid Leachable - Total Metals (Aluminum, Antimony, Arsenic, etc.).

Notes:
MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation
m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; mg/kg = milligram per kilogram; < = below detection limit; '-' = no data
a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent

Legend table for symbols: underline (exceeds BC CSR DW guideline), double underline (exceeds BC CSR ICS guideline), round brackets (exceeds BC CSR TSIP guideline), square brackets (exceeds BC CSR GWtoFSW guideline), braces brackets (exceeds BC CSR Generic guideline).

Table 2 - Results of Soil Analyses (Tailings Samples)
MPMC - Detailed Site Investigation
Mount Polley Mine, BC

Main data table with columns for Sample ID, Coordinates, Easting Northing, Units, BC CSR Standards (Human Health, Ecological Health, Generic, Background), and various parameters (pH, Organic Carbon, Moisture, Grain Size, Plant Available Nutrients, Organic/Inorganic Carbon, Stong Acid Leachable - Total Metals).

Notes:
MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation
m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; mg/kg = milligram per kilogram; < = below detection limit; '-' = no data
a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent

Table 2 - Results of Soil Analyses (Tailings Samples)
MPMC - Detailed Site Investigation
Mount Polley Mine, BC

Table with columns for Sample ID, Coordinates, Easting Northing, Units, BC CSR Standards (Human Health, Ecological Health, Generic, Background), and 17 sampling locations (ST11-02 to ST17-03). Rows include Physical Parameters (pH, TOC, etc.), Grain Size, Plant Available Nutrients, Organic/Inorganic Carbon, and Strong Acid Leachable - Total Metals.

Notes:
MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation
m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; mg/kg = milligram per kilogram; < = below detection limit; '-' = no data

a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent
Legend:
underline exceeds BC CSR DW guideline
double underline exceeds BC CSR ICS guideline
[round brackets] exceeds BC CSR TSIP guideline
[square brackets] exceeds BC CSR GWtoFSW guideline
{braces brackets} exceeds BC CSR Generic guideline

**Table 6 - Summary of Local Reference Metal Concentrations
MPMC - Detailed Site Investigation
Mount Polley Mine, BC**

Total Metals	Local Reference (Background)					
	Number of Samples	Number of Exceedances of MCS ¹	Minimum	Maximum	Average	95th Percentile
Strong Acid Leachable - Total Metals						
Aluminum	33	0	6270	56100	18164	44080

Vanadium	45	0	15	133	67	113
Zinc	45	0	16	149	69	144
Zirconium	10	0	1.0	4.7	2.6	4.5

Notes:

All concentrations are in mg/kg

1. MCS = Most conservative standard. Metal concentrations were compared to the MCS protective of human and ecological health.

Notes:
 All parameter units in milligrams per kilogram (mg/kg), unless otherwise noted.
 FDA = Field Duplicate Available; FD = Field Duplicate; QA/QC = Quality Assurance/Quality Control
 NA = Not Applicable; NC = Not Calculated; Mean = average of two values
 "-" = no data; m bgs = metres below ground surface; mV = millivolt
 Relative percent difference (RPD) = the difference between two values divided by the mean of the two values. **Golders' acceptable RPD is less than or equal to 35%.**
 RPD is calculated when the concentration is greater than five times the detection limit.
 Difference factor (DF) = absolute difference between two values divided by the method detection limit. **Golders' acceptable DF is less than or equal to 2.0.**
 DF is calculated when the concentration is less than five times the detection limit.

Notes:
All parameter units in milligrams per kilogram (mg/kg), unless otherwise noted.
FDA = Field Duplicate Available; FD = Field Duplicate; QA/QC = Quality Assurance/Quality Control
NA = Not Applicable; NC = Not Calculated; Mean = average of two values
*- = no data; m bgs = metres below ground surface; mV = millivolt
Relative percent difference (RPD) = the difference between two values divided by the mean of the two values. **Golders' acceptable RPD is less than or equal to 35%.**
RPD is calculated when the concentration is greater than five times the detection limit.
Difference factor (DF) = absolute difference between two values divided by the method detection limit. **Golders' acceptable DF is less than or equal to 2.0.**
DF is calculated when the concentration is less than five times the detection limit.

Soil Sampling Methods

ATTACHMENT 1 Soil Sampling Methods

Sampling procedures were carried out in accordance with the MoE Guidance document #1 Technical Guidance on Contaminated Sites - Site Characterization and Confirmation Testing (TG1, January 2009).

As the pits advanced, discrete soil samples were recovered at regular depth intervals from the auger flights or soil cores. Shallow soil samples were collected using a hand auger or shovel.

The soil samples were collected in pre-cleaned 125 millilitres (mL) glass soil sample jars supplied by the laboratory. Two jars of soil were collected for each sample interval to allow for breakage and laboratory re-analysis. At sample locations included in the TERA, a third jar of soil was collected. Samples jars were packed in cardboard boxes, placed in a cooler with a chain-of-custody form and several ice packs, and shipped to the laboratory.

During the Site reconnaissance (July 8 and 9, 2015), a sulphur-like odor and black soil were noted in several of the test pits. The observations were inferred to be indicative of anaerobic conditions in the ground sub-surface. In order to support the visual and olfactory observations of potential anaerobic conditions, field measurements of dissolved oxygen content (DO), pH, oxidation-reduction potential (ORP) and specific conductivity were measured in soil from both halo and reference plots.

In order to measure the field parameters, a volume (approximately 250 mL) of soil was collected from the target layer (i.e., native soil below tailings) in a standard 1 litre plastic water sample container. A slurry mixture was created by adding an equal volume of de-ionized water (1:1 ratio). The sample was stirred and allowed to equilibrate for approximately 10 minutes before sampling. Parameters of interest were measured using a multi meter calibrated to the manufacturer's instructions and recorded on field sheets.

Shallow soil samples and samples collected from the boreholes were submitted to the laboratory; selected soil samples were chosen for analysis. The samples selected for analysis were chosen based on visual observation, the stratigraphy encountered, the depth and location of the sample, and the results of field screening.

Selected soil samples were analyzed for total metals, plant available nutrients (including total available nitrogen, available ammonium, available nitrate, nitrate, nitrite, available phosphate, available potassium, and available sulphate), and physical parameters (including pH, moisture, and oxidation-reduction potential). Selected soil samples were also submitted to the laboratory for particle size analysis and analysis of organic and inorganic carbon.

Legal Site Desc:

Comments:

pH ratio adjustments have been applied to several samples due to matrix absorbency leading to lower dry weight. Samples with pH ratio adjustments: 2, 19, 34, 61, 68, 83, 90, 94, 98, 99, 107, 113, 117, 122, 124, 127, and 128. Please have this in consideration when reviewing the results.

22-SEP-2015 Metals/pH data has been added for L1654527-136.

26-OCT-2015 Metals data has been added for L1654527 -90 and -103.

Amber Springer, B.Sc

Reference Information

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974
		The sample is ignited in a combustion analyzer where carbon in the reduced CO ₂ gas is determined using a thermal conductivity detector.	
ETL-N-TOT-AVAIL-SK	Soil	Available Ammonium-N - Calculation	Soil Methods of Analysis (1993) CSSS
HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)
		Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.	
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)
		Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.	
		Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.	
MOISTURE-VA	Soil	Moisture content	ASTM D2974-00 Method A
		This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.	
N-TOT-LECO-SK	Soil	Total Nitrogen by combustion method	SSSA (1996) P. 973-974
		The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.	
N2/N3-AVAIL-KCL-SK	Soil	Nitrate, Nitrite & Nitrate+Nitrite-N(KCL	CSSS (1993) p. 26-28
		Plant available nitrate and nitrite are extracted from the sample with 2N KCl. Nitrate and Nitrite in the filtered extract are determined colorimetrically by Technicon auto-analyzer or flow injection analyzer at 520 nm.	
NH4-AVAIL-SK	Soil	Available Ammonium-N	CSSS(1993) 4.2/COMM SOIL SCI 19(6)
		Ammonium (NH ₄ -N) is extracted from the soil using 2 N KCl. Ammonium in the extract is mixed with hypochlorite and salicylate to form indophenol blue, which is determined colorimetrically by auto analysis at 660 nm.	
NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)
		Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.	
		Reference: Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28	
ORP-SHKFL96-VA	Soil	ORP by Electrode (96 hour SHAKEFLASK)	BC MIN. OF ENERGY AND MINES
		This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 96 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter. The sample is then analysed using procedures carried out in accordance "ASTM" method D1498-00 "Oxidation-Reduction Potential of Water" published by the American Society for Testing and Materials (ASTM), May 2000. Results are reported as observed oxidation-reduction potential of the platinum metal-reference electrode employed, in mV.	
PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL
		This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.	
PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)
		Plant available phosphorus and potassium are extracted from the soil using Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassium is determined by flame emission at 770 nm.	
SO4-AVAIL-SK	Soil	Available Sulfate-S	REC METH SOIL ANAL - AB. AG(1988)
		Plant available sulfate in the soil is extracted using a weak calcium chloride solution. Sulfate in the extract is determined by ICP-OES.	

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Reference Information

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

08-028545	10-384855	10-384856	10-384857	10-384858
10-384859	10-389818	10-389819	10-389820	10-389821
10-471688	14-429590			

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend & Qualifier Definitions:

- EHTR-FM: Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended.
- EHTR: Exceeded ALS recommended hold time prior to sample receipt.
- EHTL: Exceeded ALS recommended hold time prior to analysis. Sample was received less than 24 hours prior to expiry.
- EHT: Exceeded ALS recommended hold time prior to analysis.
- Rec. HT: ALS recommended hold time (see units).

Notes*:
 Where actual sampling date is not provided to ALS, the date (& time) of receipt is used for calculation purposes.
 Where actual sampling time is not provided to ALS, the earlier of 12 noon on the sampling date or the time (& date) of receipt is used for calculation purposes. Samples for L1654527 were received on 07-AUG-15 10:00.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

Quality Control Report

Workorder: L1654527

Report Date: 26-OCT-15

Page 44 of 44

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Certified Reference Material	Silver (Ag)	RM-H	L1667543-20, -21, -22, -23, -24, -25, -26, -27, -28, -29, -30, -31, -32, -33, -34, -35, -36, -37, -38
Certified Reference Material	Silver (Ag)	RM-H	L1667543-20, -21, -22, -23, -24, -25, -26, -27, -28, -29, -30, -31, -32, -33, -34, -35, -36, -37, -38

Qualifiers for Individual Parameters Listed:

Qualifier	Description
RM-H	Reference Material recovery was above ALS DQO. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)
Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.			
Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction, depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.			
MOISTURE-VA	Soil	Moisture content	ASTM D2974-00 Method A
This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.			
PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL
This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.			

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

2	3	4	5	B0024
---	---	---	---	-------

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Available Phosphate-P	DLHC	L1698939-1, -2
Duplicate	Available Potassium	DLHC	L1698939-1, -2
Duplicate	Selenium (Se)	DUP-H	L1698939-1, -2

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974
The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.			
ETL-N-TOT-AVAIL-SK	Soil	Available Ammonium-N - Calculation	Soil Methods of Analysis (1993) CSSS
HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)
Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.			
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)
Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.			
Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.			
MOISTURE-VA	Soil	Moisture content	ASTM D2974-00 Method A
This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.			
N-TOT-LECO-SK	Soil	Total Nitrogen by combustion method	SSSA (1996) P. 973-974
The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.			
N2/N3-AVAIL-KCL-SK	Soil	Nitrate, Nitrite & Nitrate+Nitrite-N(KCL	CSSS (1993) p. 26-28
Plant available nitrate and nitrite are extracted from the sample with 2N KCl. Nitrate and Nitrite in the filtered extract are determined colorimetrically by Technicon auto-analyzer or flow injection analyzer at 520 nm.			
NH4-AVAIL-SK	Soil	Available Ammonium-N	CSSS(1993) 4.2/COMM SOIL SCI 19(6)
Ammonium (NH4-N) is extracted from the soil using 2 N KCl. Ammonium in the extract is mixed with hypochlorite and salicylate to form indophenol blue, which is determined colorimetrically by auto analysis at 660 nm.			
NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)
Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.			
Reference: Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28			
ORP-SHKFL96-VA	Soil	ORP by Electrode (96 hour SHAKEFLASK)	BC MIN. OF ENERGY AND MINES
This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 96 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter. The sample is then analysed using procedures carried out in accordance "ASTM" method D1498-00 "Oxidation-Reduction Potential of Water" published by the American Society for Testing and Materials (ASTM), May 2000. Results are reported as observed oxidation-reduction potential of the platinum metal-reference electrode employed, in mV.			
PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL
This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.			

Reference Information

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)
Plant available phosphorus and potassium are extracted from the soil using Modified Kelowna solution. Phosphorus in the soil extract is determined colorimetrically at 880 nm, while potassium is determined by flame emission at 770 nm.			
PSA-PIPET-DETAIL-SK	Soil	Particle size - Sieve and Pipette	SSIR-51 METHOD 3.2.1
Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

trish_miller@golder.com
rzapfgilje@golder.com**FACTUAL DATA REPORT ON GROUNDWATER QUALITY
HAZELTINE CREEK FLOODPLAIN, AUGUST 2015****1.0 INTRODUCTION**

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with the following summary of groundwater quality data collected by Golder personnel along the Hazeltine Creek floodplain on August 3 and 4, 2015. A total of eight groundwater samples were collected:

- Four mini-piezometers installed in the tailings;
- One “shallow pit well” installed at a background location;
- Two grab samples from small groundwater springs; and
- One seep sample.

Two of the mini-piezometers were located at the bottom of the canyon along Transect 3 (Figure 1); one at the top of the canyon along Transect 6 (Figure 2); and one upstream of the Gavin lake bridge along Transect 14 (Figure 4).

The background mini-piezometer was located near Edney creek upstream of the Edney creek bridge (Figure 5). The two grab samples were located slightly downstream of Transect 10 (Figure 3). The seep sample was collected near GW15-06 (Figure 4). The mini-piezometers were installed more than 10 metres (m) upgradient of the nearest surface water body. Mini-piezometers were installed to depths of between 0.68 and 1.98 m depending on depth to water (0.11 to 0.75 m). All well screens were installed within the tailings layer to measure potential leaching of metals from the tailings into the groundwater.

This technical memorandum presents the groundwater data from the sampling conducted during August 2015 in the Hazeltine Creek floodplain. The memorandum provides factual information only. Interpretation of the data will be provided in the Detailed Site Investigation report. The factual information provided include:

- Sampling type and locations of samples collected;
- Sampling procedures and methods;
- Quality Assurance/Quality Control procedures; and
- Analytical results.

2.0 METHODS

2.1 Well Installation

A total of four groundwater mini-piezometers were hand installed. Holes were hand augured to depths ranging between 0.68 and 1.98 m depending on the depth to water. Before installation, the holes were purged for a minimum of 20 minutes until the turbidity significantly decreased. A PVC pipe with a slit screen was installed into the auger hole (Photograph 1). Screen length was generally 0.4 m, but in one case (GW15-02) the screen length was 0.75 m to prevent fines from clogging the screen. After PVC pipe installation, the hole was filled with Target 10/20 filter sand to 0.20 m above the top of screen in order to form a sand pack around the well screen. The remainder of the hole was filled with hydrated bentonite chips to seal the well. After installation the mini-piezometer was purged a minimum of three times to develop the well (Photograph 2).

Several attempts were made to hand auger a borehole for installation of a mini-piezometer. However, the attempts were unsuccessful because of difficult hand augering conditions and encountering refusal. Instead, a hole was dug to act as a temporary 'shallow pit well'. The hole was purged for 30 minutes until the groundwater ran clear and then pit was allowed to recharge.

2.2 Groundwater Sampling

The newly installed groundwater mini-piezometers were sampled on August 3 and 4, 2015 following standard low flow sampling procedures. Samples were obtained using dedicated 6-mm (1/4 inch) polyethylene tubing and a geotech peristaltic pump set to a purge rate of approximately 150 to 250 mL/min (Photograph 3). In three of the five mini-piezometers (GW15-01, GW15-02, and GW15-06) the recharge rate was not sufficient to permit continuous sampling. Groundwater was sampled until five centimetres of water remained in the well. The well was then allowed to recharge back to the initial water depth before sampling was continued. Field parameters were monitored and recorded during the groundwater well purging prior to sampling, including: temperature, pH, specific conductivity (SPC), oxidation-reduction potential (ORP), total dissolved solids (TDS) and dissolved oxygen (DO). Representative groundwater quality was determined when measurements of these parameters demonstrated stability between subsequent measurements, and at least two well volumes had been purged. Collected samples were field filtered and preserved where necessary.

In two locations, GW15-04 and GW15-05 (Figure 3), small groundwater springs were identified. The water in these springs was clear and welled up through the sandy tailing layer. Samples were collected at the point where the groundwater daylighted.

Seep water was identified near GW15-06 upstream of the Gavin lake bridge. The seep water ran underneath the tailings layer and daylighted at a diversion trench dug along the forest edge (Photograph 4). The seep water had iron oxide and organic staining, likely due to the nearby marshy area. This water was sampled from a small pool located approximately five metres from the seep.

The following parameters were analyzed in the Field and Laboratory:

Groundwater samples	Field Parameters	Lab Parameters
GW15-01, GW15-02, GW15-06	Temp, pH, ORP, DO, TDS, SPC	Hardness, TSS, pH, ORP, Anions, Nutrients, DOC, Nitrogen, Metals
GW15-03, GW15-04, GW15-05 , Seep15-01, GW-BKG15-01	Temp, pH, ORP, DO, TDS, SPC	Hardness, TSS, pH, ORP, Anions, Nutrients, Metals

Notes: ORP – Oxidation-reduction potential; DO = dissolved oxygen; TDS = total dissolved solids; TSS = total suspended solids; SPC = specific conductivity; DOC = dissolved organic carbon

2.3 Quality Assurance and Quality Control Procedures

To document that the sampling and analytical data were interpretable, meaningful and reproducible, conformance to the Golder quality assurance and quality control (QA/QC) program was followed. This involved using QA/QC measures in both the collection (field program) and analysis (laboratory) of environmental samples.

The following discussion includes a brief summary of the QA/QC measures implemented by Golder during the field program and during our review of the data, as well as the QA/QC measures implemented by the analytical laboratory.

Quality control measures use in the well development, sample collection, preservation and shipment included the following:

- Well development and sampling methods were consistent with established Golder protocols and provincial/federal requirements;
- Field notes were recorded during the investigation and have been stored in the project file;
- Sample locations were recorded and marked in the field; and
- Samples were filtered, preserved (where appropriate), put on ice and subsequently transported to the laboratory using Golder chain-of-custody procedures.

The quality assurance measures for the field program included:

- Submission of blind field duplicate samples. A blind field duplicate sample is a second sample of a certain media (e.g., soil; water) from the same location that is submitted to the analytical lab under a separate label such that the lab has no prior knowledge that it is a duplicate.
- For duplicate samples, either the relative percent difference (RPD) or difference factor (DF) was used to evaluate the sample result variability, depending on the magnitude of the concentrations. The RPD is a measure of the variability between two outcomes from the same procedure is calculated by:

$$absolute\left(\frac{(x_1 + x_2)}{average(x_1, x_2)}\right) \times 100$$

where x_1 is the original sample result and x_2 is the blind field duplicate result. In general, the RPD should not be more than 35% on average, or a maximum of 50%, depending on the parameter and the concentration. A RPD greater than 30% may reflect “in bottle” variability or variation in the test process. RPD is calculated when sample results are equal to or greater than five times the laboratory method detection limit. DF is the absolute difference between the two values divided by the method detection limit and is calculated when sample results are less than five times the method detection limit but not less than the method detection limit. In general, DF should be less than 2.

The following criteria were considered acceptable for laboratory QA/QC samples:

- For organic and inorganic analytes, analytical duplicates should exhibit less than 35% RPD on average, and no more than 50% for a specific analyte.
- Analytical results for reference materials or spiked standards should be within 10% of certified values for inorganic elements or 30% of certified values for organic compounds.
- Analytical blanks should be less than the detection limits used for the specific analysis.
- Certification by the Canadian Association for Laboratory Accreditation Inc. (CALA) for analytical methods used for this program.
- Reports from the laboratory were internally reviewed prior to submission to Golder. If internal QA/QC problems are encountered, the field samples and internal QA/QC samples are re-analysed.

3.0 GROUNDWATER QUALITY RESULTS

Groundwater quality results are presented in Table 2. Results were screened against CSR Schedule 6 Generic Numerical Water Standards for Protection of Freshwater Aquatic Life. No exceedances of these standards were found. Concentrations of copper and selenium in the groundwater samples were also below the BC Water Quality Guidelines for the Protection of Freshwater Aquatic Life. Summary statistics for all parameters are presented Tables 3, 4 and 5.

Table 1 shows the summary of copper and selenium concentrations in the groundwater and background samples as well as the geochemistry humidity cells and column tests conducted by SRK Consulting (Canada) Inc. Detailed geochemistry results can be found in Appendix B.

Table 1: Summary of Copper and Selenium Concentrations

Parameter	Sample size (n)	Minimum	Maximum	Average	CSR Standard (AW-F) ¹	CSR Standard (DW)
Tailings						
pH	7	7.0	8.1	7.6	-	-
Copper	7	0.001	0.029	0.0068	0.080 – 0.090	
Selenium	7	<0.001	<0.001	<0.001	0.010	0.010
Background						
pH	1	7.7	7.7	7.7	-	-
Copper	1	0.0024	0.0024	0.0024	0.080 – 0.090	
Selenium	1	<0.0010	<0.0010	<0.0010	0.010	0.010
Humidity Cells						
pH	7	~7.95	~8.2	~8.1	-	-
Copper	7	~0.006	~0.07	~0.008	0.080 – 0.090	
Selenium	7	~0.0006	~0.007	~0.005	0.010	0.010
Column Tests						
pH	3	~8.1	~8.1	~8.1	-	-
Copper	3	~0.004	~0.022	~0.012	0.080 – 0.090	
Selenium	3	~0.004	~0.013	~0.008	0.010	0.010

Notes:

All units are in mg/L unless otherwise noted

CSR Schedule 6 Generic Numerical Water Standards for Protection of Freshwater Aquatic Life

CSR Schedule 6 Generic Numerical Water Standards for Protection of Drinking Water

3.1 QA/QC Results

One field duplicate collected from GW15-03 was submitted for physical tests, and metal analysis for a total of 11.1% field duplicate analysis; meeting the data quality objective (DQO) of 10%. The results of the field duplicate analysis are presented in Table 6.

The RPDs calculated for physical tests, dissolved organic carbon, and metals indicated that, of the analytes with detectable concentrations, the sample had RPD values that ranged from 0.5% to 49%, with an average RPD of 6.7%. RPDs were generally less than 12% with the exception of total phosphorus and total suspended solids. The RPDs for total phosphorus and total suspended solids were 36% and 49%, respectively, which is still within the maximum QA/QC objective of 50% and is therefore considered acceptable.

Where the RPD calculation was not applicable, DFs were calculated. All calculated DF values were less than the QA/QC objective of 2, and ranged from 0 to 0.92 with an average of 0.20.

Hold times were met for all parameters. Due to the 15-minute hold time for ORP and pH, these parameters were measured in the field, and data reported in Table 2 represent field measurements.

The data is therefore considered reproducible and suitable for the assessment of groundwater quality.

4.0 STATEMENT OF LIMITATIONS

This report was prepared for the exclusive use of MPMC. The report is based on data and information collected during investigations conducted by Golder Associates Ltd. personnel. It is based solely on the conditions of the subject property at the time of the site investigation conducted in August, 2015, as described in this technical memorandum. The data presented in this memorandum represent groundwater conditions encountered at the sampling locations tested during this time period. Groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors. Golder Associates Ltd. makes no warranty, expressed or implied, and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

The findings and conclusions documented in this report have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this report, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this report. All third parties relying on this report do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder's report or other work product. Golder is not responsible for any unauthorized use or modifications of this report.

MPMC may rely on the information contained in this report subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this report, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein. With respect to regulatory compliance issues, regulatory statutes are subject to interpretation. These interpretations and the regulations themselves may change over time, thus MPMC should review these issues.

If new information is discovered during future work Golder should be requested to re-evaluate the conclusions of this report and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this report is affected by any change of site conditions, purpose, development plans or significant delay from the date of this report in initiating or completing the project.

5.0 CLOSURE

We trust that this technical memo provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at 604 787-6707.

Notes:

All concentrations in milligrams per litre (mg/L), unless otherwise noted.

MPMC = Mount Polley Mining Company FDA = field duplicate available; DUP = duplicate sample; < = below detection limit; "-" = not measured; H = hardness-dependent; pH = pH-dependent; Cl = Chloride-dependent ; V = valence dependent, VI refers to chromium VI and III refers to chromium III.

1. Standards from British Columbia Contaminated Sites Regulation (BC CSR; Updated to January 31, 2014), Schedule 6 Generic Numerical Water Standards. The most conservative standard has been applied for the protection of the following site-specific pathway: FW = groundwater flow to surface water used by freshwater aquatic life

a) Fluoride standard is hardness dependent. Since all samples had hardness >50 mg/L the applicable standard is 3000 mg/L for protection of freshwater aquatic life.

123 Indicates concentration exceeding the BC CSR Schedule 6 Groundwater Standards

Zinc	7	0.005	0.025	0.013	0.9-2.4	5

Table Notes:

1. Units shown are in mg/L unless otherwise noted.
2. Standards shown are from the BC Contaminated Sites Regulation.
3. Standards chromium are valence dependent (Chromium 6+ and Chromium 3+).

Notes:

All parameter units in milligrams per kilogram (mg/kg), unless otherwise noted.

FDA = Field Duplicate Available; FD = Field Duplicate; m bgs = metres below ground surface; QA/QC = Quality Assurance/Quality Control

NA = Not Applicable; NC = Not Calculated; Mean = average of two values

Relative percent difference (RPD) = the difference between two values divided by the mean of the two values.

Golders' acceptable RPD is less than or equal to 35%.

RPD is calculated when the concentration is greater than five times the detection limit.

Difference factor (DF) = absolute difference between two values divided by the method detection limit.

Golders' acceptable DF is less than or equal to 2.0.

DF is calculated when the concentration is less than five times the detection limit.

Matrix Spike	Molybdenum (Mo)-Dissolved	MS-B	L1652569-1, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Sulfate (SO4)	MS-B	L1652569-1, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Phosphorus (P)-Total	MS-B	L1652569-3, -4, -5, -6, -7, -8
Matrix Spike	Phosphorus (P)-Total	MS-B	L1652569-3, -4, -5, -6, -7, -8

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLA	Detection Limit adjusted for required dilution
DLM	Detection Limit Adjusted due to sample matrix effects.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
PEHT	Parameter Exceeded Recommended Holding Time Prior to Analysis
SP	Sample was Preserved at the laboratory
SRU	Sample Received Unpreserved. Results may be biased low for indicated parameter(s)

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ACY-PCT-VA	Water	Acidity by Automatic Titration	APHA 2310 "Acidity"
<p>This analysis is carried out using procedures adapted from APHA Method 2310 "Acidity". Acidity is determined by potentiometric titration to a specified endpoint.</p> <p>Samples of industrial wastes, acid mine drainage, or other solutions that contain appreciable amounts of hydrolyzable metal ions such as aluminum, iron, and manganese may require hot peroxide treatment to ensure oxidation and hydrolysis of reduced forms of polyvalent cations. Acidity results may be highly variable if this procedure is not followed. Results in this report for 'Acidity (as CaCO3)' have not been peroxide treated.</p>			
ACY-PCT-VA	Water	Acidity by Automatic Titration	APHA 2310 Acidity
<p>This analysis is carried out using procedures adapted from APHA Method 2310 "Acidity". Acidity is determined by potentiometric titration to a specified endpoint.</p> <p>Samples of industrial wastes, acid mine drainage, or other solutions that contain appreciable amounts of hydrolyzable metal ions such as aluminum, iron, and manganese may require hot peroxide treatment to ensure oxidation and hydrolysis of reduced forms of polyvalent cations. Acidity results may be highly variable if this procedure is not followed. Results in this report for 'Acidity (as CaCO3)' have not been peroxide treated.</p>			
ALK-COL-VA	Water	Alkalinity by Colourimetric (Automated)	EPA 310.2
<p>This analysis is carried out using procedures adapted from EPA Method 310.2 "Alkalinity". Total Alkalinity is determined using the methyl orange colourimetric method.</p>			
ALK-TITR-VA	Water	Alkalinity Species by Titration	APHA 2320 Alkalinity
<p>This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.</p>			
BR-L-IC-N-VA	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)
<p>Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.</p>			
CARBONS-DOC-VA	Water	Dissolved organic carbon by combustion	APHA 5310B TOTAL ORGANIC CARBON (TOC)
<p>This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)". Dissolved carbon (DOC) fractions are determined by filtering the sample through a 0.45 micron membrane filter prior to analysis.</p>			
CL-IC-N-VA	Water	Chloride in Water by IC	EPA 300.1 (mod)
<p>Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.</p>			
EC-PCT-VA	Water	Conductivity (Automated)	APHA 2510 Auto. Conduc.
<p>This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.</p>			
F-IC-N-VA	Water	Fluoride in Water by IC	EPA 300.1 (mod)
<p>Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.</p>			
HARDNESS-CALC-VA	Water	Hardness	APHA 2340B
<p>Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.</p>			

Reference Information

HG-D-CVAA-VA	Water	Diss. Mercury in Water by CVAAS or CVAFS	APHA 3030B/EPA 1631E (mod)
Water samples are filtered (0.45 um), preserved with hydrochloric acid, then undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS or CVAFS.			
HG-DIS-CVAFS-VA	Water	Dissolved Hg in Water by CVAFS LOR=50ppt	APHA 3030B/EPA 1631E (mod)
This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by filtration (EPA Method 3005A) and involves a cold-oxidation of the acidified sample using bromine monochloride prior to reduction of the sample with stannous chloride. Instrumental analysis is by cold vapour atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).			
MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)
Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.			
Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.			
MET-DIS-ICP-VA	Water	Dissolved Metals in Water by ICPOES	EPA SW-846 3005A/6010B
This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedure involves filtration (EPA Method 3005A) and analysis by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).			
N-T-COL-VA	Water	Total Nitrogen in water by Colour	APHA Method 4500-P (J) / NEMI 5735
This analysis is carried out using procedures adapted from APHA Method 4500-P (J) "Persulphate Method for Simultaneous Determination of Total Nitrogen and Total Phosphorus" and National Environmental Methods Index - Nemi method 5735.			
NH3-F-VA	Water	Ammonia in Water by Fluorescence	APHA 4500 NH3-NITROGEN (AMMONIA)
This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.			
NH3-F-VA	Water	Ammonia in Water by Fluorescence	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC
This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.			
NO2-L-IC-N-VA	Water	Nitrite in Water by IC (Low Level)	EPA 300.1 (mod)
Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.			
NO3-L-IC-N-VA	Water	Nitrate in Water by IC (Low Level)	EPA 300.1 (mod)
Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.			
ORP-VA	Water	Oxidation reduction potential by Elect.	ASTM D1498-00
This analysis is carried out in accordance with the procedure described in the "ASTM" method D1498-00 "Oxidation-Reduction Potential of Water" published by the American Society for Testing and Materials (ASTM), May 2000. Results are reported as observed oxidation-reduction potential of the platinum metal-reference electrode employed, in mV.			
It is recommended that this analysis be conducted in the field.			
P-T-PRES-COL-VA	Water	Total P in Water by Colour	APHA 4500-P Phosphorus
This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.			
PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H "pH Value"
This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode			
It is recommended that this analysis be conducted in the field.			
PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H pH Value
This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode			
It is recommended that this analysis be conducted in the field.			
PO4-DO-COL-VA	Water	Diss. Orthophosphate in Water by Colour	APHA 4500-P Phosphorus
This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.			
S-DIS-ICP-VA	Water	Dissolved Sulfur in Water by ICPOES	EPA SW-846 3005A/6010B

Reference Information

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven, or filtration (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

Method Limitation: This method will not give total sulfur results for all samples. Sulfide or other volatile forms of sulfur that may be present in submitted samples, is often lost during the sampling, preservation and analysis process. The data reported as total and/or dissolved sulfur represents all non-volatile forms of sulfur present in a particular sample.

SO4-IC-N-VA Water Sulfate in Water by IC EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TSS-VA Water Total Suspended Solids by Gravimetric APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

14-471689

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Workorder: L1652569

Report Date: 24-SEP-15

Page 14 of 17

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Legend & Qualifier Definitions:

EHTR-FM: Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended.
EHTR: Exceeded ALS recommended hold time prior to sample receipt.
EHTL: Exceeded ALS recommended hold time prior to analysis. Sample was received less than 24 hours prior to expiry.
EHT: Exceeded ALS recommended hold time prior to analysis.
Rec. HT: ALS recommended hold time (see units).

Notes*:

Where actual sampling date is not provided to ALS, the date (& time) of receipt is used for calculation purposes.
Where actual sampling time is not provided to ALS, the earlier of 12 noon on the sampling date or the time (& date) of receipt is used for calculation purposes. Samples for L1652569 were received on 05-AUG-15 08:30.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Lab Work Order #	L1652569
Project P.O. #	
Job Reference	1411734/11000
Legal Site Description	
C of C Numbers	14-471689

Case Narrative/Comments

24-SEP-2015 Additional data is included for all samples.

Work Order Qualifiers:

Water sample(s) for dissolved mercury analysis was not submitted in glass or PTFE container with HCl preservative. Results may be biased low.

Qualifier
WSMD

A handwritten signature in black ink that reads "Amber Springer".

Amber Springer, B.Sc
Account Manager

Qualifier Legend
SRU Sample Received Unpreserved. Results may be biased low for indicated parameter(s)
DLM Detection Limit Adjusted due to sample matrix effects.
SP Sample was Preserved at the laboratory
DLA Detection Limit adjusted for required dilution
PEHT Parameter Exceeded Recommended Holding Time Prior to Analysis

Results of Analysis L1652569

Job Reference 141 1734/11000
Report To Kamin McMillan, GOLDR ASSOCIATES LTD.
Date Received 5-Aug-2015 8:30
Report Date 24-Sep-2015 15:58
Report Revision 2

Main data table with columns: Parameter, ALS ID, Client Sample ID, ALS Test Code, Results, Detection Limit, Units, Qual, Date Sampled, Time Sampled, Prep Date, Analysis Date, QC Lot, QC Eval, Hold Time, Matrix, Class. It lists various chemical and physical tests for metals, nutrients, and organics.

Qualifier Legend
DLA Detection Limit adjusted for required dilution
DLM Detection Limit Adjusted due to sample matrix effects.
PEHT Parameter Exceeded Recommended Holding Time Prior to Analysis
SP Sample was Preserved at the laboratory.
SRU Sample Received Unpreserved. Results may be biased low for indicated parameter(s)

Evaluation Legend
QC Lot met ALS Data Quality Objectives
QC Lot did not meet ALS Data Quality Objectives

Duplicates L1652569

Report Date 24-Sep-2015 15:58
Report Revision 2

ALS Test Code	ALS Test Description	Lab Location	Matrix	Method Reference	Methodology Description
Physical Tests (Water)					
EC-PCT-VA	Conductivity (Automated)	Vancouver	Water	APHA 2510 Auto. Conduc.	This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.
HARDNESS-CALC-VA	Hardness	Vancouver	Water	APHA 2340B	Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO ₃ equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.
ORP-VA	Oxidation reduction potential by Elect.	Vancouver	Water	ASTM D1498-00	This analysis is carried out in accordance with the procedure described in the "ASTM" method D1498-00 "Oxidation-Reduction Potential of Water" published by the American Society for Testing and Materials (ASTM), May 2000. Results are reported as observed oxidation-reduction potential of the platinum metal-reference electrode employed, in mV.
PH-PCT-VA	pH by Meter (Automated)	Vancouver	Water	APHA 4500-H pH Value	It is recommended that this analysis be conducted in the field. This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode
TSS-VA	Total Suspended Solids by Gravimetric	Vancouver	Water	APHA 2540 D - GRAVIMETRIC	It is recommended that this analysis be conducted in the field. This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter. TSS is determined by drying the filter at 104 degrees celsius.
Anions and Nutrients (Water)					
ACY-PCT-VA	Acidity by Automatic Titration	Vancouver	Water	APHA 2310 Acidity	This analysis is carried out using procedures adapted from APHA Method 2310 "Acidity". Acidity is determined by potentiometric titration to a specified endpoint. Samples of industrial wastes, acid mine drainage, or other solutions that contain appreciable amounts of hydrolyzable metal ions such as aluminum, iron, and manganese may require hot peroxide treatment to ensure oxidation and hydrolysis of reduced forms of polyvalent cations. Acidity results may be highly variable if this procedure is not followed. Results in this report for 'Acidity (as CaCO ₃)' have not been peroxide treated.
ALK-COL-VA	Alkalinity by Colourimetric (Automated)	Vancouver	Water	EPA 310.2	This analysis is carried out using procedures adapted from EPA Method 310.2 "Alkalinity". Total Alkalinity is determined using the methyl orange colourimetric method.
ALK-TITR-VA	Alkalinity Species by Titration	Vancouver	Water	APHA 2320 Alkalinity	This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
BR-L-IC-N-VA	Bromide in Water by IC (Low Level)	Vancouver	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
CL-IC-N-VA	Chloride in Water by IC	Vancouver	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
F-IC-N-VA	Fluoride in Water by IC	Vancouver	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
N-T-COL-VA	Total Nitrogen in water by Colour	Vancouver	Water	APHA Method 4500-P (J) / NEMI 5735	This analysis is carried out using procedures adapted from APHA Method 4500-P (J) "Persulphate Method for Simultaneous Determination of Total Nitrogen and Total Phosphorus" and National Environmental Methods Index - Nemi method 5735.
NH3-F-VA	Ammonia in Water by Fluorescence	Vancouver	Water	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC	This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry; "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.
NO2-L-IC-N-VA	Nitrite in Water by IC (Low Level)	Vancouver	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
NO3-L-IC-N-VA	Nitrate in Water by IC (Low Level)	Vancouver	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
P-T-PRES-COL-VA	Total P in Water by Colour	Vancouver	Water	APHA 4500-P Phosphorus	This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.
PO4-DO-COL-VA	Diss. Orthophosphate in Water by Colour	Vancouver	Water	APHA 4500-P Phosphorus	This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.
SO4-IC-N-VA	Sulfate in Water by IC	Vancouver	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Organic / Inorganic Carbon (Water)					
CARBONS-DOC-VA	Dissolved organic carbon by combustion	Vancouver	Water	APHA 5310B TOTAL ORGANIC CARBON (TOC)	This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)". Dissolved carbon (DOC) fractions are determined by filtering the sample through a 0.45 micron membrane filter prior to analysis.
Dissolved Metals (Water)					
HG-D-CVAA-VA	Diss. Mercury in Water by CVAAS or CVAFS	Vancouver	Water	APHA 3030B/EPA 1631E (mod)	Water samples are filtered (0.45 um), preserved with hydrochloric acid, then undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS or CVAFS.
HG-DIS-CVAFS-VA	Dissolved Hg in Water by CVAFS LOR=50ppt	Vancouver	Water	APHA 3030B/EPA 1631E (mod)	This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by filtration (EPA Method 3005A) and involves a cold-oxidation of the acidified sample using bromine monochloride prior to reduction of the sample with stannous chloride. Instrumental analysis is by cold vapour atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).
MET-D-CCMS-VA	Dissolved Metals in Water by CRC ICMS	Vancouver	Water	APHA 3030B/6020A (mod)	Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
MET-DIS-ICP-VA	Dissolved Metals in Water by ICPOES	Vancouver	Water	EPA SW-846 3005A/6010B	This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedure involves filtration (EPA Method 3005A) and analysis by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

Methodology L1652569

Job Reference 1411734/11000

Report Date 24-Sep-2015 15:58
Report Revision 2

ALS Test Code	ALS Test Description	Lab Location	Matrix	Method Reference
S-DIS-ICP-VA	Dissolved Sulfur in Water by ICPOES	Vancouver	Water	EPA SW-846 3005A/6010B

Methodology Description

This analysis is carried out using procedures adapted from "Standard Methods for the Examination of Water and Wastewater" published by the American Public Health Association, and with procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846 published by the United States Environmental Protection Agency (EPA). The procedures may involve preliminary sample treatment by acid digestion, using either hotblock or microwave oven, or filtration (EPA Method 3005A). Instrumental analysis is by inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

Method Limitation: This method will not give total sulfur results for all samples. Sulfide or other volatile forms of sulfur that may be present in submitted samples, is often lost during the sampling, preservation and analysis process. The data reported as total and/or dissolved sulfur represents all non-volatile forms of sulfur present in a particular sample.

Legend & Qualifier Definitions

EHTR-FM: Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended.
EHTR: Exceeded ALS recommended hold time prior to sample receipt.
EHTL: Exceeded ALS recommended hold time prior to analysis. Sample was received less than 24 hours prior to expiry.
EHT: Exceeded ALS recommended hold time prior to analysis.
Rec. HT: ALS recommended hold time (see units).

Notes*:

Where actual sampling date is not provided to ALS, the date (& time) of receipt is used for calculation purposes.
Where actual sampling time is not provided to ALS, the earlier of 12 noon on the sampling date or the time (& date) of receipt is used for calculation purposes.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of specific requirements, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or CCME (where applicable).

jvandenberg@golder.com**MOUNT POLLEY SURFACE WATER QUALITY IMPACT ASSESSMENT UPDATE,
MARCH TO AUGUST 2015**

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with the following update to the Surface Water Quality Impact Assessment (WQIA) that was submitted as part of the Post-Event Environmental Impact Assessment Report (PEEIAR) in June 2015 (Golder 2015a). The 'event' refers to the tailings dam failure that occurred at the Mount Polley Mine on August 4, 2014, when the Tailings Storage Facility (TSF) Perimeter Embankment failed and there was a subsequent debris flow into the receiving environment. The time period considered in the WQIA was August 2014 to April 2015. This update to the WQIA focuses primarily on data generated by post-event water quality monitoring undertaken by MPMC over a six month period between March and August 2015. This period was selected as a cutoff for this update, however, MPMC water quality monitoring is ongoing. Note that there is some overlap in dates covered by the original WQIA and this document because the dataset was being generated during the preparation of the PEEIAR in March and April 2015. Monitoring of post-event receiving environment has also been carried out by the BC Ministry of Environment (BC MoE) for audit purposes; these results are reported elsewhere (<http://www.env.gov.bc.ca/epd/mount-polley/>).

1.0 INTRODUCTION

The interim findings of the WQIA concluded that there were measured changes in water quality in Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River as a result of the event, but that evidence available at the time of report preparation did not indicate that constituents of the TSF materials had resulted in toxicity in the water column. Post-event monitoring is being undertaken by MPMC to support the continued evaluation of water quality and the potential for toxicity in these waterbodies.

This technical memorandum is intended to provide an update to the interim findings of the PEEIAR WQIA and to characterize water quality conditions relevant to the Detailed Site Investigation (DSI) and Human Health and Ecological Risk Assessment (HHERA). The DSI and HHERA are being undertaken as a requirement of the Pollution Abatement Order issued by the BC MoE in response to the tailings dam failure to satisfy the requirements of the Provincial *Environmental Management Act* and the *Contaminated Sites Regulation* (CSR).

Following consultation with the BC MoE in July 2015¹, Hazeltine Creek is to be considered a receiving environment for the DSI and HHERA, and accordingly, it is considered a receiving environment for this WQIA update. In order of water flow, the receiving environments evaluated are Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River (Attachment 1).

Following initial screening of water quality data using relevant BC water quality guidelines (BC WQGs) and CSR standards, contaminants of potential concern (COPCs) were identified (see Section 3.1) for the receiving environments listed above. Post-event changes in receiving environment water quality, with respect to identified COPCs, were evaluated relative to applicable BC WQGs and CSR standards for the time period from March to August 2015 (Section 3.2). In Section 4, the results from this updated water quality assessment are discussed with reference to whether each COPC will be carried forward for further assessment as contaminants of concern (COCs) in the DSI. In Section 5, COCs are identified for consideration in the problem formulation components of the HHERA.

2.0 METHODS

2.1 Data Collection and Compilation

The assessment relied on water quality data collected by MPMC from March to August 2015 in accordance with the Post TSF-Breach 2015 Monitoring Plan (MPMC 2015), in addition to post-event data previously reported in the PEEIAR WQIA (Golder 2015a). In general, 2015 monitoring focused on routine stations, but some station locations were moved, replaced, added, or removed, consistent with the evolution of the post-event program and in consultation with regulatory agencies (MPMC 2015). A summary of monitoring stations and sampling frequencies for the time period between March and August is presented in Attachment 2.

The monitoring program evolved during the first year following the event in consideration of factors that included, but were not limited to: monitoring results, safety and logistical constraints, recommendations from the BC MoE, and seasonal conditions. A number of stations in Polley Lake, Hazeltine Creek, and Quesnel Lake were consistently monitored, typically either weekly or monthly; while other stations were monitored on a more intermittent basis or were briefly monitored for a specific purpose. A compilation of discrete water sample data collected at stations monitored by MPMC from August 2014 to August 2015, inclusive, are appended at the end of this technical memorandum in Attachment 8.

Between March and August 2015, depth profiles of field parameters were recorded throughout the water column and water samples were collected for chemical analysis at designated stations shown in Attachment 1. At the Polley Lake stations, discrete water samples were taken at 5 m depth intervals from the surface to close to the lake bottom, except when the water column was fully mixed at overturn, when samples were taken at 10 m depth intervals. The depth range sampled in Polley Lake was 0 to 20 m and approximately 2 m from the lake bottom. In Quesnel Lake the depth range sampled was station dependent consistent with previous reported post-event sampling in Golder (2015a) (depths sampled are provided in Attachment 2). Field methods were consistent with those described in Appendix B of the PEEIAR for water quality monitoring undertaken by MPMC between August 2014 and April 2015 (Golder 2015a). Continuous data loggers were installed to record field parameter measurements at station HAC-01b at the outflow of Hazeltine Creek and QUR-1 in the Quesnel River (i.e., conductivity, dissolved oxygen, pH, temperature, and turbidity) at 15 minute intervals.

¹ Verbal communication with the BC MoE Land Remediation Section following their review of the July 15, 2015, DSI and HHERA work plan.

Analytical and field monitoring data verified as reliable based on a quality assurance/quality control (QA/QC) assessment by MPMC, as well as station location information, were uploaded by MPMC to their water quality database. MPMC provided Golder with electronic data collected from March to August 2015 for this WQIA update. These data were used as received from MPMC with an additional check of transcription by Golder prior to use in COPC screening. The process of sample continuity and data quality verification by MPMC is documented in Appendix B of the PEEIAR for post-event data collected prior to March 2015 (Golder 2015a). These QA/QC procedures were followed through August 2015 and a summary of the findings of the MPMC QA/QC program for water quality data collected from March to August 2015 is provided in Attachment 3.

The majority of data collected between March and August 2015 met data quality objectives specified in Appendix B of Golder (2015a). Objectives that were not met mainly related to variability between duplicate samples, possibly due to environmental heterogeneity or interferences in the analytical method. The QA/QC results were considered acceptable because the overall number of data that did not meet objectives was low, and the observed variability did not influence the findings of this WQIA update.

2.2 COPC Identification

Discrete water quality data collected by MPMC at stations monitored between March and August 2015 (shown in Attachment 1) were compiled and screened to identify COPCs. The purpose of the COPC screening shown in Attachment 4 was to identify those parameters that remained elevated as of March 2015, in order to focus the WQIA update on those substances that might be of longer-term consequence regarding potential impacts on water quality. Data compiled for all stations sampled within a given area (i.e., Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River) were evaluated as one dataset for COPC screening. Subsequent data analysis of COPC temporal trends focused on a representative subset of monitoring stations for each area (as described in Section 2.3).

Substances were identified as COPCs if they were greater than pre-event concentrations and applicable guidelines based on the most sensitive receiving environment water use. Golder (2015a) identified the following known environmental uses on Quesnel Lake, particularly with respect to the West Basin, to determine the most sensitive water use for the downstream receiving environment.

- Commercial, recreational, and aboriginal fisheries;
- Recreational uses such as scenery and wildlife viewing, swimming, boating, kayaking, canoeing, waterskiing/tubing/wakeboarding, and in the winter snowmobiling and ice fishing when ice conditions allow; and
- Drinking and residential water use for domestic purposes.

For the WQIA update, maximum and 95th percentile parameter concentrations calculated for each receiving environment area were compared to the following regulatory criteria:

- BC WQGs for aquatic life (or most sensitive end use identified in Table 3-4 of Golder 2015a²);
- BC drinking water guidelines (BC MOE 2015a);
- CSR Schedule 6 standards for aquatic life (CSR 2014);
- CSR Schedule 6 drinking water standards (CSR 2014); and
- CSR Schedule 6 livestock water standards (as a surrogate for wildlife water) (CSR 2014).

Based on this screening, COPCs were conservatively identified for the four receiving environment areas for the purpose of evaluating potential water quality impacts to aquatic life, wildlife water, or drinking water. The screening was two-tiered: first, an initial screening stage identified parameters with maximum upper limit concentrations below BC WQGs. These water quality parameters were not carried further in the screening process. Second, for parameters with concentrations above BC WQGs, 95th percentile concentrations were calculated and screened against the regulatory criteria listed above. Water quality parameters were identified as COPCs if 95th percentile concentrations were above the lowest applicable criteria (Attachment 4, Tables 1-5) and were higher than the 95th percentile pre-event baseline concentration provided in Golder (2015a).

Maximum and 95th percentile concentrations represented upper limit concentrations in the post-event water quality dataset. Water quality parameters were not identified as COPCs if post-event upper limit concentrations were below the lowest applicable criteria. The lowest applicable criteria were typically BC WQGs; conservative environmental quality benchmarks with built-in safety factors that represent concentrations below which adverse impacts on water quality are not expected. Pre-event data were available for Polley Lake, Hazeltine Creek, and Quesnel River and these data are summarized in Golder (2015a). As described in Golder (2015a), pre-event data for Quesnel Lake data were limited to nutrient-related monitoring surveys primarily focused around Horsefly Bay just east of Cariboo Island.

Parameters without BC WQGs were not identified as COPCs in the PEEIAR WQIA based on an evaluation of post-event data up to February 2015. Concentrations of these parameters in the weeks and months following the event were not considered to be of environmental concern. Subsequently, the same parameters were not considered to be COPCs in the WQIA update.

² With the exception of molybdenum, total aluminum, and pH, the most sensitive receiving environment use was the protection of aquatic life. For molybdenum, the most conservative 30-d BC WQG value was adopted (i.e., irrigation assuming the copper: molybdenum ratio is less than 2:1 *in lieu* of a 30-d value for wildlife). For total aluminum, the most conservative maximum BC WQG was adopted (i.e., water for wildlife) because aquatic life guidelines are based only on dissolved aluminum.

2.3 COPC Evaluation

Changes in COPC concentrations were evaluated qualitatively (see Section 2.3.2) over time at representative stations previously assessed in the PEEIAR WQIA (Golder 2015a), although replacement stations were included as appropriate, consistent with the evolution of the post-event monitoring program.

2.3.1 Representative Station Selection

Ten representative stations in the downstream aquatic receiving environment for the WQIA update were monitored either weekly or monthly from August 2014 to August 2015. Datasets for some monitoring stations were combined to provide a continuous data record³. Rationale for the selection of each representative monitoring station is provided below.

- **Two stations on Polley Lake (P1 and P2).** Station P1 located at the north end of Polley Lake and Station P2 located to the south of the lake. These two stations represented the deepest areas of the lake and provided geographical coverage.
- **Three stations in Hazeltine Creek.** One station in upper Hazeltine Creek (HAC-05), one station in lower Hazeltine Creek (HAC-08) above the two sedimentation ponds, and one station at the outflow of Hazeltine Creek (HAC-01) below the sedimentation ponds. These ponds became operational in December 2014 and were designed to reduce loadings of suspended particulate matter in lower Hazeltine Creek and as a consequence inputs to Quesnel Lake. In upper Hazeltine Creek, Station HAC-05 has been the most frequently sampled since the event, and in lower Hazeltine Creek, Station HAC-01 has been the most frequently sampled (Attachment 2). Data from HAC-01 represent water quality at the outflow of Hazeltine Creek below the sedimentation ponds at the confluence with Quesnel Lake. Monitoring at Station HAC-08 began in late January 2015.
 - As described in Attachment 2 and Golder (2015a), the HAC-01 water quality monitoring station in lower Hazeltine Creek was moved slightly over time to adapt to changes in the creek channel due to rehabilitation activities and construction of sedimentation ponds (a change in location was indicated with a subsequent letter in the station code). Samples collected at HAC-01, HAC-01a, HAC-01b, HAC-01c in lower Hazeltine Creek have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-01/a/b/c).
- **Four stations in Quesnel Lake.** One near-field station, two mid-field stations located west of Cariboo Island, and one far-field station located east of Cariboo Island.
 - *Near-field:* Station QUL-66 is located close to the mouth of Hazeltine Creek, and was replaced by stations QUL-55 in March 2015 and QUL-55a in July 2015, when the creek mouth was re-routed. The Pollution Abatement Order 107461 amendment issued June 15, 2015, by the BC MoE (2015b), specified turbidity requirements for this station and surrounding profile data stations.

³ As described in Golder (2015a) some lake stations were not sampled during the winter months due to health and safety concerns and issues related to access. Hazeltine Creek was a managed system undergoing rehabilitation and so some stations had to be moved over time consistent with activities within the creek.

- *Mid-field:* Station QUL-18 represents one of the deepest points in the West Basin and is located north-west of the Hazeltine Creek mouth, towards the Quesnel River between QUL-66 and QUL-21. The Pollution Abatement Order 107461 amendment issued June 15, 2015, by the BC MoE (2015b) also specified turbidity requirements for this station. Station QUL-2/2a is a mid-field station located east of the Hazeltine Creek mouth west of Cariboo Island. Both stations QUL-2 and QUL-2a were monitored following the event until lake turnover in 2014, but monitoring only at QUL-2a was continued in 2015. Data from stations QUL-2 and QUL-2a were pooled to provide a combined post-event dataset that extended to August 2015.
- *Far-Field:* Station QUL-120/120a is located east of Cariboo Island towards the main body of the lake and was assessed with regards to turbidity measures of the plume. Data from stations QUL-120 and QUL-120a were pooled to provide a combined post-event dataset that extended to August 2015.
- **One Quesnel River station:** Station QUR-1 is located at the Quesnel River Research Centre near the community of Likely and reflects water quality at the outflow of Quesnel Lake. This station was routinely monitored by MPMC during the post-event period.

2.3.2 Changes in COPC Concentrations Over Time

Instantaneous measurements and rolling 30-day (d) average values for each COPC were assessed qualitatively and were compared against applicable provincial guidelines and standards to assess changes in water quality as a result of the event⁴.

- Instantaneous measurements were compared against the short-term maximum BC WQGs (where available) for the most sensitive water use to evaluate intermittent or transient impacts on aquatic life. These concentrations were also compared against CSR Schedule 6 standards for aquatic life, CSR Schedule 6 drinking water standards, and CSR Schedule 6 livestock water standards (as a surrogate for wildlife water). CSR standards were shown on relevant graphs where reported concentrations exceeded these standards; otherwise the CSR standards were not shown because they are often much higher than the y-axis maxima and therefore including them would compress the observed data downwards.
- Rolling 30-d average values were calculated and compared against long-term average BC WQGs that are intended to prevent sub-lethal and lethal effects on the most sensitive species and life stage for an indefinite time period. The 30-d mean guidelines are intended to be applied to mean concentrations of a minimum of five samples collected over a 30-d time period (BC MoE 2015a).

Temporal and spatial trends in the concentrations of each COPC were discussed (see Section 3.0) with a focus on those parameters that remained elevated from March to August 2015, under the assumption that these parameters could therefore be of longer-term potential consequence regarding impacts on water quality.

⁴ Substitutions were not made for values that were reported as less than the method detection limit (MDL) and these values were set equal to the MDL for purposes of plotting data, calculating 30-d averages.

2.3.3 Turbidity Requirements of Pollution Abatement Order 107461

A Pollution Abatement Order 107461 amendment was issued June 15, 2015, by the BC MoE (2015b) and specified that MPMC must meet the following requirements with respect to water quality.

- Turbidity at the monitoring sites QUL-54, QUL-55, QUL-56 (and subsequently replacement stations QUL-54a, QUL-55a, and QUL-56a) of no greater than 2 NTU rolling average above background (i.e., 1 NTU), at any monitored depth, over a period of 30 days using a minimum of five weekly samples.
- Turbidity at the monitoring site QUL-18 of no greater than 1 NTU above background at any monitored depth.

To assess compliance with amended Pollution Abatement Order 107461, depth profile measurements of turbidity were plotted for near-field stations QUL-54/54a, QUL-55/55a, QUL-56/56a and the western mid-field station QUL-18. The plots were then interpreted to identify time periods where non-compliance was observed.

3.0 RESULTS

3.1 COPC Identification

The screening process described in Section 2.2 for data collected between March and August 2015 identified the following COPCs that required further evaluation of post-event concentrations (bolded in Table 1):

- molybdenum in Polley Lake;
- turbidity in Quesnel Lake and Quesnel River;
- copper in Quesnel Lake; and
- turbidity, TSS, and a number of metals in Hazeltine Creek.

Table 1: Contaminants of Potential Concern Identified in the Receiving Environment Based on Water Quality Monitoring from March through August 2015¹

Waterbody	COPC: Physical ^{2,3}	COPC: Total Metals ²	COPC: Dissolved Metals ²	COPC: Non-Metal Substances
Polley Lake	<i>no substances</i>	molybdenum	molybdenum	<i>no substances</i>
Hazeltine Creek	turbidity, total suspended solids	aluminum, arsenic, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, molybdenum, titanium, zinc	copper, molybdenum	<i>no substances</i>
Quesnel Lake	turbidity	copper	<i>no substances</i>	<i>no substances</i>
Quesnel River	turbidity⁴	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>

Notes:

- 1) Parameters were identified based on 95th percentile of measured values exceeding the BC WQG or CSR standard for the most sensitive end use and exceedance of the pre-event 95th percentile concentration.
- 2) Bolded COPCs were evaluated further in the WQIA update. Metals not bolded had 95th percentile concentrations that only exceeded CSR standards (i.e., total cadmium, total titanium), but did not exceed BC WQGs (dissolved cadmium concentrations did not exceed BC WQGs). These metals were not evaluated further and were conservatively retained for the HHERA.
- 3) Background turbidity concentrations are 1.5 NTU in Hazeltine Creek and 1 NTU in Quesnel Lake and Quesnel River.
- 4) Turbidity was identified as a COPC for Quesnel River based on in-situ data from a continuous logger.

With respect to Hazeltine Creek, suspended particulate matter, measured as TSS and turbidity, and the total forms of 14 metals were identified as COPCs for the period March to August 2015 (Table 1). Of those 14 metals, copper and molybdenum were also identified as COPCs in their dissolved forms. Subsequent evaluation of COPCs identified for Hazeltine Creek focused on those metals that exceeded BC WQGs, while metals that only exceeded CSR standards (i.e., total cadmium, total titanium) were conservatively retained as COPCs in Section 5 for further evaluation in the HHERA. Levels of suspended particulate matter in Hazeltine Creek initially decreased in December and January to those that represented 'clear-flow conditions' in the creek following the commissioning of the sedimentation ponds in December (Golder 2015a) and the onset of low flow freezing conditions. From February to May 2015, particulate matter levels increased in the creek as a result of construction activities along the creek channel that coincided with an early freshet (as illustrated in the photos provided in Attachment 6). These turbid flow episodes were associated with peak concentrations of metal COPCs above BC WQGs and pre-event concentrations in Hazeltine Creek.

In-situ pH values measured when discrete samples were taken from the four waterbodies were mostly within the BC WQG range of 6.5 to 9.0 for aquatic life⁵ and the BC WQG range of 6.5 to 8.5 for drinking water⁶. Based on these data, pH was not identified as a COPC consistent with the PEEIAR WQIA.

The PEEIAR WQIA identified dissolved oxygen (DO) as a COPC in Polley Lake, but DO was not of potential concern in Quesnel Lake, Hazeltine Creek, or Quesnel River. From May to June 2015, DO concentrations in Polley Lake were above the minimum BC WQG of 5 mg/L, but in July and August 2015 concentrations at depth were less than 5 mg/L, indicative of hypoxic conditions (as shown for Station P2 in Attachment 5). These late summer DO conditions were similar to those described for Polley Lake prior to the event by Minnow (2014): in late summer the lake underwent thermal stratification and hypoxic conditions were evident at depths greater than 20 m. Given that DO conditions in Polley Lake resemble pre-event conditions, DO was not identified as a COPC for this lake.

3.2 Changes in COPC Concentrations Over Time

The following section describes post-event changes in receiving environment water quality with respect to COPCs identified in Section 3.1. Changes in COPC concentrations over time from March to August 2015 are discussed below relative to relevant BC WQGs and CSR standards. Post-event concentrations from August 2014 to February 2015 previously reported in the PEEIAR WQIA (Golder 2015a) are provided in each figure for context and discussed where appropriate in the text to facilitate interpretation of data collected between March and August 2015. Results are presented according to each group of COPCs (i.e., suspended particulate matter, metals, nutrients), then within each COPC group. Changes in specific COPCs are discussed for each waterbody.

Data shown for Hazeltine Creek and Quesnel River represent discrete surface grab samples collected as described in the PEEIAR WQIA, except where a continuous data logger measured turbidity. Quesnel Lake and Polley Lake data are from discrete grab samples taken at various depths and were categorized as either surface (1-20 m) or deep (>20 m) for the purpose of evaluating changes over time.

⁵ With the exception of 4% of samples in Polley Lake and 2% of samples in Quesnel River that exceeded BC WQG upper limit of 9.0 (MPMC unpublished data)

⁶ With the exception of: 20% of samples in Polley Lake and 4% of samples in Quesnel Lake that exceeded BC WQG upper limit of 8.5 (MPMC unpublished data)

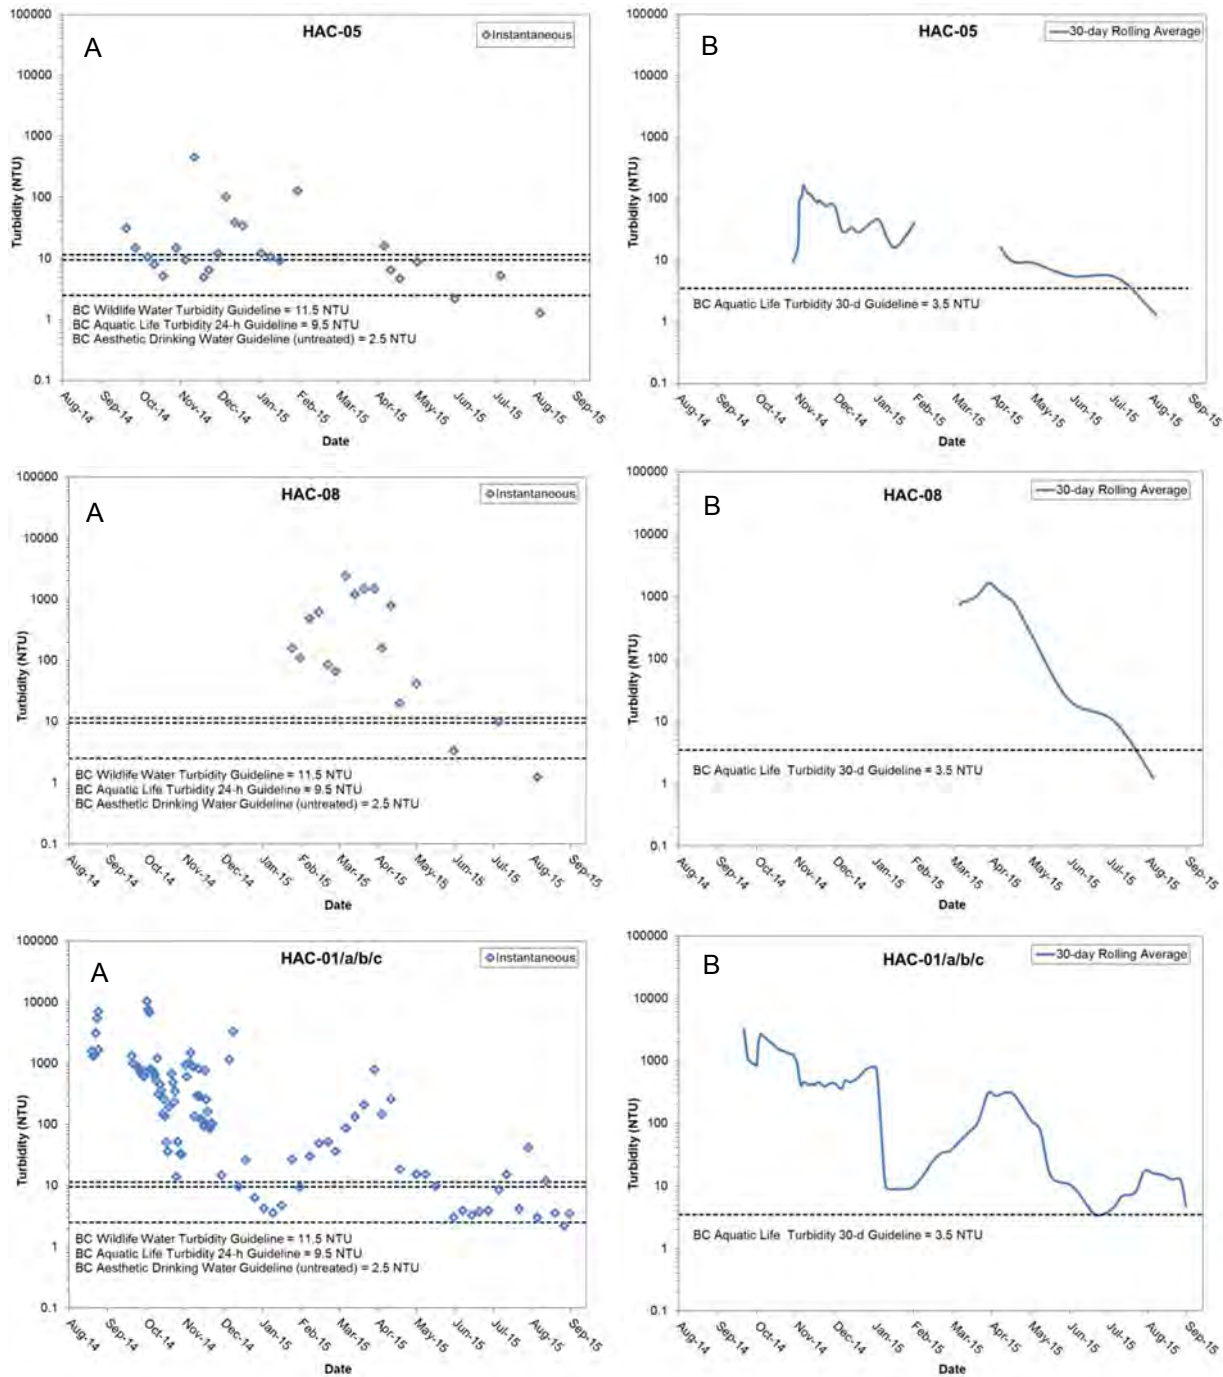

3.2.1 Suspended Particulate Matter (Turbidity/TSS)

Both TSS and turbidity, were identified as COPCs in Hazeltine Creek from March to August 2015, whereas downstream in Quesnel Lake and Quesnel River, only turbidity was identified as a COPC. Larger suspended solids captured in the TSS measurement tend to settle out more quickly than the finer particulates measured by turbidity that might travel further downstream.

3.2.1.1 Hazeltine Creek

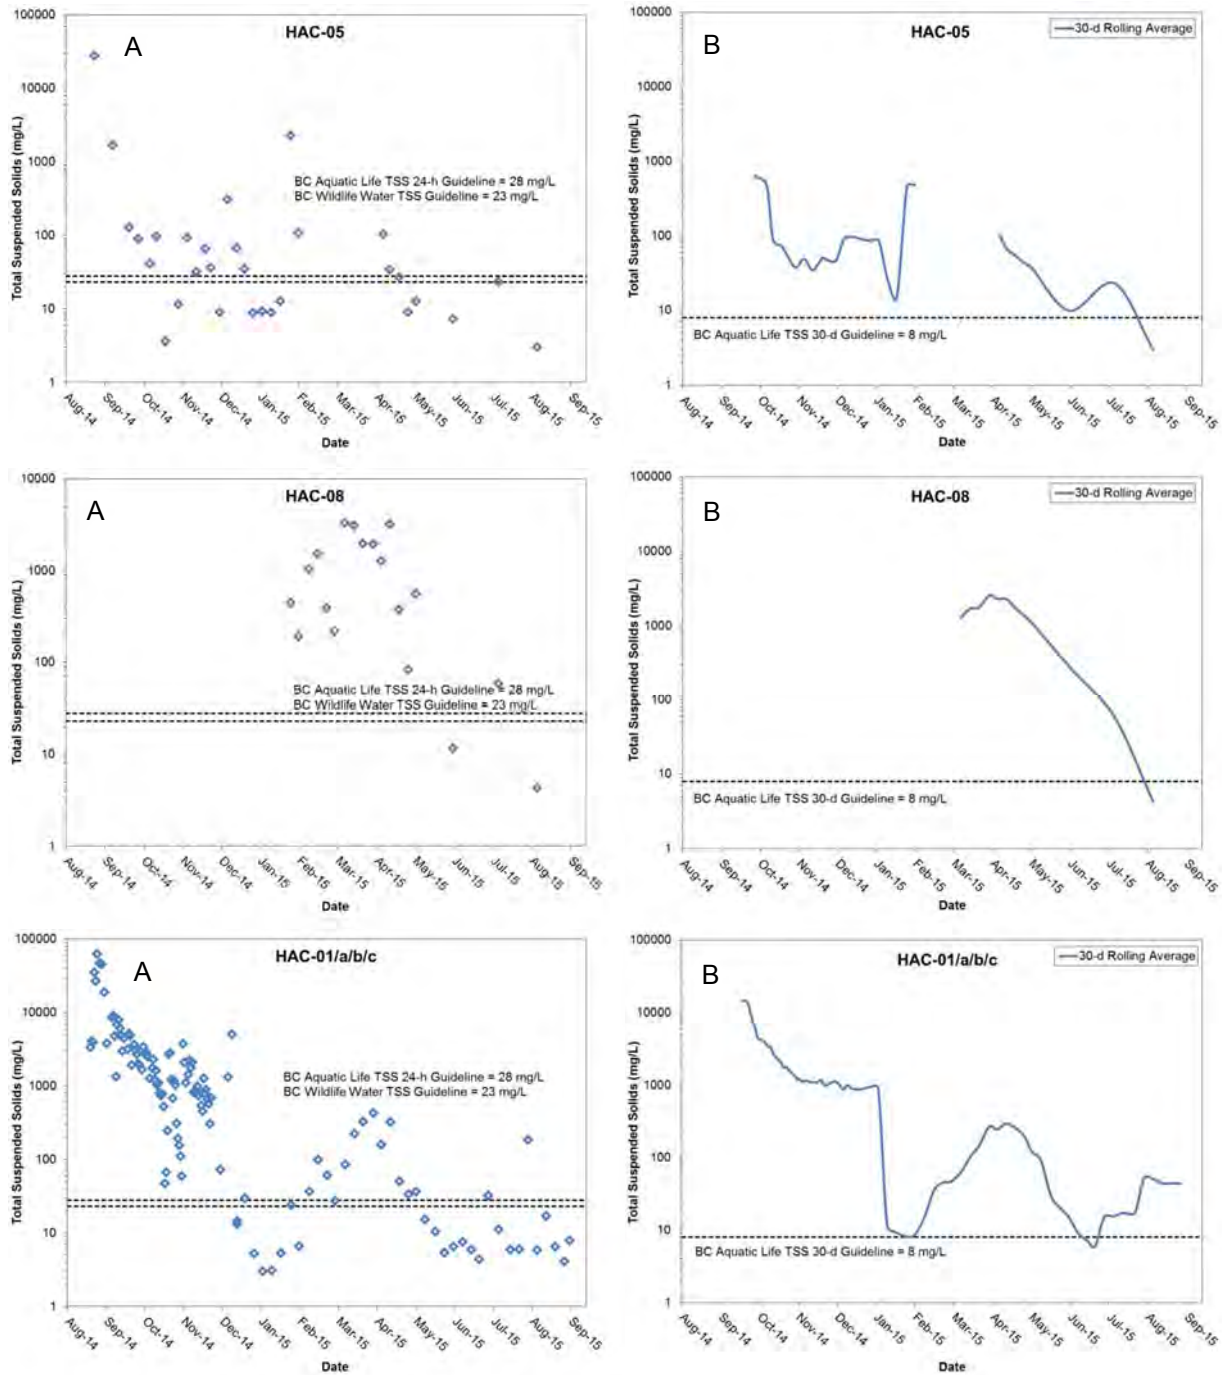

Turbidity and TSS in Hazeltine Creek were measured above BC WQGs following the event and exhibited a general decrease over time at stations HAC-05 and HAC-01/a/b/c from August 2014 through August 2015, and at HAC-08 from April to August 2015 (Figure 1 and Figure 2). Although two sedimentation ponds were commissioned in lower Hazeltine Creek in December 2014, and have been considered to be effective at reducing sediment loads most of the time, spikes in turbidity and TSS were observed downstream at HAC-01/a/b/c between late January and April 2015. This increase in turbidity was attributed to an early freshet and ongoing remediation works along the creek channel. Stabilization and rock armouring of the creek channel was completed on May 11, 2015, which corresponded with a reduction in turbidity. Peaks in turbidity at HAC-01/a/b/c again in late July and mid-August corresponded with construction activities related to a change in discharge location of the creek and maintenance of the sedimentation ponds at that time (pers. comm. S. Litke), rather than due to specific precipitation events (Attachment 6, Figure 5).

In upper Hazeltine Creek (HAC-05) and lower Hazeltine Creek above the sedimentation ponds (HAC-08), turbidity and TSS decreased below the 24-h BC WQG for aquatic life and BC WQG for wildlife water as of May 2015. The corresponding 30-d average concentrations decreased below the 30-d BC WQG for aquatic life in August 2015. As indicated in Figure 1, Station HAC-05 was not sampled between February and April due to active construction activity in the surrounding area. As of May 2015, the majority of measurements of both TSS and turbidity at the outflow of Hazeltine Creek (HAC-01/a/b/c) decreased below the 24-h BC WQGs for aquatic life and BC WQGs for wildlife water, but remained above the 30-d BC WQGs through August 2015. Turbidity at the outflow of Hazeltine Creek remained above the BC aesthetic drinking water guideline for untreated water through August.

Note: Baseline assumed equal to pre-event median turbidity of 1.5 NTU. Gaps represent >30 d between sampling.

Figure 1: Post-event Instantaneous (A) and Rolling 30-day Average (B) Turbidity Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltnie Creek.

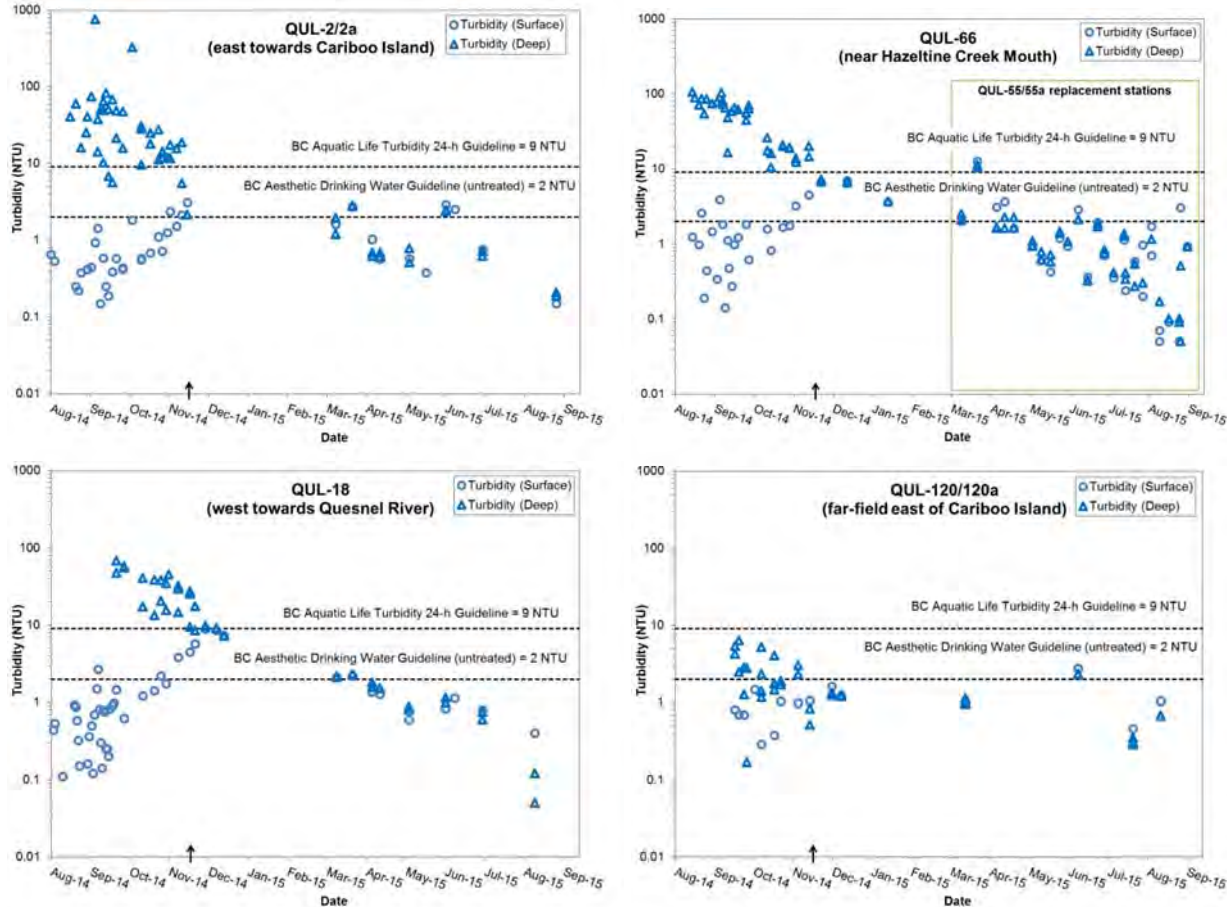

Note: Baseline assumed equal to the MDL of 3 mg/L. Gaps represent >30 d between sampling.

Figure 2: Post-event Instantaneous (A) and Rolling 30-day Average (B) TSS Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltime Creek.

3.2.1.2 Quesnel Lake

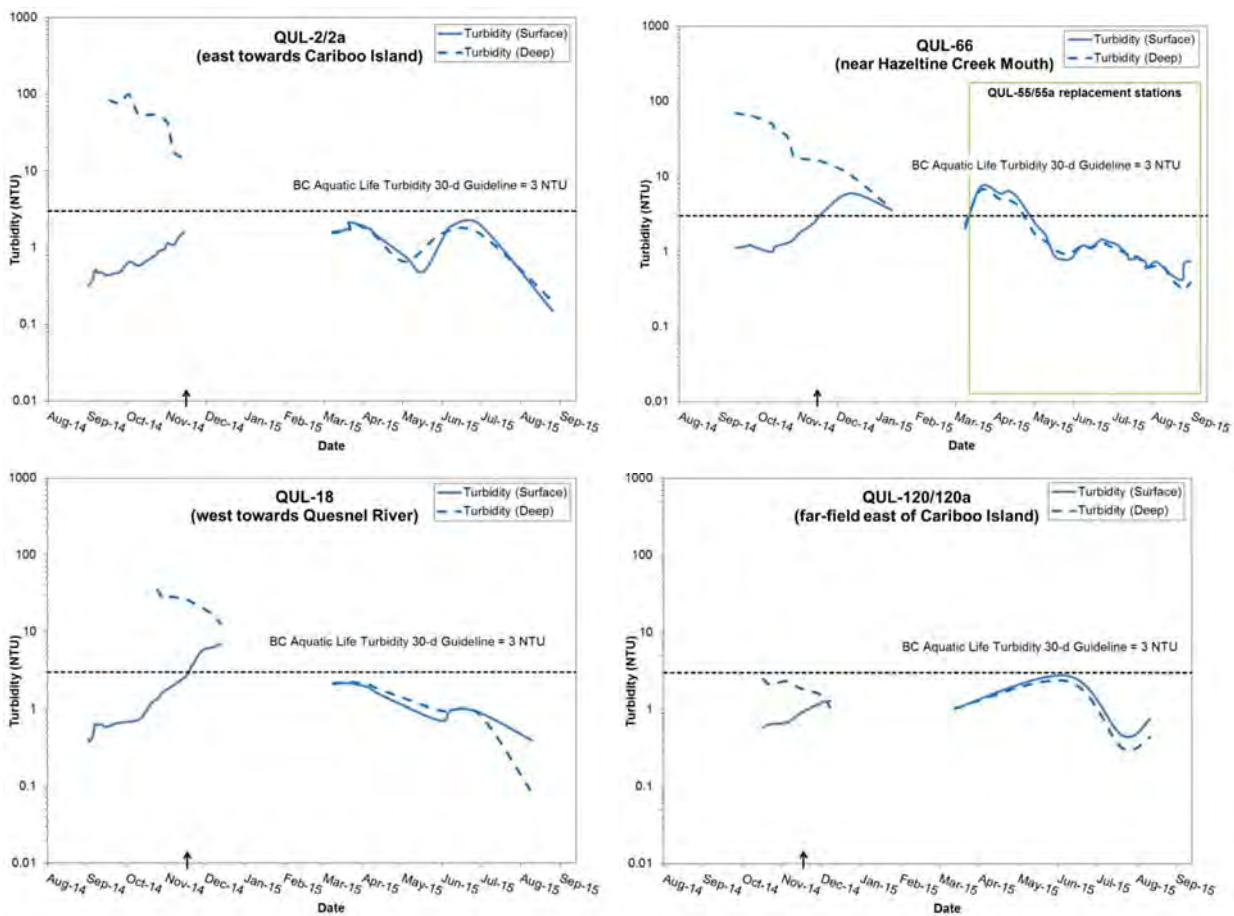

Following the event, turbidity was elevated at depth above 24-h BC WQGs in the West Basin of Quesnel Lake, but was not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Figure 3). Turbidity concentrations at depth decreased over time at stations QUL-2/2a, QUL-66/55/55a, and QUL-18 and were below or near BC WQGs by April 2015. Concentrations remained below BC WQGs through August 2015. At the surface, turbidity levels generally remained below guideline values with the exception of some exceedances of the aesthetic drinking water guideline for untreated water around the time of fall lake turnover in mid-November 2014 and occasionally into spring (Figure 3). Turbidity was measured above 2 NTU in June at both surface and depth at QUL-2/2a, QUL-66/55/55a, and QUL-120/120a. Given that the increase was observed at several stations including the far-field station, and turbidity in Hazeltine Creek was not abnormally high during that period, the temporary increase in turbidity was likely due to factors besides the mine, such as natural inputs from tributaries. Relative to the changes in turbidity that were observed during fall turnover in 2014, water quality did not appear to be influenced by spring turnover in 2015 as turbidity concentrations were similar at surface and depth during March and April, which is when turnover is expected to occur.

Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Background assumed equal to 1 NTU.

Figure 3: Post-event Instantaneous Turbidity Concentrations at Stations QUL-2/2a, QUL-66/55/55a, QUL-18, and QUL-120/120a, Quesnel Lake.

Thirty-day average concentrations of turbidity at depth were above the 30-d BC WQG at stations in the West Basin following the event and decreased over time to below the guideline at all four stations by May 2015 (Figure 4). Concentrations at surface were generally below the guideline, except where fall turnover in mid-November 2014 resulted in vertical mixing and elevated turbidity at the surface. At QUL-66/55/55a, near the mouth of Hazeltine Creek, the 30-d average concentrations at surface and at depth were elevated throughout March and April 2015 due to inputs of turbid water from Hazeltine Creek during this period. Turbidity declined from May through August 2015 consistent with a similar general decline in Hazeltine Creek as described in Section 3.2.1.1. For the other stations located further away from the mouth of Hazeltine Creek, 30-d average concentrations remained below the respective guideline from March through August 2015 (Figure 4). Overall, 30-d average concentrations of turbidity at the four Quesnel Lake stations showed a decreasing trend over time to below BC WQGs, from August 2014 to August 2015.

Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Background assumed equal to 1 NTU. Gaps represent >30 d between sampling.

Figure 4: Post-event Rolling 30-day Average Turbidity Concentrations at Stations QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a, Quesnel Lake.

Pollution Abatement Order Requirements: Turbidity

Near-Field Stations

Weekly depth profiles of field parameters were conducted at stations QUL-54, QUL-55, and QUL-56 near the mouth of Hazeltine Creek from March until late July 2015, when the outlet of Hazeltine Creek was redirected. Stations QUL-54a, QUL-55a, and QUL-56a were established near the new outlet to replace the previous stations and monitoring was continued at the same frequency.

- At QUL-55, turbidity was elevated up to 13 NTU throughout the water column on March 24, 2015, but thereafter rarely exceeded 3 NTU (i.e., criterion of 2 NTU above background of 1 NTU) between weekly sampling events (Figure 5). The same trends were observed for QUL-54 and QUL-56 during this period, but at these stations turbidity values in March were typically lower than those reported for QUL-55, remaining below 7 NTU (Attachment 6, Figures 6-7).
- From late July to August 2015 turbidity was less than 3 NTU at stations QUL-54a, QUL-55a, and QUL-56a except for an exceedance of up to 14 NTU around 7 m depth at QUL-56a in late July (Attachment 6, Figures 8-10). It is possible the observed temporary increase in turbidity close to the mouth of Hazeltine Creek was due to sediment mobilization as a result of construction of the new outlet to Quesnel Lake that occurred within this time period.

Note: The contour at 3 NTU represents the criterion of 2 NTU above background (1 NTU).

Figure 5: Contours of Turbidity Measured In-situ over Time at Station QUL-55 in Quesnel Lake (March to July 2015).

Western Mid-Field Station

At Station QUL-18, depth profiles of field parameters were recorded on 13 dates between March and August 2015, at a frequency of twice per month. On March 24, 2015, turbidity ranged from 2.5 to 4.5 NTU throughout the water column and exceeded the criterion of 1 NTU above background (Figure 6). This corresponded with observations of elevated turbidity at near-field Quesnel Lake stations on this date (i.e., QUL-55, see Figure 5). At other mid-field stations (QUL-2a east and QUL-21a west) turbidity was 2.8 NTU throughout the water column on this date (data not shown). Other than slight exceedance of this turbidity criterion at QUL-18 on March 12 and June 10, turbidity throughout the water column was below 2 NTU through to August.

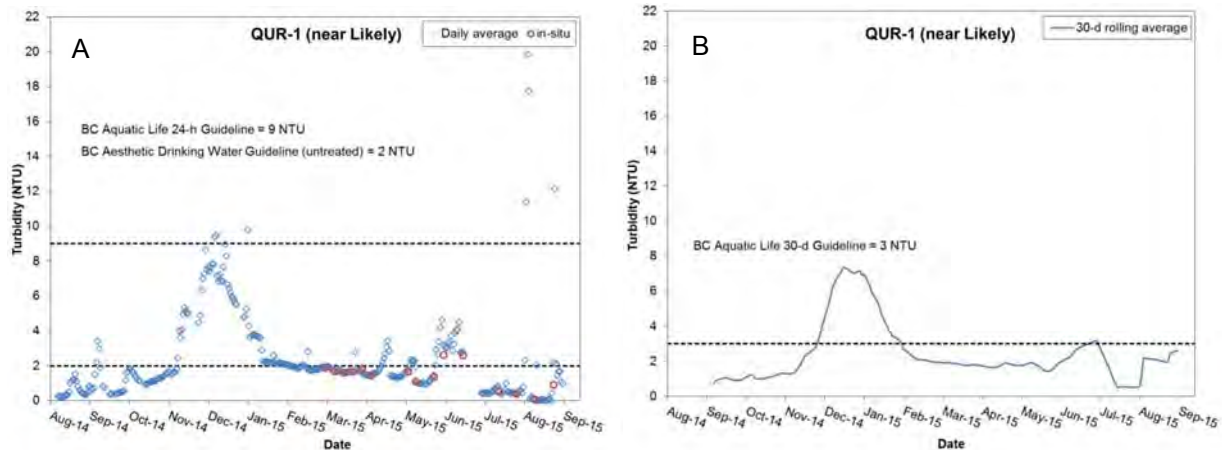

Note: Dotted line indicates criterion of 1 NTU above the background (1 NTU).

Figure 6: Depth Profiles of Turbidity at Station QUL-18 in Quesnel Lake (March to August 2015).

3.2.1.3 Quesnel River

Following the event, turbidity concentrations at Station QUR-1 were below the 24-h BC WQG for aquatic life, with the exception of a few exceedances in December 2014 and July and August 2015 (Figure 7). Turbidity spiked from late November 2014 to late January 2015, due to fall turnover of Quesnel Lake and mixing of deep turbid water, and the 30-d average concentration exceeded the 30-d BC WQG for aquatic life during this period. From mid-February through to the end of August 2015, turbidity concentrations in the river were below the 30-d BC WQG (Figure 7). Turbidity intermittently exceeded the BC aesthetic drinking water guideline for untreated water through to August 2015, but daily averages were typically below this guideline. The higher turbidity values recorded in June and August were not corroborated by in-situ measurements taken with a portable turbidity meter during collection of water samples on an alternating weekly basis (Figure 7). These higher turbidity readings are thought to be attributed to sensor fouling, in addition to the Sonde potentially being exposed from the water in August (pers. comm. S. Litke). The Sonde was moved and redeployed in early September 2015.

Note: Background assumed equal to 1 NTU.

Figure 7: Post-event Instantaneous (A) and Rolling 30-day Average (B) Turbidity Concentrations at Station QUR-1 near Likely, Quesnel River.

3.2.2 Metals

Screening of data collected between March and August 2015 identified molybdenum to be a COPC in Polley Lake and copper to be a COPC in Quesnel Lake. No metals were identified to be of potential concern in Quesnel River. A number of metals were identified to be COPCs in Hazeltine Creek, including copper and molybdenum (Table 1).

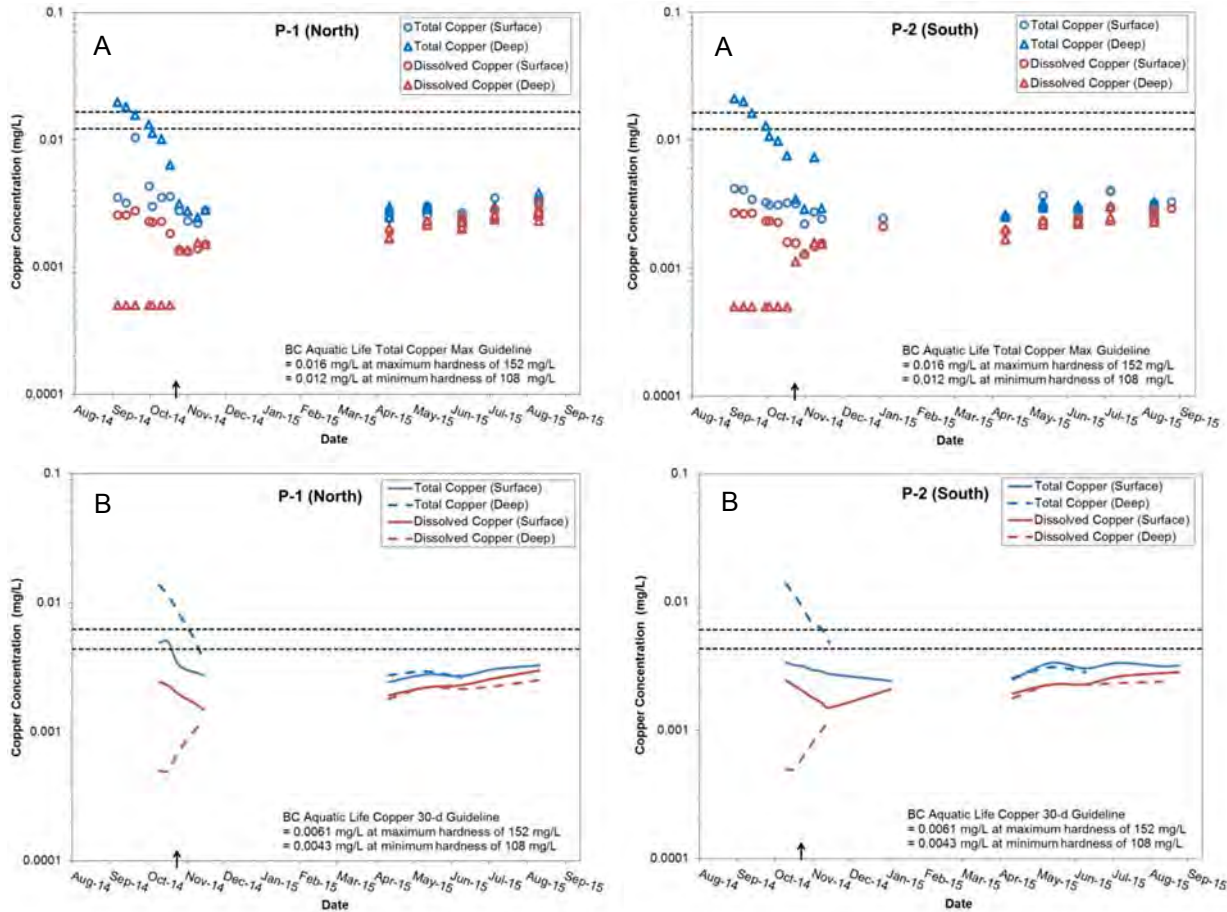

The PEEIAR WQIA identified copper as the COPC of primary interest because total and dissolved forms were reported to be above BC WQGs during the post-event period evaluated from August 2014 to February 2015 (Golder 2015a). It was therefore appropriate in this WQIA update to evaluate post-event changes in copper concentrations over a one-year period until August 2015 in the four monitored waterbodies, regardless of whether copper screened in as a COPC based on concentrations measured from March to August. With respect to other metals identified as COPCs in the PEEIAR WQIA, they were only evaluated further if they screened in as COPCs based on concentrations measured from March to August (Table 1).

Selenium was not identified as a COPC in Table 1 given that concentrations were below guidelines in the monitored waterbodies. However, due to previous concerns regarding a historic selenium source to Polley Lake that has since been mitigated and related monitoring efforts prior to the event (Minnow 2014), trends in selenium concentrations were evaluated further in Polley Lake, Hazeltine Creek, and the near-field area of Quesnel Lake close to the Hazeltine Creek mouth.

3.2.2.1 Polley Lake

Copper

Although initially elevated after the event, total copper concentrations at depth in Polley Lake decreased over time to below applicable BC WQGs by fall turnover in mid-November (Figure 8). Post-event dissolved copper concentrations were consistently below BC WQGs. By April 2015, total and dissolved copper concentrations had converged and stabilized to between 0.002 and 0.003 mg/L through the end of August 2015 (Figure 8).

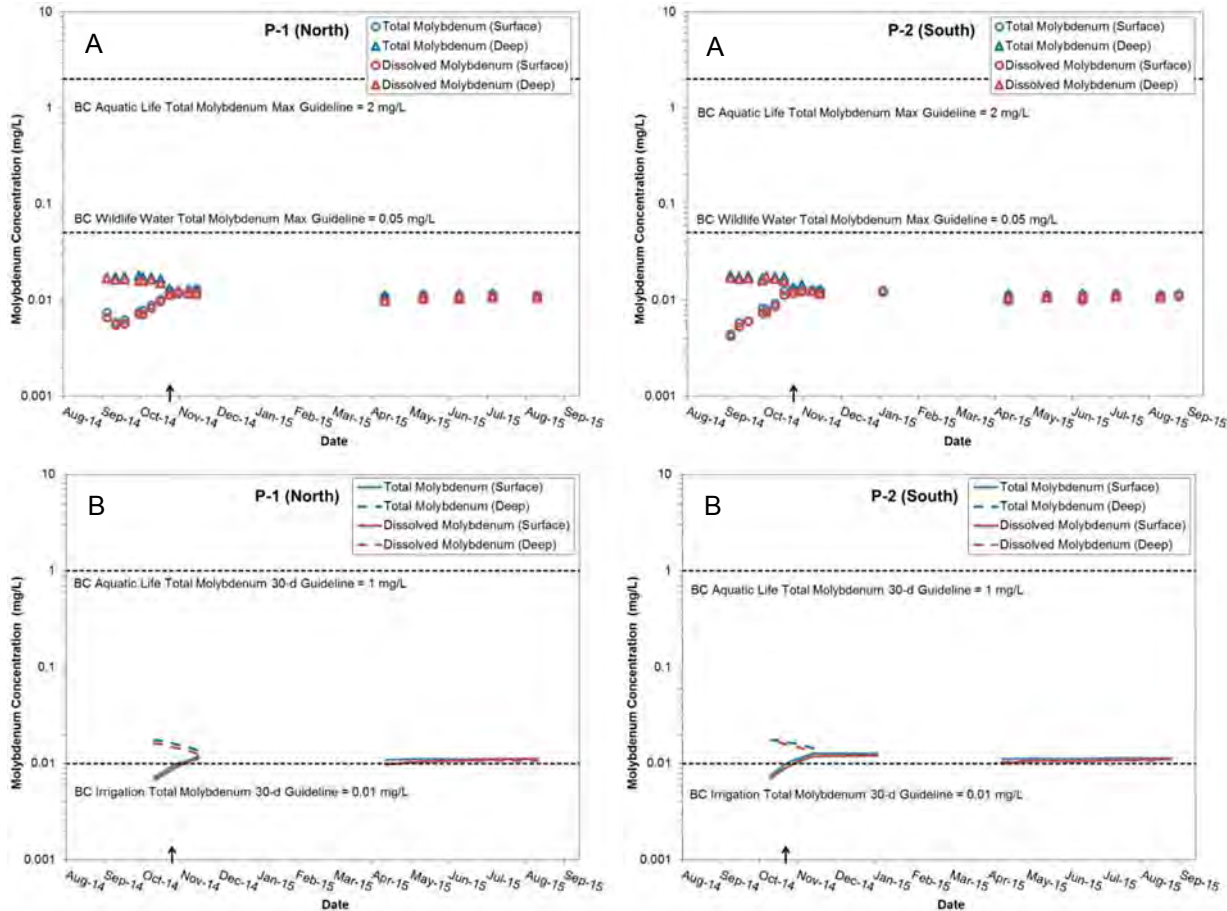

Note: Arrow represents the approximate timing of late-October turnover in Polley Lake. Gaps represent >30 d between sampling.

Figure 8: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Stations P1 and P2, Polley Lake

Molybdenum

Total and dissolved molybdenum concentrations at stations P1 and P2 in Polley Lake were similar and consistently below the maximum BC WQGs for aquatic life and wildlife water following the event through August 2015 (Figure 9). Concentrations at depth were higher than at the surface until fall turnover, when the water column was vertically mixed and concentrations remained stable at around 0.01 mg/L thereafter.

The 30-d average concentrations of molybdenum were consistently below the 30-d BC WQG for aquatic life, but slightly exceeded the 30-d BC WQG for irrigation (Figure 9). The BC WQG for irrigation was considered in the assessment because it is conservatively expected to be protective of ruminant wildlife that might be exposed through dietary uptake from irrigated plant foods. However, only aquatic vegetation along the edges of Polley Lake is expected to be in contact with lake water because the lake is not used as an irrigation source; consequently, there has been little potential for uptake of molybdenum by ruminant wildlife. Additional discussion regarding the potential for molybdenum uptake by ruminant wildlife in Polley Lake is provided in Golder (2015a).

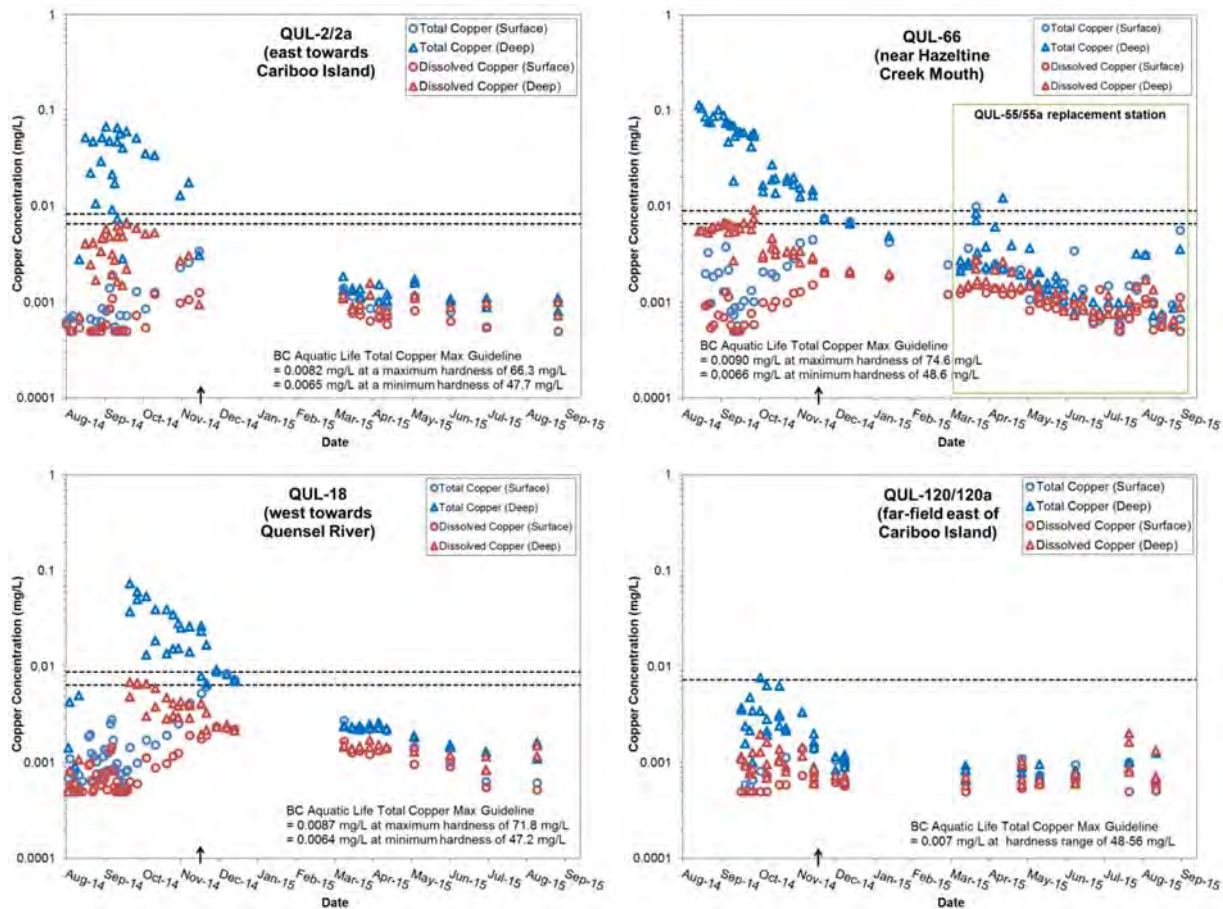

Note: Arrow represents the approximate timing of late-October turnover in Polley Lake. Gaps represent >30 d between sampling.

Figure 9: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Molybdenum Concentrations at Stations P1 and P2, Polley Lake.

3.2.2.2 Quesnel Lake

Copper

Following the event, total copper concentrations at depth were elevated above the maximum BC WQG for aquatic life in the West Basin of Quesnel Lake, but were not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Figure 10). Dissolved concentrations (surface and depth) and total concentrations at the surface were typically below the maximum BC WQGs. Total copper concentrations at depth decreased over time, converged with surface and dissolved concentrations by early March 2015, and were below the maximum BC WQG by April. As of late August 2015, copper concentrations reported for QUL-66/55/55a (near the mouth of Hazeltine Creek) were generally similar to concentrations reported elsewhere in the lake, including the far-field station (QUL-120/120a) east of Cariboo Island (Figure 10), with the exception of a few measurements that were higher than the norm, but nonetheless below guidelines. These elevated measurements at the near-field stations are likely associated with periods when Hazeltine Creek flows were more turbid and contained higher TSS levels, as a result of rehabilitation and construction work during that period.

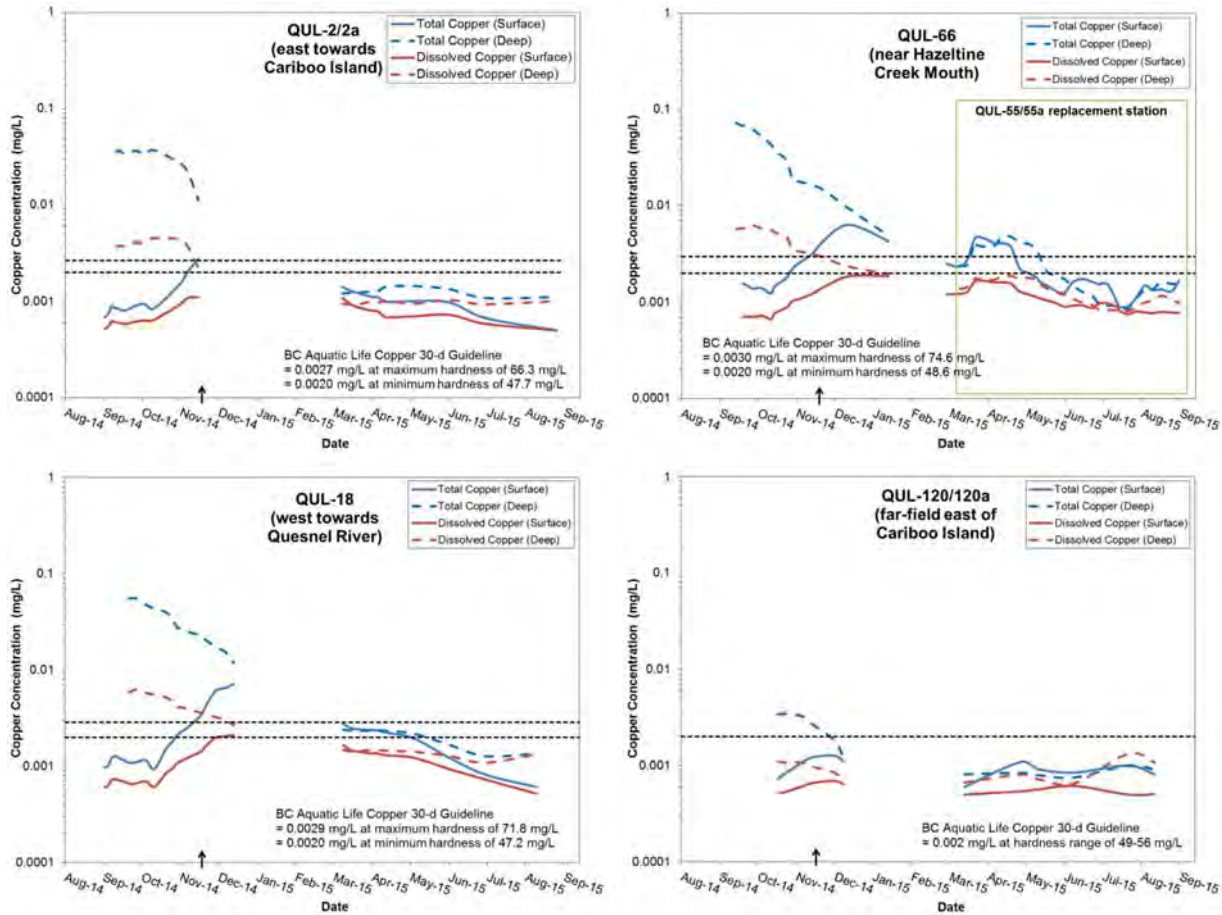

Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 10: Post-event Instantaneous Total and Dissolved Copper Concentrations at Stations QUL-2/2a, QUL-66/55/55a, QUL-18, and QUL-120/120a, Quesnel Lake.

Following the event, 30-d average concentrations of total and dissolved copper at depth were elevated above surface concentrations and the 30-d BC WQG for aquatic life at stations in the West Basin (Figure 11). At mid-field stations QUL-2/2a and QUL-18, 30-d average concentrations decreased below the BC WQG by March 2015 (Figure 11). At near-field Station QUL-66/55/55a, near the mouth of Hazeltine Creek, the 30-d average for total copper remained elevated above the BC WQG from March to May 2015, reflective of higher turbidity levels associated with Hazeltine Creek during this period and a concurrent increase in total and dissolved copper concentrations at HAC-01/a/b/c (see Section 3.2.2.4).

Total and dissolved concentrations of copper at each of the four Quesnel Lake stations remained at around 0.001 mg/L by June 2015.

Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Gaps represent >30 d between sampling.

Figure 11: Post-event Rolling 30-day Average Total and Dissolved Copper Concentrations at Stations QUL-2/2a, QUL-66/55/55a, QUL-18, and QUL-120/120a, Quesnel Lake.

3.2.2.3 Quesnel River

Copper

Total copper concentrations at Station QUR-1 in Quesnel River peaked in December, reflecting increased turbidity during this period, and exceeded the maximum BC WQG until January 2015 (Figure 12). Dissolved copper concentrations were substantially lower than the maximum BC WQG for aquatic life throughout the sampling period. By May 2015, total copper concentrations converged with dissolved concentrations, which would suggest that most of the copper associated with suspended particulate matter had settled out of the water column.

The 30-d average concentrations of total copper declined from a peak in January 2015 to below the 30-d BC WQG for aquatic life by mid-April and continued to decline through August (Figure 12). The 30-d average dissolved concentrations were slightly above the most conservative 30-d BC WQG between December and mid-January, but also declined through to August.

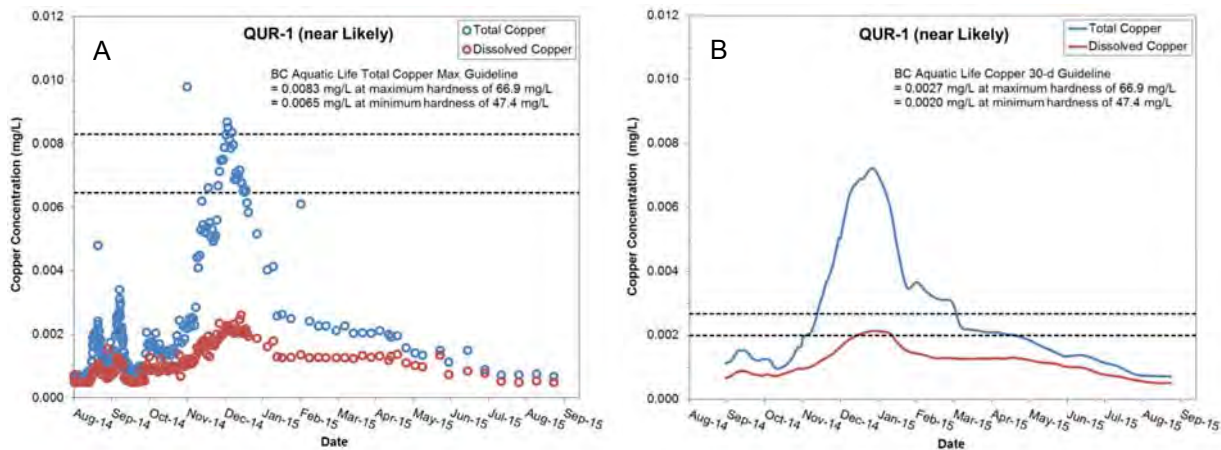

Figure 12: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Station QUR-1 near Likely, Quesnel River.

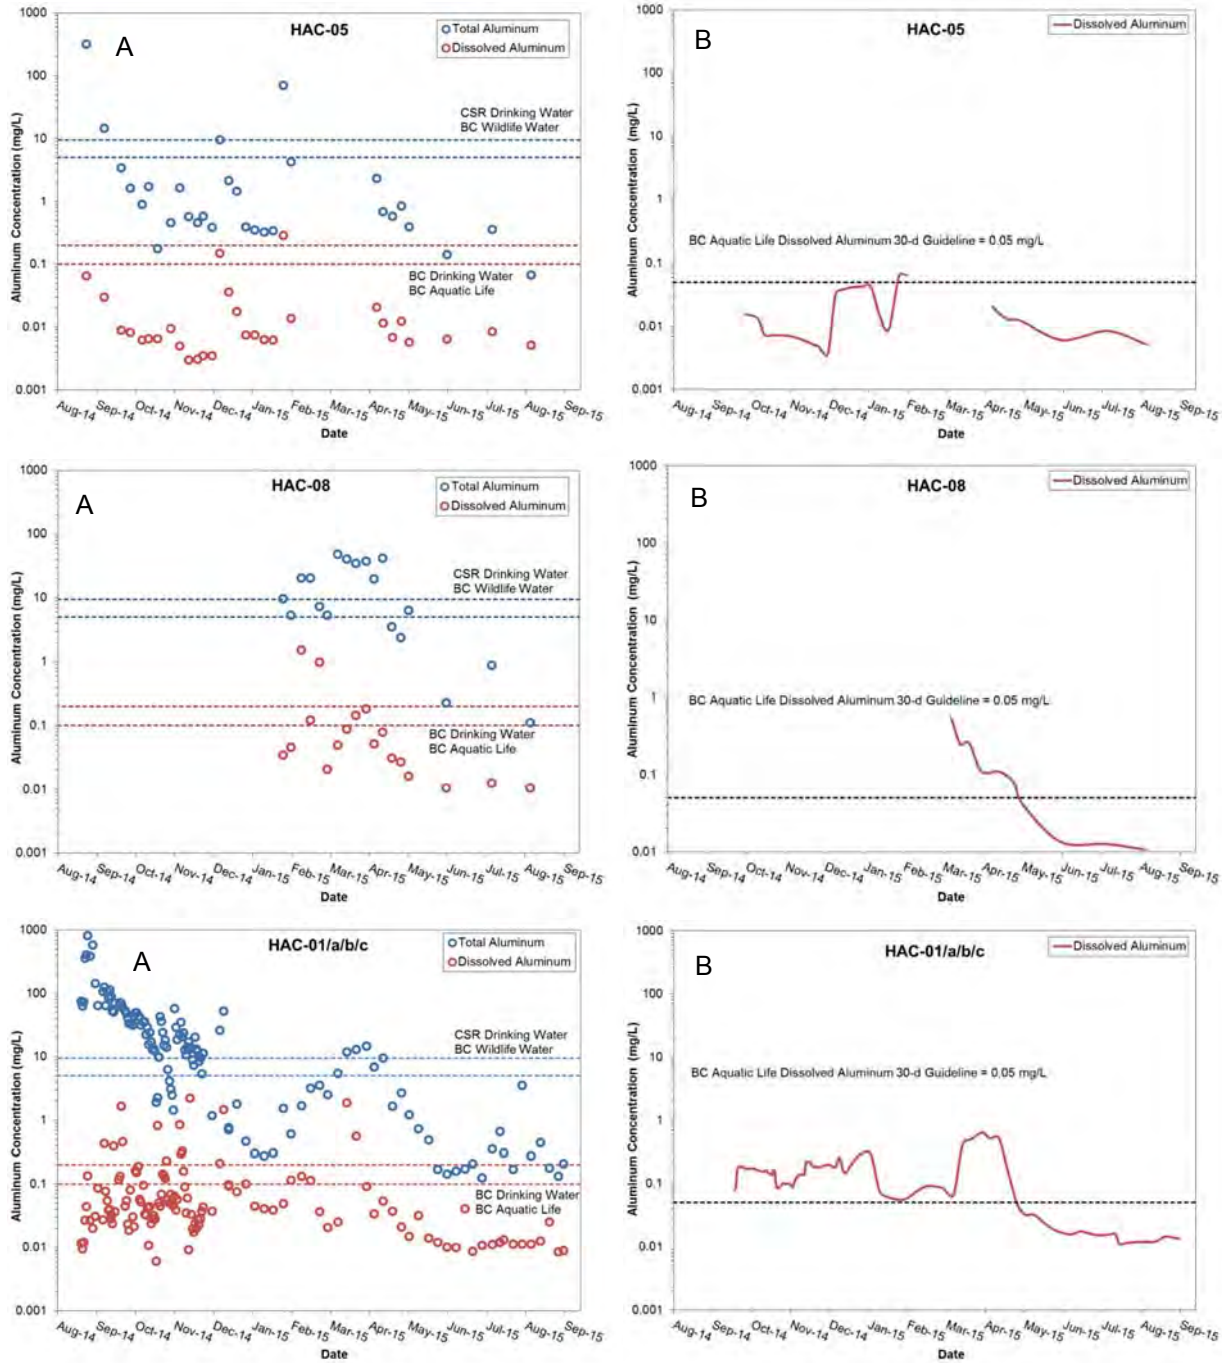

3.2.2.4 Hazeltine Creek

Hazeltine Creek was not defined as a receiving environment in the PEEIAR because the creek was not considered to be fish habitat during the period assessed based on rationale provided in Golder (2015a). For the purpose of the DSI, however, Hazeltine Creek is considered as part of the receiving environment. Spatial and temporal trends in creek water quality are presented graphically for the four metals identified as COPCs in Table 1 that had the largest magnitude of guideline exceedance (i.e., aluminum, copper, chromium, and iron). Trends are shown for Station HAC-05 in upper Hazeltine Creek, Station HAC-08 upstream of the sedimentation ponds, and Station HAC-01/a/b/c downstream of the sedimentation ponds in lower Hazeltine Creek.

Aluminum

In upper Hazeltine Creek (HAC-05), aluminum concentrations remained below BC WQGs or CSR standards for drinking water, wildlife water, and aquatic life following the event through August 2015, with a few exceptions (Figure 13). In the lower creek, total and dissolved aluminum concentrations at HAC-01/a/b/c were above corresponding maximum BC WQGs and CSR standards following the event until December 2014, and again from February to April 2015 (Figure 13). Aluminum concentrations were similarly elevated at HAC-08 during this period in 2015. From May through August 2015, concentrations in lower Hazeltine decreased below maximum guidelines.

The 30-d average dissolved concentrations at stations HAC-05, HAC-08, HAC-01/a/b/c were consistently above the 30-d dissolved aluminum BC WQG for aquatic life until late April 2015 and then decreased below guidelines through August 2015 (Figure 13). Elevated aluminum concentrations at stations in lower Hazeltine Creek reflected the increased turbidity during the same time period.

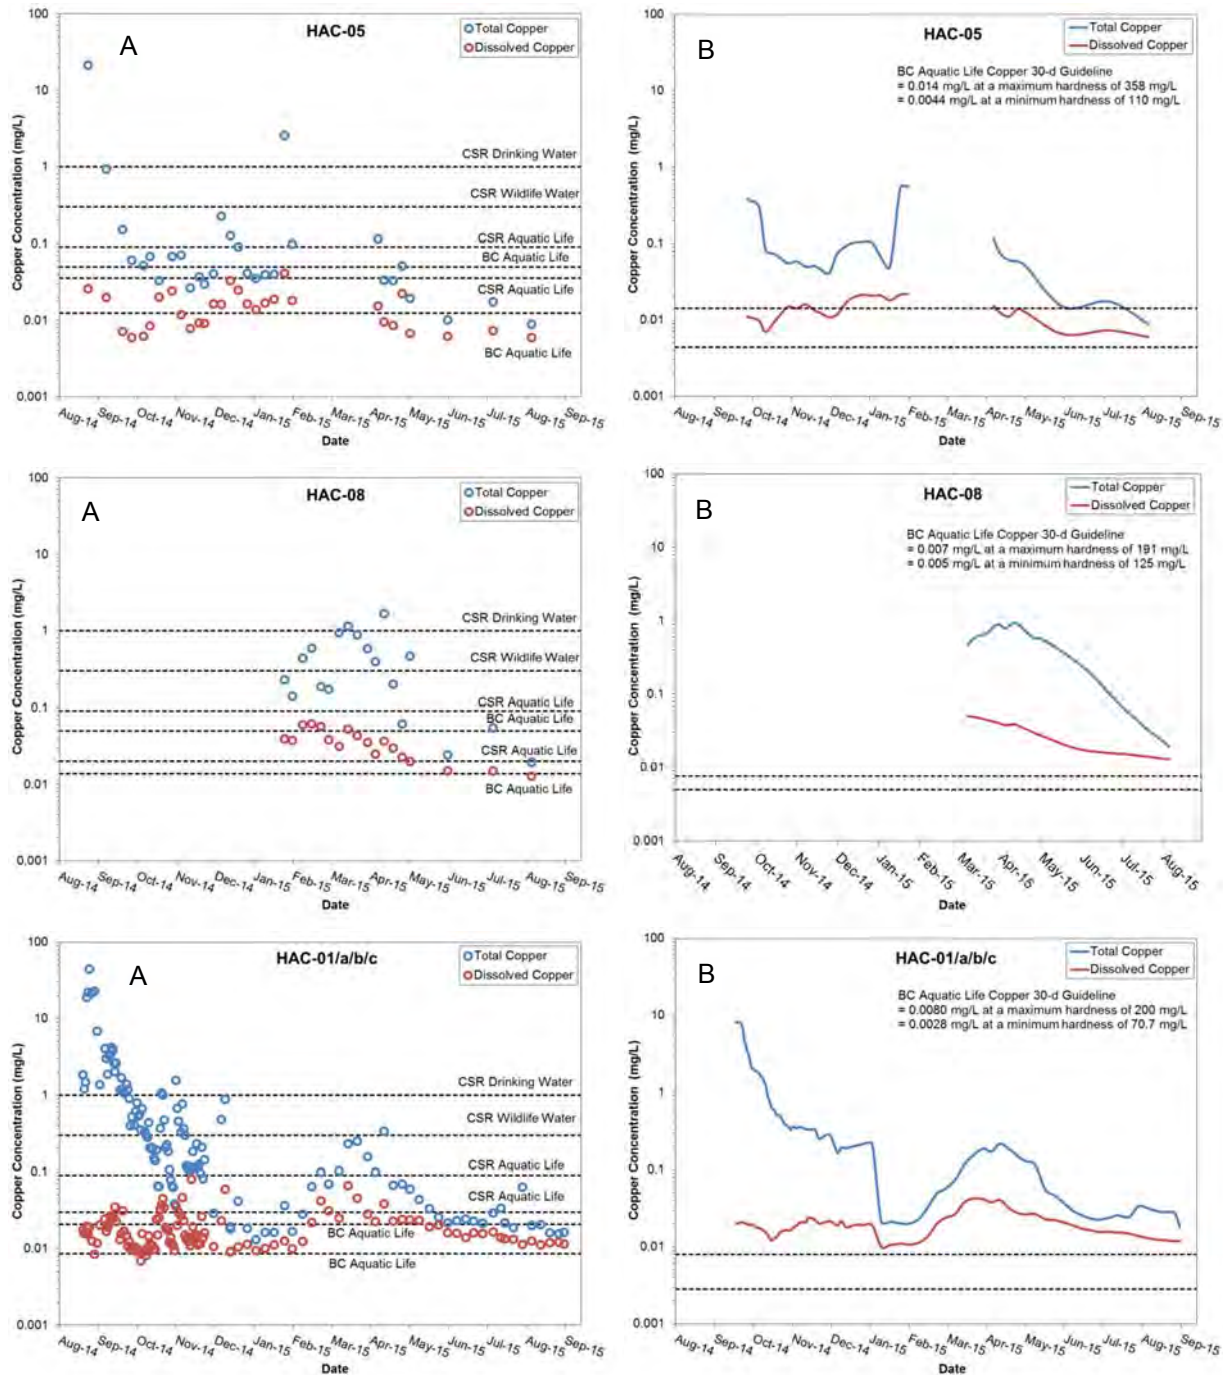

Note: CSR – Schedule 6 Drinking Water Total Aluminum Standard = 9.5 mg/L; BC Wildlife Water Total Aluminum Max Guideline = 5 mg/L; BC Drinking Water Dissolved Aluminum Max Guideline = 0.2 mg/L; BC Aquatic Life Dissolved Aluminum Max Guideline = 0.1 mg/L. Dashed line colour corresponds to total or dissolved values. Gaps represent >30 d between sampling.

Figure 13: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Aluminum Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

Copper

Following the event and until June 2015, total copper concentrations in Hazeltine Creek were typically above BC WQGs and CSR standards for aquatic life (Figure 14). From June to August 2015, total concentrations in the upper creek were mostly below the maximum BC WQG when minimum hardness conditions were considered. Total concentrations at HAC-08 and HAC-01/a/b/c decreased over time, but showed the same trend of peak concentrations in March 2015 that corresponded with increased turbidity and total forms of other metals during turbid flow episodes that occurred during the early freshet and ongoing rehabilitation work in the creek. Total concentrations decreased below CSR standards by May 2015 and remained within the range of BC WQGs based on the range of hardness observed at this station. Dissolved concentrations at HAC-05, HAC-08, and HAC-01/a/b/c were typically below the maximum BC WQG with the exception of several guideline exceedances that occurred between February and April 2015 (Figure 14).

In the upper creek, 30-d average concentrations of total and dissolved copper were mostly above the 30-d BC WQGs for aquatic life based on maximum and minimum hardness, respectively (Figure 14). Thirty-day average concentrations in the lower creek were consistently above the 30-d BC WQG calculated using the reported hardness range, but appear to continue to decline.

Note: CSR – Schedule 6 Drinking Water Total Copper Standard = 1 mg/L; CSR – Schedule 6 Wildlife Water Standard = 0.3 mg/L; CSR – Schedule 6 Aquatic Life Total Copper Standard = 0.03-0.09 mg/L; BC Aquatic Life Total Copper Max Guideline = 0.009-0.04 mg/L. Gaps represent >30 d between sampling.

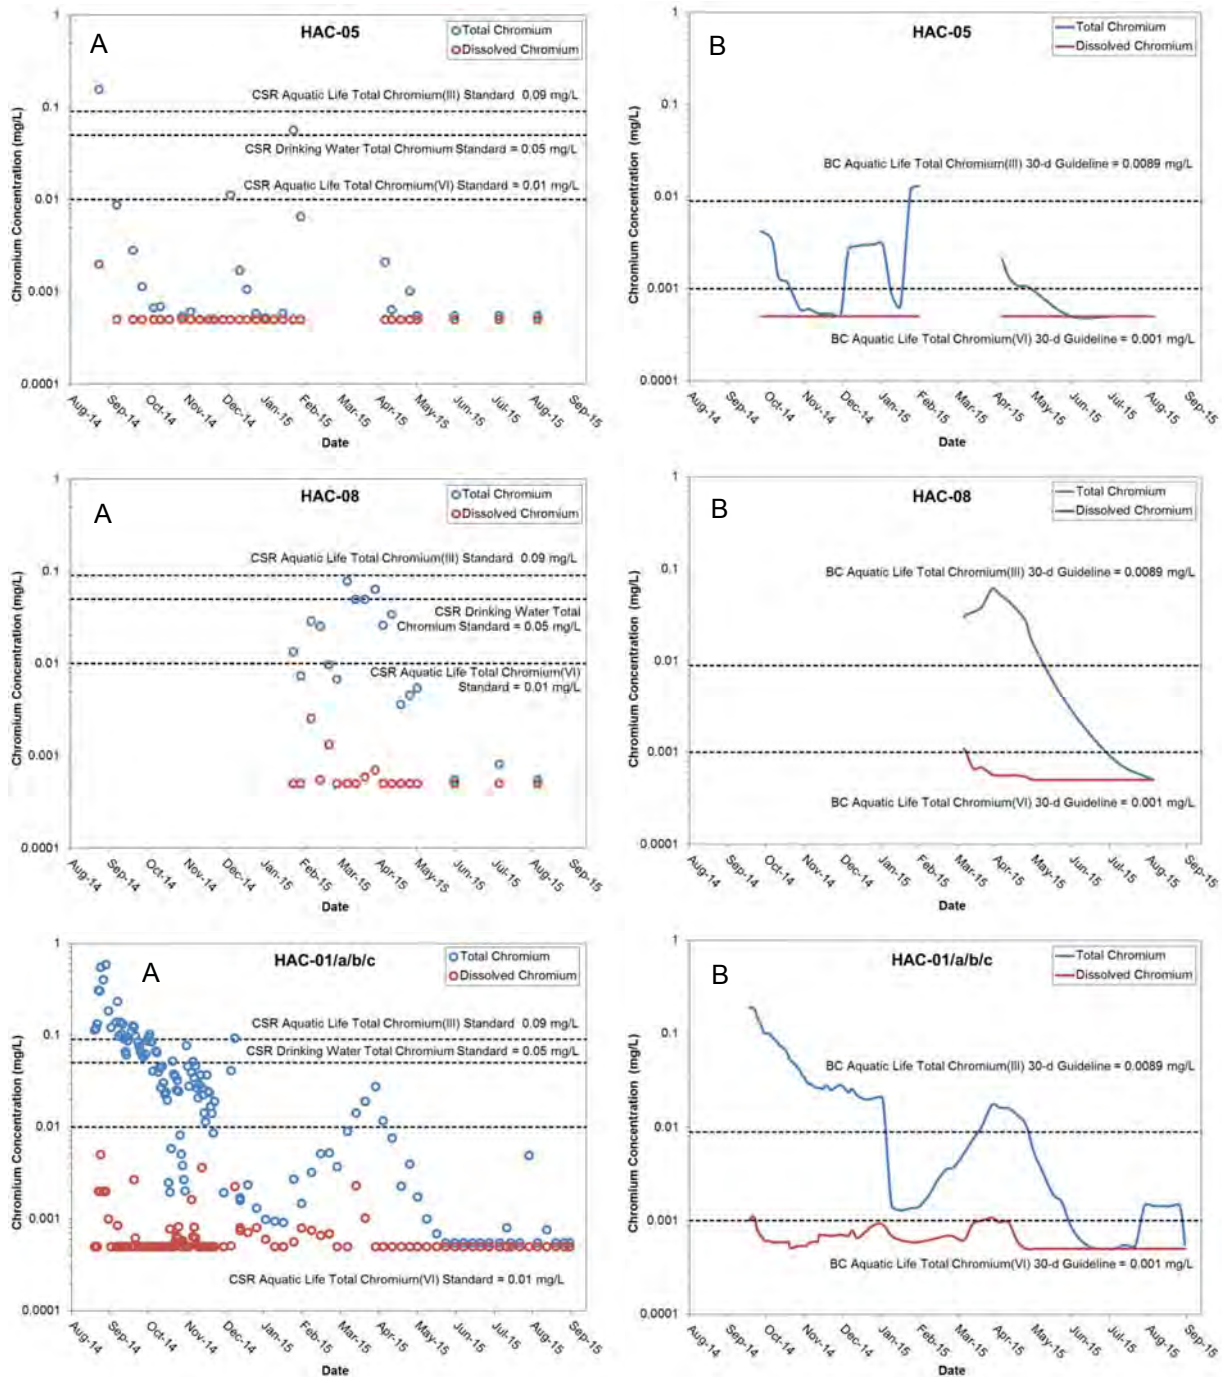

Figure 14: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazelton Creek.

Chromium

As discussed in Golder (2015a), the available speciation data for Hazeltine Creek indicates the dominant chromium species in Hazeltine Creek was chromium III, which is less toxic than the chromium VI form. However, as a conservative measure, guidelines and standards for both chromium species were considered in this assessment.

At the upper creek station, total concentrations were typically below the CSR Standards for drinking water and aquatic life; however, one sample collected immediately after the event exceeded the Cr-III CSR standard (Figure 15). Total concentrations fluctuated through December 2014 and January 2015, and 30-d average concentrations typically did not exceed the 30-d BC (Cr-III) WQG. In the lower creek, total concentrations at HAC-01/a/b/c were above CSR standards following the event and into early January 2015 and showed the same peak in concentration in March 2015 as was observed for total forms of other metals (Figure 15). The 30-d average concentration of total chromium also exceeded the 30-d BC (Cr-III) WQG during March (Figure 15). Total chromium concentrations were similarly elevated at HAC-08 during this period in 2015. Total concentrations had decreased below CSR standards and the 30-d BC (Cr-III) WQG by May and June 2015, respectively.

Dissolved concentrations in Hazeltine Creek were consistently below the BC WQGs and CSR standards.

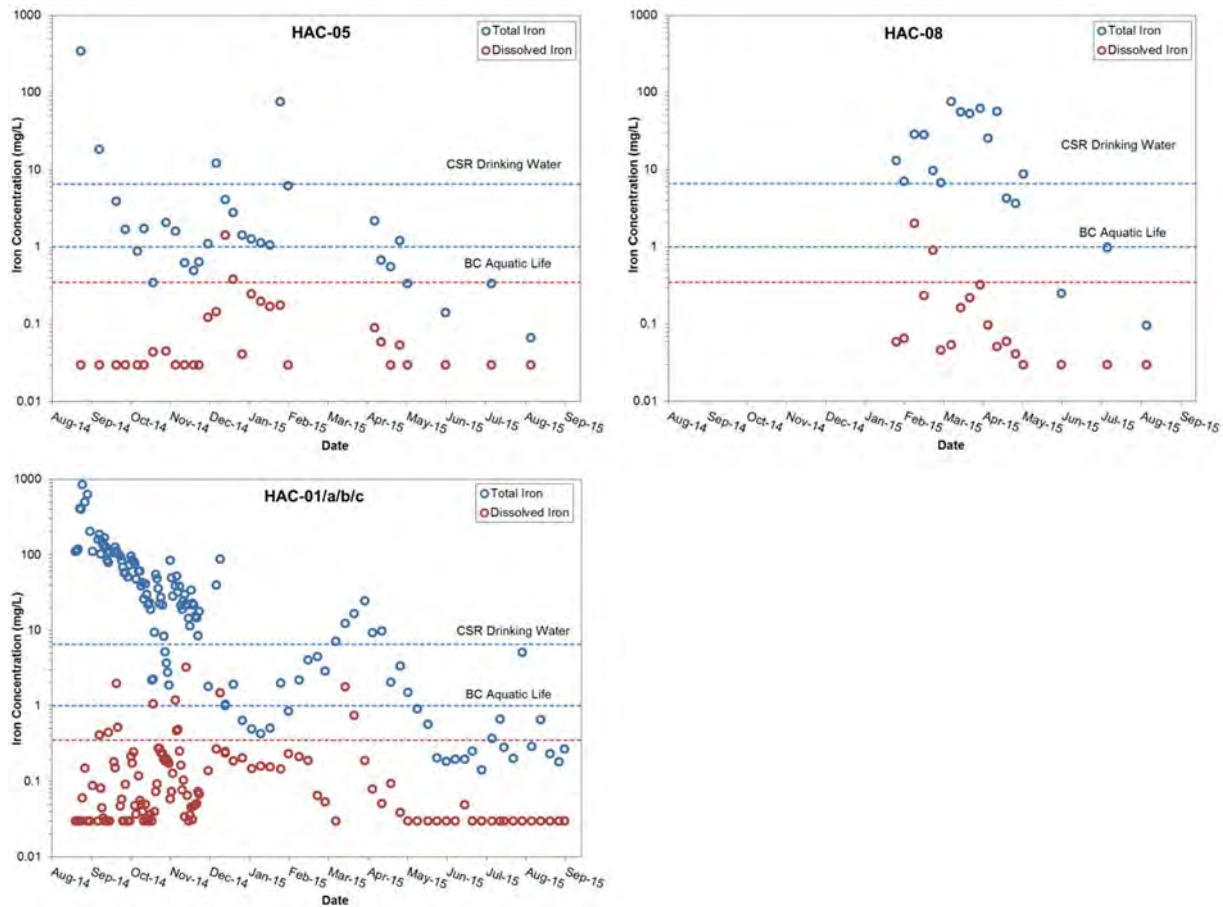

Note: Gaps represent >30 d between sampling.

Figure 15: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Chromium Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltille Creek.

Iron

Total iron concentrations at the upper station HAC-05 exceeded the CSR drinking water standard intermittently following the event and exceeded the BC WQG for aquatic life consistently until May 2015 (Figure 16). Dissolved iron concentrations were typically below the BC WQG for dissolved iron at this station.

In lower Hazeltine Creek, total iron concentrations at HAC-01/a/b/c were elevated immediately following the event and remained so into late November 2014, after which concentrations decreased below guidelines until they peaked again in March 2015. Total iron concentrations were similarly elevated at HAC-08 during this period in 2015. Total iron concentrations showed the same peaks observed for concentrations of total forms of other metals. Total concentrations exceeded the CSR standard and BC WQG during these periods, then decreased below CSR standard and BC WQG by mid-May (Figure 16). The exception was a single event in August in which total values at both lower stations were more than ten times the preceding and subsequent values taken in July and August. Dissolved concentrations were variable after the event through April 2015, but typically did not exceed the BC WQG and were close to the limit of detection after April 2015.

Note: CSR – Schedule 6 Drinking Water Total Iron Standard = 6.5 mg/L; BC Aquatic Life Total Iron Max Guideline = 1 mg/L; BC Aquatic Life Dissolved Iron Max Guideline = 0.35 mg/L. Dashed line colour corresponds to total or dissolved values.

Figure 16: Post-event Instantaneous Total and Dissolved Iron Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

Other Metals

Spatial and temporal trends for other metals identified as COPCs in Table 1 are presented graphically in Attachment 7 and described below. Note that the order of COPCS presented in Attachment 7 follows the order presented below.

Arsenic

Total arsenic concentrations at Station HAC-05 in upper Hazeltine Creek were initially elevated after the event, but were typically below BC WQGs and CSR standards for aquatic life, wildlife water, and drinking water from September 2014 through August 2015 (Attachment 7). Total and dissolved concentrations converged with time and likely resulted from erosion controls in the creek.

In lower Hazeltine Creek, total concentrations at HAC-08 exceeded maximum BC WQGs and CSR standards in January through April 2015 and remained below guidelines thereafter (Attachment 7). Thirty-day average concentrations of total arsenic were consistently above the 30-d BC WQG for aquatic life until June 2015. Total concentrations at HAC-01/a/b/c exceeded maximum BC WQGs and CSR standards following the event until December 2014 (Attachment 7). Total concentrations decreased over time and remained below guidelines from December 2014 through August 2015. Thirty-day average concentrations of total arsenic were consistently above the 30-d BC WQG for aquatic life until January 2015 and slightly exceeded the guideline in April 2015. Since May 2015, 30-d average concentrations have been below the 30-d BC WQG. Dissolved concentrations remained well below guidelines at all three stations and at all times since September 2014.

Molybdenum

Total and dissolved concentrations of molybdenum at stations HAC-05 and HAC-01/a/b/c were elevated above the BC WQG for wildlife water immediately following the event, but were consistently below maximum BC WQGs from September 2014 through August 2015 (Attachment 7). Molybdenum concentrations at HAC-08 were consistently below guidelines during the monitoring period in 2015. Total and dissolved concentrations were similar throughout the sampling period. Thirty-day average concentrations were well below the 30-d BC WQG for aquatic life and only slightly above the most conservative 30-d BC WQG for irrigation through August 2015, similar to that observed for Polley Lake (Section 3.2.2.1).

Cadmium and Titanium

Total forms of these metals were identified as COPCs in Table 1 based on the 95th percentile values exceeding CSR standards. Consequently, total cadmium and total titanium will be retained as COCs in the DSI (Section 5.0). Dissolved cadmium was not identified as a COPC based on comparison to the BC WQG which is a dissolved guideline. There is no BC WQG for titanium.

Beryllium, Cobalt, Lead, and Manganese

Total forms of these metals were identified as COPCs in Table 1 based on 95th percentile values exceeding the corresponding 30-d BC WQGs for aquatic life.

In upper Hazeltine Creek, 30-d average concentrations of these metals did not exceed the 30-d BC WQGs from March through August 2015 (Attachment 7). In lower Hazeltine Creek, peak concentrations of these metals were identified in March and April relative to other months in 2015 (Attachment 7). Thirty-day average concentrations of total beryllium and cobalt were above the 30-d BC WQGs from March to June at HAC-08 and March to May at HAC-01/a/b/c and decreased below guidelines thereafter. With respect to lead and manganese, 30-d average concentrations at HAC-08 exceeded the 30-d BC WQG under the most conservative site-specific hardness scenario (i.e., lowest hardness) from March to May, but did not exceed the 30-d BC WQGs at HAC-01/a/b/c from March through August 2015.

Zinc

Total zinc was identified as a COPC in Table 1 based on 95th percentile values exceeding the maximum and 30-d BC WQGs for aquatic life under the most conservative site-specific hardness scenario (i.e., lowest hardness).

In upper Hazeltine Creek, total zinc did not exceed BC WQGs from March through August 2015 (Attachment 5). In lower Hazeltine Creek, peak concentrations were identified in February and March relative to other months in 2015 (Attachment 7). At these lower creek stations, instantaneous concentrations only exceeded the most conservative maximum BC WQG in February and March at HAC-08 and in March at HAC-01/a/b/c, and then decreased below the guideline thereafter. The 30-d average concentrations at the lower creek stations exceeded the most conservative 30-d BC WQG from February to June 2015 and decreased below the guideline thereafter.

3.2.3 Selenium

Prior to the event, selenium concentration trends in water, sediment, and biota in Polley Lake were being monitored by MPMC in response to the identification of increasing selenium concentrations in the lake attributed to a mine-related source that was controlled through mitigation measures in 2009 (Minnow 2014). Between 2006 and 2009, selenium increased two-fold above baseline in Polley Lake to a maximum concentration of 0.0019 mg/L due to selenium inputs from North Bell Dump seepage and runoff from the eastern side of the mine site. Concentrations then decreased to approximately 0.0007 mg/L from 2009 to 2013 following construction of a runoff collection system (Minnow 2014).

After the event, total and dissolved concentrations of selenium were similar to each other throughout Polley Lake and did not reflect the trend of higher total concentrations at depth that was observed for copper (Attachment 7). Concentrations remained stable at around 0.0009 mg/L from November 2014 through August 2015. In Hazeltine Creek, selenium was measured above guidelines immediately after the event with total concentrations higher than dissolved. Concentrations decreased to below guidelines by October 2014. Total and dissolved concentrations converged by December 2014, and stabilized at around 0.001 mg/L through August 2015. At station QUL-66/55/55a close to the mouth of Hazeltine Creek, total and dissolved concentrations were measured at or near the detection limits from August 2014 through August 2015. Note that the analytical detection limit for selenium was improved in March 2015 (see Attachment 7, Figure 15), which led to an apparent decrease in concentrations in Quesnel Lake.

Overall, post-event selenium concentrations in Polley Lake, Hazeltine Creek, and the near-field environment of Quesnel Lake remained stable below guidelines or decreased to below guidelines shortly after the event and remained stable thereafter. Current BC water quality guidelines are protective of toxicity to aquatic life, including the potential for food chain accumulation. Since the concentrations are below these guidelines, concentrations of selenium in water as a result of the tailings dam failure are not considered to be a risk to aquatic life.

3.2.4 Nutrients: Phosphorus

Phosphorus was not identified as a COPC for Polley and Quesnel lakes based on screening of total phosphorus (TP) data collected in these lakes from March to August 2015 (Table 1). Concentrations of total and dissolved phosphorus and orthophosphate were, however, evaluated further over time to assess event-related changes at representative lake stations. Unlike some of the nitrogen forms (e.g., ammonia and nitrite), phosphorus is not toxic to aquatic biota, but rather phosphorus tends to limit primary productivity in freshwater lake environments (Environment Canada 2004). Instantaneous concentrations of TP at surface and depth in Polley and Quesnel lakes were compared to the BC WQG range for lakes (i.e., 0.005 to 0.015 mg/L; BC MoE 2015a) that is

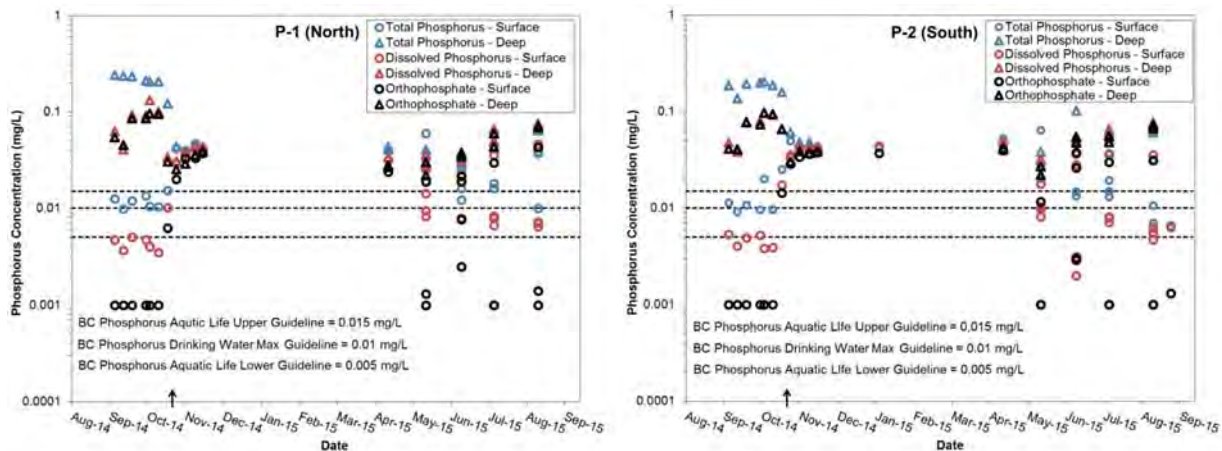

intended to be applied to the spring turnover concentration or the mean epilimnetic growing season concentration (May to September). An assessment of event-related changes in phosphorus and subsequent potential impacts on primary productivity based on this guideline comparison is therefore conservative, as reflected in the discussion of results for each lake. Consistent with the approach taken in the PEEIAR, the evaluation of event-related changes in waterborne phosphorus is intended to be integrated with biological information to assess potential impacts on lake productivity in the HHERA.

3.2.5 Polley Lake

Following the event and through August 2015, concentrations of TP at the surface in Polley Lake were within the pre-event range of concentrations reported in the PEEIAR for Polley Lake. Pre-event TP concentrations were defined as: mean = 0.041 mg/L; 95th percentile = 0.094 mg/L.; minimum = 0.0046 mg/L (Appendix A; Golder 2015a). Both pre-event mean and upper limit concentrations were above the BC WQG range of 0.005 to 0.015 mg/L. This is consistent with the observation by Minnow (2014) that the trophic status of the lake changed from oligotrophic/mesotrophic to mesotrophic/eutrophic in 2012, two years prior to the event. At depth, TP concentrations were elevated above pre-event concentrations prior to fall turnover (Figure 17).

Dissolved phosphorus and orthophosphate were also higher at depth compared to the surface. In deep samples, concentrations of dissolved phosphorus and orthophosphate were similar; but surface samples contained orthophosphate concentrations near or below the detection limit. Pre-event dissolved phosphorus concentrations were defined as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.002 mg/L; pre-event orthophosphate concentrations were defined as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.001 mg/L (Appendix A; Golder 2015a).

From April through August 2015, a number of total and dissolved phosphorus concentrations and deep orthophosphate concentrations were above the TP BC WQG range (Figure 17). Concentrations were, however, within or below the range of pre-event concentrations reported in the PEEIAR for Polley Lake and so no event-related changes to phosphorus concentrations in Polley Lake were identified from April through August.

Note: Arrow represents the approximate timing of late-October turnover in Polley Lake.

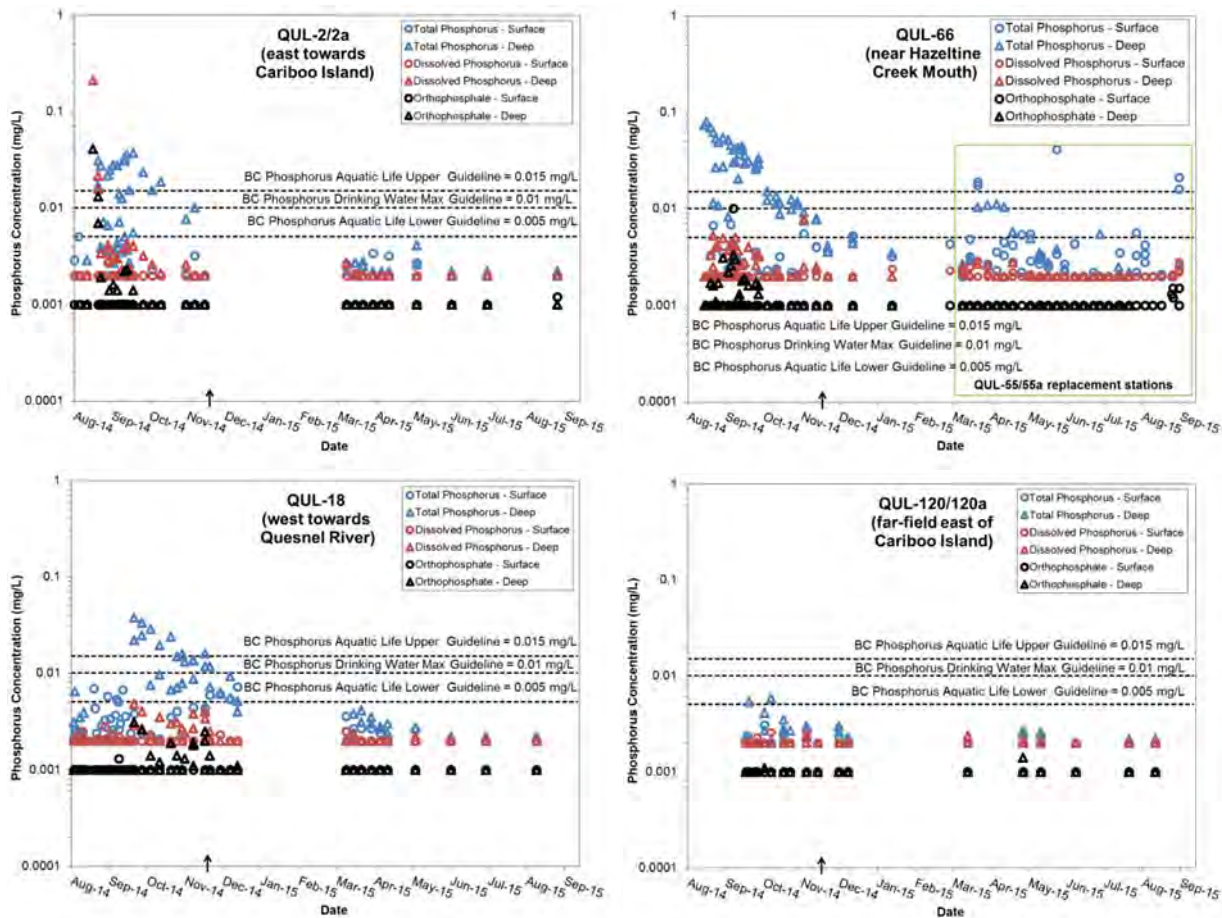

Figure 17: Post-event Instantaneous Total and Dissolved Phosphorus and Orthophosphate at Stations P1 and P2, Polley Lake.

3.2.5.1 Quesnel Lake

After the event, TP concentrations at depth exceeded the BC WQG range in the West Basin of Quesnel Lake, but were not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Figure 18). By fall turnover, TP concentrations had substantially decreased in the West Basin of Quesnel Lake. Through August 2015, TP concentrations were below the BC WQG range and resembled pre-event concentrations with the exception of a few intermittent exceedances at near-field station QUL-66/55/55a, near the mouth of Hazeltine Creek (Figure 18). Pre-event TP concentrations were defined as: median = 0.004 mg/L; 95th percentile = 0.008 mg/L; minimum = <0.002 (Appendix A; Golder 2015a).

At the near-field, mid-field, and far-field stations, dissolved phosphorus and orthophosphate concentrations reported between March and August were below pre-event concentrations (Figure 18). Pre-event dissolved phosphorus concentrations were defined as: median = 0.003 mg/L; 95th percentile = 0.004mg/L; minimum= <0.002. Pre-event orthophosphate concentrations were defined as: median = 0.003 mg/L; 95th percentile = 0.005mg/L; minimum = <0.001 (Appendix A; Golder 2015a).

Collectively, an evaluation of the phosphorus data collected between March and August suggest that event-related changes of concern for phosphorus were not evident in Quesnel Lake.

Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 18: Post-event Instantaneous Total and Dissolved Phosphorus and Orthophosphate at Stations QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a, Quesnel Lake.

4.0 DISCUSSION OF CONTAMINANTS OF POTENTIAL CONCERN

Following initial screening of water quality data using relevant BC WQGs and CSR standards, COPCs were identified for the receiving environment as described in Section 2.2. In this section, the results presented in Section 3 are discussed with reference to whether each COPC will be carried forward for further assessment as Contaminants of Concern (COCs) in the DSI.

Changes in concentrations of COPCs were evaluated for stations selected to be representative of Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River. Where appropriate, COPCs were assessed with respect to concentrations in the near-field (i.e., close to the Hazeltine Creek mouth), mid-field, and far-field areas of Quesnel Lake to provide a spatial representation of lake concentrations. COPCs in Hazeltine Creek were evaluated in the upper creek near the TSF and in the lower creek both upstream and downstream of the sedimentation ponds. Turbidity and copper were evaluated in Quesnel River near the community of Likely downstream of the outflow from Quesnel Lake.

Post-event changes in COPCs evaluated for the DSI are summarized in Tables 2 and 3, which indicate whether guideline exceedances occurred at surface or at depth during two consecutive time periods; between March and May 2015 and between June and August 2015. These time periods are generally reflective of turbid episodes in Hazeltine Creek (March to May) and clear-flow conditions (June to August) in Hazeltine Creek that influenced the nature of inputs to Quesnel Lake (i.e., higher suspended particulate matter and potentially metal inputs during turbid episodes). Consistent with the PEEIAR WQIA, the updated assessment for the DSI was based on comparison to BC WQGs for the protection of aquatic life, but consideration was also given to whether turbidity levels met the requirements specified in amended Pollution Abatement Order 107461. For comparative purposes, Tables 2 and 3 also shows post-event changes in COPCs documented in the PEEIAR WQIA for two consecutive time periods; between August and November 2014 and between November 2014 and April 2015.

Table 2: Summary of Post-Event Changes in Suspended Particulate Matter over Time in Polley Lake, Quesnel Lake, and Quesnel River in Relation to the PEEIAR WQIA and the WQIA Update for the DSI

Study Area	Contaminant of Potential Concern	PEEIAR WQIA				WQIA Update for the DSI			
		Event to Fall Lake Turnover (August 2014 to November 2014)		Fall Lake Turnover to April 2015		March to May 2015		June to August 2015

- (a) Focus on the four metals identified as COPCs in Table 1 that had the largest magnitude of guideline exceedance (i.e., aluminum, copper, chromium, and iron). See Section 3.2.2.4 for an assessment of all identified COPCs
- (b) Comparison to chromium (III) WQGs
- (c) Total iron concentrations were below the total maximum BC WQG except one value recorded in August at HAC-01 (see further discussion in Section 3.2.2.4)
- (d) Concentrations began to increase above the 30-d BC WQG range (based on the range of hardness) in October 2014

● = Concentrations are below applicable BC WQGs at representative stations or are below pre-event concentrations

● = Concentrations exceed applicable BC WQGs and are above pre-event concentrations in one or more samples from at least one representative station

4.1 Changes in Water Quality from March to August 2015

4.1.1 Hazeltine Creek

As described in Section 3.2.2.4 and shown in Tables 2 and 3, some COPC guideline exceedances occurred in Hazeltine Creek during February, March, April, and May 2015, when turbid flow periods were evident in the creek due to restoration activities that also coincided with the onset of an early freshet. Turbid flow periods were characterized by elevated concentrations of particulate matter and some metals (mainly total forms) that resulted in increased inputs of these parameters to the near-field environment in Quesnel Lake. Clear-flow conditions, which were defined by instantaneous measures of turbidity less than 9.5 NTU⁷, prevailed in Hazeltine Creek during January, June, July, and August of 2015, with the exception of brief periods of turbidity at the end of July and the middle August. The brief turbid periods in late summer did not correspond with rainfall events (Attachment 6, Figure 5), but were likely a result of the change in discharge location of the creek at that time and maintenance activities in the sedimentation ponds (pers. comm. S. Litke). Photographs showing turbid and clear-flow conditions are shown in Attachment 6, Figures 1-4.

Under clear-flow conditions only total and dissolved copper exceeded BC WQGs for the protection of aquatic life (Attachment 4: Table 4-6). Copper therefore remains the primary substance of concern in Hazeltine Creek. When the creek is subject to erosion resulting in turbid flow events, turbidity and TSS and some other metals such as iron, aluminum, and chromium may also exceed BC WQGs.

4.1.2 Polley Lake

Levels of TSS, turbidity, and copper were low in Polley Lake and have remained below guidelines throughout 2015 for the period assessed. Molybdenum concentrations were below the wildlife water maximum guideline, but were near the most conservative chronic BC WQG (irrigation end use) expected to be protective of ruminant wildlife that might be particularly sensitive to dietary exposure. Molybdenum was not included in Table 3 because, as discussed in Section 3.2.2.1, adverse effects to wildlife are not expected due to a low potential for sustained dietary exposure and the low magnitude of exceedance of the most conservative chronic guideline for irrigation. Total phosphorus concentrations remained within the range previously observed in Polley Lake prior to the event.

4.1.3 Quesnel Lake

Levels of TSS and turbidity were low in the far-field area of Quesnel Lake and remained below guidelines throughout 2015 for the period assessed. In the West Basin of Quesnel Lake, TSS levels were also low and below guidelines, with the exception of some higher levels recorded in the near-field area at the mouth of Hazeltine Creek. Pollution Abatement Order requirements for the near-field and mid-field (west) stations were not always met between March and June 2015. In July and August 2015, turbidity levels were below long-term chronic guidelines in Quesnel Lake and Pollution Abatement Order requirements were met.

In the West Basin of Quesnel Lake, iron and chromium continued to be below BC WQGs. Within the West Basin, event-related changes in total copper were still identified close to the mouth of Hazeltine Creek and at the western mid-field station further away from the mouth, but not at the eastern mid-field station or at the far-field station east of Cariboo Island where concentrations were below guidelines.

⁷ Equivalent to the 24-h BC WQG of +8 NTU above the median pre-event background of 1.5 NTU

Dissolved copper concentrations remained below the BC WQG for total copper at these stations. Observed trends in total copper concentrations at these lake stations were related to particulate copper inputs from Hazeltine Creek to the lake in March through May, when TSS and turbidity concentrations were higher relative to other months in 2015.

From March through August 2015, instantaneous TP concentrations were below the BC WQG range and resembled pre-event concentrations with the exception of a few higher concentrations recorded at near-field Station QUL-66/55/55a, near the mouth of Hazeltine Creek. At the near-field, mid-field and far-field stations, dissolved phosphorus and orthophosphate concentrations reported during the same time period were below pre-event concentrations. The evaluation of phosphorus water data collected between March and August 2015, suggested that event-related changes that might be of concern with respect to the potential for a change in lake trophic status, were not evident in Quesnel Lake.

The updated evaluation of changes in water quality for the DSI confirmed an overall decreasing trend in COPCs since the event. Guideline exceedances generally occurred within a localised area close to the Hazeltine Creek mouth and likely reflected periodically higher levels of sediment transported to the lake from Hazeltine Creek.

This guidelines-based assessment is reliant on BC WQGs that are conservative in their derivation and should not be used for remediation purposes. As discussed by Golder (2015a), two sedimentation ponds were commissioned in lower Hazeltine Creek in December 2014 to manage erosion from exposed banks in Hazeltine Creek, but peaks in TSS have periodically occurred with a localised influence on Quesnel Lake. Ideally, more direct measures of toxicity should be used that take into consideration the mixture of contaminants and other parameters in the water. The results of the follow-up toxicity testing program (March to August 2015) with water samples sampled throughout the post-event period provided a more realistic assessment of potential impact of changes in water quality to aquatic life. These results are presented and discussed in the problem formulation component of the aquatic risk assessment (Golder 2015b). The findings of the toxicity testing program indicate that, although there were still some localised changes in water quality in Quesnel Lake between March and August 2015, toxicological testing results do not show toxicity in the water column and confirm the interim findings of the PEEIAR WQIA.

4.1.4 Quesnel River

Similar to the eastern far-field area of Quesnel Lake, water quality in Quesnel River between March and August did not exhibit event-related changes that were identified to be of concern with respect to exceedance of water quality guidelines or a departure from pre-event conditions.

5.0 IDENTIFICATION OF CONTAMINANTS OF CONCERN FOR THE HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT

Based on the evaluation of water quality conditions from March through August 2015, COCs are identified below for consideration in the problem formulation components of the HHERA. The risk assessment will focus on water quality uses related to aquatic life, wildlife water, and drinking water for human consumption. Contaminants of concern are identified separately for each of these uses in Tables 4 through 6 based on the findings of the WQIA update and exceedances of BC WQGs or CSR standards specific to the use under consideration. Consistent with the WQIA update presented above, the influence of turbid flow versus clear-flow conditions in Hazeltine Creek on creek and lake water quality has been considered in the identification of COCs. Pre-event background conditions were also considered.

Table 4: Summary of Contaminants of Concern Identified for Aquatic Life Based on Data Collected from March to August 2015

Study Area	Parameters Identified as Contaminants of Concern for the HHERA ¹
Polley Lake²	<i>no substances</i>
Hazeltine Creek²: turbid episodes	<ul style="list-style-type: none"> turbidity, total suspended solids total metals: aluminum, arsenic, beryllium, cadmium, chromium, cobalt, copper, iron, titanium, zinc, dissolved aluminum and copper
Hazeltine Creek²: clear-flow conditions	<ul style="list-style-type: none"> total and dissolved copper
Quesnel Lake: clear-flow conditions in Hazeltine Creek	<i>no substances</i>
Quesnel Lake: turbid episodes in Hazeltine Creek	<ul style="list-style-type: none"> <u>Near-field</u>: turbidity, total copper <u>Mid-field west</u>: turbidity, and total copper <u>Mid-field east</u>: no substances <u>Far-field</u>: no substances
Quesnel River	<i>no substances</i>

Note:

- Parameters were identified based on exceedance of BC WQGs for aquatic life or CSR aquatic life standards and were above pre-event concentrations in one or more samples from at least one representative station.
- Molybdenum in Polley Lake and Hazeltine Creek exceeded the 30-d BC WQG for irrigation, but did not exceed the maximum BC WQG for aquatic life or the CSR aquatic life standard; therefore, molybdenum was not retained as a COC for aquatic life.

Table 5: Summary of Contaminants of Concern Identified for Wildlife Water Based on Data Collected from March to August 2015

Study Area	Parameters Identified as Contaminants of Concern for the HHERA ¹
Polley Lake	<i>no substances</i>
Hazeltine Creek²: turbid episodes	<ul style="list-style-type: none"> turbidity, total suspended solids total metals: aluminum, copper, iron
Hazeltine Creek²: clear-flow conditions	<ul style="list-style-type: none"> total suspended solids
Quesnel Lake	<i>no substances</i>
Quesnel River	<i>no substances</i>

Note:

- Parameters were identified based on exceedance of BC WQGs for wildlife water or CSR wildlife water standards and were above pre-event concentrations in one or more samples from at least one representative station.
- Molybdenum in Polley Lake and Hazeltine Creek exceeded the 30-d BC WQG for irrigation, but did not exceed the maximum BC WQG for wildlife water or the CSR wildlife water standard; therefore, molybdenum was not retained as a COC for wildlife water.

Table 6: Summary of Contaminants of Concern Identified for Drinking Water Based on Data Collected from March to August 2015

Study Area	Parameters Identified as Contaminants of Concern for the HHERA ¹
Polley Lake	<i>no substances</i>
Hazeltine Creek: turbid episodes	<ul style="list-style-type: none"> turbidity total metals: aluminum, arsenic, iron, lead, manganese
Hazeltine Creek: clear-flow conditions	<ul style="list-style-type: none"> turbidity – untreated water only
Quesnel Lake	<ul style="list-style-type: none"> turbidity – untreated water only
Quesnel River	<ul style="list-style-type: none"> turbidity – untreated water only

Note:

- Parameters were identified based on exceedance of BC drinking WQGs or CSR drinking water standards and were above pre-event concentrations in one or more samples from at least one representative station.

6.0 STATEMENT OF LIMITATIONS

This technical memorandum was prepared for the exclusive use of MPMC. The inferences concerning the data, site and receiving environment conditions contained in this memorandum are based on information obtained during investigations conducted at the site by Golder Associates Ltd. (Golder), other consultants and MPMC, and are based solely on the condition of the site at the time of the site studies and subsequent investigations and remediation and other information obtained by Golder, as described in this memorandum. Soil, surface water and groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors.

In evaluating the subject site and water quality data, Golder has relied in good faith on information provided. The factual data, interpretations and recommendations pertain to a specific project as described in this memorandum, based on the information obtained during the assessment by Golder on the dates cited in the memorandum, and are not applicable to any other project or site location. Golder accepts no responsibility for any deficiency or inaccuracy contained in this memorandum as a result of reliance on the aforementioned information.

The findings and conclusions documented in this memorandum have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this memorandum at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this memorandum, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this memorandum. All third parties relying on this memorandum do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder's memorandum or other work product. Golder is not responsible for any unauthorized use or modifications of this memorandum.

MPMC may rely on the information contained in this memorandum subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this memorandum, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein.

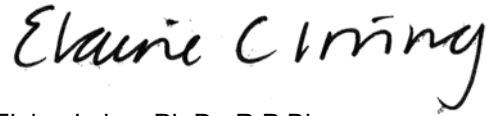

If new information is discovered during future work, including excavations, sampling, soil boring, predictive geochemistry or other investigations, Golder should be requested to re-evaluate the conclusions of this memorandum and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this memorandum is affected by any change of site conditions, purpose, development plans or significant delay from the date of this memorandum in initiating or completing the project.

7.0 CLOSURE

We trust that this Technical Memorandum provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at (604) 296-4200.

QUL-ZOO-8	Profile only for zooplankton	-	-	-	-	-	-	2	-	-	Profiled 7/8/2015 and 8/20/2015	

Notes

Routine samples were taken throughout the period according to 2015 Post-Breach Environmental Monitoring Plan
 Routine stations are consistently monitored; typically either weekly, bi-weekly (every 2 weeks), monthly, or bi-monthly (twice per month)
 Continuous logger measures field parameters (i.e., pH, temperature, specific conductivity, DO, and turbidity) every 15 minute:

a) All equipment blanks carried out on MPMC Kemmerer 1 (used for all Polley Lake and Quesnel Lake sampling)

b) Additional duplicate sample was taken as part of another MPMC water quality monitoring program

Table 3-2. Summary of Data Quality Objective Exceedances, March to August 2015

Date	Sample ID	Parameter(s) RPD > DQO	BC WQG Exceedance
5-Mar-2015	De-ionized Water Blank	Dissolved Organic Carbon	No
18-Mar-2015	QUL-55X-0m	Turbidity, Manganese-D	No (turbidity exceedance of chronic guideline in original sample, but not duplicate; no associated 30-d guideline exceedance)
24-Mar-2015	HAC-01bX	Turbidity	Turbidity exceedance in original and duplicate
24-Mar-2015	QUL-2aX-0m	Copper-T	No
1-Apr-2015	EDC-01X	Ammonia, Phosphorus-T, DOC, Aluminum-D, Iron-D	Aluminum-D exceedance in original and duplicate
21-Apr-2015	QUL-55X-0m	Nitrogen-T	No
28-Apr-2015	HAC-05X	Phosphorus-T, Aluminum-T, Cadmium-T, Cobalt-T, Iron-T, Lead-T, Titanium-T, Vanadium-T	Iron-T exceedance in original, but not duplicate

Notes

D - dissolved, T - total

RPD - relative percent difference, DQO - data quality objective

BC WQG - BC water quality guideline

ATTACHMENT 4

**Post-event Water Quality in Polley Lake, Hazeltine Creek,
Quesnel Lake, and Quesnel River, March to August 2015**

Table with columns: Parameter, Units, BC Water Quality Guidelines for the Protection of Freshwater Aquatic Life, BC Drinking Water Quality Guidelines, CSR-Schedule 6, Polley Lake, Hazeltine Creek, Quesnel Lake, Quesnel River. Rows include Physical Parameters (Conductivity, Turbidity, Hardness, etc.), Major Ions (Alkalinity, Chloride, etc.), Nutrients (Ammonia, Nitrate, etc.), Total Metals (Aluminum, Antimony, etc.), and Dissolved Metals (Aluminum, Antimony, etc.).

A = approved guideline, W = working guideline, Min = Minimum concentration requirement based on life stage
nm = not measured
< = reported value is <MDL
CSR-Schedule 6 Generic Numerical Water Standards: Aquatic life standards assume minimum 1:10 dilution available, available at http://www.bclaws.ca/Recon/document/ID/freeside/375_96_08 accessed October 8 2011
BC WQGs for total metals substituted where dissolved metal WQGs do not exist
a) BC Water Quality (BCWQ) guidelines for the protection of freshwater aquatic life, except where noted (WW = wildlife water, IR = irrigation), available at http://www2.gov.bc.ca/gov/content/environment/air-land-water/water/water-quality/water-quality-guidelines/approved-water-quality-guidelines, accessed October 8 2015
b) BC WQ guideline for the protection of drinking water, available at http://www2.gov.bc.ca/gov/content/environment/air-land-water/water/water-quality/water-quality-guidelines, accessed October 8 2015
c) CSR Generic Numerical Water Standards for the protection of aquatic life
d) CSR Generic Numerical Water Standards for the protection of drinking water
e) hardness dependent F guideline: BC Max WQG (mg/L) = 0.4 at hardness <10 mg/L, otherwise = (-51.73 + (92.57 * log(hardness))) * 0.01
f) hardness dependent sulphate guideline: BC 30-d WQG (mg/L) = 128 at hardness <30 mg/L, at hardness 31-75 mg/L = 218, at hardness 76-180 mg/L = 309, at hardness 181-250 mg/L = 429, at hardness >250 mg/L determine base on site water
g) pH and temperature dependent ammonia guideline: values selected from Tables 3 and 4 in BC WQG based on maximum temperature of 20°C and pH 8.2
h) chloride dependent nitrite guideline: BC Max WQG (mg/L) = 0.06 at Cl <2 mg/L, at Cl 2-4 mg/L = 0.12, at Cl 4-6 mg/L = 0.18, at Cl 6-8 mg/L = 0.24, at Cl 8-10 = 0.30, at Cl >10 = 0.1
BC 30-d WQG (mg/L) = 0.02 mg/L at Cl <2 mg/L, at Cl 2-4 mg/L = 0.04, at Cl 4-6 mg/L = 0.06, at Cl 6-8 mg/L = 0.08, at Cl 8-10 mg/L = 0.1, at Cl >10 = 0.1
i) pH dependent dissolved Al guideline: BC Max WQG (mg/L) = 0.1 at pH >= 6.5, at pH <6.5 = EXP(1.209-2.426*(pH)+0.286*(pH^2)); BC 30-d WQG (mg/L) = 0.05 at pH >= 6.5, at pH <6.5 = EXP(1.6-3.327*(median pH)+0.402*(median pH^2)); minimum baseline surface water pH = 5.57
j) hardness dependent dissolved Cd guideline: max BC WQG (mg/L) = (exp(1.03*ln(hardness)-5.274))/1000 BC 30-d WQG (mg/L) = (exp(0.736*ln(hardness)-4.943))/1000
k) guideline is for Cr(VI)
l) hardness dependent Cu guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness <= 50 mg/L, at hardness >50 mg/L = 0.04*hardness/1000
m) hardness dependent Pb
n) hardness dependent Mn guideline: BC Max WQG (mg/L) = 0.01102*(hardness)+0.54; BC 30-d WQG (mg/L) = 0.0044*hardness+0.60
o) BC 30-d WQG (mg/L) = 0.0001/(MeHg/THg), where MeHg is mass (or concentration) of methyl mercury and THg is total mass (or concentration) of mercury in a given water volume; assumed = 0.00001 at 1% MeHg
p) hardness dependent Ni guideline: BC 30-d WQG = 0.025 at hardness <60 mg/L, at hardness 60-120 mg/L = 0.065, at hardness 120-180 mg/L = 0.11, at hardness >180 mg/L = 0.15
q) hardness dependent Ag guideline: BC Max WQG (mg/L) = 0.0001 at hardness <100 mg/L, at hardness >100 mg/L = 0.003; BC 30-d WQG (mg/L) = 0.00005 at hardness <100 mg/L, at hardness > 100 mg/L = 0.0015
r) hardness dependent Zn guideline: BC Max WQG (mg/L) = (33+0.75(hardness-90))/1000; BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/1000
s) up to 10 - highly sensitive to acid inputs; 10 to 20 - moderately sensitive; over 20 - low sensitivity. Refer to calcium regarding sensitivity to acid inputs, the more restrictive of calcium or alkalinity is applicable.
t) up to 4 - highly sensitive to acid inputs; 4 to 8 - moderately sensitive; over 8 - low sensitivity. Refer to alkalinity, the more restrictive of calcium or alkalinity applies.
u) CSR Standard may not protect all amphibians. Consult director for further advice.
v) CSR Standard varies with chloride concentration. Consult director for further advice.
w) value exceeds BC Drinking Water Quality Guidelines for turbidity only for untreated water
x) CSR Standard varies with pH and temperature. 10°C is assumed.
y) CSR Standard to protect freshwater aquatic life.
z) CSR Standard is hardness dependent.
aa) Wildlife Water values are the lowest of CSR Generic Numerical Water Standards for Livestock Water or the Canadian Water Quality Guidelines for the Protection of Agriculture Water Uses - Livestock. For parameters without these standards or guidelines, either the CSR Schedule 6 Generic Numerical Water Standards and Schedule 10 Generic Numerical Soil and Water Standards for Drinking Water were used.
bb) Background turbidity is 1.5 NTU for Hazeltine Creek and 1.0 NTU for Polley Lake, Quesnel Lake, and Quesnel River
cc) Background is equal to MDL of 3.0 mg/L for total suspended solids.

Legend table with 2 columns: Value and Description. Values include 123, 123, 123, 123, 123. Descriptions include: Indicates concentration exceeding the BC Max WQ Guideline, Indicates concentration exceeding the BC 30-d WQ Guideline, Indicates concentration exceeding the BC Drinking Water Guideline, Indicates concentration exceeding CSR aquatic life, Indicates concentration exceeding CSR drinking water, Indicates concentration exceeding CSR wildlife water.

Table 4-2: Post-event Water Quality in Polley Lake, March to August 2015

ADDENDUM TO MOUNT POLLEY SURFACE WATER QUALITY IMPACT ASSESSMENT UPDATE

Dear Ms. Hughes:

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with the following addendum to the Surface Water Quality Impact Assessment (WQIA) update undertaken by Golder (2016). This addendum is intended to provide an update on post-event water quality conditions in Polley Lake, Hazeltine Creek, Lower Edney Creek, Quesnel Lake, and Quesnel River primarily based on water quality monitoring undertaken by MPMC from September to December 2015 and in consideration of 2015 data collected from January through August by MPMC and previously reported by Golder.

1.0 INTRODUCTION

This addendum represents the second update to the original water quality impact assessment (WQIA) for the Post-Event Environmental Impact Assessment Report (PEEIAR) (Golder 2015a). The 'event' refers to the tailings dam failure that occurred at the Mount Polley Mine on August 4, 2014, when the Tailings Storage Facility (TSF) Perimeter Embankment failed and there was a subsequent debris flow into the receiving environment.

A chronology of post-event water quality assessments submitted to MPMC by Golder is summarized below. The assessment approach has involved the progressive evaluation of data collected by MPMC during their post-breach monitoring program that was initiated following the event in August 2014.

- **Original WQIA for the PEEIAR** (Golder 2015a) was based on water quality data collected by MPMC just after the event from August to 2014 to April 2015.

- **Surface WQIA Update** undertaken by Golder (2016) to provide an update to the original PEEIAR WQIA and to inform the Detailed Site Investigation (DSI) for the forthcoming Human Health and Ecological Risk Assessment (HHERA). The HHERA is being completed in 2016 in response to the Pollution Abatement Order (BC MoE 2015a). The WQIA update primarily considered water quality data collected by MPMC from March to August 2015, with consideration of post-event data collected prior to March 2015 as needed to evaluate temporal trends.
- **Addendum to the Surface WQIA Update** presented here is intended to provide an update to the two preceding post-event assessments. The addendum includes previously unreported data collected by MPMC from September to December, 2015.

The objective of the addendum is to evaluate water quality data collected by MPMC in 2015 to assess temporal trends of contaminants of potential concern through to December 2015 in Polley Lake, Hazeltine Creek, Lower Edney Creek, Quesnel Lake and Quesnel River.

2.0 METHODS

Water quality data collected from receiving environments in Polley Lake, Hazeltine Creek (including lower Edney Creek), Quesnel Lake, and Quesnel River were screened using relevant BC water quality guidelines (BC WQGs) (BC MoE 2015b, BC MoE 2015c) and *Contaminated Sites Regulation* (CSR) standards (CSR 2014). For contaminants of potential concern (COPCs) identified for further evaluation as described in Section 2.2, temporal trends were evaluated within the context of applicable BC WQGs and CSR standards. Based on this evaluation contaminants that remained of concern in each receiving environment by the end of 2015 were identified.

2.1 Data Collection and Compilation

The addendum focussed on water quality data collected by MPMC in 2015, including data collected between September and December 2015 that had not previously been evaluated. Data collected from January to August 2015 were reported in the two previous assessments (Golder 2015a, 2016).

From September to December 2015, water quality samples were collected in accordance with the Post TSF-Breach 2015 Monitoring Plan (MPMC 2015); methods are described in Golder (2016). In general, the addendum focused on stations assessed in the WQIA (Golder 2016; Figure 1); however due to the continued evolution of the post-breach monitoring program, a small number of stations were moved, renamed, added, or discontinued. A summary of updated monitoring stations and sampling frequencies is provided in Table A1.

Following completion of quality assurance/quality control (QA/QC) and database entry procedures, MPMC provided Golder with updated electronic data files containing water quality data for September through December 2015 (Table A2). These data were used as received from MPMC with an additional check of transcription by Golder prior to being screened to identify COPCs.

2.2 COPC Identification

To confirm COPCs for the updated assessment, discrete water quality data collected from September through December 2015 were compiled and screened against BC WQGs and CSR standards. Data compiled for all stations sampled within a given area (i.e., Polley Lake, Hazeltine and Edney creeks, Quesnel Lake, and Quesnel River) were evaluated as one dataset per area, for screening purposes. Substances were classified as COPCs based on criteria described in the WQIA (Golder 2016); however, in this addendum maximum concentrations of each substance were used to conservatively identify COPCs.

2.3 COPC Evaluation

Changes in COPC concentrations in 2015 were evaluated qualitatively over time at representative stations previously assessed in the original PEEIAR WQIA (Golder 2015a) and the WQIA update (Golder 2016), as well as at additional representative stations identified during the post-event monitoring program. This updated 2015 assessment included 13 representative stations that are described below with additional details provided in Table A1.

- **Polley Lake:** Station P1 and P2 that have been routinely sampled since August 2014.
- **Hazeltine Creek:** Stations HAC-10, HAC-05/a, HAC-08/a, and HAC-01/a/b/c, listed in order from upstream to downstream.
 - Station HAC-10 is the furthest upstream station in Hazeltine Creek and is located downstream of the Polley Lake inflow. Data collected at this station from April through December 2015 were expected to contribute to a greater spatial representation of water quality conditions in the creek.
 - Station HAC-05 was moved upstream of the Gavin Lake Road bridge to avoid potential water quality impacts associated with the road. HAC-05 and HAC-05a (upstream of the bridge) have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-05/a).
 - Station HAC-08 was temporarily moved downstream of the Ditch Road bridge. HAC-08 and HAC-08a (downstream of the bridge) have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-08/a).
 - HAC-01/a/b/c is located immediately downstream of the sedimentation ponds close to the confluence with Quesnel Lake. This station represents water quality at the outflow of Hazeltine Creek and was the most frequently sampled station in the creek between August 2014 and October 2015. To adapt to changes in the creek channel due to rehabilitation activities and construction of sedimentation ponds HAC-01/a/b/c has been moved slightly over time (a change in location was indicated with a subsequent letter in the station code). Samples collected at HAC-01, HAC-01a, HAC-01b, and HAC 01c in lower Hazeltine Creek have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-01/a/b/c). This station was discontinued in October, 2015 due to lack of flow through the lower sedimentation pond and was replaced by monitoring at HAC-12 in the upper sedimentation pond.

- **Lower Edney Creek:** Stations EDC-01 and EDC-02 are located below the sedimentation ponds close to the confluence with Quesnel Lake.
 - Station EDC-01 was sampled before and after Hazeltine and Edney creeks were re-directed. Data collected at this station from February through December 2015 were expected to contribute to a greater spatial representation of water quality conditions.
 - Station EDC-02 is located downstream of the confluence with Hazeltine Creek. Data collected at this station from February through July 2015 were expected to contribute to a greater spatial representation of water quality conditions.
- **Quesnel Lake:** Stations QUL-2/2/a, QUL-66, QUL-18, and QUL-120/120a.
 - Station QUL-66 was replaced by QUL-55, QUL-55a, and then QUL-58 due to changes in the location of the Hazeltine Creek outflow into the lake. These stations have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., are collectively referred to as QUL-66 throughout this addendum).

Stations meeting the following criteria were not included in the COPC evaluation:

- stations not previously assessed as a representative station (Golder 2015a, 2016);
- stations do not contribute to a greater spatial representation of water quality conditions; and
- stations with all parameter concentrations below relevant BC WQGs or CSRs, based on the results of the initial screening step described in Section 2.2.

2.3.1 Changes in COPC Concentrations Over Time

Instantaneous measurements and/or rolling 30-day (d) average values for each COPC were assessed qualitatively and compared to BC WQGs and CSR standards. Data values, guidelines, and standards were plotted and compared based on the methods outline in Section 2.3.2 of the WQIA update (Golder 2016).

Concentrations reported as less than the method detection limit (MDL) were set equal to the MDL for purposes of plotting data and calculating 30-d averages. Typically, 30-d averages would be calculated using, at a minimum, data from at least five samples per 30-d period. If only monthly data were available, and reported concentrations were not stable from month-to-month, plotted 30-d rolling average concentrations were replaced with instantaneous data values (see appended figures 2 to 21). For the relevant figures, instantaneous data shown on the 30-d rolling average plots were identified by open circles connected by dashed lines.

As in the previous WQIA assessments (i.e., Golder 2015a, 2016), water quality trends for identified COPCs were evaluated against hardness-dependent WQGs calculated using hardness concentrations measured during the post-event period. Minimum and maximum hardness concentrations reported for each receiving environment area (i.e., Polley Lake, Hazeltine and Edney creeks, Quesnel Lake, and Quesnel River) during the post-event period were used, rather than station-specific minimums and maximums. With respect to Quesnel Lake and Quesnel River, exposure mean hardness values in 2015 were sufficiently similar to pre-event mean hardness values; for other waterbodies such as Hazeltine Creek and Polley Lake, exposure hardness in 2015 was higher than the pre-event mean hardness value reported prior to the event. Consequently, for Hazeltine Creek and Polley Lake, 2015

data were also compared to WQGs calculated based on mean pre-event hardness concentrations for these waterbodies as previously reported in the original PEEIAR WQIA (Golder 2015a). These guidelines provided conservative lower guideline boundaries for COPCs based on conditions not necessarily reflective of those present in these waterbodies in 2015. It should however be noted that for some receiving environments, such as Hazeltine Creek, the pre-event hardness value was higher than the minimum hardness value measured in 2015 and therefore did not represent the most conservative exposure condition.

3.0 RESULTS

3.1 COPC Identification

Table 1 contains a list of the COPCs identified for this assessment based on the COPCs examined in the PEEIAR (Golder 2015) and the WQIA update (Golder 2016) and confirmed by screening data from September to December 2015 against guidelines and standards. Dissolved aluminum and total and dissolved selenium were identified as COPCs for Hazeltine Creek and Edney Creek, based on elevated concentrations in the September to December 2015 dataset.

Table 1: Contaminants of Potential Concern (COPCs) Identified in the Receiving Environment Based on Water Quality Monitoring in 2015¹

Waterbody	COPC: Physical ²	COPC: Total Metals	COPC: Dissolved Metals	COPC: Non-Metal Substances
Polley Lake	<i>no substances</i>	copper	copper	TP
Hazeltine Creek and Edney Creek	turbidity, TSS	aluminum, arsenic, beryllium, chromium, cobalt, copper, iron, lead, manganese, selenium, zinc	aluminum, copper, selenium	<i>no substances</i>
Quesnel Lake	turbidity (QUL-66 only)	copper	<i>no substances</i>	TP (QUL-66 only)
Quesnel River	turbidity³	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>

Notes: TP = total phosphorus; TSS = total suspended solids; QUL = Quesnel Lake

1. Refer to Golder (2015) (January to April 2015), Golder (2016) (March to August 2015) and Section 2.2 (September to December 2015)
2. Background turbidity concentrations are 1.5 NTU in Hazeltine Creek based on pre-event median value and 1 NTU in Quesnel Lake and Quesnel River.
3. Turbidity was identified as a COPC for Quesnel River based on in-situ data from a continuous logger.

To be conservative in the assessment for Polley Lake, copper was retained as a COPC because it was considered a primary COPC for the PEEIAR (Golder 2015a) and was assessed in the WQIA update (Golder 2016) even though the maximum copper concentration from September to December was below applicable guidelines. Total phosphorus was retained as a COPC for Polley Lake and Quesnel Lake because the maximum concentrations were above the BC WQG range and data are intended to be integrated with biological information to assess potential impacts on lake productivity.

3.2 Changes in COPC Concentrations Over Time

The following section describes post-event changes in receiving environment water quality with respect to COPCs listed in Table 1. Changes in COPC concentrations over time from January through December 2015 are discussed below in comparison to relevant BC WQGs and CSR standards. Results are presented according to each group of COPCs (i.e., suspended particulate matter, metals, nutrients), then within each COPC group. Changes in specific COPCs are discussed for each waterbody.

Data shown for Hazeltine Creek and Quesnel River represent discrete surface grab samples collected as described in the PEEIAR WQIA (Golder 2016), except where a continuous data logger measured turbidity. Quesnel Lake and Polley Lake data are from discrete grab samples taken at various depths and were categorized as either surface (1-20 m) or deep (greater than [$>$] 20 m) for the purpose of evaluating changes over time.

3.2.1 Suspended Particulate Matter (Turbidity/TSS)

3.2.1.1 Hazeltine Creek and Edney Creek

Turbidity levels in Hazeltine Creek showed a progressive decrease from peak levels in the first few months of 2015 to levels closer to applicable BC WQGs by the end of the year. However, levels in upper Hazeltine Creek (HAC-10 and HAC-05/a) and the lower creek above the sedimentation ponds (HAC-08/a) fluctuated during September-December 2015. During this time monthly concentrations at these stations were occasionally above the maximum and 30-d BC WQGs (Figure 2).

In lower Edney Creek at EDC-01 turbidity levels were typically below maximum and 30-d guideline values, except for a spike in October 2015. Turbidity levels at EDC-02 exhibited a general decrease over time until the station was discontinued in July 2015; however, concentrations were predominantly above the 30-d guideline. Elevated turbidity observed at HAC-01/a/b/c throughout July and August continued through September and October (Figure 2) with reported concentrations above the 24-h aquatic life and/or 30-d guidelines. Turbidity concentrations in Hazeltine Creek and Edney Creek were routinely above the BC WQG for untreated drinking water but were within the turbidity range reported for the creek prior to the event.

A similar progressive decline in TSS concentrations was also observed in Hazeltine Creek from peak concentrations in the first few months of 2015 to concentrations below BC WQGs by the end of the year (with the exception of HAC-08/a). Concentrations of TSS at HAC-10, HAC-05/a, and HAC-01/ab/c in Hazeltine Creek and at EDC-01 in Edney Creek were consistently below the 24-h aquatic life and 30-d guidelines throughout September-December 2015 (Figure 3). Before the station was discontinued in July 2015, TSS concentrations at EDC-02 exhibited a general decrease that was similar to the temporal trend observed at HAC-01/a/b/c (Golder 2016; Figure 3). Concentrations at HAC-08/a were variable throughout September-December 2015 and were intermittently above the 24-h aquatic life and 30-d guidelines.

3.2.1.2 Quesnel Lake

Turbidity concentrations measured at the surface and at depth in Quesnel Lake at stations QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a were below BC WQGs from approximately April through August 2015 (Golder 2016). At the surface at QUL-66, turbidity levels generally remained below guideline values with the exception of a single exceedance of the aesthetic drinking water guideline for untreated water and the 30-d aquatic life guideline in spring 2015. Turbidity at QUL-66 continued to decline through September and remained below guidelines into December 2015 with concentrations close to or below background (1 NTU) (Figure 4).

3.2.1.3 Quesnel River

Daily average and in-situ turbidity concentrations at station QUR-1 in Quesnel River showed a progressive decrease over time throughout 2015. Turbidity levels remained well below guidelines with the exception of a few intermittent spikes measured by the continuous data recorder (Figure 5). The elevated values measured by the

continuous recorder were not corroborated by the in-situ grab sample data and as discussed in Golder (2016) these measurements can be influenced by fouling associated with long-term deployment.

3.2.2 Copper

3.2.2.1 Polley Lake

Copper concentrations measured in Polley Lake were not elevated above BC WQGs during the March-August 2015 period, and so copper was no longer considered a COPC by the WQIA update (Golder 2016). However, as described in Section 3.1, copper was retained in this addendum because it is considered a primary COPC within the overall context of the PEEIAR. Both total and dissolved concentrations were below BC WQGs, with the exception of the total 30-d rolling average concentration associated with surface samples collected at P2 in early November 2015 that approximated the most conservative 30-d guideline based on pre-event hardness (Figure 6).

3.2.2.2 Quesnel Lake

Total and dissolved copper concentrations measured in Quesnel Lake were typically below maximum BC WQGs by the end of April 2015 (Golder 2016). By late August 2015, copper concentrations reported for QUL-66 near the mouth of Hazeltine Creek were similar or only slightly elevated relative to concentrations reported elsewhere in the lake, including the far field station (QUL-120/120a) east of Cariboo Island (Golder 2016). Total and dissolved copper concentrations at QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a were below maximum and 30-d guidelines from September through December 2015, with the exception of a single monthly sample collected at near-field (QUL-66) and far-field (QUL-120/120a) stations in September (Figure 7). The corresponding monthly sample in September at the mid-field west station (QUL-18) approximated the most conservative 30-d guideline based on minimum measured hardness.

3.2.2.3 Quesnel River

No metals were identified as COPCs for the receiving environment in Quesnel River in the original WQIA and the WQIA update; this was also the case for data collected from September to December 2015.

3.2.2.4 Hazeltine Creek and Edney Creek Discrete Grab Samples (Instantaneous values)

In upper Hazeltine Creek at HAC-05/a, total copper concentrations were above the maximum BC WQG (based on measured maximum hardness) from January to May 2015, after which concentrations decreased to concentrations below the maximum guideline (based on mean pre-event hardness) by the end of the year (Figure 8). From April to December 2015 total concentrations were below applicable CSR standards. Dissolved concentrations at HAC-05/a were within the WQG range based on measured hardness but were above the WQG based on pre-event hardness until May 2015. Dissolved concentrations decreased thereafter and were below the WQG based on pre-event hardness from May to December 2015. At the most upstream station (HAC-10) total and dissolved concentrations followed a similar trends to those described for HAC-05/a.

In lower Hazeltine Creek (HAC-08/a, EDC-01, EDC-02, HAC-01/a/b/c), total concentrations peaked above BC maximum WQGs and at least one CSR standard¹ from February through April (Figure 8). Total concentrations then decreased at all four stations to concentrations within the BC maximum guideline range (based on measured hardness values) by the end of the year and generally remained above the maximum guideline based on pre-event hardness. Dissolved concentrations at HAC-08/a and HAC-01/a/b/c peaked above the maximum guideline and were within the CSR aquatic life standard range based on measured hardness. Dissolved concentrations decreased thereafter at these stations and were below the maximum guideline based on pre-event hardness at both HAC-08/a and HAC-01/a/b/c by the end of the year. The same was true for EDC-01.

Thirty-Day Rolling Average Values

During the months prior to June, total copper concentrations in upper and lower Hazeltine Creek (HAC-05/a, HAC-08/a, EDC-02, HAC-01/a/b/c) peaked above the 30-d BC WQG range based on measured hardness (Figure 8). Concentrations then decreased to values within the 30-d guideline range based on measured hardness and remained above the guideline based on pre-event hardness. Dissolved concentrations in the lower creek (HAC-08/a, HAC-01/a/b/c) only peaked above the 30-d guideline range (based on measured hardness) from March to May, with a subsequent decrease to concentrations within this guideline range. Concentrations remained above the 30-d guideline based on pre-event hardness (Figure 8). Dissolved concentrations at the other Hazeltine Creek stations were within the 30-d guideline range based on measured hardness and either approximated or were above the guideline based on pre-event hardness.

3.2.3 Other Metals

3.2.3.1 Hazeltine Creek and Edney Creek

Aluminum

In upper Hazeltine Creek (HAC-10, HAC-05/a), total and dissolved concentrations remained below maximum guideline values in 2015, with the exception of a single sample in January at HAC-05/a. In lower Hazeltine Creek (HAC-08/a, EDC-01, EDC-02, HAC-01/a/b/c), concentrations peaked in February through April and were above or approximated maximum guideline values; concentrations then decreased below guidelines by May and remained stable until the end of the year. Concentrations at HAC-05/a in upper Hazeltine and HAC-08/a in lower Hazeltine showed slight increases in November and December, based on monthly sampling; in the case of HAC-08/a concentrations approximated maximum guidelines for the protection of aquatic life (Figure 9).

Dissolved concentrations were above the 30-d dissolved guideline in lower Hazeltine Creek until May and June, when they decreased below this guideline and remained relatively stable until November, when concentrations at HAC-05/a and HAC-08/a increased to approach but not exceed the 30-d guideline value (Figure 10).

Arsenic

Total arsenic was evaluated as a COPC in the WQIA update, based on guideline exceedances that occurred in Hazeltine Creek in spring 2015 (Golder 2016; Figure 11). During this time concentrations at HAC-08/a peaked

¹ The CSR standard for aquatic life at the Edney Creek stations; the CSR for wildlife at HAC-01/a/b/c, and the CSR for drinking water at HAC-08/a.

above the CSR drinking water and wildlife standards as well as the BC drinking water maximum guideline. Thirty-day rolling average total concentrations at HAC-08/a also peaked above the 30-d BC WQG during this time, before decreasing to concentrations more typical of the other stations on the creek by August. Total concentrations at the stations in Hazeltine and Edney creeks shown on Figure 11 were typically well below the maximum and 30-d guidelines from June through December, with the exception of two measurements at HAC-08/a upstream of the sediment ponds in September and December.

Beryllium

Thirty-day rolling average total concentrations were elevated above the 30-d WQG at HAC-08/a and HAC-01/a/b/c during spring 2015 (Figure 12). Concentrations at EDC-02 were also elevated during this time. From July through December 2015, total concentrations at the Hazeltine and Edney Creek stations were below guideline values and were at or near the MDL, with the exception of one sample collected at HAC-08/a in December 2015 that was detected above the WQG (Figure 12).

Chromium

As discussed in Golder (2015a), the available speciation data for Hazeltine Creek indicates the dominant chromium species in Hazeltine Creek was chromium (III), which is less toxic than the chromium (VI) form. However, as a conservative measure, guidelines and standards for both chromium species have been considered when assessing water quality in Hazeltine Creek.

Total chromium was evaluated as a COPC in the WQIA update, largely based on guideline exceedances recorded in spring 2015 in Hazeltine Creek at stations HAC-08/a, HAC-05/a, and HAC-01/a/b/c (Golder 2016; Figure 13). However, by June 2015, total concentrations in Hazeltine Creek had decreased below the most conservative guidelines shown on Figure 13. In 2015, concentrations at stations HAC-10 and EDC-01 and EDC-02 in Edney Creek exhibited temporal trends similar to those previously reported for other stations in Hazeltine Creek (Figure 13).

Total chromium concentrations measured at the Hazeltine and Edney creek stations were below applicable maximum guidelines from June to December 2015, and many were at or near the MDL. The same was true for total 30-d rolling average concentrations that were below the Cr(III) and Cr(VI) 30-day guidelines at all stations, with the exception of intermittent exceedances of the Cr(VI) guideline by total concentrations at HAC-08/a and HAC-01/a/b/c that were still below the more applicable Cr(III) 30-day guideline.

Cobalt

Instantaneous total concentrations reported in 2015 for the Hazeltine Creek stations shown on Figure 14 were below the maximum BC WQG. Thirty-day average total concentrations were above the 30-d BC WQG from March to June at HAC-08/a and March to May at HAC-01/a/b/c, then decreased below the 30-d guideline thereafter (Figure 14). Stations EDC-01 and EDC-02 exhibited a similar temporal trend over the time period leading up to the end of August 2015, but did not exceed the guideline. Total concentrations remained stable well below the 30-d guideline from September through December, with the exception of intermittent values in the monthly September and December samples at HAC-08/a that approached or approximated the guideline.

Iron

Total concentrations at stations in lower Hazeltine Creek were consistently above the BC maximum WQG for aquatic life and the CSR drinking water standard until May 2015 (Figure 15). The higher CSR standard was mostly exceeded at HAC-08/a and HAC-01/a/b/c, with only a few exceedances at other stations. From May to December, total concentrations remained below this guideline, with the exception of one sampling event in August, during which total values at HAC-08/a and HAC-01/a/b/c were more than ten times the preceding and subsequent values recorded in July and August (Golder 2016). Intermittent values measured in September and December at station HAC-08/a were above the BC maximum guideline. Concentrations at the other stations monitored in 2015 were below the BC maximum guideline.

Lead

Total lead was assessed as a COPC in the WQIA update (Golder 2016). In upper Hazeltine Creek, instantaneous concentrations were typically below guideline values in 2015 and 30-d average concentrations were below the long-term average guideline, with the exception of a concentration reported for HAC-05/a in January that was also above the CSR drinking water standard (Figure 16). In lower Hazeltine Creek, after peaking in March through April, rolling 30-d average concentrations declined below the 30-d BC WQG in May and remained relatively stable through the end of December. The exception was an intermittent increase at HAC-08/a in December that approached the 30-d guideline range shown on Figure 16.

Manganese

Total concentrations were below BC maximum WQGs and the CSR drinking water standard (Figure 17). The exceptions were total concentrations at HAC-05/a (January and February) and HAC-08/a (February to April) that were within the BC maximum guideline range, and concentrations at HAC-01/a/b/c (February to April) that were below the BC maximum guideline but above the CSR drinking water standard. Rolling-average 30-d manganese concentrations in Hazeltine Creek stations were below the 30-day guideline based on measured hardness and pre-event hardness, with the exception of HAC-08/a (March through May) and HAC-05/a (January and February) (Figure 17).

Selenium

The WQIA update indicated that post-event selenium concentrations in Hazeltine Creek remained stable below applicable guidelines/standards or decreased below these regulatory benchmarks shortly after the event, remaining stable thereafter (Golder 2016). In 2015, instantaneous and rolling 30-day average concentrations remained well below applicable BC WQGs and CSR standards with the exception of the monthly sampling event in December 2015 at HAC-05/a and HAC-08/a located below the authorized discharge of treated effluent that commenced in December 2015 (Figure 18). Continued monitoring of water quality in Hazeltine Creek through March 2016 confirmed that selenium concentrations at HAC-05/a and HAC-08/a are above the BC WQGs and CSR drinking water and aquatic life standards (MPMC, unpublished data). However, concentrations showed a progressive decrease from 0.024 mg/L in December to 0.014 mg/L in March at HAC-05/a and from 0.020 mg/L in December to 0.012 mg/L in March at HAC-08/a. Selenium concentrations reported at these stations between December 2015 and March 2016 are within the range predicted by Golder (2015b) that did not consider Hazeltine Creek to be a receiving environment in the short-term, but rather a conduit to Quesnel Lake, where fish were

present and potential breeding habitat for aquatic feeding birds is more prevalent. Water quality continues to be monitored in Hazeltine Creek, including stations downstream of the authorized discharge of treated effluent.

Zinc

Total and 30-d rolling average concentrations reported for HAC-05/a, HAC-08/a, EDC-02, and HAC-01/a/b/c between January and June were typically within the BC WQG range based on measured hardness and above BC WQGs calculated using mean pre-event hardness (Figure 19). Concentrations reported for the other stations shown on Figure 19 were below the BC maximum guideline range. Between June and December, total and 30-day rolling average concentrations for all stations shown on Figure 19 were below the most conservative BC WQG, with the exception of a few intermittent values for HAC-08/a.

3.2.4 Nutrients: Total Phosphorus

3.2.4.1 Polley Lake

Following the event and through August 2015, concentrations of total phosphorus (TP) at the surface in Polley Lake were within the pre-event range of concentrations reported in the PEEIAR for Polley Lake (Golder 2015a). Pre-event TP concentrations were defined as: mean = 0.041 mg/L; 95th percentile = 0.094 mg/L.; minimum = 0.0046 mg/L. Both pre-event mean and upper limit concentrations were above applicable BC WQGs (i.e., 0.005 to 0.015 mg/L). This is consistent with the observation by Minnow (2014) that the trophic status of the lake changed from oligotrophic/mesotrophic to mesotrophic/eutrophic by 2012, two years prior to the event.

Prior to fall turnover in 2014, concentrations of all three forms of phosphorus at depth were elevated above pre-event concentrations, unlike surface concentrations that were within pre-event concentration ranges (Golder 2016). Pre-event dissolved phosphorus concentrations were defined in Golder (2015) as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.002 mg/L; pre-event orthophosphate concentrations were defined as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.001 mg/L (Appendix A; Golder 2015a). Several months after the 2014 fall turnover, in April 2015, total and dissolved phosphorus and orthophosphate concentrations measured at depth were within or below these pre-event concentration ranges reported in the PEEIAR (Figure 20).

From July to October, there was a greater degree of disparity in phosphorus concentrations between those measured at the surface and those measured at depth. Higher concentrations above the TP WQG range were reported at depth and these concentrations remained relatively stable over the summer months, whereas surface concentrations decreased to concentrations within or below the TP WQG range. The noted disparity was likely the result of lake stratification during the summer, such that after mixing during fall turnover, concentrations measured at the surface and at depth in November were similar. Sampling in Polley Lake was suspended in November due to the onset of winter conditions.

Golder (2016) concluded that in 2015 there were no event-related changes to phosphorus concentrations in Polley Lake based on an analysis of data collected from April through August 2015. This conclusion is supported by data collected from September through November shown on Figure 20.

3.2.4.2 Quesnel Lake

After the event, TP concentrations at depth exceeded the BC WQG range in the West Basin of Quesnel Lake, but were not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Golder 2015a). By fall turnover in 2014, TP concentrations had substantially decreased in the West Basin of Quesnel Lake. Through August 2015, TP concentrations were below the BC WQG range and resembled pre-event concentrations with the exception of a few intermittent exceedances at near-field station QUL-66, near the mouth of Hazeltine Creek (Golder 2016; Figure 21). At the near-field, mid-field, and far-field stations, dissolved phosphorus and orthophosphate concentrations reported between March and August were below pre-event concentrations (Golder 2016; Figure 21).

Collectively, an evaluation of the phosphorus data collected between March and August 2015 suggest that event-related changes of concern for phosphorus were not evident in Quesnel Lake (Golder 2016). After September 2015, total phosphorus concentrations were intermittently above the most conservative BC WQG at near-field station QUL-66, near the mouth of Hazeltine Creek, but did not exceed the drinking water BC WQG or the upper boundary of the aquatic life guideline. Dissolved and orthophosphate concentrations remained at or near the MDL through to the end of December 2015 (Figure 21).

4.0 SUMMARY OF CHANGES IN WATER QUALITY IN 2015

Based on the evaluation of water quality trends in this addendum, the following parameters remain as COPCs due to measured concentrations in December 2015 that remain above BC WQGs and CSR Standards (Table 2). A summary of water quality during 2015 in each receiving environment is provided below.

Table 2: Contaminants that Remain of Potential Concern in the Receiving Environment Based on Water Quality Monitoring as of December 2015

Waterbody	COPC: Physical ²	COPC: Total Metals	COPC: Dissolved Metals	COPC: Non-Metal Substances
Polley Lake	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>
Hazeltine Creek and Edney Creek	turbidity, TSS	copper, selenium	copper, selenium	<i>no substances</i>
Quesnel Lake	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>
Quesnel River	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>	<i>no substances</i>

Notes: TSS = total suspended solids

4.1.1 Hazeltine Creek

As described in Golder (2016), there were exceedances of total metal WQGs and CSR standards in Hazeltine Creek in the first half of 2015, mainly during turbid flow periods typically associated with elevated concentrations of particulate matter. Clear-flow conditions ensued upon the completion of channel stabilization activities that typically resulted in much lower concentrations of particulate matter and subsequently lower concentrations of total forms of various metals.

The majority of metals identified as COPCs by Golder (2016) had decreased to below guideline levels by mid-summer and remained stable through December 2015, with a few noted exceptions (e.g., beryllium, chromium, and cobalt at HAC-08/a). By December 2015, only total and dissolved copper consistently exceeded BC WQGs for the protection of aquatic life. Copper, turbidity and total suspended solids therefore remain the primary substances of concern in Hazeltine Creek.

Concomitant with the initiation of the authorized discharge of treated effluent in December 2015, selenium concentrations increased at HAC-05/a and HAC-08/a, located close to and downstream from the discharge location, respectively. Even though the most sensitive receptors to selenium (i.e., egg laying vertebrates) are either excluded (fish) or are limited in number (aquatic feeding birds), selenium is also conservatively flagged to be of concern in Hazeltine Creek. However, as discussed in Section 3.2.2.4, concentrations appear to have decreased in the first quarter of 2016 by 1- 2 times compared to the concentrations reported in December 2015.

Copper therefore remains the primary substance of concern in Hazeltine Creek based on the 2015 data. When the creek is subject to erosion resulting in turbid flow events, turbidity, TSS, and some other metals also exceed guidelines. Selenium is conservatively flagged to be of concern but concentrations appear to be decreasing following the initial discharge of treated effluent to the creek; and selenium will continue to be monitored as part of routine monitoring programs.

4.1.2 Polley Lake

Levels of TSS, turbidity, and copper were low in Polley Lake and remained below guidelines throughout 2015. With respect to nutrients, total phosphorus concentrations were within the range observed in Polley Lake prior to the event. Therefore no contaminants remained of concern by December 2015 in Polley Lake.

4.1.3 Quesnel Lake

Levels of TSS and turbidity were low in the far-field area of Quesnel Lake as well as in the West Basin and remained below guidelines throughout 2015, with the exception of some higher levels recorded in the near-field area at the mouth of Hazeltine Creek when turbid inflows from Hazeltine Creek were present from March to May 2015. Close to the mouth of Hazeltine Creek, turbidity progressively declined between June and December to levels close to or below background (1 NTU).

Within the West Basin, total copper was below applicable BC WQGs and CSR standards in the near-field, mid-field and far-field stations. Exceptions to this were instances where concentrations were above applicable BC WQGs between March and May in the near-field close to the mouth of Hazeltine Creek and to a lesser extent at the western mid-field station further away from the mouth. These higher total concentrations coincided with turbid flow periods in Hazeltine Creek and dissolved concentrations did not exceed BC WQGs. Other metals monitored at the Quesnel Lake stations in 2015 were below applicable BC WQGs and CSR standards.

In agreement with Golder (2016), phosphorus data collected throughout 2015 suggested that event-related changes of concern with respect to the potential for a change in lake trophic status were not evident in Quesnel Lake.

Based on the evaluation of the 2015 dataset, no contaminants remained of concern by December in Quesnel Lake.

4.1.4 Quesnel River

Similar to the eastern far-field area of Quesnel Lake, water quality in Quesnel River between March and August did not exhibit event-related changes that were identified to be of concern with respect to exceedance of water quality guidelines. Therefore no contaminants remained of concern by December 2015 in Quesnel River.

5.0 STATEMENT OF LIMITATIONS

This technical memorandum was prepared for the exclusive use of MPMC. The inferences concerning the data, site and receiving environment conditions contained in this memorandum are based on information obtained during investigations conducted at the site by Golder Associates Ltd. (Golder), other consultants and MPMC, and are based solely on the condition of the site at the time of the site studies and subsequent investigations and remediation and other information obtained by Golder, as described in this memorandum. Soil, surface water and groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors.

In evaluating the subject site and water quality data, Golder has relied in good faith on information provided. The factual data, interpretations and recommendations pertain to a specific project as described in this memorandum, based on the information obtained during the assessment by Golder on the dates cited in the memorandum, and are not applicable to any other project or site location. Golder accepts no responsibility for any deficiency or inaccuracy contained in this memorandum as a result of reliance on the aforementioned information.

The findings and conclusions documented in this memorandum have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this memorandum at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this memorandum, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this memorandum. All third parties relying on this memorandum do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder's memorandum or other work product. Golder is not responsible for any unauthorized use or modifications of this memorandum.

MPMC may rely on the information contained in this memorandum subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this memorandum, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein.

If new information is discovered during future work, including excavations, sampling, soil boring, predictive geochemistry or other investigations, Golder should be requested to re-evaluate the conclusions of this memorandum and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this memorandum is affected by any change of site conditions, purpose, development plans or significant delay from the date of this memorandum in initiating or completing the project.

6.0 CLOSURE

We trust that this Addendum provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at (604) 296-4200.

Table A1: Summary of Mount Polley TSF Breach Water Quality Monitoring Program, September to December 2015

Area	Station Name	Sample Location Type	Frequency	Comments
Polley Lake	P1	Routine	Monthly	
	P2	Routine	Monthly	
Upper Hazeltine	HAC-05	Routine	Weekly-Monthly	Weekly samples transitioned to monthly. Replaced by HAC-05a upstream of the bridge after 10/1/2015, except for one sample collected 12/22/2015.
	HAC-05a	Routine	Weekly	Established upstream of the Gavin Lake Road bridge to replace HAC-05 as of 11/2/2015.
	HAC-10	Routine	Weekly-Monthly	Weekly samples transitioned to monthly as of 5/4/2015.
Lower Hazeltine	HAC-01c	Routine	Weekly	Established at new outlet of HAC 7/31/2015. Discontinued 10/5/2015 due to lack of flow through lower sedimentation pond. Replaced by HAC-12.
	HAC-08	Routine	Weekly-Monthly	Temporarily replaced by HAC-08a downstream of the bridge between 8/6/2015 and 10/1/2015.
	HAC-08a	Routine	Weekly-Monthly	Temporarily sampled on 9/8/2015, in place of HAC-08.
	HAC-12	Routine	Weekly	Established 11/2/2015 to replace HAC-01/a/b/c. Located in the upper sedimentation pond.
	HAC-13	Routine	Weekly	Established in upper HAC, upstream of the discharge, on 12/3/2015.
Edney Creek	EDC-01	Routine	Weekly-Monthly	Weekly samples transitioned to monthly.
	EDC-02	Routine	Weekly	Downstream of confluence with HAC; discontinued after HAC/EDC redirected 7/25/2015.
Quesnel River	QUR-1	Routine	Weekly-Bi-weekly	Weekly samples transitioned to bi-weekly.
Quesnel Lake	QUL-2a	Routine	Weekly-Monthly	Weekly samples transitioned to monthly.
	QUL-18	Routine	Weekly-Monthly	Weekly samples transitioned to monthly.
	QUL-21a	Routine profile only	-	
	QUL-40a	Routine	Monthly	
	QUL-42	Routine	Monthly	In Mitchell Bay, east of HAC mouth and just before the sill. Established 9/17/2015.
	QUL-54	Routine profile only	-	Replaced by QUL-54a when HAC redirected 7/25/2015. However, was sampled weekly in October 2015.
	QUL-54a	Routine profile only	-	Established to replace QUL-54 when HAC redirected 7/25/2015. Discontinued after 10/5/2015 and replaced by QUL-57.
	QUL-55	Routine	Weekly	Discontinued and replaced by QUL-55a when HAC redirected 7/25/2015. However, was sampled weekly in October 2015.
	QUL-55a	Routine	Weekly	Established to replace QUL-55 when HAC redirected 7/25/2015. Discontinued 10/5/2015 and replaced with QUL-58.
	QUL-56	Routine profile only	-	Discontinued when HAC redirected 7/25/2015. Sampled weekly in October 2015.
	QUL-56a	Routine profile only	-	Established to replace QUL-56 when HAC redirected 7/25/2015. Sampled 7/28/2015, 10/1/2015, and 10/5/2015 only. Discontinued and replaced by QUL-59.
	QUL-57	Routine	Weekly	Located in the IDZ of the effluent discharge in QUL. Established 12/9/2015 as a replacement for QUL-54/54a.
	QUL-58	Routine	Monthly-Weekly	Located in the IDZ of the effluent discharge in QUL. Established 11/5/2015 to replace QUL-55/55a; transitioned to weekly sampling 12/2/2015.
	QUL-59	Routine	Weekly	Located in the IDZ of the effluent discharge in QUL. Established 12/2/2015 to replace QUL-56/56a.
	QUL-66a	Routine profile only	-	2015 sampling limited to October and November only.
	QUL-79	Routine profile only	-	2015 sampling limited to October and November only.
QUL-120a	Routine	Monthly		
QUL-ZOO-1	Profile only for zooplankton	-	Profiled 7/8/2015, 8/20/2015, and 9/10/2015.	
QUL-ZOO-7	Profile only for zooplankton	-	Profiled 7/8/2015, 8/20/2015, and 9/10/2015.	
QUL-ZOO-8	Profile only for zooplankton	-	Profiled 7/8/2015, 8/20/2015, and 9/10/2015.	

Notes

Routine samples were taken throughout the period according to 2015 Post-Breach Environmental Monitoring Plan

Routine stations are consistently monitored; typically either weekly, bi-weekly (every 2 weeks), monthly, or bi-monthly (twice per month)

HAC = Hazeltine Creek; EDC = Edney Creek; QUR = Quesnel River; QUL = Quesnel Lake; IDZ = initial dilution zone; ZOO = zooplankton station.

TABLE A2

**Tabulated Discrete Water Quality Grab Data Collected from
Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River,
September to December 2015**

Provided on CD

Memorandum

Date: April 8, 2016

To: Dale Reimer, Mount Polley Mining Corporation

From: Pierre Stecko, Minnow Environmental Inc.

Cc: Colleen Hughes, Katie McMahan, Mount Polley Mining Corporation
'Lyn Anglin, Imperial Metals Corporation

Re: Results of Diffusive Gradients in Thin Films Device Deployment – August to October 2015

The ongoing assessment of the impact to aquatic environmental health following the failure of the Mount Polley tailings dam in August 2014 includes monitoring of water and sediment chemistry. A number of evaluations have indicated low mobility of metals in Mount Polley tailings and tailings-influenced sediment (e.g., SRK 2015a,b; Minnow 2015a, 2016) and this has been supported by the results of water quality monitoring (Golder 2015). Water quality monitoring has focused on total and dissolved metals, both of which over-represent the metal fraction that is available for uptake by aquatic organisms in natural surface waters (i.e., free metal ions and weakly complexed metals, often referred to as the “labile” metal fraction).

This memorandum provides a brief summary and interpretation of metal concentration results associated with diffusive gradients in thin films (DGT) passive sampling devices deployed in waterbodies adjacent to the Mount Polley Mine from August to October 2015. The objective of the deployment of DGT devices in waterbodies adjacent to the Mount Polley Mine was to characterize concentrations of DGT-labile metal in water overlying sediments impacted by the Mount Polley Mine tailings dam failure relative to reference areas.

Background

DGT devices are small devices that contain a membrane filter, a gel diffusion layer and a gel binding layer (e.g., Davison and Zhang 1994). The devices are designed to accumulate labile (free and weakly complexed) substances by diffusion in a controlled manner. Labile metals are the fraction of metals that are considered to be potentially bioavailable (i.e., that can be readily transported across biological membranes of aquatic organisms; e.g., Campbell and Tessier 1996; Luoma and Rainbow 2008). DGT devices used in this

evaluation are optimized for metals and include a 0.45 μm Millipore™ cellulose nitrate membrane, a polyacrylamide gel diffusion layer, and a mixed binding layer composed of Chelex-100™ and Metsorb™ binding resins, all housed in a small polypropylene container approximately two inches in diameter (Panther et al. 2014). Only the membrane is exposed to the sampling environment (as a “window” in the DGT device). Labile metals diffuse through the membrane and gel diffusion layer and are captured in the resin. Following deployment for a time period that results in accumulation to detectable concentrations (but not to resin saturation, which can be calculated based on water chemistry data and avoided), the DGT devices are retrieved and the resin removed, digested, and analyzed. Analytical results are expressed as the mass of metal accumulated in the resin, which can also be used to back-calculate average labile metal concentrations during deployment. DGT-measured labile metal concentrations better represent the fraction of metals that are potentially bioavailable than do total or dissolved concentrations (e.g., Tusseau-Vuillemin 2004; Martin 2008; Simpson et al. 2012; Peijnenburg et al. 2014; Greenberg et al. 2014). This is because total metals include metals associated with particulate and dissolved binding materials (ligands), and dissolved metals include metals associated with binding materials (ligands) that are dissolved and those associated with very small particles and colloids (<0.45 μm in diameter).

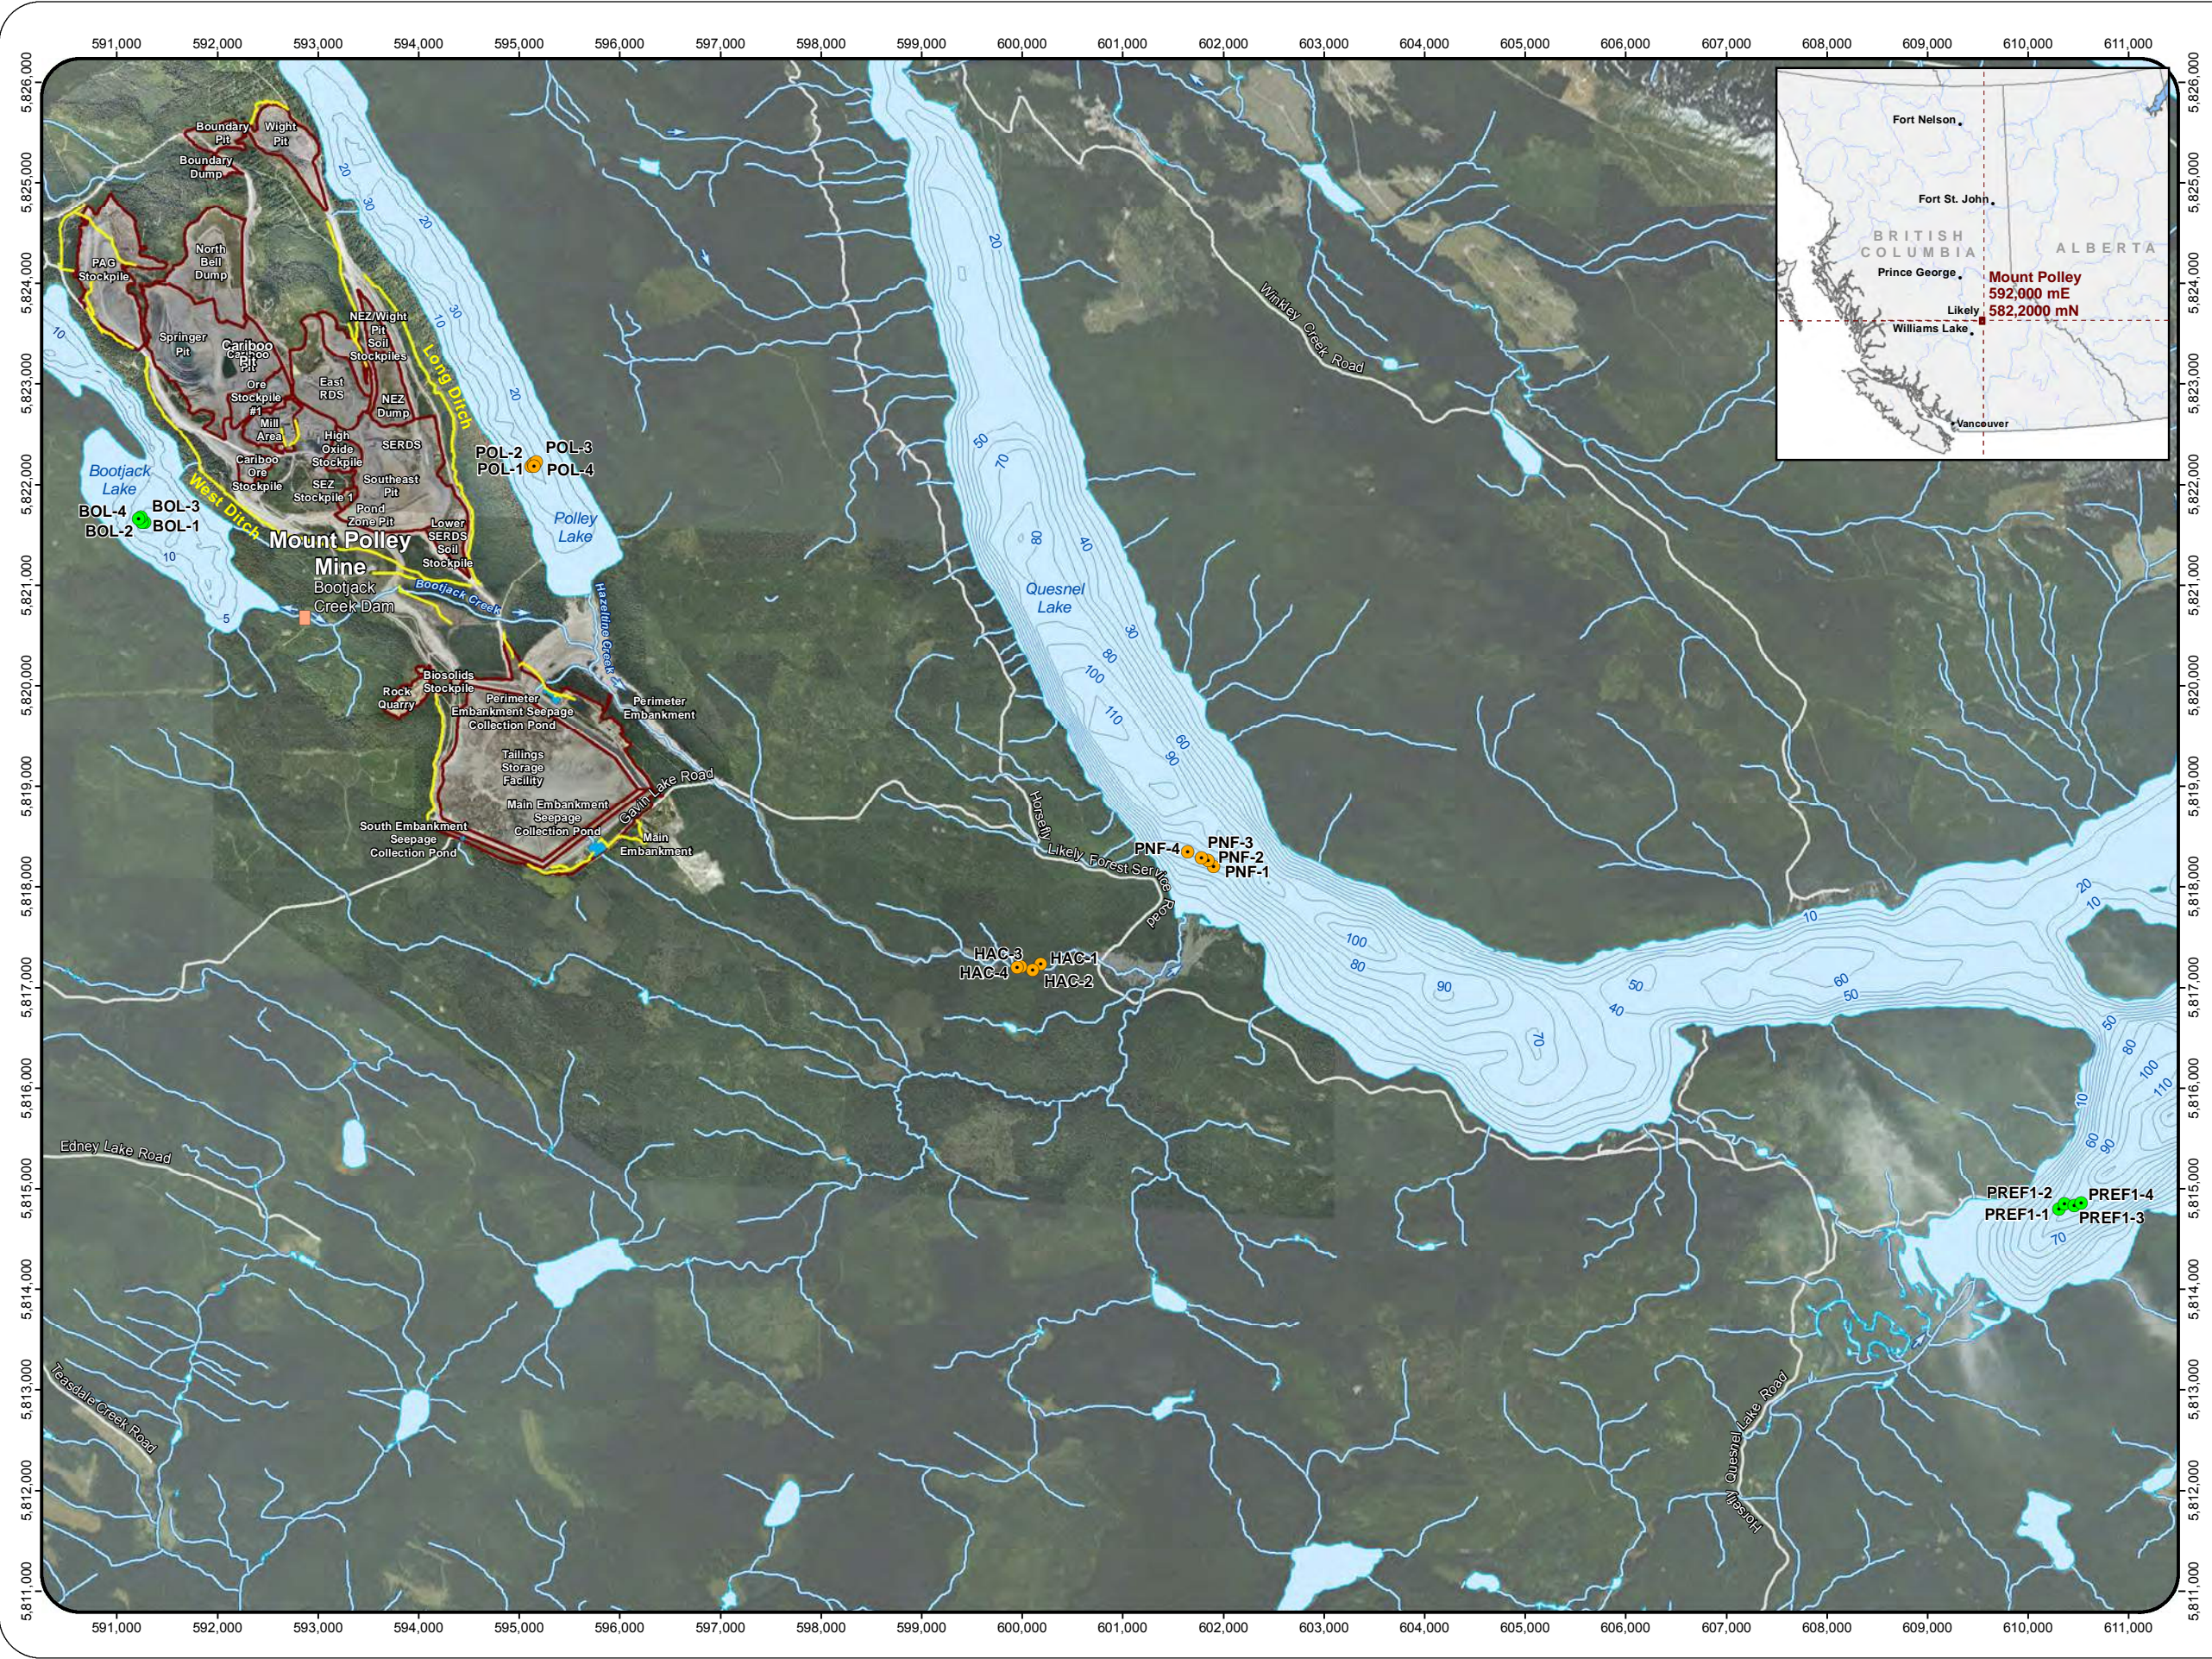

Methods

Study Design

A simple study was undertaken to characterize labile metal concentrations using DGT devices in water overlying sediments at areas impacted by the tailings dam failure, as well as at un-impacted reference areas. DGT devices were deployed at five areas from late August to early October 2015; two lake areas impacted by the tailings dam failure, two reference areas for the impacted lake areas, and Hazeltine Creek (Figure 1; Appendix Table A1). Four replicate DGT devices were deployed at each area.

Deployment and Retrieval

In lakes, DGT devices were installed in the lower water column approximately one meter above the sediment surface. This was achieved by placing a line with anchor and float at each sample location. A flat tray was placed above the anchor to prevent excessive sinking into the sediment. A loop was tied in the rope one meter above the tray and the DGT device was tied to the loop using fishing line. In Hazeltine Creek, DGT devices were placed in small pools within a canyon (Figure 1), where they were tied to a loop of rope, which was then tied to two brick anchors placed in the creek in a manner that kept them approximately 15 centimeters above the creek bottom. At the time of sampling, Hazeltine Creek was not

considered to be fish habitat as: 1) access to fish was blocked; and 2) it was subject to rehabilitation. During all DGT deployments, exposure to air was kept to a minimum (less than one minute) to avoid desiccation of the DGT devices.

DGT devices were retrieved 34 to 38 days after deployment (Appendix Table A1). DGT devices in Polley Lake, Bootjack Lake and Hazeltine Creek were retrieved by hand hauling, whereas DGT devices in Quesnel Lake (mean depth approximately 100 meters) were retrieved with the assistance of a commercial line hauler (Ace Line Hauler Brutus Plus 40). Upon retrieval, DGT devices were handled with care while wearing metal free disposable nitrile gloves. Particular care was taken not to touch the DGT window. Each DGT device was gently rinsed with metal free water and placed into a labelled glass soil jar with a few drops of metal free water to prevent desiccation. Jars were then placed into clean Ziploc™ bags and then into a dedicated cooler with ice packs, where they were maintained cool prior to transport to the field laboratory. At the field laboratory, the bagged jars were placed in a refrigerator and held until shipment to the analytical laboratory. After collection of all DGT devices, the DGT devices (in bagged jars) were placed in a cooler with frozen ice packs and a chain-of-custody form was prepared and packed with the samples. Coolers were shipped overnight for next day delivery to Maxxam Analytics (Burnaby, BC).

Supporting Measures

Supporting information collected at each deployment location included GPS (Geographic Positioning System) coordinates, sampling depth, Secchi depth (lakes only), field meter measurements of temperature, specific conductance, dissolved oxygen and pH (using a YSI EXO™ handheld portable field meter equipped with YSI EXO2™ Sonde), site photographs (including photographs of the DGT devices), and notes on the presence or absence of any fouling of the DGT devices. Supporting water samples were also collected from each sampling area, including field-filtered samples for dissolved analytes (0.45 µm filter). Water samples were placed into a dedicated cooler with frozen ice packs, where they were maintained cool prior to transport to the field laboratory where they were placed in a refrigerator and held until shipment to the analytical laboratory. At program completion, water samples were placed in a cooler with frozen ice packs and a chain-of-custody form was prepared and packed with the samples. Coolers were shipped overnight for next day delivery to ALS Environmental (Burnaby, BC).

Laboratory Analysis

Upon receipt of the DGT devices, Maxxam opened the coolers, measured temperature to verify the maintenance of cold samples, removed each device from the coolers, logged the sample, and assigned each sample a unique sample identification code. A sample receipt

confirmation was then sent to Minnow for verification. Laboratory analysis of the DGT devices involved dismantling the devices followed by digestion of the resin to provide a determination of total metal in the resin by ICP-MS (Inductively Coupled Plasma – Mass Spectrometry). Free metal ion was subsequently calculated by Maxxam based on total metal in the resin, water temperature during deployment, total deployment time, and manufacturer-supplied peer-reviewed diffusion coefficients, which, in turn, are based on Fick's first law of diffusion (Zhang and Davison 1995; Panther et al. 2014). Upon completion of the analyses, a data report was provided by Maxxam to Minnow electronically in Adobe Acrobat Portable Document Format (PDF; Appendix C) and in MSExcel. Similarly, upon receipt of the water samples, ALS Environmental opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and assigned each sample a unique identification code. A sample receipt confirmation was then sent to MPMC and Minnow for verification. Laboratory analyses included all analytes in the Mount Polley routine surface water quality monitoring program, including total and dissolved metals by ICP-MS. Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow electronically in Adobe Acrobat PDF (Appendix D) and in MSExcel.

Data Analysis

Upon receipt of the analytical data, a Data Quality Assessment (DQA) was completed, including an examination of data completeness, method detection limits achieved, field blank and travel blank results, laboratory precision, laboratory accuracy, and field precision. Following the completion of DQA, in-situ water quality data, DGT mass accumulation data, and DGT-based free metal concentration data were summarized by area, by calculating mean, standard deviation, standard error and 95% confidence limits. In-situ water quality data and DGT-based free metal concentration data were then evaluated by comparing concentrations of detectable analytes in failure-affected areas (Polley Lake and Quesnel Lake exposed area) to reference concentrations. In-situ water quality data and DGT-based free metal concentration data were also compared to British Columbia Water Quality Guidelines (BCWQG) for the protection of aquatic life (BCMOE 2016). Lastly, concentrations of DGT-detectable analytes were compared to total and dissolved concentrations.

Results

Supporting Measures

Supporting meter measurements indicated some differences between Polley Lake (impacted by the 2014 dam failure) and Bootjack Lake (reference), whereas conditions in

the impacted area of Quesnel Lake were very similar to the Quesnel Lake reference (Appendix Table A.2; Appendix Figures A.1 and A.2). Differences between Polley and Bootjack lakes included lower temperature and higher dissolved oxygen at depth in Polley Lake, as well as slightly higher pH and specific conductance throughout the water column of Polley Lake (Appendix Figure A.1). Specific conductance and pH of Hazeltine Creek were notably higher (up to 439 $\mu\text{S}/\text{cm}$ and 8.46 pH units; Appendix Table A.2) than at any of the other area evaluated.

Conventional Water Chemistry

Data Quality Assessment indicated good water data quality, meaning that data can be used with a high level of confidence for interpretation and the derivation of conclusions (Appendix B). Copper was the only analyte present at impacted areas at total concentrations greater than BCWQG (Appendix Table C.2). At Hazeltine Creek, which is not currently fish habitat, mean total copper concentration was 0.015 mg/L (compared to an applicable hardness-based 30-day BCWQG of 0.0083 mg/L). At the Quesnel Lake near-field exposed area, mean total copper concentration was 0.0021 mg/L (compared to a mean hardness-based 30-day BCWQG of 0.0023 mg/L), but total concentration at deployment (0.0027 mg/L) was slightly greater than the applicable BCWQG (Appendix Table C.2). Concentrations of total manganese and dissolved iron in water samples from reference Bootjack Lake were elevated relative to BCWQG at DGT deployment and retrieval, but were not similarly elevated at impacted areas (Appendix Table C.2).

DGT Device Results

Data Quality Assessment indicated good DGT data quality with the exception of one trip blank result that suggested contamination but was inconsistent with field blank results and individual sample results (Appendix B). A total of 13 metals accumulated in DGT devices to detectable concentrations (Appendix Table D.1). Four of these (copper, manganese, iron and zinc) were previously identified as Parameters of Interest (POIs) representing the chemical influence of the tailings dam failure on sediment quality (Minnow 2015a) and two more (phosphorus and molybdenum) were previously identified as POIs representing the chemical influence of the tailings dam failure on water quality (Golder 2015).

Examination of total, dissolved, and time-weighted average labile concentrations of the POIs (Appendix Table C.2 and Table 1, respectively) indicated that copper was the only DGT-detectable analyte with some concentrations greater than BCWQG (above) and a spatial pattern consistent with impact from the tailings dam failure (i.e., greater concentrations at the impacted lake areas than at reference lake areas; Figure 2a; Appendix Figures D.1 to D.6). DGT-labile copper concentrations were detectable in Hazeltine Creek

¹ open bars indicate less than detect results

and Polley Lake only (0.0056 ± 0.0005 mg/L and 0.00039 ± 0.00007 mg/L, respectively; Table 1 and Figure 2a). Despite average sediment copper concentrations of 823 mg/kg at Polley Lake versus 382 mg/kg at Bootjack Lake, and despite average sediment copper concentrations of 859 mg/kg at the Quesnel Lake profundal exposed area versus 55.1 mg/kg at the Quesnel Lake profundal reference area (Appendix Table D.3), near-bottom DGT-labile copper concentrations at all of these lake areas were ≤ 0.0004 mg/L (Figure 2a). This suggests limited mobility of the sediment-associated copper, which is consistent with previous observations of limited mobility and bioavailability of metals associated with Mount Polley tailings and tailings-influenced sediments (e.g., SRK 2015a,b; Minnow 2015a, 2016).

Concentrations of total copper greater than the 30-day BCWQG for the protection of aquatic life were observed at Hazeltine Creek and at the Quesnel Lake profundal exposed area (Appendix Table C.2). As previously indicated, Hazeltine Creek is not currently considered fish habitat. At the Quesnel Lake profundal exposed area, concentration of total copper was slightly greater than the 30-day BCWQG at deployment (0.0027 mg/L versus an applicable BCWG of 0.0023 mg/L) but not at retrieval (Appendix Table C.2). Dissolved copper was 54% of total, indicating that approximately half the total copper concentration was particulate (Figure 2b; Appendix Table D.3). DGT-labile copper was a fraction of total and dissolved (<13% and <25%, respectively; Figure 2b; Appendix Table D.3). This indicates that a substantial fraction of copper classified as dissolved after filtration using a 0.45 μm filter is not DGT-labile (i.e., is not in free ion and/or weakly complexed forms) and an even larger fraction of total metal is not DGT-labile.

Although copper was the only POI with a spatial pattern consistent with impact from the tailings dam failure, measurement of DGT-labile metal concentrations provided some perspective on water concentrations of several additional metals. Despite the near-bottom concentrations of total manganese and dissolved iron greater than BCWQG at Bootjack Lake (perhaps related to low near-bottom dissolved oxygen concentrations), DGT-labile concentrations were low and the DGT-labile fraction was 30% for iron and only 6% for manganese (Appendix Table D.3; Appendix Figures D.2 and D.3). This suggests that the majority of total and dissolved iron and manganese was in fine colloidal form unavailable to the DGT-device. Molybdenum was present at total concentrations well below BCWQG, but was highest at Hazeltine Creek and Polley Lake, suggesting some influence of proximity to the Mount Polley Mine (Appendix Figure D.4). The DGT-labile molybdenum fraction was highest at Polley Lake, where it was approximately 30% of total and dissolved concentrations (Appendix Table D.3). Phosphorus concentrations in Polley and Bootjack lakes were greater than the BCWQG range for lakes supporting salmonids, but were only DGT-detectable in Bootjack Lake, with DGT-labile concentrations of 24% and 34% of total

and dissolved phosphorus, respectively (Appendix Figure D.5; Appendix Table D.3). Lastly, one of the four replicate DGT-labile zinc results for Quesnel Lake was elevated (0.015 mg/L; Appendix Table D.1). Although this may represent an anomaly, verification is justified.

Summary

Measurement of DGT-labile metal concentrations (i.e., free metal ions and weakly complexed metals) in water near the bottom of lakes impacted by the Mount Polley Mine tailings dam failure (Polley Lake and Quesnel Lake) indicate DGT-labile metal concentrations that are a fraction of total and dissolved. For copper, the POI of greatest concern and the only DGT-detectable analyte with elevated total concentrations and a spatial pattern consistent with impact from the tailings dam failure, DGT-labile concentrations were less than 13% of total and less than 25% of dissolved concentrations in bottom waters of these lakes. These low concentrations add to the weight-of-evidence of the apparent post-depositional stability of the Mount Polley tailings and tailings-impacted sediment (e.g., SRK 2015a,b; Minnow 2015a, 2016).

Recommendations

DGT-devices provide a promising means of evaluating the mobility of metals associated with tailings-influenced sediments and tracking labile metal concentrations over time. It is therefore recommended that DGT devices are deployed in 2016 in areas impacted by the 2014 tailings dam failure. Lower method detection limits can likely be achieved by extending the deployment period.

B1.0 INTRODUCTION

Data Quality Assessment (DQA) was conducted on data collected as part of the Mount Polley Mining Corporation 2015 Diffusive Gradients in Thin Films (DGT) Device Deployment. The objective of the DQA is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

B1.1 Background

A variety of factors can influence the physical, chemical and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Inconsistencies in sampling or laboratory methods, use of instruments that are inadequately calibrated or which cannot measure to the desired level of accuracy or precision, and contamination of samples in the field or laboratory are just some of the potential factors that can lead to the reporting of data that do not accurately reflect actual environmental conditions. Depending on the magnitude of the problem, inaccuracy or imprecision have the potential to affect the reliability of any conclusions made from the data. Therefore, it is important to ensure that programs incorporate appropriate steps to control the non-natural sources of data variability (i.e., minimize the variability that does not reflect natural spatial and temporal variability in the environment) and thus assure the quality of the data.

Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. DQA involves comparison of actual field and laboratory measurement performance to data quality objectives (DQOs) established for a particular study, such as evaluation of method detection limits, blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). Only trusted and certified laboratories (e.g., analytical chemistry laboratories certified by Canadian Association for Laboratory Accreditation [CALA]) were involved in the current program and such certified laboratories have rigorous internal quality assurance programs that ensure the highest possible quality.

DQOs were established a-priori at the outset of the program to reflect reasonable and achievable performance expectations. Programs involving a large number of samples and analytes usually yield some results that exceed the DQOs. This is particularly so for multi-element scans since the analytical conditions are not necessarily optimal for every

element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the parameters fail to meet the DQOs. Overall, the intent of DQA is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of this project.

B1.2 Types of Quality Control Samples

Several types of quality control (QC) samples were assessed based on samples collected (or prepared) in the field and laboratory. These samples include the following:

- **Blanks** are samples of de-ionized water, sampling devices, and/or appropriate reagent(s) that are handled and analyzed the same way as regular samples. These samples will reflect any contamination that occurred in the field (in the case of field or trip blanks) or the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be non-detectable, although a data quality objective of twice the method detection limit allows for slight “noise” around the detection limit.
- **Fabrication Controls** are blank DGT resins that are digested and analyzed in the same manner as regular samples. The fabrication controls account for interferences or contamination from the DGT sampler components, storage and analysis.
- **Field Duplicates** are replicate samples collected from a randomly selected field station using identical collection and handling methods that are then analyzed separately in the laboratory. The duplicate samples are handled and analyzed in an identical manner in the laboratory. The data from field duplicate samples reflect natural variability, as well as the variability associated with sample collection methods, and therefore provide a measure of field precision.
- **Laboratory Duplicates** are replicate sub-samples created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.
- **Certified Reference Materials and QC Standards** are samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to target results

to provide a measure of analytical accuracy. The results are reported as the percent of the known amount that was recovered in the analysis.

B2.0 WATER SAMPLES

B2.1 Detection Limits

Method detection limits (MDLs) achieved by ALS Environmental for the supporting water samples were examined and assessed in all cases where sample results were reported as less than the MDL. For analytes for which a water quality guideline for the protection of aquatic life is available, the MDL should be lower than the guideline value (Table B.1). All reported MDLs were lower than the applicable guideline values (Table B.1), and were therefore of good quality for effective data interpretation.

B2.2 Laboratory Blank Sample Analysis

All laboratory blank results reported for the ALS Environmental laboratory reports L1666722, L1668250, L1684482, L1685536 (a total of 657 results) were non-detectable with the exception of a handful of results (0.6% of results; Appendix C). Detectable laboratory method blank results were reported for alkalinity and conductivity but in all cases the associated sample results were at least five times greater than the blank levels, therefore the sample results were deemed reliable by the laboratory (Appendix C). Overall, this indicates no inadvertent contamination of samples within the laboratory during analysis.

B2.3 Data Precision

Field Duplicate Samples

One duplicate water sample was collected in the field as part of the water sampling conducted to support the evaluation of Diffusive Gradient in Thin-Film (DGT) passive samplers deployed in Hazeltine Creek, Polley Lake, Bootjack Lake and Quesnel Lake. The duplicates showed excellent agreement in concentrations of all analytes except dissolved orthophosphate, dissolved phosphorus, and total silver which had relative percent differences (RPD) among the duplicates of 40.0%, 43.1%, and 57.1%, respectively (Table B.2). Although the data quality objective of a relative percent difference (RPD) of $\leq 25\%$ was not met for these three analytes, each analyte had low reported results, with one detectable and one undetectable result. Consequently, although the absolute difference was small (approximately 0.001 mg/L in the case of dissolved orthophosphate and dissolved phosphorus and < 0.00001 mg/L in the case of silver) the relative percent differences exceeded the DQO (Table B.2). Overall, the field

duplicate sampling did not indicate any inconsistencies in sampling technique nor issues that could impair data interpretability.

Laboratory Duplicate Samples

All laboratory duplicate results evaluated within laboratory reports L1666722, L1668250, L1684482, L1685536 (1,474 results in total) met ALS Environmental's data quality objectives for the parameters reported (generally < 25% RPD; Appendix C). Among the four laboratory reports, 34 laboratory duplicate samples were evaluated for dissolved metals and alkalinity, 33 for conductivity, 30 for pH, sulphate, and nitrate, and 29 samples were evaluated for nitrite. In addition, 25 laboratory duplicate samples were evaluated for the precision of fluoride, 23 for chloride, 17 for total nitrogen, 15 for ammonia, 13 for dissolved orthophosphate, 12 for total suspended solids and turbidity, and 11 for dissolved organic carbon. Ten laboratory duplicate samples were assessed for precision of total dissolved solids results, five samples for total metals and dissolved phosphorus, and three samples were evaluated for the precision of total phosphorus results. Overall, the laboratory precision achieved in this study is considered good.

B2.4 Data Accuracy

The accuracy of laboratory data from within laboratory reports L1666722, L1668250, L1684482, L1685536 was assessed based on the results of certified reference materials (CRM), laboratory control samples (LCS) and matrix spike samples (MS; Appendix C). Specifically, the following CRM samples were used among the four laboratory reports to assess the accuracy of various analyses; forty one CRM samples were analysed to assess the accuracy of pH and conductivity analyses, forty for alkalinity, twenty five for ammonia, sixteen for turbidity, nine for dissolved orthophosphate, five for dissolved phosphorus, and four CRM samples were used to assess the accuracy of total phosphorus analyses (Appendix C). Sixteen LCS samples were used to evaluate the accuracy of total nitrogen samples, twelve for total suspended solids and dissolved organic carbon analyses, and eleven samples were used to assess chloride, fluoride, nitrate, nitrite, and sulfate analyses accuracy. An additional ten LCS samples were used to assess the accuracy of total dissolved solids analyses, five for total metals, and four LCS samples were analysed to evaluate the accuracy of dissolved metals analyses (Appendix C). Finally, MS samples were also used to assess the accuracy of multiple parameters, with twenty eight MS samples used to evaluate the accuracy of dissolved metals, nitrite, and sulphate analyses, fourteen for ammonia and total nitrogen accuracy, eight for dissolved orthophosphate, eight for dissolved organic carbon, five for total metals and dissolved phosphorus

accuracy, and four MS samples used to assess the accuracy of total phosphorus analyses (Appendix C). All CRM, LCS, and MS results (a total of 1,479 results) met ALS Environmental's data quality objectives for accuracy (Appendix C) and thus laboratory accuracy associated with water samples in this study is considered excellent.

B2.5 Holding Time and General Laboratory Flags

Several hold times were exceeded due to the combination of short optimal hold times and remote sampling (Appendix C). Analytes for which recommended hold times were exceeded included nitrate/nitrite (3-day hold time), pH (15-minute hold time), dissolved phosphorus (3-day hold time), turbidity (3-day hold time), and dissolved orthophosphate (3-day hold time). Results associated with the hold time exceedances appear not to have been affected as they were comparable to those associated with samples where hold times were met, or comparable to field measures in the case of pH. Furthermore, water samples were collected primarily to provide supporting water metals concentration data for the deployed Diffusive Gradient in Thin-Film (DGT) passive samplers and hold time for metals analyses were not exceeded, therefore the observed hold time exceedances will not affect data interpretability. There were no general laboratory flags associated with the water quality data (Appendix C).

B3.0 DGT SAMPLES

B3.1 Detection Limits

Method detection limits (MDLs) and reporting detection limits (RDLs) achieved by Maxxam for the DGT devices were reported for both mass analyses and for estimated average water concentrations (Appendix D). Data quality assessment of MDLs and RDLs is focussed on the average water concentrations as these are ultimately the data of greatest interest, and because water quality guidelines for the protection of aquatic life are available, the MDLs and RDLs should be lower than the guideline value. Of the analytes for which estimated average water concentrations were reported (27 analytes), some less than MDL or RDL results were returned for all but three analytes due to very low concentrations (Appendix D). However, all MDLs were well below water quality guidelines and RDLs for all but one analyte were below water quality guidelines (Table C.3). This exception occurred for chromium, where the RDL (0.0016 mg/L) was slightly greater than the guideline of 0.001 mg/L. Overall, detection limits were good and appropriate for data interpretation. In addition, chromium, the only analyte with a RDL greater than guideline, as not been identified as a parameter of interest within the study area.

B3.2 Laboratory Blank Sample Analysis

Results for the analysis of four blanks were reported in association DGT analyses – two water blanks and two method blanks. All analytes except sodium were reported as below MDL or RDL (Appendix D). This result does not indicate contamination; rather is due to a digestion solution that contains sodium (sodium hydroxide). Furthermore, all DGT data for sodium were reported as less than MDL.

B3.3 Fabrication Controls

Three fabrication control results were reported in association DGT analyses and returned results below MDL or RDL for all analytes except sodium (Appendix D). As noted above, this result does not indicate contamination; rather is due to a digestion solution that contains sodium (sodium hydroxide). Furthermore, all DGT data for sodium were reported as less than MDL.

B3.4 Field Blank Sample Analysis

Two field blanks and one trip blank were included in the program. The two field blanks returned results below MDL or RDL for all analytes (Appendix D). The trip blank returned results below MDL or RDL for all analytes except copper (Appendix D). Based on this

Table B.3: Laboratory method detection limit (MDL) evaluation for DGT-estimated average water concentrations relative to guidelines. Highlighting indicate MDLs that did not meet guideline.

Metal	Units	British Columbia Water Quality Guidelines ¹		Application (d or t)	MDLw	RDLw

¹ British Columbia Water Quality Guidelines (BCMOE 2015a,b) except for molybdenum, which is the Canadian Water Quality Guideline (CCME 2015).

² at lowest applicable hardness of 50 mg/L

result (1.06 ug in the gel), a request was sent to the analytical laboratory for re-analysis, which confirmed the original result, suggesting contamination. Despite this results, there was no evidence of contamination in the field sample results – all reference results were less than RDL (<0.39 ug) and all results from exposed areas showed good agreement among replicates.

B3.5 Data Accuracy

Spikes of cadmium, thallium and uranium were added to method blanks and DGT resins to evaluate recovery. In all cases, recovery was well within the acceptable range (Appendix D).

B3.6 Holding Time and General Laboratory Flags

There were no hold time exceedences or general laboratory flags associated with the DGT samples (Appendix D).

B4.0 DATA QUALITY STATEMENT

Water quality data collected in support of the Diffusive Gradient in Thin-Film passive sampler deployment at the Mount Polley Mine were of good quality. This was characterized by good detectability, negligible analyte concentrations in method blanks, good field and laboratory precision, and good laboratory accuracy. Therefore, the supporting water quality data can be used with a high level of confidence in the derivation of conclusions. Similarly, the DGT data were characterized by good detectability, as well as negligible analyte concentrations in most blanks and all fabrication controls. Copper was detected in a trip blank, suggesting contamination, but was not supported by results from two field blanks, nor in the field samples themselves, which had low concentrations in reference areas and higher concentrations with good agreement among stations at the exposed areas. Although this data point is considered to most likely represent an anomaly, it does detract from the overall confidence in DGT copper results.

¹ British Columbia Water Quality Guidelines (BCMOE 2015a,b) except for molybdenum, which is the Canadian Water Quality Guideline (CCME 2015).

² Hardness value of 50 mg/L is representative of Quesnel Lake and Bootjack Lake, 130 mg/L is representative of Polley Lake, and 200 mg/L is representative of Hazeltine Creek. However, exact hardness values were used in the data screening presented in Table C.2.

³ Applicable to low chloride water (<2 mg/L chloride) as observed at all sampling locations.

⁴ Ammonia guideline values were selected based on a high pH (8.4) and temperature (15°C)

⁵ Applicable to lakes where salmonids are the predominant fish species

⁶ Guideline for Chromium VI (0.001 mg/L) was selected, as this is the principal species found in surface waters.

⁷ 30-d guideline when hardness is greater than 90 mg/L is $7.5 + 0.75(\text{hardness} - 90)$ and maximum is $33 + 0.75(\text{hardness} - 90)$

DGT MASS ANALYSIS REPORT

MAXXAM JOB #: B5K6077 (C.O.C. #08412522, #08412523, #08412524)

Maxxam (Burnaby) Job #: B588897

Received: 2015/10/09, 08:30 AM

Sample Matrix: SOLID (DGT)
Samples Received: 23

Analyses	Quantity	Instrumental Analysis	Primary Reference
Free metals in DGT units	23	CAM SOP-00447	DGT Research, Technical Document

Remarks:

DGT water samplers loaded with Chelex-Metsorb resin gel were purchased from Griffith University (Brisbane, Australia). Samplers were received by Maxxam and were shipped to the client as received, on ice.

Upon receipt after deployment, DGTs were digested along with 3 fabrication controls, 4 blanks and 4 spikes for quality control purposes. The procedures for instrumental analyses were based on CAM SOP-00447/16 with some deviations due to the different nature of the matrix. The sample preparation and digestion procedures were in line with the practices recommended by the DGT Supplier^{1, 2} and with the additional method optimization by Maxxam.

¹DGT – for measurements in waters, soils and sediments. Technical Documentation published by DGT Research Ltd. <http://www.dgtresearch.com/dgtresearch/dgtresearch.pdf>

²Panther, J., Bennett, W., Welsh, D. and Teasdale, P. (2014). Simultaneous measurement of trace metals and oxyanion concentrations in water using Diffusive Gradients in Thin Films with a Chelex-Metsorb mixed binding layer. *Analytical Chemistry*, 86, 427-434.

Due to the extent of the deviations taken from the stated SOP, this analysis is not considered as accredited. This analysis has not been fully validated. A detailed description of the DGT preparation, digestion, analysis, and calculation of metal detection limits is available upon request.

The Chelex-Metsorb resin is selective towards di- and tri-valent cationic metal species and oxyanionic species; as a result, monovalent metal species including Lithium (Li), Sodium (Na), Potassium (K), and Silver (Ag) have extremely low affinity and data for these metals should be interpreted with caution. Similarly Calcium (Ca),

despite being divalent is known to have a low affinity for this resin. Titanium cannot be reported because the Chelex-Metsorb is a titanium-based resin.

We trust this report is sufficient for your purposes. If you have any questions or concerns, please do not hesitate to contact the undersigned.

Sincerely,

A handwritten signature in blue ink that reads "Heather Lord." The signature is written in a cursive, flowing style.

- 1 – Metal has very low affinity for the resin
- 2 – Metal cannot be reported when using Chelex-Metsorb resin (titanium based resin)
- 3 – MDL and RDL were raised due to presence in the fabrication controls and/or blanks (see QA report)

Notes:

- a. The data presented here have not been rounded due to the wide range of concentrations reported and to facilitate further data manipulation. In any final data presentation, only two significant figures should be reported.
- b. <MDL: Target compound not detected (below Method Detection Limit).
- c. <RDL: Target compound detected above MDL but below Reporting Detection Limit.

- 3 – MDL and RDL were raised due to presence in the fabrication controls and/or blanks (see QA report)

Notes:

- a. The data presented here have not been rounded due to the wide range of concentrations reported and to facilitate further data manipulation. In any final data presentation, only two significant figures should be reported.
- b. <MDL: Target compound not detected (below Method Detection Limit).
- c. <RDL: Target compound detected above MDL but below Reporting Detection Limit.

Analyses	Quantity	Lab Analyses	Primary Reference
Free metals in water by DGT	23	CAM SOP-00447	DGT Research, Technical Document

Remarks:

This report provides the estimated integrated water concentrations during the DGT sampler deployments. Accumulated masses of free metals in the DGT devices have been reported separately for the above-noted job number.

Water concentrations were estimated based on the masses of free metals accumulated in the DGT devices along with the reported average temperature and deployment time, known diffusion coefficients and physical properties of the DGT devices.

We trust this report is sufficient for your purposes. If you have any questions or concerns, please do not hesitate to contact the undersigned.

Sincerely,

Heather Lord, Ph.D.
Manager, Environmental R&D
Maxxam Analytics Corporation

Angel Rodriguez-Lafuente, Ph.D.

- 1 DLs increased due to presence in the fabrication control or in the method blanks
- 2 DLs increased due to presence in the trip blank or in the field blanks
- 3 No gel or water diffusion coefficient reported, water concentrations cannot be calculated
- 4 Metal has low affinity for the resin; reported values should be interpreted with caution
- 5 Metal cannot be reported when using a Chelex-Metsorb resin
- 6 Metal present as oxyanion

MDLw – Method Detection Limit in water
 RDLw – Reporting Detection Limit in water
 C_w – Estimated concentration in water

MDLw – Method Detection Limit in water
 RDLw – Reporting Detection Limit in water
 C_w – Estimated concentration in water

Quality Assurance Notes

1. Estimated water concentrations (C_w), Method Detection Limits (MDL_w) and Reporting Detection Limits (RDL_w) were calculated using the average temperature and DGT deployment times reported by the client.
2. A single average Detection Limit is reported for samples from the same site as the temperature and deployment time variability was considered to be not significant compared with analytical variance.
3. The following DGT specifications, provided by the supplier, were used for the water concentration estimations:
 - Diffusive layer thickness, gel plus membrane, (Δg) = 0.90 mm
 - Area of exposed diffusive layer = 3.14 cm²
 - Volume of resin = 0.2 mL
4. Diffusion coefficients in diffusive gel at 25 °C were taken from the Technical Documentation published by DGT Research LTD and other published literature values. Where diffusion coefficients in the diffusion gel were not available, water diffusion coefficients at 25°C were used. Diffusion coefficients at 25 °C were, in turn, used to calculate the diffusion coefficients at the average temperature of deployment.
5. Diffusion coefficients for Bi, B and Sn were not reported in the available sources and therefore water concentration estimates for these metals have not been included in this report. These can be calculated in the future if appropriate diffusion coefficients become available.
6. The Chelex-Metsorb resin is selective towards di- and tri-valent cationic metal species and oxyanionic species; as a result, monovalent metal species including Lithium (Li), Sodium (Na), Potassium (K), and Silver (Ag) have extremely low affinity and data for these metals should be interpreted with caution. Calcium (Ca), despite being divalent, is also known to have a low affinity for this resin.
7. Titanium (Ti) cannot be reported when using a Chelex-Metsorb mixed binding layer because Metsorb is a titanium-based resin.
8. All results have been rounded to two significant figures.
9. All DGTS, including fabrication controls, trip blanks and field blanks were from the same lot of DGTS, obtained from the supplier at the same time. Trip blanks and field blanks were shipped to accompany the deployed DGTS while the fabrication controls were retained in the lab for QC purposes. Copper was detected in the trip blank DGT (N14283), which was shipped to the field, double sealed in zip-lock bags and stored by the client along with the field blanks during the deployment. We note that copper was not detected in the laboratory method blank prepared from the same reagents that were used for all of the resin digests. Copper was also not detected in any of the fabrication controls or most importantly, any of the field blanks. Because of this we suggest the presence of copper in the trip blank may be considered as spurious and we determined that it was not necessary to increase the copper Detection Limits of estimated water concentrations.

Re: Sediment Quality Data Report - August 2015 Collections

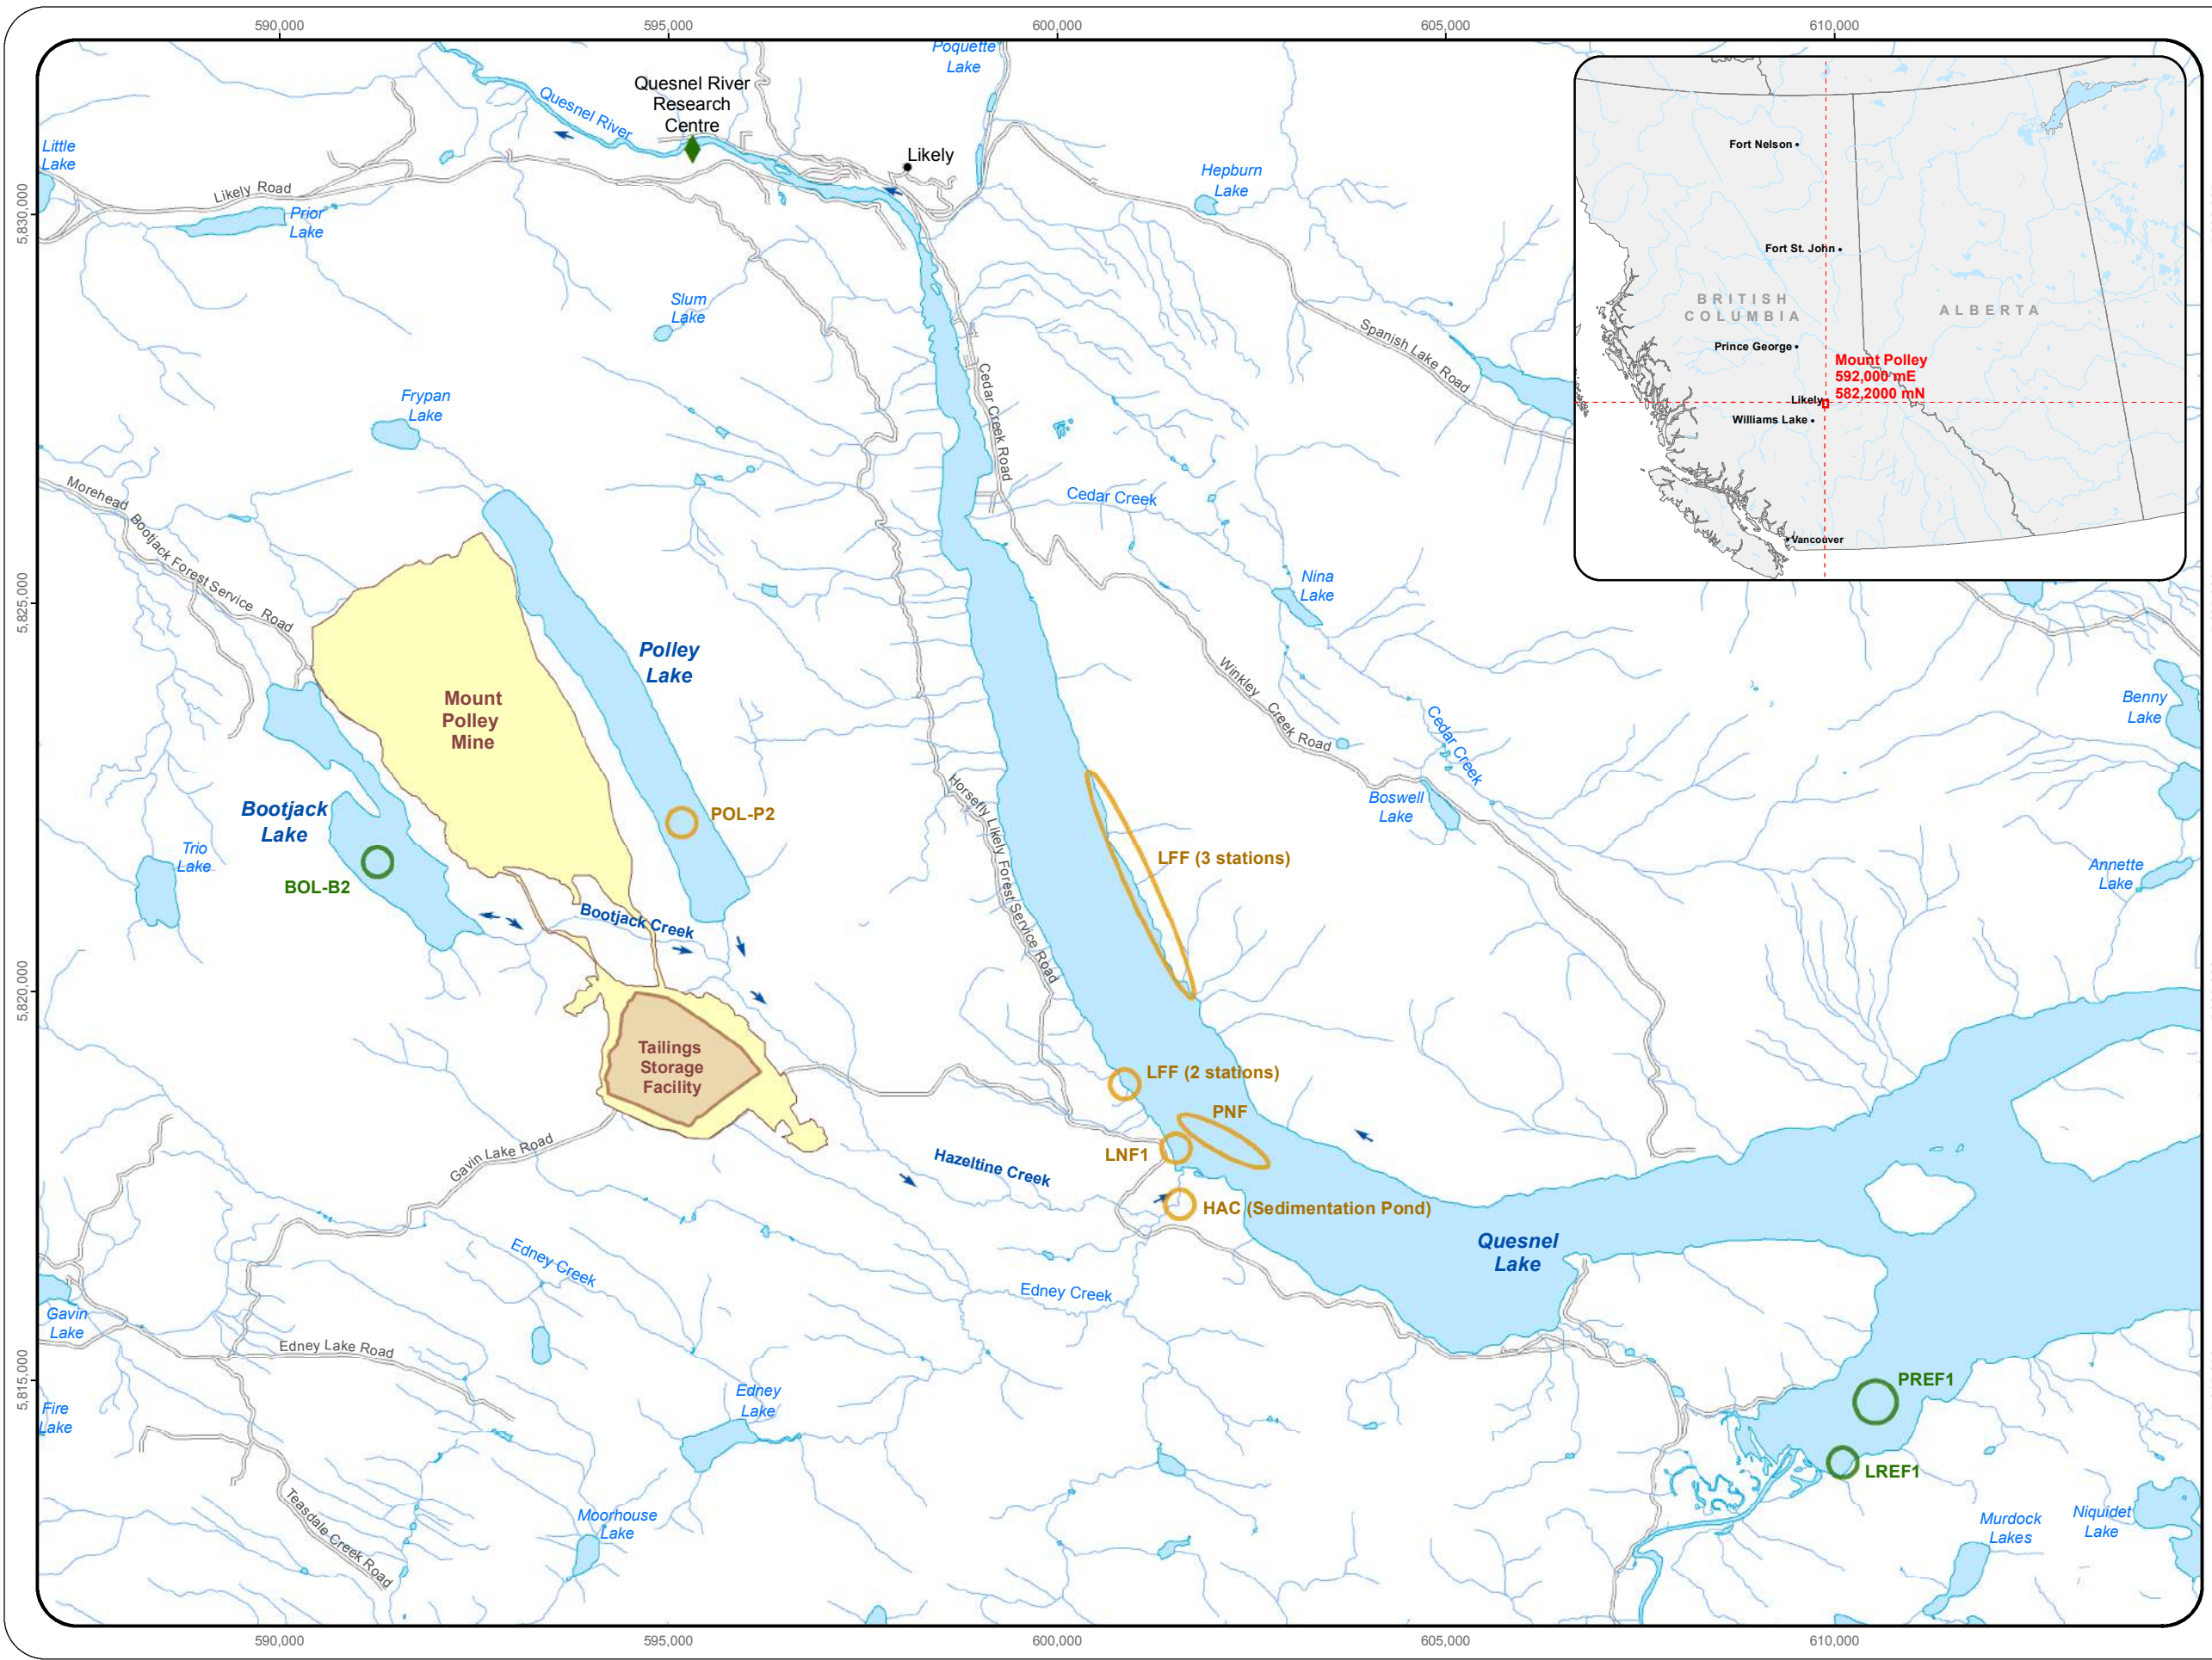

This memorandum provides a brief summary of sediment quality data collected by Minnow Environmental Inc. on behalf of the Mount Polley Mining Corporation (MPMC) in the vicinity of the Mount Polley Mine (Figure 1). Sediment samples were collected in August 2015 from three waterbodies (Polley Lake, Hazeltine Creek and Quesnel Lake) affected by the August 4th 2014 failure of the Mount Polley Tailings Dam and from corresponding reference areas. The purpose of this memorandum is to provide data to be used by Golder Associates in a Detailed Site Investigation Report required under the British Columbia Contaminated Sites Regulation (Government of British Columbia 1996).

Methods

Sediment samples were collected between August 13th and 26th 2015 at stations in Polley Lake, Bootjack Lake, the Hazeltine Creek Sedimentation Pond and Quesnel Lake (Figure 1; Appendix Table A.1). Where possible, samples were collected from the same locations and using the same methods as in 2014 (Minnow 2015).

Sampling

Briefly, in Polley and Bootjack lakes, sediments for the analysis of metals and total organic carbon (TOC) were collected using a Kajak-Brinkhurst (KB) corer in accordance with technical guidance for gravity coring outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for Environmental Effects Monitoring (EEM; Environment Canada 2012). Sediment samples for particle size distribution were collected using a petite ponar grab sampler (15.24 cm x 15.24 cm; 0.023 m² sampling area). Five replicate stations were sampled to represent each area (Appendix Table A.1). All core samples were extruded into a core collar and then cut using a core knife to collect the top 3 cm of sediment, which was then transferred into a

Figure 1: Mount Polley Sediment Quality Monitoring Areas, August 2015.

250 mL glass sampling jar labeled with the project number, sample location and collection date. The procedure was then repeated to provide a composite sample of sufficient volume for the required analyses. All sampling equipment was rinsed between stations using site water

In Quesnel Lake, sediment samples from littoral habitats were collected using a stainless steel petite ponar grab sampler and sediment samples from profundal habitats were collected using a stainless steel petite or standard ponar grab sampler (22.86 cm x 22.86 cm; 0.052 m² sampling area) in accordance with technical guidance outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for EEM (Environment Canada 2012). Profundal grab samples (mean depth approximately 100 meters) were collected with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). Three to five replicate stations were sampled to represent each sampling area (Appendix Table A.1). At each station, composite samples of the top three centimeters of surficial sediment of three to ten acceptable grabs (i.e., full to each edge of the sampler) were collected. Each grab was collected into a plastic tote and observed for completeness and any unusual characteristics. If the sample was deemed acceptable, surficial material to a depth of 3 centimeters was transferred to a second tote using a stainless steel spoon. Remaining sediment was discarded. The procedure was then repeated for all subsequent grabs. The material within the tote was homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars labeled with the project number, sample location and collection date. All sampling equipment was rinsed between stations using site water.

In the Hazeltine Creek Sedimentation Pond, sediment samples were collected using a stainless steel spoon. Five replicate stations were sampled to represent each sampling area (Appendix Table A.1). At each sampling station, a composite sediment sample was prepared from ten spoons of sediment. Surficial sediment was carefully collected to ensure the capture of a uniform depth (top 3 cm) and to limit disturbance that could result in loss of fines. Each spoonful was placed into a plastic tote. After ten scoops were collected, the material within the tote was homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars labeled with the project number, sample location and collection date. All sampling equipment was rinsed between stations using site water.

Field duplicate (split) sediment samples were collected at a frequency of 10% for quality assurance/quality control (QA/QC) purposes. Supporting information collected at each

sampling site included GPS (Geographic Positioning System) coordinates, sampling depth, Secchi depth (lakes only), field meter measurements of temperature, specific conductance, dissolved oxygen and pH (using a YSI EXO™ handheld portable field meter equipped with YSI EXO2™ Sonde), site photographs (including photographs of sediment samples), and notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). Immediately after collection, samples were placed into a cooler with ice packs, where they were maintained cool prior to transport to the field laboratory where they were placed in a refrigerator and held until shipment to the analytical laboratory. Sediment samples were shipped to the analytical laboratory (ALS Environmental, Burnaby BC) at minimum frequency of weekly. Prior to shipment, samples were placed in a cooler with frozen ice packs and a chain-of custody form was prepared and packed with the samples. Coolers were shipped overnight for next day delivery to ALS Environmental.

Laboratory Analysis

Upon receipt, ALS Environmental opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and assigned each sample a unique sample identification code. A sample receipt confirmation was then sent to MPMC and Minnow for verification.

Laboratory analysis included moisture content, pH, particle size distribution, total organic carbon content, total nitrogen concentration, and metal concentrations. Total organic carbon content and metal concentrations were determined in the silt/clay fraction (<63 µm diameter) in accordance with recent recommendations by the British Columbia Ministry of Environment (BCMoE 2012) and because sediment quality characterization conducted in 2014 indicated similar results in <63 µm and <2 mm sediments (Minnow 2015). Upon completion of the analyses, data reports were provided by ALS Environmental to MPMC and Minnow electronically in Adobe Acrobat Portable Document Format (PDF) and as MSEXcel files.

Data Analysis

Upon receipt of the analytical data, a Data Quality Assessment (DQA) was completed, including an examination of data completeness, method detection limits achieved, laboratory precision, laboratory accuracy, and field precision. Following the completion of DQA, sediment quality data were summarized by area, by calculating mean, median, standard deviation, standard error, 95% confidence limits, minimum and maximum. Data

were then evaluated in comparison to Contaminated Sites Regulation (CSR) criteria (Government of British Columbia 1996) and reference concentrations.

Environmental matters pertaining to contaminated sites in British Columbia generally fall under the jurisdiction of the BC Ministry of the Environment pursuant to the *Environmental Management Act (EMA)* (Government of British Columbia 2003). The key regulations under the *EMA* relating to the assessment and remediation of contaminated sites are the Contaminated Sites Regulation (Government of British Columbia 1996) and the Hazardous Waste Regulation (HWR; Government of British Columbia 1988). Within the CSR, numeric criteria for sediment listed in Schedule 9 (Government of British Columbia 1996) are used to determine if sediments are contaminated. CSR criteria have been defined for a limited number of analytes for sensitive and typical sediment environments. Sensitive sediment is defined as sediment at a site with sensitive aquatic habitat (e.g., spawning habitat) and for which sensitive management objectives apply, and typically apply to the ecologically active zone (top one meter) of sediments in an aquatic receiving environment (BCMoE 2013). Typical sediment is defined as any sediment that is not sensitive sediment (BCMoE 2013).

Reference values contained within this memorandum fall into two categories - pre-event data and data collected at reference sites in 2014 and 2015. Pre-event and reference data were compiled and used to calculate reference screening values. For each pre-event or reference dataset, 95th percentile values were calculated and compared. The highest pre-event or reference 95th percentile value was then used to screen the data from the exposed areas to identify analytes present at impacted areas at concentrations greater than pre-event and/or reference.

Results

Data Quality Assessment indicated good sediment data quality, meaning that data can be used with a high level of confidence for interpretation and the derivation of conclusions (Appendix C).

Polley Lake

Sediment collected from Polley Lake in 2015 (from the south side of the lake at Station POL-P2; Figure 1) was predominantly silt and clay, and was similar in particle size distribution to sediments collected in 2014 and from the reference lake (Bootjack Lake; Table 1; Appendix Table D.1). As observed in 2014, total organic carbon (TOC) content was lower in Polley Lake than reference (Table 1).

Table 1: Summary sediment quality data for Polley Lake and Bootjack Lake sampling areas, Mount Polley Mine, 2014 and 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

¹ Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

² Contaminated Sites Regulation (Government of British Columbia 1996).

³ Reference 95th percentiles for 2015 data were calculated using data displayed in Appendix Table D.1. For calculation of 2014 and Historical Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

⁴ t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

Sediment metal and nitrogen concentrations at Polley Lake (sampling area POL-P2) in 2015 were also very similar to those observed in 2014. Arsenic and copper were the only analytes with concentrations greater than the CSR “sensitive” criteria and reference (Table 1; Appendix Table D.1).

Copper was the only analyte with concentrations greater than the CSR “typical” criterion and reference (Table 1; Appendix Table D.1). However, copper in reference Bootjack Lake and in Polley Lake prior to the dam failure also exceeded the CSR “typical” criterion (Table 1). In 2015, the mean copper concentration in Polley Lake sediment exceeded reference by approximately 2.2-times and the CSR “typical” criterion by approximately 3.4-times (Table 1).

Hazeltine Creek Sedimentation Pond

Sediment collected from the upper Hazeltine Creek Sedimentation Pond in 2015 (Figure 1) was primarily silt and clay (92.5%), and had lower sand content than sediment collected from lower Hazeltine Creek in 2014 (Table 2; Appendix Table D.2). The high fines (silt and clay) content of this sediment was noted during 2015 field collections. Similar to 2014, the TOC content of sediment collected in 2015 was lower than observed in Hazeltine Creek pre-event (Table 2).

Metal concentrations in sediments collected in 2015 were similar to those observed in 2014, as was the nitrogen content. Arsenic and copper were the only analytes to exceed the CSR “sensitive” criteria and pre-event concentrations in Hazeltine Creek in 2015 (Table 2; Appendix Table D.2). In 2014, concentrations of both arsenic and copper exceeded the CSR “sensitive” criteria, but arsenic did not exceed pre-event concentrations (Table 2). The higher arsenic concentrations observed in 2015 are likely due to the finer particle sizes encountered in 2015.

As observed in 2014, concentrations of copper exceeded the CSR “typical” criterion as well as pre-event concentrations (Table 2; Appendix Table D.2). Copper was the only analyte to exceed the “typical” CSR criterion, with the 2015 mean copper concentration exceeding this criterion by approximately 2.0 times on average, and exceeding pre-event concentrations (in lower Hazeltine Creek) by 11.2 times on average (Table 2).

Quesnel Lake Littoral

Sediment collected from the littoral near-field area of Quesnel Lake in 2015 (LNF; Figure 1) was predominantly sand (82.4%), and had a higher sand content than sediment

Table 2: Summary sediment quality data for samples collected in lower Hazeltine Creek in 2014 and collected in the Hazeltine Creek Sedimentation Pond in 2015, Mount Polley Mine. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

¹ Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

² Contaminated Sites Regulation (Government of British Columbia 1996).

³ For calculation of Historic Hazeltine Creek 95th percentiles see Minnow (2015).

⁴ t*SE = [T distribution critical value][Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

collected from this location in 2014 (49.2%; Table 3; Appendix Table D.3). This difference in sediment composition was evident during sample collection in the field, and the decrease in the fines (silt and clay) content of sediment (49.7% in 2014, and 15.6% in 2015) may be a result of washing of fine sediment from these locations between August 2014 and August 2015. The particle size distribution of sediment collected in the littoral far-field area (Figure 1) was similar in 2014 and 2015, and was also similar to sediment collected in the Quesnel littoral reference area. As observed in 2014, the TOC content of sediment in 2015 was lower in the near-field area than in the far-field or reference areas (Table 3; Appendix Table D.3).

Concentrations of nitrogen and metals in the <63 µm (silt and clay) fraction of sediment collected from the near-field area were similar in 2014 and 2015 despite the differences in particle size distribution (Table 3). This similarity in sediment chemistry suggests that fines remaining in the near-field area were event-affected. However, aquatic organisms inhabiting this sediment would be exposed to the whole sediment, not solely the fines (<63 µm) fraction. In the far-field area, sediment concentrations of nitrogen and metals were also similar in 2014 and 2015.

As in 2014, arsenic and copper were the only analytes to exceed the CSR “sensitive” criteria as well as reference concentrations in the near-field area (Table 3; Appendix Table D.3). Copper was the only analyte in the near-field area with concentrations exceeding the CSR “typical” criterion and reference concentrations, as was also observed in 2014. The mean copper concentration of Quesnel Lake near-field area sediment exceeded the CSR “typical” criterion by approximately 2.7 times on average, and exceeded reference by approximately 13.2 times on average (Table 3). The concentrations of metals in sediment from the far-field area did not exceed CSR criteria or reference concentrations, and were generally lower than those observed in the near-field area. For instance, mean sediment arsenic and copper concentrations observed in the far-field area were approximately 3.7 and 9.8 times lower, respectively, than in the near-field area in 2015 (Table 3).

Quesnel Lake Profundal

Sediment collected from the Quesnel Lake profundal near-field area (Figure 1) was composed primarily of silt and clay (93%), with a particle size distribution similar to that observed in 2014, but which had a higher clay content (35.5%) and lower sand content (7.0%) than observed in the Quesnel Lake profundal reference area (Table 4; Appendix Table D.4). The TOC content of sediment from the near-field area was lower than that observed at the reference area, as was also observed in 2014 (Table 4).

Table 3: Summary of sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014 and 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

¹ Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

² Contaminated Sites Regulation (Government of British Columbia 1996).

³ Reference 95th percentiles for 2015 data were calculated using data displayed in Appendix Table D.3. For calculation of 2014 Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

⁴ Summary statistics for reference area LRef2 are based only on data from replicates LRef2-01 to LRef2-03 due to high sand content in replicates LRef2-04 and LRef2-52-05 (> 90%).

⁵ t*SE = [T distribution critical value][Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

Table 4: Summary of sediment quality for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014 and 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

¹ Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

² Contaminated Sites Regulation (Government of British Columbia 1996).

³ Reference 95th percentiles for 2015 data were calculated using data displayed in Appendix Table D.4. For calculation of 2014 Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

⁴ t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

Sediment concentrations of nitrogen and metals observed in the profundal near-field area in 2015 were very similar to those observed in 2014, with arsenic and copper being the only analytes with concentrations whose concentrations exceeded the CSR “sensitive” criteria (Table 4; Appendix Table D.4). Sediment arsenic concentrations exceeded one of the two reference area concentrations (PRef1), but not both, the greater of which exceeded the CSR “typical” criterion (reference area PRef2).

Copper was the only analyte observed in the profundal near-field area to exceed the CSR “typical” criterion, as was also observed in 2014 (Table 4; Appendix Table D.4). In 2015, the mean copper sediment concentration exceeded the CSR “typical” criterion by approximately 3.6 times on average, and exceeded reference concentrations by approximately 14.5 times on average (Table 4).

Summary

Copper was the only analyte observed to exceed the CSR “typical” criterion in sediment from the three waterbodies affected by the Mount Polley Tailings Dam failure (Polley Lake, Hazeltine Creek and Quesnel Lake). Copper also exceeded reference or pre-event concentrations within all three of these waterbodies. Sediment arsenic concentrations exceeded the CSR “sensitive” (but not “typical”) criterion in all 2015 sampling areas except the Quesnel Lake littoral far-field area. These “sensitive” criteria apply to the top one meter of sediments in aquatic receiving environments (BCMoE 2013). Overall, there was little difference in the chemistry of sediment from the three waterbodies affected by the Mount Polley Tailings Dam failure between the 2014 and 2015 sampling events.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AVS-COL-VA	Soil	Acid volatile sulphide by colourimetric	EPA 821/R-91-100
<p>This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The evolved hydrogen sulphide (H₂S) is carried into a basic zinc acetate (ZnAc) solution by argon gas. The acid volatile sulfide is then determined colourimetrically.</p>			
C-TOT-63UM-LECO-SK	Soil	Total Carbon by combustion method (63um)	SSSA (1996) P. 973-974
<p>The sample is ignited in a combustion analyzer where carbon in the reduced CO₂ gas is determined using a thermal conductivity detector.</p>			
C-TOT-ORG-63UM-SK	Soil	Organic Carbon by combustion method(63um)	SSSA (1996) p. 973
<p>Total Organic Carbon (C-TOT-ORG-LECO-SK, C-TOT-ORG-SK)</p> <p>Total C and inorganic C are determined on separate samples. The total C is determined by combustion and thermal conductivity detection, while inorganic C is determined by weight loss after addition of hydrochloric acid. Organic C is calculated by the difference between these two determinations.</p> <p>Reference for Total C: Nelson, D.W. and Sommers, L.E. 1996. Total Carbon, organic carbon and organic matter. P. 961-1010 In: J.M. Bartels et al. (ed.) Methods of soil analysis: Part 3 Chemical methods. (3rd ed.) ASA and SSSA, Madison, WI. Book series no. 5</p> <p>Reference for Inorganic C: Loeppert, R.H. and Suarez, D.L. 1996. Gravimetric Method for Loss of Carbon Dioxide. P. 455-456 In: J.M. Bartels et al. (ed.) Methods of soil analysis: Part 3 Chemical methods. (3rd ed.) ASA and SSSA, Madison, WI. Book series no. 5</p>			
HG-63UM-CVAF-VA	Soil	Hg in Soil by CVAFS	EPA 200.2/245.7
<p>This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).</p> <p>Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.</p> <p>Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).</p>			
HG-SEM-CVAFS-VA	Soil	Simultaneously Extracted Metals in Soil	EPA 821/R-91-100; EPA245.7
<p>This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA 245.7).</p>			
MET-63UM-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A
<p>This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).</p> <p>Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.</p>			
MET-SEM-ICP-VA	Soil	Simultaneously Extracted Metals (ICPOES)	EPA 821/R-91-100; EPA 6010B
<p>This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).</p>			
MET-TESS-CM-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #2)	Tessier Extraction 1979/EPA 6020A
<p>This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).</p> <p>Note: For Extraction #2, the extraction solution is 1M Sodium Acetate adjusted to pH 5 and is intended to extract the "Carbonate" metals.</p>			
MET-TESS-EA-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #1)	Tessier Extraction 1979/EPA 6020A

Reference Information

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #1, the extraction solution is 1M Magnesium Chloride and is intended to extract the "Exchangeable and Adsorbed" metals.

MET-TESS-FEO-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #3) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #3, the extraction solution is 0.1 M Hydroxylamine Hydrochloride in 25% v/v Acetic Acid and is intended to extract the Easily Reducible Metals and Iron Oxides .

MET-TESS-OB-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #4) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #4, the extraction solution is 0.02 M Nitric Acid followed by 3.2M Ammonium Acetate and is intended to extract the Organic Bound metals.

MET-TESS-RM-CCMS-VA Soil METALS BY CCMS (TESSIER RM EXTRACTION) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with up to 6 different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For the Tessier "RM" Extraction, the extraction solution is 50/50 mix of 1:1 Nitric Acid along with 1:1 Hydrochloric Acid, and is hot block digested as per the BC SALM procedure. This is intended to extract the Residual metals.

MOISTURE-VA Soil Moisture content ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

N-TOT-LECO-SK Soil Total Nitrogen by combustion method SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

PH-1:2-VA Soil pH in Soil (1:2 Soil:Water Extraction) BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PSA-PIPET+GRAVEL-SK Soil Particle size - Sieve and Pipette SSIR-51 METHOD 3.2.1

Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

Burt, R. (2009). Soil Survey Field and Laboratory Methods Manual. Soil Survey Investigations Report No. 5. Method 3.2.1.2.2. United States Department of Agriculture Natural Resources Conservation Service.

S-TOT-LECO-SK Soil Total Sulphur by combustion method ISO 15178:2000

The sample is ignited in a combustion analyzer where sulfur in the reduced SO₂ gas is determined using a thermal conductivity detector.

Reference Information

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AVS-COL-VA	Soil	Acid volatile sulphide by colourimetric	EPA 821/R-91-100
<p>This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The evolved hydrogen sulphide (H₂S) is carried into a basic zinc acetate (ZnAc) solution by argon gas. The acid volatile sulfide is then determined colourimetrically.</p>			
C-TOT-63UM-LECO-SK	Soil	Total Carbon by combustion method (63um)	SSSA (1996) P. 973-974
<p>The sample is ignited in a combustion analyzer where carbon in the reduced CO₂ gas is determined using a thermal conductivity detector.</p>			
C-TOT-ORG-63UM-SK	Soil	Organic Carbon by combustion method(63um)	SSSA (1996) p. 973
<p>Total Organic Carbon (C-TOT-ORG-LECO-SK, C-TOT-ORG-SK)</p> <p>Total C and inorganic C are determined on separate samples. The total C is determined by combustion and thermal conductivity detection, while inorganic C is determined by weight loss after addition of hydrochloric acid. Organic C is calculated by the difference between these two determinations.</p> <p>Reference for Total C: Nelson, D.W. and Sommers, L.E. 1996. Total Carbon, organic carbon and organic matter. P. 961-1010 In: J.M. Bartels et al. (ed.) Methods of soil analysis: Part 3 Chemical methods. (3rd ed.) ASA and SSSA, Madison, WI. Book series no. 5</p> <p>Reference for Inorganic C: Loeppert, R.H. and Suarez, D.L. 1996. Gravimetric Method for Loss of Carbon Dioxide. P. 455-456 In: J.M. Bartels et al. (ed.) Methods of soil analysis: Part 3 Chemical methods. (3rd ed.) ASA and SSSA, Madison, WI. Book series no. 5</p>			
HG-63UM-CVAF-VA	Soil	Hg in Soil by CVAFS	EPA 200.2/245.7
<p>This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).</p> <p>Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.</p> <p>Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).</p>			
HG-SEM-CVAFS-VA	Soil	Simultaneously Extracted Metals in Soil	EPA 821/R-91-100; EPA245.7
<p>This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA 245.7).</p>			
MET-63UM-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A
<p>This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).</p> <p>Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.</p>			
MET-SEM-ICP-VA	Soil	Simultaneously Extracted Metals (ICPOES)	EPA 821/R-91-100; EPA 6010B
<p>This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).</p>			
MET-TESS-CM-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #2)	Tessier Extraction 1979/EPA 6020A
<p>This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).</p> <p>Note: For Extraction #2, the extraction solution is 1M Sodium Acetate adjusted to pH 5 and is intended to extract the "Carbonate" metals.</p>			
MET-TESS-EA-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #1)	Tessier Extraction 1979/EPA 6020A

Reference Information

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #1, the extraction solution is 1M Magnesium Chloride and is intended to extract the "Exchangeable and Adsorbed" metals.

MET-TESS-FEO-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #3) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #3, the extraction solution is 0.1 M Hydroxylamine Hydrochloride in 25% v/v Acetic Acid and is intended to extract the Easily Reducible Metals and Iron Oxides .

MET-TESS-OB-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #4) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #4, the extraction solution is 0.02 M Nitric Acid followed by 3.2M Ammonium Acetate and is intended to extract the Organic Bound metals.

MET-TESS-RM-CCMS-VA Soil METALS BY CCMS (TESSIER RM EXTRACTION) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with up to 6 different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For the Tessier "RM" Extraction, the extraction solution is 50/50 mix of 1:1 Nitric Acid along with 1:1 Hydrochloric Acid, and is hot block digested as per the BC SALM procedure. This is intended to extract the Residual metals.

MOISTURE-VA Soil Moisture content ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

N-TOT-LECO-SK Soil Total Nitrogen by combustion method SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

PH-1:2-VA Soil pH in Soil (1:2 Soil:Water Extraction) BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PSA-PIPET+GRAVEL-SK Soil Particle size - Sieve and Pipette SSIR-51 METHOD 3.2.1

Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

Burt, R. (2009). Soil Survey Field and Laboratory Methods Manual. Soil Survey Investigations Report No. 5. Method 3.2.1.2.2. United States Department of Agriculture Natural Resources Conservation Service.

S-TOT-LECO-SK Soil Total Sulphur by combustion method ISO 15178:2000

The sample is ignited in a combustion analyzer where sulfur in the reduced SO₂ gas is determined using a thermal conductivity detector.

Reference Information

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

1 2

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Report Date: 02-OCT-15

Page 7 of 7

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

C1.0 INTRODUCTION

Data Quality Assessment (DQA) was conducted on data collected as part of the Mount Polley Mining Corporation (MPMC) Sediment Quality Data Report. The objective of DQA is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

C1.1 Background

A variety of factors can influence the physical, chemical and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Depending on the magnitude of the problem, inaccuracy or imprecision have the potential to affect the reliability of any conclusions made from the data. Therefore, it is important to ensure that programs incorporate appropriate steps to control the non-natural sources of data variability (i.e., minimize the variability that does not reflect natural spatial and temporal variability in the environment) and thus assure the quality of the data.

Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. DQA involves comparison of actual field and laboratory measurement performance to data quality objectives (DQOs) established for a particular study, such as evaluation of method detection limits, blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). A trusted analytical laboratory certified by Canadian Association for Laboratory Accreditation (CALA) with a rigorous internal quality assurance program was selected to ensure the highest possible quality.

DQOs were established a-priori to reflect reasonable and achievable performance expectations. Programs involving a large number of samples and analytes usually yield some results that exceed the DQOs. This is particularly so for multi-element scans since the analytical conditions are not necessarily optimal for every element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the parameters fail to meet the DQOs. Overall, the intent of DQA is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of this project.

C1.2 Types of Quality Control Samples

Several types of quality control (QC) samples were assessed based on samples collected (or prepared) in the field and laboratory. These samples include the following:

- **Blanks** are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed the same way as regular samples. These samples will reflect any contamination that occurred in the field (in the case of field or trip blanks) or the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be non-detectable, although a data quality objective of twice the method detection limit allows for slight “noise” around the detection limit.
- **Field Duplicates** are sub-sample pairs collected from a randomly selected field station using identical collection and handling methods that are then analyzed separately in the laboratory. The duplicate samples are handled and analyzed in an identical manner in the laboratory. The data from field duplicate samples reflect natural variability, as well as the variability associated with sample collection methods, and therefore provide a measure of field precision.
- **Laboratory Duplicates** are sub-sample pairs created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.
- **Certified Reference Materials and QC Standards** are samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to target results to provide a measure of analytical accuracy. The results are reported as the percent of the known amount that was recovered in the analysis.

C2.0 SEDIMENT SAMPLES

C2.1 Holding Time and General Laboratory Flags

All sediment analyses were conducted within ALS Environmental's recommended hold times. There were no general laboratory flags associated with either analytical report (i.e., ALS Environmental Report L1661656 and L1664712; Appendix B).

C2.2 Method Detection Limits

Analytical laboratory reports (Appendix B) were examined to provide an inventory of analytes for which sample results were less than the method detection limit (MDL). Only seven analytes – percent gravel, percent sand, total organic carbon, bismuth, boron, total sulphur and thallium - had results reported as less than MDL. None of these analytes have applicable CSR criteria (Table C.1), and therefore the achieved MDLs were appropriate for the study and the rare instances of results reported as <MDL did not adversely affect data interpretability.

C2.3 Laboratory Blank Sample Analysis

All of the reported method blank results were non-detectable (Appendix B). Thus, the method blank results for this study suggest no inadvertent sample contamination within the laboratory.

C2.4 Data Precision

Field Duplicate Samples

Four field duplicate samples were collected for quality assurance (Table C.2). Evaluation of precision associated with sediment physical and chemical characteristics indicated excellent precision. The only occurrence of a relative percent difference (RPD) between duplicates of greater than the DQO of 40% was for percent clay in a sample from the littoral reference area (Table C.2). These duplicate samples had a low proportion of clay sized particles (6.3% and 3.5%). Consequently, although the absolute difference was small (2.8%), the relative percent difference was 57.4% (Table C.2). Overall, the precision associated with sediment quality analyses is suitable.

Laboratory Duplicate Samples

Two laboratory duplicate samples were evaluated for metals; and another ten laboratory duplicate samples were evaluated for a combination of moisture, pH, particle size, total

Table C.1: Laboratory method detection limit (MDL) evaluation for basic sediment chemistry analyses relative to generic numerical sediment criteria. Only analytes with <MDL values are reported.

Analyte		Units	BC CSR Criteria ^{1,2}		Maximum Method Detection Limit Achieved

nitrogen, total organic carbon, and total sulfur (Appendix B). All laboratory duplicate results (97 in total) met ALS Environmental's data quality objective of <30% RPD (Appendix B) and thus laboratory precision achieved in this study is considered good.

C2.5 Data Accuracy

Data accuracy was evaluated based on results of certified reference materials (CRM), internal reference materials (IRM) and laboratory control samples (LCS; Appendix B). Specifically, six CRM and two LCS samples were used to evaluate the accuracy of metal analyses, three IRM samples were used to evaluate the accuracy of particle size, total nitrogen, total organic carbon and Sulphur, and another eight LCS samples were evaluated for moisture and pH (Appendix B). All CRM, IRM and LCS results (274 in total) met ALS Environmental's data quality objectives for accuracy (Appendix B) and thus laboratory accuracy achieved in this study is considered good.

C3.0 DATA QUALITY STATEMENT

Data collected for the August 2015 sediment quality survey at the Mount Polley Mine was of good quality as characterized by good detectability, negligible analyte concentrations in method blanks, good field and laboratory precision, and good laboratory accuracy. Therefore, associated data can be used with a high level of confidence in the derivation of conclusions.

APPENDIX D
SEDIMENT QUALITY DATA

Table D.1: Raw sediment quality data for Polley Lake and Bootjack Lake sampling areas, Mount Polley Mine, 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

¹ Reported moisture, pH, and total nitrogen data are based on bulk sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

² Contaminated Sites Regulation (Government of British Columbia 1996)

³ The maximum historic reference 95th percentile value from among upper and lower Hazeltine Creek is displayed for each parameter. For calculation of Historic Reference 95th percentiles see Minnow (2015).

Table D.3: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

¹ Reported moisture, pH, and total nitrogen data are based on bulk sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

² Contaminated Sites Regulation (Government of British Columbia 1996)

³ 2015 Reference 95th percentiles were calculated using displayed data. For calculation of 2014 Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

⁴ The maximum reference 95th percentile value from among reference areas sampled in 2014 (LREF1 and LREF2) is displayed for each parameter. Refer to Minnow (2015) for raw data.

Table D.3: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Re: Application of the SEM-AVS Method and Selective Extraction Analysis in Evaluating Sediments Collected in the Vicinity of the Mount Polley Mine - August 2015

In the ongoing assessment of the potential impact to aquatic environmental health following the failure of the Mount Polley tailings dam in August 2014, it is critical to develop an understanding of the post-depositional stability of tailings-derived materials released to the aquatic receiving environment. A number of evaluations have been undertaken to date to advance this understanding, and have generally indicated low mobility of tailings-associated metals (e.g., SRK 2015a,b; Minnow 2015a). This memorandum summarizes the application of the SEM-AVS (Simultaneously Extracted Metals - Acid Volatile Sulphide) method of evaluating potential metal mobility and toxicity (e.g., DiToro et al. 1990) and supporting Selective Extraction Analysis (SEA) to sediment collected in the vicinity of the Mount Polley Mine (Figures 1 and 2). Samples were collected in August 2015 from two waterbodies (Polley Lake and Quesnel Lake) affected by the dam failure, and from corresponding reference areas. The purpose of this memorandum is to apply the SEM-AVS method to the collected sediments in order to assess the mobility of sediment metals using both SEM-AVS and SEA, assess the potential for sediment toxicity to aquatic biota, and to evaluate of the utility of the SEM-AVS method in sediments from the mine-impacted areas of Polley Lake and Quesnel Lake.

Background

The evaluation of sediment chemistry results discussed in this memorandum is part of the ongoing assessment of the environmental impact of the Mount Polley tailings dam failure which occurred on August 4th 2014. Geochemical investigations were conducted in 2014 (SRK 2015a; Minnow 2015a) and 2015 (SRK 2015b), and generally indicated that the mineralogy /

geochemical characteristics of the Mount Polley tailings, and materials deposited to receiving environments, was such that the mobility of associated metals is expected to be low. The post-depositional stability of mine-derived sediments is critical to understanding potential impact to water quality and to aquatic life. Two sediment chemical methods were employed to advance understanding of these potential impacts; the SEM-AVS method and Selective Extraction Analyses (SEA; or “Tessier” extractions).

The SEM-AVS method (Di Toro et al. 1990; Di Toro et al. 1992) provides a means of assessing the potential toxicity of metals in anoxic sediments by relating the concentrations of solid phase acid volatile sulphide (AVS) that occur under anoxic conditions to concentrations of cationic simultaneously extracted metals (SEM; copper, cadmium, lead, nickel, zinc, and silver). Free metals can react with available AVS and partition from the interstitial water to the solid phase as insoluble metal sulphides, thereby decreasing the bioavailable metal concentrations and potential toxicity to aquatic biota (Di Toro et al. 1990). This method can be used to predict a lack of toxicity in anoxic sediments where the concentration of AVS exceeds that of the SEM (i.e. ratio of SEM/AVS < 1) and has been shown to be successful at doing so (Di Toro et al. 2005). However there are some limitations to the method applicability. For instance, although the SEM-AVS method can predict a lack of toxicity, it is not intended to predict the occurrence of toxicity when SEM is in excess of AVS (Di Toro et al. 2005; USEPA 2005). In addition, the SEM-AVS method is not appropriate for application to oxidized sediments which only have trace concentrations of AVS present, with the lower limit of method applicability estimated to be approximately 1 $\mu\text{mol/g}$ (or 32 mg/kg) of AVS (Di Toro et al. 1990). Both of these limitations are owing to the fact that the method does not explicitly consider other sediment constituents that are available for metal complexation (Di Toro et al. 2005; USEPA 2005), such as organic carbon, iron and manganese oxides, and carbonates (in oxidized sediments), among others. Therefore, limitations of the SEM-AVS method should be carefully considered in data interpretation, and caution should be applied to the interpretation of results from sediments with trace AVS concentrations.

Selective extraction analyses (SEA) were used as a second tool in further evaluating the current limits to metal mobility in the sediment. These extractions provide an indication of the fraction of “total” metal in sediment that could be mobilized under differing circumstances and, importantly from the perspective of exposure characterization, the fraction of “total” metal that could not realistically be mobilized (e.g., Tessier and Campbell 1987). The reagents typically used in the selective extraction analyses are weaker than reagents in the analysis of “total metal” concentrations in sediments, in an effort to mimic the fraction (or fractions) of sediment-

associated metal that could be released under natural conditions. Comparisons of SEA results between 2014 (Minnow 2015a) and the current sampling year (2015) can also be used in evaluating potential geochemical changes that could affect metal mobility within tailings-impacted sediments over time.

Methods

Sediment samples were collected between August 13th and 24th 2015 from impacted areas of Polley Lake and Quesnel Lake, and corresponding reference areas (Figures 1 and 2). Samples were collected from the same locations used in 2014 (Appendix Table A.1), and using the same methods (Minnow 2015a) wherever possible.

Sampling

Sediments were collected from Polley Lake, Bootjack Lake, and Quesnel Lake for the analysis of SEM and AVS, SEA (or “Tessier” extractions), and total organic carbon (TOC). In Polley and Bootjack lakes, sediments were collected for these analyses using a Kajak-Brinkhurst (KB) corer in accordance with technical guidance for gravity coring outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for Environmental Effects Monitoring (EEM; Environment Canada 2012). Briefly, all retrieved core samples were examined, and if acceptable, were extruded into a core collar, cut using a core knife to collect the top 3 cm of sediment, and transferred into a 250 mL glass sampling jar labelled with the project number, sample location, collection date, and required analyses. Sediment collected for the analysis of SEA and TOC was then transferred into one or more labelled sampling jars, while sediment collected for SEM and AVS analyses was transferred into a separate labelled 250 mL glass sampling jar. This procedure was repeated to provide composite samples of sufficient volume for the required analyses (a minimum of three cores per sample). The sulphide ion measured in SEM and AVS analyses is unstable in the presence oxygen (USEPA 1991); therefore sampling jars containing sediment for these analyses were filled completely to ensure minimum headspace. Within both Polley and Bootjack lakes, sediment was collected for SEM and AVS analyses from five replicate stations to represent each area, while sediment for SEA (Tessier) and TOC analysis was collected from five replicate stations within Polley Lake, and from three replicate stations within Bootjack Lake (Appendix Table A.1). All sampling equipment was rinsed between stations using site water.

In Quesnel Lake, sediment samples were collected from profundal habitats using a stainless steel petite ponar (15.2 cm x 15.2 cm; 0.023 m² sampling area) or standard ponar (22.9 cm

x 22.9 cm; 0.052 m² sampling area) grab sampler in accordance with technical guidance outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for EEM (Environment Canada 2012). Profundal grab samples (mean depth approximately 100 meters) were collected with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). Sediment was collected for SEM and AVS analyses from five replicate stations within both the exposed (near-field) and reference areas, while sediment for SEA and TOC analyses was collected from five replicate stations within the exposed (near-field) area, and from three replicate stations within the profundal reference area (Appendix Table A.1). At each station, composite samples of the top three centimeters of surficial sediment of three to six acceptable grabs (i.e., full to each edge of the sampler) were collected. Each grab was collected into a plastic tote and observed for completeness and any unusual characteristics. If the sample was deemed acceptable, surficial material to a depth of 3 centimeters was transferred using a stainless steel spoon directly into a labeled 250 mL glass sampling jar for SEM and AVS analyses (without homogenization in order to limit oxidation), and into a tote for collection for SEA and TOC analyses, and the remaining sediment was discarded. Sampling jars containing sediment for SEM and AVS analyses were capped between grabs to limit oxidation. This procedure was repeated for all subsequent grabs. When sufficient grabs had been collected, material obtained for SEA and TOC analyses was homogenized using a stainless steel spoon prior to being transferred into 250 mL glass sampling jars. Sampling jars containing sediment for SEM and AVS analyses were completely filled to eliminate headspace and minimize potential oxidation. All sampling jars were labelled with the project number, sample location and collection date, and all sampling equipment was rinsed between stations using site water.

Field duplicate (split) sediment samples were collected at a frequency of 10% for quality assurance/quality control (QA/QC) purposes. Supporting information collected at each sampling site included GPS (Geographic Positioning System) coordinates, sampling depth, Secchi depth, field meter measurements of temperature, specific conductance, dissolved oxygen and pH (using a YSI EXO™ handheld portable field meter equipped with YSI EXO2™ Sonde), site photographs (including photographs of sediment samples), and notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). Immediately after collection, samples were placed into a cooler with ice packs, where they were maintained cool prior to transport to the field laboratory. At the field laboratory, samples collected for SEA and TOC analyses were placed directly in a refrigerator, whereas the samples collected for SEM and AVS analyses

were sealed in a double layer of large Ziploc bags that were each purged and filled with nitrogen gas in order to minimize sample oxidation. All samples were then held in a refrigerator until shipment to the analytical laboratory. Sediment samples were shipped to the analytical laboratory (ALS Environmental, Burnaby, BC) at minimum frequency of weekly. Prior to shipment, samples were placed in a cooler with frozen ice packs and a chain-of custody form was prepared and packed with the samples. Coolers were shipped overnight for next day delivery to ALS Environmental.

Laboratory Analysis

Upon receipt, ALS Environmental opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and assigned each sample a unique identification code. A sample receipt confirmation was then sent to MPMC and Minnow for verification.

Laboratory analyses included simultaneously extracted metals and acid volatile sulphides, selective extraction analyses, and total organic carbon analyses. Total organic carbon was determined in the silt/clay fraction (<63 µm diameter) to compliment metal concentrations measured in this sediment fraction reported in a previous memorandum (Minnow 2015b). Upon completion of these analyses (detailed below), data reports were provided by ALS Environmental to MPMC and Minnow electronically in Adobe Acrobat Portable Document Format (PDF), and as MSEXcel files.

The analysis of SEM and AVS in sediment was performed according to the USEPA Method EPA-821-R-91-100 (USEPA 1991). This analysis consisted of the cold extraction of sediment in hydrochloric acid, reported to release readily extractable reactive sulphides which are referred to as AVS. The concentrations of the reactive metals that are concurrently extracted during the cold acid extraction were also measured, and are referred to as SEM (ICMM 2007). The SEM-AVS method has been verified for 5 divalent metals (cadmium, copper, lead, nickel, and zinc), and one monovalent metal (silver; Wang and Chapman 1999). These have been shown to react with the AVS present in anoxic sediments to form insoluble metal sulphides that are generally not available for uptake by biota, and therefore non-toxic (McGrath et al. 2002; Di Toro et al. 2005). However, the SEM-AVS method is invalid in fully oxidized sediments where the AVS concentration is zero or near-zero, with the lower limit of method applicability being approximately 1 µmol/g (or 32 mg/kg; Di Toro et al. 1990). In these cases, metal partitioning would likely be controlled by other sediment constituents (Di Toro et al. 1990), such as iron and manganese oxides and organic carbon. The concurrent release of SEM and AVS does not necessarily indicate

that the SEM are bound to sulphides alone in the sediment (Allen et al. 1993; ICMM 2007). Total SEM is the sum of metals belonging to any metal-bearing phase that is released in the cold acid extraction (Allen et al. 1993; Di Toro et al. 1996). In Mount Polley tailings and tailings-influenced sediments for example, a significant amount of copper has been shown to be associated with the non-sulphide fraction of these sediments (likely as silicate chlorite), which is relatively stable at neutral pH, but which can leach under acidic conditions (SRK 2015a,b). The SEM-AVS method could therefore overestimate metal availability if the metals released as SEM during the cold acid extraction were bound to other constituents other than readily extractable reactive sulphides alone in the sediment (Fang et al. 2005). This may occur especially in oxidized sediments where trace amounts of AVS are present, and metal partitioning is dominated by other sediment phases. Concentrations of simultaneously extracted silver were not reported by the analytical laboratory and are not included in this report. Silver was not identified as a parameter of interest for either of the exposed sampling areas (Minnow 2015a).

Selective extraction analyses were performed using the sequential extraction scheme of Tessier et al. (1979) in order to allow comparison with the results of sediments analysed using this method in 2014 (Minnow 2015a). Selective extractions are useful in providing an indication of the fraction of “total” metal that could be mobilized under different circumstances, and provide a rough characterization of metal oxides (i.e., iron and manganese oxides) within the “Easily Reducible and Iron Oxides” fraction. The Tessier extraction method involves five sequential extraction steps of increasing strength, with each extraction step representing a fraction of sediment-associated metals that could be released under varying conditions: 1) changes in ionic strength (exchangeable & adsorbed metals fraction); 2) changes in pH (carbonate fraction); 3) reducing conditions such as those that could occur with diagenesis (easily reducible metals and iron oxides fraction); and 4) oxidizing conditions (organic and mineral bound metals fraction) (Tessier et al. 1979). The final digest in the procedure is a strong acid (aqua regia) digest that mobilizes metals resistant to the first four digestion steps (providing a residual metals fraction), and is the same digest used to mobilize “total” metals in the conventional chemical characterization of metals (although it does not digest all mineral forms and is not a true total).

Data Analysis

Upon receipt of the analytical data, a Data Quality Assessment (DQA) was completed, including an examination of data completeness, method detection limits achieved, laboratory and field precision, and laboratory accuracy. Following completion of the DQA,

sediment quality data (SEM and AVS, TOC, and SEA) were summarized by area, by calculating mean, median, standard deviation, standard error, 95% confidence limits, and minimum and maximum.

Total SEM data were compared to AVS data to determine whether SEM were in excess of AVS. This was achieved by calculating the ratio of total SEM/AVS, as well as the difference between total SEM and AVS $[(\Sigma \text{ total SEM})-(\text{AVS})]$. If the former is less than one or the latter is less than zero, AVS is in excess of SEM and the SEM is likely present as insoluble sulphide complexes. If the reverse is true (the former is greater than one or the latter is greater than zero), the latter is referred to as excess SEM, and is an indicator that AVS is insufficient to bind the SEM and of the importance of other metal-binding phases in influencing the bioavailability of excess SEM (Hansen et al. 1996; ICMM 2007; e.g., organic carbon, iron oxides, manganese oxides, carbonates). For samples with excess SEM, a binding sequence calculation was used to determine the concentration of each of the five SEM in excess of available AVS. This was accomplished for each sample by allocating the available AVS on a 1:1 molar basis to the individual SEM (copper, lead, cadmium, zinc, and nickel), according to the sequence of their relative sulphide solubility product constants. Therefore, available AVS was assigned to the five SEM in the following order: 1) copper, 2) lead, 3) cadmium, 4) zinc, 5) nickel (low to high sulphide solubility products; K_{sp}), until the AVS was exhausted. Simultaneously extracted mercury data were provided by the laboratory, however SEM-AVS calculations were limited to the five aforementioned metals for which the method has been verified in anoxic sediments (Wang and Chapman 1999). SEM were considered to likely be present as insoluble sulphide complexes if AVS was assigned to the SEM concentration in binding sequence calculations. If AVS was not allocated to a particular SEM concentration due to exhaustion of AVS earlier in the binding sequence (more likely for those metals at the end of the sequence), the SEM was considered to be in excess. Excess SEM represents the fraction of SEM with the potential to exist in the free metal form, but it is important to note that this is only if it is not bound to other sediment constituents (McGrath et al. 2002; e.g., organic carbon, or iron and manganese oxides, carbonates). In order to account for potential binding to total organic carbon, excess SEM concentrations (i.e., where total SEM > AVS), were related to the organic carbon content of sediment by calculating the organic carbon-normalized excess SEM value ($\mu\text{mol excess SEM/gOC}$). This was achieved by using the following equation: $([\text{Excess Total SEM}]/\text{fOC})$, where fOC is the fraction of sediment organic carbon, in grams of Organic Carbon/gram of Dry Weight (Di Toro et al. 2005; USEPA 2005).

SEA data collected in 2015 were compared to data collected from the same sampling stations in 2014. Mean metal concentrations in each of the fractions were compared among the two sampling years (2014 and 2015), by calculating relative percent differences. Concentrations of the parameters of interest (POIs) identified in 2014 for Polley Lake (arsenic, copper, iron, and zinc) and for Quesnel Lake profundal (arsenic, copper, iron, manganese, and nickel) sampling areas (Minnow 2015a) were further evaluated to compare the partitioning of these metals among the extracted fractions.

Results

The reported sediment chemistry results were of good quality as characterized by: 1) good detectability as demonstrated by the majority of method detection limits (MDL) meeting predicted laboratory MDLs (Appendix Table C.1); 2) negligible analyte concentrations in the majority (97%) of laboratory method blank samples; 3) good data precision, with all field (Appendix Table C.2) and laboratory duplicate results meeting data quality objectives; and 4) good laboratory accuracy, with all certified reference materials and standards results meeting data quality objectives. Additional details regarding the data quality assessment are presented in Appendix C.

Polley Lake

Simultaneously Extracted Metals and Acid Volatile Sulphides

Sediment collected from the south basin of Polley Lake in August 2015 (sampling area POL-P2; Figure 1) had SEM/AVS ratios of less than one, with the exception of the sampling station POL-P2-2 (Figure 3; Appendix Table C.3). This is similar to results observed in the corresponding reference area (BOL-B2 in Bootjack Lake), where SEM/AVS ratios were less than one for all samples (Figure 3; Appendix Table C.3). Accordingly, the difference between total SEM and AVS ($[\Sigma \text{ total SEM}] - [\text{AVS}]$) was less than zero for the majority of Polley Lake samples, indicating excess SEM was not present (Figure 4). These results indicate that the majority of sediment samples from the south basin of Polley Lake are predicted to be non-toxic because SEM within these sediments are likely present as insoluble metal sulphides (Di Toro et al. 1996; McGrath et al. 2002; Di Toro et al. 2005), which are present in the solid phase (i.e., not occurring in the interstitial water) and of limited bioavailability and toxicity to aquatic biota (Di Toro et al. 1990).

Total SEM exceeded the available AVS in one Polley Lake sample, as mentioned above (POL-P2-2). Concentrations of copper and total organic carbon in this sample were the highest in the sampling area and were accompanied by a low AVS concentration (<1.1

Figure 3: Sum of Simultaneously Extracted Metals (SEM) relative to Acid Volatile Sulphide (AVS) concentrations in sediment, Mount Polley Mine, August 2015. Samples with a SEM/AVS ratio of greater than one fall above the dotted line.

Figure 4: Difference between the sum of Simultaneously Extracted Metals (SEM) and Acid Volatile Sulphide (AVS) concentrations (Σ SEM-AVS) in sediment , Mount Polley Mine, August 2015.

*Negative values indicate that AVS is in excess of SEM, and SEM are likely bound as insoluble metal-sulfide complexes.

$\mu\text{mol/g}$ or 35 mg/kg), while all other samples from this area had AVS concentrations $> 10 \mu\text{mol/g}$ (321 mg/kg; Table C.3). A tailings influence in these sediments would be expected to result in high copper, low total organic carbon, and low AVS concentrations, and this sample is therefore anomalous. In this sample, simultaneously extracted copper was the highest of the excess SEM concentrations ($3.99 \mu\text{mol/g}$ or 254 mg/kg), as calculated using the excess SEM binding sequence (Figure 5; Appendix Table C.4). However, the presence of excess simultaneously extracted copper (and the remaining excess SEM; Figure 5) does not indicate that these metals are necessarily available for uptake by benthic biota. As discussed above, SEM concentrations do not necessarily only represent metals that are bound to sulphides in the sediment (Allen et al. 1993; ICMM 2007), but also include metals belonging to any metal-bearing phase that is released in the cold acid extraction (Allen et al. 1993; Di Toro et al. 1996). There is therefore a possibility that copper bound to sediment constituents other than sulphides may be released during the cold acid extraction. In the Mount Polley tailings and tailings-influenced sediments, copper has been shown to be associated with the non-sulphide fraction, and can be leached under acidic conditions (SRK 2015 a,b). This potential release of copper from the non-sulphide fraction during the cold acid extraction would result in an overestimation of the available copper.

The binding of excess SEM by other constituents in the sediment (e.g., organic carbon, iron and manganese oxides, carbonates) can also affect the bioavailability, and therefore toxicity, of these metals (Di Toro et al. 1990; Di Toro et al. 2005). Di Toro et al. (2005) have proposed the calculation of an organic carbon-normalized excess SEM as a means of accounting for the partitioning of excess SEM to organic carbon, and predicting toxicity (McGrath et al. 2002; Di Toro et al. 2005; USEPA 2005). Based on relationships between toxicity testing results and organic carbon-normalized excess SEM concentrations, it has been predicted that toxicity to biota is unlikely when organic carbon-normalized SEM concentrations are below $130 \mu\text{mol/gOC}$ (USEPA 2005). The organic carbon-normalized excess SEM concentration for sample POL-P2-2 fell well below this value ($46.2 \mu\text{mol/gOC}$; Figure 6; Appendix Table C.3), indicating that toxicity is not expected to benthic organisms in all sediment collected from the Polley Lake south basin in 2015. This is further supported by the toxicity testing of sediment from this area (P2) in 2014 following the tailings dam failure (Minnow 2015a), which reported no effects to the survival and growth of either *Hyalella azteca* or *Chironomus dilutus* in short term tests (14 and 10-day tests, respectively).

Selectively Extracted Metals (Tessier)

Selective Extraction Analyses were performed on sediment from Polley Lake and a reference area (Bootjack Lake) to assist in further identifying the potential mobility of metals in these sediments, and to provide temporal comparison to 2014 SEA data. Concentrations of all metals evaluated within the five extraction phases were generally similar between the 2014 and 2015 sampling events, with 68% of all Polley Lake results being similar among sampling years (< 30% Relative Percent Difference), and 73% of all reference results being similar among years (Appendix Table C.5). More specifically, the partitioning of the metals identified as Parameters of Interest (POIs; arsenic, copper, iron, and zinc) in mine-influenced sediment from Polley Lake in 2014 (Minnow 2015a) was very similar in 2014 and 2015, and similar to the partitioning of metals observed in reference sediment (despite differing mean metal concentrations). With the exception of copper, the POIs were generally present primarily in the residual phase, as was observed in 2014 (Figure 7; Appendix Table C.6). This indicates that the majority of the concentrations of these POIs are unlikely to be mobilized under any conditions that could realistically occur in the environment, and are therefore not considered to be biologically available (e.g., Tessier et al. 1979; Campbell and Tessier 1996).

Copper concentrations were primarily present in the “organic and mineral bound metals” fraction, similar to sediment SEA results from Polley Lake (P2) in 2014, and similar to reference sediment results in both 2014 and 2015 (Figure 7; Appendix Table C.6). Separate investigation of the mineralogy and mineral solubility of Mount Polley tailings, and tailings-influenced sediments, indicated that copper was predominantly associated with chalcopyrite and chlorite minerals (SRK 2015a), and a significant amount of copper (29 – 66%) was associated with the non-sulphide fraction (likely in the mineral form of silicate chlorite; SRK 2015b), and presented a low risk of mobilization under environmentally realistic conditions (SRK 2015a,b). The similarities observed in metal partitioning in Polley Lake sediment in 2014 and 2015, and to reference sediment, indicate that concentrations of the POIs are likely not currently mobile among the sediment fractions.

Quesnel Lake Profundal

Simultaneously Extracted Metals and Acid Volatile Sulphides

Sediment collected from the profundal near-field (PNF; exposed) sampling area of Quesnel Lake had SEM/AVS ratios substantially greater than one (mean ratio = 33.1; Figure 3; Appendix Table C.7), and concentrations of excess total SEM > 4.5 µmol/g (mean = 8.73 µmol/g; Figure 4; Appendix Table C.7). In contrast, the majority of reference (PREF1)

Figure 7: Concentrations of selectively extracted parameters of interest in Polley Lake (exposed) and the associated reference area (Bootjack Lake) sampled in 2014 and 2015, Mount Polley Mine. Selective extractions included Exchangeable & Adsorbed Metals (Ex), Carbonate Metals (Carb), Easily Reducible Metals and Iron Oxides (ER&Fe), Organic and Mineral Bound Metals (O), and Residual Metals (Res).

TEL = Threshold (or Lowest) Effect Level; PEL = Probable (or Severe) Effect Level (BCMOE 2015). Mean values are shown with a < symbol if all data used in their calculation were below the method detection limit (MDL).

samples had SEM/AVS ratios less than one (Figure 3; Appendix Table C.7), and differences between total SEM and AVS ($[\Sigma \text{ total SEM}] - [\text{AVS}]$) below zero (mean = $-0.96 \mu\text{mol/g}$; Figure 4; Appendix Table C.7). Based on the SEM-AVS method, reference samples were predicted to be non-toxic. SEM within these samples were likely present in the solid phase as insoluble metal sulphides (Di Toro et al. 1996; McGrath et al. 2002; Di Toro et al. 2005), and therefore of limited bioavailability and toxicity to aquatic biota (Di Toro et al. 1990). In exposed sediment from the near-field profundal area, the presence of excess SEM in all samples indicated that available AVS was insufficient to bind the SEM present and limit bioavailability. This result is not surprising given the fact that copper (the most prevalent excess SEM in these sediments) is significantly associated with the non-sulphide fraction of Mount Polley Tailings and tailings-influenced sediments (SRK 2015b). Due to the low AVS concentrations in this sediment ($< 0.40 \mu\text{mol/g}$ or 12.8 mg/kg), consideration should be given to the limitations of the SEM-AVS method. As discussed previously, use of the SEM-AVS method is not appropriate for oxidized sediments with only trace amounts of AVS, with the lower limit of the method being $1 \mu\text{mol/g}$ (or 32 mg/kg ; Di Toro et al. 1990). The partitioning of metals in these oxic sediments is likely controlled by other sediment constituents (Di Toro et al. 1990), such as organic carbon, iron and manganese oxides, and carbonates. Given that the SEM-AVS method does not consider other sediment components available for metal complexation, the presence of excess SEM cannot be used to predict the occurrence of toxicity (Di Toro et al. 2005).

Concentrations of each of the five SEM (copper, lead, cadmium, zinc, and nickel) were calculated for samples with excess SEM using the established binding sequence (Appendix Table C.4). Within the exposed sediment, AVS concentrations were less than the MDL in all samples and were exhausted in the first step of the binding sequence (copper; Appendix Table C.4). Copper had the highest excess concentrations ($4.2\text{-}12.5 \mu\text{mol/g}$ or $267\text{-}794 \text{ mg/kg}$), but concentrations of the remaining excess SEM (lead, cadmium, zinc and nickel) were also present in all exposed sediment samples (Figure 5; Appendix Table C.4). Within reference sediment, application of the SEM-AVS binding sequence resulted in the calculation of excess zinc and nickel at relatively low concentrations ($< 19 \text{ mg/kg}$; Figure 5; Appendix Table C.4). As previously mentioned, the SEM-AVS method has been shown to perform well at predicting a lack of toxicity to biota in anoxic sediments due to binding by AVS, but was not intended to suggest toxicity in sediments where total SEM is in excess of AVS (Di Toro et al. 2005), and is not appropriate for use when sediment AVS concentrations are less than $1 \mu\text{mol/g}$ (or 32 mg/kg ; Di Toro et al. 1990). Therefore, the presence of excess simultaneously extracted copper (and the remaining SEM) in excess of AVS in the exposed

area does not indicate that these metals are necessarily available for uptake by benthic biota.

Calculation of organic carbon-normalized excess SEM is a means of taking the potential complexation of excess SEM with organic carbon into consideration (Di Toro et al. 2005). In near-field (exposed) sediment, organic carbon-normalized excess SEM concentrations ranged from 2,473 to 3,447 $\mu\text{mol/gOC}$ (Figure 6; Appendix Table C.7). Those in the reference area (for the two samples which had excess total SEM) ranged from 5.3 to 24.5 $\mu\text{mol/gOC}$ (Figure 6; Appendix Table C.7), substantially lower than the concentration for which sediment toxicity is unexpected (i.e., $< 130 \mu\text{mol/gOC}$; USEPA 2005). The calculated values for exposed area sediment fell well above this range, indicating that the organic carbon present in exposed sediment (which is very low; $< 0.52\%$) is insufficient to bind SEM and limit bioavailability. However, the complexation of metals to other sediment constituents (i.e., iron and manganese oxides) may also serve to limit bioavailability, but are not accounted for in this calculation (Di Toro et al. 2005). Predictions about the potential toxicity of exposed sediments therefore cannot be made based on the organic carbon-normalized excess SEM concentrations alone. As described previously, total SEM is the sum of metals of any metal-bearing phase that is released in the cold acid extraction used for the SEM and AVS method (Allen et al. 1993; Di Toro et al. 1996), and therefore does not necessarily only represent metals that are bound to sulphides in the sediment (Allen et al. 1993; ICMM 2007). As such, the SEM-AVS method overestimates metal availability if metals are bound to other constituents in the sediment (i.e. iron and manganese oxides), and are extracted as SEM (Fang et al. 2005). This is an important consideration for the profundal exposed sediments which are characterized as oxic sediments, with low organic carbon content, low AVS concentrations (Appendix Table C.7), and in which copper is likely significantly associated with the non-sulphide portion of the substrates (as was demonstrated for Mount Polley tailings and tailings-influenced sediments; SRK 2015b). Given these facts, it is probable that the SEM (particularly copper) extracted from the near-field sediment were bound to sediment constituents other than sulphides, leading to an overestimation of the availability of metals in these oxidized sediments.

Overall, data from Quesnel Lake indicate that toxicity is not predicted in reference sediments, while the available AVS and organic carbon present in exposed sediment is insufficient to bind SEM. Based on the SEM-AVS method and the available data, sediment toxicity predictions cannot be made for the near-field (exposed) sampling area. However, previous mineral and mineral solubility investigations of the Mount Polley tailings, and of

tailings-influenced sediments, have indicated that the mobility of tailings-associated metals (copper in particular) is expected to be low (SRK 2015a,b).

Selectively Extracted Metals (Tessier)

Selective Extraction Analyses of sediment from exposed (near-field) and reference (Horsefly Bay) areas of Quesnel Lake were performed to further assist in assessing the potential mobility of metals in these sediments, and provide temporal comparison with 2014 data. Concentrations of all metals evaluated within the five extraction phases were generally similar between the 2014 and 2015 sampling events, with 74% of all profundal near-field area (PNF) results being similar among sampling years (< 30% Relative Percent Difference), and 84% of all reference results being similar among years (Appendix Table C.5). Five POIs (arsenic, copper, iron, manganese, and nickel) were identified in Quesnel Lake profundal sediment in 2014 following the tailings dam failure (Minnow 2015a). Partitioning of these POIs in the near-field sediment was very similar among sampling years, and relatively similar to the partitioning observed in reference sediment (PREF1), with the exception of a higher proportion of manganese in the residual phase of near-field sediment (Figure 8; Appendix Tables C.5 and C.8). Concentrations of the POIs (with the exception of copper) were present primarily in the residual phase of sediment collected in both 2014 and 2015 (Figure 8; Appendix Table C.8). This indicated that the majority of these metal concentrations are unlikely to be mobilized under any conditions that could realistically occur in the environment, and are therefore not considered to be biologically available (e.g., Tessier et al. 1979; Campbell and Tessier 1996).

Copper concentrations in the near-field sediment existed primarily in the “organic and mineral bound metals” phase, while copper in the reference area was primarily (> 58%) present in the residual phase (Figure 8; Appendix Table C.8). This difference in copper partitioning between the profundal near-field and reference areas of Quesnel Lake was also observed in 2014 (Minnow 2015a). Investigations of mineralogy, mineral solubility, and SEA of Mount Polley tailings and of tailings-influenced sediments identified copper to be of low mobilization risk under environmentally realistic conditions (SRK 2015 a,b). In addition, the observed similarities in POI partitioning within the profundal near field sediment in 2014 and 2015 indicate that these metals currently have limited mobility.

Summary

Application of the SEM-AVS method was successful in documenting an excess of AVS over SEM in sediments from Polley Lake and therefore predicting an absence of toxicity. Free metals within these sediments were likely present in the solid phase (as insoluble metal

Figure 8: Concentrations of selectively extracted parameters of interest in exposed (PNF) and reference (PREF1) areas of Quesnel Lake sampled in 2014 and 2015, Mount Polley Mine. sulphides), and of limited bioavailability and toxicity to aquatic biota. This finding is consistent with short term toxicity testing of sediment from this area in 2014 which reported no effects on the survival or growth of test organisms. SEM-AVS results for mine-influenced sediment from a deep area in Quesnel Lake indicated that available AVS and organic carbon concentrations were very low, and were insufficient to bind and limit the bioavailability of SEM. The SEM-AVS method can predict an absence of mobility and toxicity (i.e., metal binding by excess AVS), but cannot predict mobility and toxicity (DiToro et al. 2005; USEPA 2005) as it does not consider other metal binding constituents present in oxic sediment. The SEM-AVS method is not appropriate for application to oxic and sub-oxic sediments with very low AVS concentrations, such as the Quesnel Lake deep near-field sediment. Additionally, the cold acid extraction method used to determine SEM concentrations may release metals that are bound to other sediment constituents (such as organic carbon, iron oxide, manganese oxide, carbonate, and/or a non-sulphide mineral - likely silicate chlorite) in addition to those bound to sulphides, resulting in an overestimation of metal availability. As such, predictions of the potential for sediment toxicity in Quesnel Lake deep near-field exposed sediment cannot be made based on the SEM-AVS method and the available data alone. Previous geochemical investigations, however, have indicated that the mobility of tailings-associated metals is expected to be low (SRK 2015a,b). The data collected from both Polley Lake and Quesnel Lake can serve as components in further understanding the bioavailability and chemical stability of metals within these mine-influenced sediments. SEA (Tessier extraction) results demonstrated that the partitioning of POIs was similar among sampling years in mine-influenced sediment from both Polley Lake and Quesnel Lake. This indicated that the POIs are not currently mobile among the sediment fractions.

APPENDIX B

ANALYTICAL REPORTS

MOUNT POLLEY MINING CORP.
ATTN: Colleen Hughes
PO Box 12
Likely BC VOL 1N0

Date Received: 21-AUG-15
Report Date: 06-OCT-15 15:29 (MT)
Version: FINAL REV. 4

Client Phone: 250-790-2215

Certificate of Analysis

Lab Work Order #: L1661656
Project P.O. #: NOT SUBMITTED
Job Reference:
C of C Numbers:
Legal Site Desc:

Comments: Tessier sequential extraction and AVS/SEM analyses are not included in this report.

23-SEP-2015 Revision 2: The report to company has been modified.

6-OCT-2015 Revision 4: This revision includes data for AVS/SEM and Tessier Sequential Extraction analysis only.

Can Dang
Senior Account Manager

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Method Blank	Calcium (Ca)-Leachable	B	L1661656-1, -15, -17, -3, -4, -5, -6, -7, -8
Method Blank	Strontium (Sr)-Leachable	B	L1661656-1, -15, -17, -3, -4, -5, -6, -7, -8
Method Blank	Calcium (Ca)-Leachable	B	L1661656-19, -21, -23, -25, -27, -29, -33
Method Blank	Strontium (Sr)-Leachable	B	L1661656-19, -21, -23, -25, -27, -29, -33
Duplicate	Nickel (Ni)-Leachable	DLB	L1661656-19, -21, -23, -25, -27, -29, -33
Method Blank	Nickel (Ni)-Leachable	MB-LOR	L1661656-1, -15, -17, -3, -4, -5, -6, -7, -8
Method Blank	Nickel (Ni)-Leachable	MB-LOR	L1661656-19, -21, -23, -25, -27, -29, -33

Qualifiers for Individual Parameters Listed:

Qualifier	Description
B	Method Blank exceeds ALS DQO. All associated sample results are at least 5 times greater than blank levels and are considered reliable.
DLB	Detection Limit Raised. Analyte detected at comparable level in Method Blank.
DLHM	Detection Limit Adjusted: Sample has High Moisture Content
DLM	Detection Limit Adjusted due to sample matrix effects.
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AVS-COL-VA	Soil	Acid volatile sulphide by colourimetric	EPA 821/R-91-100
This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The evolved hydrogen sulphide (H ₂ S) is carried into a basic zinc acetate (ZnAc) solution by argon gas. The acid volatile sulfide is then determined colourimetrically.			
C-TOT-63UM-LECO-SK	Soil	Total Carbon by combustion method (63um)	SSSA (1996) P. 973-974
The sample is ignited in a combustion analyzer where carbon in the reduced CO ₂ gas is determined using a thermal conductivity detector.			
C-TOT-ORG-63UM-SK	Soil	Organic Carbon by combustion method(63um)	SSSA (1996) p. 973
Total Organic Carbon (C-TOT-ORG-LECO-SK, C-TOT-ORG-SK)			
Total C and inorganic C are determined on separate samples. The total C is determined by combustion and thermal conductivity detection, while inorganic C is determined by weight loss after addition of hydrochloric acid. Organic C is calculated by the difference between these two determinations.			
Reference for Total C: Nelson, D.W. and Sommers, L.E. 1996. Total Carbon, organic carbon and organic matter. P. 961-1010 In: J.M. Bartels et al. (ed.) Methods of soil analysis: Part 3 Chemical methods. (3rd ed.) ASA and SSSA, Madison, WI. Book series no. 5			
Reference for Inorganic C: Loeppert, R.H. and Suarez, D.L. 1996. Gravimetric Method for Loss of Carbon Dioxide. P. 455-456 In: J.M. Bartels et al. (ed.) Methods of soil analysis: Part 3 Chemical methods. (3rd ed.) ASA and SSSA, Madison, WI. Book series no. 5			
HG-63UM-CVAF-VA	Soil	Hg in Soil by CVAFS	EPA 200.2/245.7
This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).			
Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.			
Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).			
HG-SEM-CVAFS-VA	Soil	Simultaneously Extracted Metals in Soil	EPA 821/R-91-100; EPA245.7
This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA 245.7).			
MET-63UM-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A
This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of			

Reference Information

Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

MET-SEM-ICP-VA Soil Simultaneously Extracted Metals (ICPOES) EPA 821/R-91-100; EPA 6010B

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-TESS-CM-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #2) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #2, the extraction solution is 1M Sodium Acetate adjusted to pH 5 and is intended to extract the "Carbonate" metals.

MET-TESS-EA-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #1) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #1, the extraction solution is 1M Magnesium Chloride and is intended to extract the "Exchangeable and Adsorbed" metals.

MET-TESS-FEO-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #3) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #3, the extraction solution is 0.1 M Hydroxylamine Hydrochloride in 25% v/v Acetic Acid and is intended to extract the Easily Reducible Metals and Iron Oxides .

MET-TESS-OB-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #4) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #4, the extraction solution is 0.02 M Nitric Acid followed by 3.2M Ammonium Acetate and is intended to extract the Organic Bound metals.

MET-TESS-RM-CCMS-VA Soil METALS BY CCMS (TESSIER RM EXTRACTION) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with up to 6 different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For the Tessier "RM" Extraction, the extraction solution is 50/50 mix of 1:1 Nitric Acid along with 1:1 Hydrochloric Acid, and is hot block digested as per the BC SALM procedure. This is intended to extract the Residual metals.

MOISTURE-VA Soil Moisture content ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

N-TOT-LECO-SK Soil Total Nitrogen by combustion method SSSA (1996) P. 973-974

Reference Information

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

PH-1:2-VA Soil pH in Soil (1:2 Soil:Water Extraction) BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PSA-PIPET+GRAVEL-SK Soil Particle size - Sieve and Pipette SSIR-51 METHOD 3.2.1

Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

Burt, R. (2009). Soil Survey Field and Laboratory Methods Manual. Soil Survey Investigations Report No. 5. Method 3.2.1.2.2. United States Department of Agriculture Natural Resources Conservation Service.

S-TOT-LECO-SK Soil Total Sulphur by combustion method ISO 15178:2000

The sample is ignited in a combustion analyzer where sulfur in the reduced SO₂ gas is determined using a thermal conductivity detector.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Workorder: L1661656

Report Date: 06-OCT-15

Client: MOUNT POLLEY MINING CORP.

PO Box 12

Likely BC VOL 1N0

Page 27 of 27

Contact: Colleen Hughes

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
B	Method Blank exceeds ALS DQO. All associated sample results are at least 5 times greater than blank levels and are considered reliable.
DLB	Detection Limit Raised. Analyte detected at comparable level in Method Blank.
J	Duplicate results and limits are expressed in terms of absolute difference.
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

16-08-2015 10:00

Failure to complete all portions of this form may delay analysis. Please fill in this form LEGIBLY. By the use of this form the user acknowledges and agrees with the Terms and Conditions as specified on the back page of the white - report copy.

1. If any water samples are taken from a Regulated Drinking Water (DW) System, please submit using an Authorized DW COC form.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Method Blank	Calcium (Ca)-Leachable	B	L1664712-13
Method Blank	Strontium (Sr)-Leachable	B	L1664712-13
Duplicate	Nickel (Ni)-Leachable	DLB	L1664712-13
Method Blank	Nickel (Ni)-Leachable	MB-LOR	L1664712-13

Qualifiers for Individual Parameters Listed:

Qualifier	Description
B	Method Blank exceeds ALS DQO. All associated sample results are at least 5 times greater than blank levels and are considered reliable.
DLB	Detection Limit Raised. Analyte detected at comparable level in Method Blank.
DLM	Detection Limit Adjusted due to sample matrix effects.
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
---------------	--------	------------------	--------------------

AVS-COL-VA Soil Acid volatile sulphide by colourimetric EPA 821/R-91-100
 This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The evolved hydrogen sulphide (H₂S) is carried into a basic zinc acetate (ZnAc) solution by argon gas. The acid volatile sulfide is then determined colourimetrically.

C-TOT-63UM-LECO-SK Soil Total Carbon by combustion method (63um) SSSA (1996) P. 973-974
 The sample is ignited in a combustion analyzer where carbon in the reduced CO₂ gas is determined using a thermal conductivity detector.

C-TOT-ORG-63UM-SK Soil Organic Carbon by combustion method(63um) SSSA (1996) p. 973
 Total Organic Carbon (C-TOT-ORG-LECO-SK, C-TOT-ORG-SK)

Total C and inorganic C are determined on separate samples. The total C is determined by combustion and thermal conductivity detection, while inorganic C is determined by weight loss after addition of hydrochloric acid. Organic C is calculated by the difference between these two determinations.

HG-63UM-CVAF-VA Soil Hg in Soil by CVAFS EPA 200.2/245.7

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).

HG-SEM-CVAFS-VA Soil Simultaneously Extracted Metals in Soil EPA 821/R-91-100; EPA245.7

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA 245.7).

MET-63UM-CCMS-VA Soil Metals in Soil by CRC ICPMS EPA 200.2/6020A

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may

Reference Information

be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

MET-SEM-ICP-VA Soil Simultaneously Extracted Metals (ICPOES) EPA 821/R-91-100; EPA 6010B

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-TESS-CM-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #2) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #2, the extraction solution is 1M Sodium Acetate adjusted to pH 5 and is intended to extract the "Carbonate" metals.

MET-TESS-EA-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #1) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #1, the extraction solution is 1M Magnesium Chloride and is intended to extract the "Exchangeable and Adsorbed" metals.

MET-TESS-FEO-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #3) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #3, the extraction solution is 0.1 M Hydroxylamine Hydrochloride in 25% v/v Acetic Acid and is intended to extract the Easily Reducible Metals and Iron Oxides .

MET-TESS-OB-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #4) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #4, the extraction solution is 0.02 M Nitric Acid followed by 3.2M Ammonium Acetate and is intended to extract the Organic Bound metals.

MET-TESS-RM-CCMS-VA Soil METALS BY CCMS (TESSIER RM EXTRACTION) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with up to 6 different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For the Tessier "RM" Extraction, the extraction solution is 50/50 mix of 1:1 Nitric Acid along with 1:1 Hydrochloric Acid, and is hot block digested as per the BC SALM procedure. This is intended to extract the Residual metals.

MOISTURE-VA Soil Moisture content ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

N-TOT-LECO-SK Soil Total Nitrogen by combustion method SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

PH-1:2-VA Soil pH in Soil (1:2 Soil:Water Extraction) BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH

Reference Information

probe.

PSA-PIPET+GRAVEL-SK Soil Particle size - Sieve and Pipette SSIR-51 METHOD 3.2.1

Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

Burt, R. (2009). Soil Survey Field and Laboratory Methods Manual. Soil Survey Investigations Report No. 5. Method 3.2.1.2.2. United States Department of Agriculture Natural Resources Conservation Service.

S-TOT-LECO-SK Soil Total Sulphur by combustion method ISO 15178:2000

The sample is ignited in a combustion analyzer where sulfur in the reduced SO₂ gas is determined using a thermal conductivity detector.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

1	2
---	---

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
B	Method Blank exceeds ALS DQO. All associated sample results are at least 5 times greater than blank levels and are considered reliable.
J	Duplicate results and limits are expressed in terms of absolute difference.
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

ALS Form 0206 v03 Form 04 January 2014

Failure to complete all portions of this form may delay analysis. Please fill in this form LEGIBLY. By the use of this form the user acknowledges and agrees with the Terms and Conditions as specified on the back page of the white - report copy.

1. If any water samples are taken from a Regulated Drinking Water (DW) System, please submit using an Authorized DW COC form.

APPENDIX C
SEDIMENT QUALITY DATA

C1.0 DATA QUALITY ASSESSMENT OF SEDIMENT SAMPLES

C1.1 Method Detection Limits

Method detection limits (MDLs) of the analytical laboratory reports (Appendix B) were examined and assessed in all cases where sample results were reported as less than the MDL. Target MDLs for moisture, Acid Volatile Sulphide (AVS), and Simultaneously Extractable Metals (SEM) were provided by the analytical laboratory (ALS Environmental) as a component of the analytical laboratory quote prior to sample submission and analysis (Table C.1). The target MDL for moisture was met in all cases, but the target MDL for AVS analyses was not met for 5 of the 22 samples analysed which had results < MDL. In general, where < MDL results were reported for AVS (32% of samples) the achieved detection limits for AVS were lower than the sum of SEM metals reported and therefore had little effect on data interpretability. For SEM analyses in sediment, target MDLs were not achieved for cadmium, lead, and nickel in 12 of the 22 samples due to high sample moisture content requiring an adjustment of the detection limits for these three analytes. Given that these metals have not been shown to be parameters of interest or indicator parameters in the collected sediment (Minnow 2015a), this did not affect data interpretation. Overall, MDLs achieved for the moisture, AVS, and SEM analyses were appropriate for the study, and did not adversely affect data interpretability.

MDLs achieved in the selective extraction analyses (SEA or “Tessier” extractions) met the laboratory target MDLs for most metals and extractants (Table C.1), with the exception of the following: 1) nickel in “exchangeable” extracts; and 2) antimony, beryllium, bismuth, cadmium, lithium, molybdenum, phosphorus, selenium, silver, thallium, tin and titanium in the “easily reducible and iron oxide” extracts. The target MDL for nickel in the “exchangeable” extract was exceeded in 11 of the 18 reported results due to detection of the analyte in a method blank and an accompanying increase in detection limit. Within the “easily reducible and iron oxide” extract, the target MDLs were exceeded for the results of 12 analytes within 8 of the 17 analysed samples, with the detection limits raised for analyte results in these samples due to sample matrix interferences. None of these 12 analytes, however, have been shown to be parameters of interest or indicator parameters in sediment from these sampling areas (Minnow 2015a), therefore data interpretation was not affected. For data interpretation, SEA results were primarily used to provide perspective on the relative distribution of metals among extracts (or “phases”), and results below the target MDLs did not impair interpretation. Copper is the primary parameter of

interest in the collected sediment (i.e. Minnow 2015a), and target MDLs were met for all SEA extracts. Overall, the cases of achieved MDLs higher than target had a negligible effect on data interpretability.

C1.2 Laboratory Blank Sample Analysis

All of the method blank results within laboratory reports L1661656 and L1664712 associated with moisture, AVS, and SEM analyses were non-detectable (Appendix B) and are therefore considered reliable. Only eleven (3%) of the 405 laboratory method blank samples associated with selective extraction analyses (Tessier) were detectable. Eight of these detectable method blank samples were associated with sample results at least five-times greater than blank levels, and are therefore considered reliable. For the rest (three method blank samples), the Limits of Reporting were adjusted by the laboratory for samples with results below five-times blank level (Appendix B). Consequently, these data are also considered reliable. The method blank results for this study indicate no inadvertent contamination of samples within the laboratory during sediment analysis

C1.3 Data Precision

Field Duplicate Samples

Two field duplicate samples were collected for quality assurance (Table C.2). The relative percent difference (RPD) between duplicates was less than the DQO of 40% for all the parameters reported (moisture, AVS, SEM, and SEA results). Overall, the precision associated with sediment quality analyses is considered excellent.

Laboratory Duplicate Samples

Within the two laboratory reports L1661656 and L1664712, five laboratory duplicate samples were evaluated for moisture; two laboratory duplicate samples were evaluated for AVS and SEM, and another three laboratory duplicates were evaluated for SEA metals (Appendix B). All laboratory duplicate results (370 in total) met ALS Environmental's data quality objectives of < 25% RPD for moisture, < 40% RPD for AVS, and <30% RPD for SEM and SEA metals (Appendix B), and thus laboratory precision achieved in this study is considered good.

C1.4 Data Accuracy

Data accuracy within the laboratory reports L1661656 and L1664712 was evaluated based on results of certified reference materials (CRM) and laboratory control samples (LCS; Appendix B). Specifically, two CRM samples were used to evaluate the accuracy

of SEM metals analyses, nine LCS were used to evaluate the accuracy of moisture analyses, two LCS samples were used to assess the accuracy of AVS analyses, and three LCS were used to evaluate the accuracy of SEA metals analyses (Appendix B). All CRM and LCS results (368 in total) met ALS Environmental's data quality objectives for accuracy (Appendix B) and thus laboratory accuracy achieved in this study is considered good.

C1.5 Holding Time and General Laboratory Flags

All sediment analyses were conducted within ALS Environmental's recommended hold times. There were no general laboratory flags associated with either analytical report (ALS Environmental Report L1661656 and L1664712; Appendix B).

Table C.1: Laboratory method detection limit (MDL) evaluation for sediment chemistry analysis (Simultaneously Extracted Metals, Acid Volatile Sulphides, and Selective Extraction Analyses) relative to laboratory target method detection limits. Only analytes with < MDL values are reported.

Parameter	Units	ALS Laboratory Target Method Detection Limit	Maximum Method Detection Limit Achieved

SEM/AVS ratio exceeds 1; SEM is in excess of AVS present.

¹ Summary statistics were calculated using method detection limit (MDL) values if data were below the MDL, and were shown with a < symbol if all data used in their calculation were below the MDL. If MDLs were variable, means were reported as < the maximum MDL and this value was used in 95% confidence limit calculations.

² Analytical reports presenting this total organic carbon (TOC) data were provided with a previous memorandum (Minnow 2015b), and are not included in the present report.

³ Excess SEM (SEM in excess of AVS) may exist in the free metal form if not bound to other constituents (i.e. organic carbon).

⁴ Organic carbon-normalized excess SEM = [Excess SEM/fraction OC], where fraction OC is the organic carbon content (Di Toro et al 2005). The mean TOC was used in calculations if data were not available for each station (i.e. BOL-B2).

Available AVS exhausted at this step of SEM binding sequence

¹ Concentrations of excess SEM were calculated according to the binding sequence of SEM with AVS, as determined by the solubility coefficient of each metal sulfide (Di Toro 1990; ICMM 2007).

² Excess SEM (SEM in excess of AVS) may exist in the free metal form if not bound to other constituents (i.e. organic carbon).

Table C.4: Calculation of Simultaneously Extractable Metal (SEM) concentrations in excess of Acid Volatile Sulphides (AVS) present in sediment, Mount Polley Mine, August 2015 ¹.

 Available AVS exhausted at this step of SEM binding sequence

¹ Concentrations of excess SEM were calculated according to the binding sequence of SEM with AVS, as determined by the solubility coefficient of each metal sulfide (Di Toro 1990; ICMM 2007).

² Excess SEM (SEM in excess of AVS) may exist in the free metal form if not bound to other constituents (i.e. organic carbon).

Table C.5: Comparison of Selectively Extracted (Tessier extraction) metals data for Polley Lake, Bootjack Lake, and Quesnel Lake sediment sampling areas, Mount Polley Mine, 2014 and 2015 ¹.

Re: Investigation of the Influence of Sediment Physical Characteristics on Sediment Toxicity Test Results

This memorandum provides a summary of an investigation of the influence of sediment physical characteristics, including total organic carbon (TOC) content and particle size, on sediment toxicity test results. The investigation is a follow-up to observations of effects on survival and growth in standard toxicity tests of *Chironomus dilutus* and *Hyalella azteca* (Environment Canada 1997, 2013) conducted on sediments influenced by Mount Polley mine tailings, as reported in an assessment undertaken in 2014 (Minnow 2015a).

Background

Characterization of the impact of the Mount Polley Mine tailings dam failure (August 4, 2014) on sediment quality of Polley Lake, Hazeltine Creek and Quesnel Lake included sediment toxicity testing using 10-day tests of the midge *C. dilutus* and 14-day tests of the amphipod *H. azteca* (Minnow 2015a; using approved biological test methods of Environment Canada 1997, 2013). This toxicity testing indicated effects to the survival and growth of both test organisms in tailings-affected sediments collected in Hazeltine Creek and in deep areas of Quesnel Lake, limited effects to the survival of *C. dilutus* (only) in near-field locations of Polley Lake, and to *C. dilutus* growth (only) in shallow areas of Quesnel Lake. Sediments collected from Hazeltine Creek and the deep areas of Quesnel Lake, in particular, were atypical of sediments generally present in aquatic environments, those collected from reference areas, and/or those from the same locations pre-event. Physical differences included uniform particle size, relatively high density, and relatively low TOC content. Chemical differences included elevated metal concentrations.

In Hazeltine Creek, Polley Lake, Quesnel Lake shallow and Quesnel Lake deep areas, negative correlations between sediment chemistry and toxicity test endpoints of survival and growth were observed (Minnow 2015a). However, in Hazeltine Creek and Quesnel Lake, the sediment and tailings mixtures differed from the naturally occurring sediments on the basis of the physical factors listed above, and positive correlations between sediment TOC content and toxicity test endpoints of survival and growth were also observed (Minnow 2015a). Therefore, the cause of the measured effects was not clear. Given this uncertainty, and the geochemical results indicating that the tailings were relatively inert (SRK 2015a,b), it was considered premature to attribute the effects solely to copper or other metals (Minnow 2015a; Golder 2015).

This purpose of this study was to address uncertainty identified in the initial sediment toxicity testing. A two step approach was used:

1. review the published literature regarding the influence of sediment organic carbon and sediment particle size distribution on *C. dilutus* and *H. azteca* toxicity test results; and
2. design and implement a study to test the influence of these variables as they relate to the sediments that have been impacted by the Mount Polley tailings.

Brief Literature Review

A brief literature review was undertaken, starting with the reference documents for the tests that were implemented (Biological Test Methods of Environment Canada 1997, 2013). This brief review indicated that relatively few studies have been undertaken that specifically investigate the influence of sediment particle size distribution and/or sediment organic matter content on the results of sediment toxicity tests. It also indicated that the studies that did investigate these influences did not investigate sediment as atypical as the Mount Polley tailings-affected sediments and that the studies were generally designed to determine if the tests met their performance criteria (control survival of $\geq 70\%$ for *C. dilutus* and $\geq 80\%$ for *H. azteca*).

The Biological Test Method Document for *C. tentans* (the former species name of *C. dilutus*) provides several references indicating that survival is affected by sediment organic matter content and that growth is affected by sediment particle size and by sediment organic matter content (Appendix A). They report that *C. tentans* and *C. riparius* can tolerate a wide range of substrates (e.g., Ingersoll and Nelson 1990; Ankley et al. 1994), but that *C. tentans* survival and growth were enhanced in coarser substrates (Ankley et al. 1994 and Bedard

1989, respectively). They report conflicting results on the influence of organic matter. Milani et al. (1996) reported that survival and growth of *C. riparius* was not influenced by organic carbon over a range from 0.6% to 8.8%, whereas Suedel et al. (1993) reported *C. tentans* intolerance to sediments with organic content less than 1% and Suedel and Rodgers (1994a) reported poor survival of *C. tentans* of 0.5% or lower. In comparison, sediments collected from the areas most impacted by Mount Polley mine tailings - Hazeltine Creek and Quesnel Lake - had TOC concentrations of 0.2% or lower (Minnow 2015a).

In addition to the findings cited in the Biological Test Method document, an independent review of the literature was undertaken. As indicated above, Suedel and Rodgers (1994a) found that *C. tentans* was tolerant (survival $\geq 80\%$) of all particle size regimes examined (i.e., 0 to 100% sand, 0 to 100% silt, and 0 to 60% clay). However, they also noted a significant positive correlation between *C. tentans* survival and percent silt and organic matter (Suedel and Rodgers 1994a). Similarly, Sibley et al. (1998) found a significant decrease in *C. tentans* survival in life cycle tests with exposure to 8 μm sediment, which is comparable to the grain size of clay. Even in studies that did not identify statistically significant effects of particle size on *C. tentans*, poorest survival occurred in clay samples (Suedel and Rodgers 1994a; Sibley et al. 1998). For example, Sibley et al. (1998) reported poorest survival at 20 days in fine sediment (8 μm), corroborated by other life cycle endpoints (total emergence, time to first emergence, rate of emergence, number of egg masses). Ankley et al. (1994) summarized results of 10-day tests of larval *C. tentans* held in 50 samples of uncontaminated Great Lakes sediment having particle sizes ranging from 95% clay to 100% sand and an organic carbon content from 0.3 to 8.1%, and suggested that growth might have been slightly influenced by grain size, with some improvement in growth in coarser sediments. Similarly, as indicated in the Biological Test Method document, an influence of particle size on growth was observed by Bedard (1989), who noted that growth of larval *C. tentans* was enhanced in the laboratory by coarser substrates with $>80\%$ sand. Overall, although findings are not in complete agreement among studies, several clearly indicate that that particle size distribution can influence the results of tests of *C. dilutus*.

The influence of organic matter on the growth of *C. tentans* is clearer than that of particle size. This is perhaps not surprising as it is required for food and for case building (e.g., Oliver 1971). For example, Suedel and Rodgers (1994a) documented a minimum organic matter requirement between 0.76% and 0.91% when *C. tentans* were fed daily during 10-day exposures. Suedel and Rodgers (1994a) also found poor (10 to 50%) survival rates for

C. tentans (fed daily) in tests of field-collected sediment from “relatively pristine areas” which were low (0.12 to 0.19%) in organic content, that organic content of 0.5% caused a significant reduction in percent survival, that only 33% of larvae survived in formulated control sediment with 0.0% organic content, and that larval *C. tentans* survived well if organic content was 3 to 5%.

The influence of particle size and organic carbon seems to be less well studied and less clear for *H. azteca* than for *C. dilutus*, which is consistent with their relative behaviours – *H. azteca* is largely epibenthic whereas *C. dilutus* is infaunal. The Biological Test Method Document for *H. azteca* (Environment Canada 2013) cites several studies that suggest tolerance to a wide range of particle size and organic content (Appendix A). For example, Ingersoll and Nelson (1990), Ankley et al. (1994) and Suedel and Rodgers (1994b) indicate that survival of *H. azteca* was greater than 80% over a wide range of particle sizes and organic content tested. The Biological Test Method document reports an influence of organic matter on tolerance to a surfactant (Cano et al. 1996), but this result is likely due to chemical sorption rather than a direct influence on the organism.

In addition to the findings cited in the Biological Test Method document, an independent review of the literature was undertaken. Ankley et al. (1994) covered a wide range of particle sizes and organic carbon content using natural sediments (e.g., from >90% clay to almost 100% sand and from 0.3% to 8.1% TOC), but only one sample had high clay content. Suedel and Rodgers (1994b) did not test sediment with more than 5% clay, but covered a wide range of organic matter content (0.13% to 7.8%) and concluded that *H. azteca* is a more appropriate organism than *C. tentans* for evaluating sediments with organic matter content <1.0%. However, as Ankley et al. (1994) state with respect to their study, these studies exhibited a limited response range for *H. azteca* and therefore the probability of identifying additional parameters influencing the assay results was low. This is largely because the studies were simply designed to determine whether the tests met acceptability criteria (survival \geq 80%) rather than to investigate potential differences due to physical factors. More recently, an effect of organic matter on the growth of *H. azteca* was demonstrated by Orr et al. (2004), who documented a significant decrease in length from exposure to sediment with low organic matter content (1.52%) and a clear trend of increasing length with increasing organic matter. Orr et al. (2004) suggest that, although amphipods are fed daily in sediment toxicity tests, food resources may limit growth in sediment with low organic matter content. Furthermore, although caution should be applied to extrapolating across species, it is notable that fine-grained uncontaminated sediments

have been found to impact survival of the marine amphipod *Rhepoxynius abronius* (Ott 1986; DeWitt et al. 1988), reportedly due to suffocation when burrowing is attempted (DeWitt et al. 1988).

Review of the available literature provides clear evidence that survival and growth of *C. dilutus* can be affected by sediment particle size distribution and organic matter content. In the case of *H. azteca*, there is no evidence in the scientific literature of an effect of sediment particle size distribution or organic matter content on survival, but there is clear evidence of an effect of sediment organic matter content on growth. However, there is evidence of an effect of fine particles on the survival of the marine amphipod *R. abronius*. Overall, the results of the literature review are summed up well by Suedel and Rodgers (1994a) observation that “sediment toxicity may be due to physical and biological characteristics as well as chemical contamination of sediments. The ability to distinguish between these effects would reduce the probability of concluding that a sediment is chemically toxic when it is not.”

Methods

Study Design

A simple investigation was designed to evaluate the influence of sediment TOC content and particle size distribution on toxicity test results using *C. dilutus* and *H. azteca*, and to verify previous results (Table 1). Key questions include:

- Does sediment TOC content affect the results of sediment toxicity tests?
- Does particle size distribution affect the results of sediment toxicity tests?
- Are results similar to those observed in 2014 (Minnow 2015a)?

The first question was asked because sediment TOC in certain tailings-influenced areas (e.g., Hazeltine Creek and Quesnel Lake) was much lower than reference or historical and below levels that have been observed (in the scientific literature) to adversely affect survival and/or growth. This question was addressed by adding TOC to the tailings affected sediment, to reference sediment and to controls (Table 1). The second question was asked because sediment particle size distribution in certain tailings-influenced areas (e.g., Hazeltine Creek and Quesnel Lake) differed substantially from reference or historical and may affect survival and/or growth. This question was addressed by adding a clay control to better represent the fine sediments of the Quesnel Lake profundal area (Table 1). The third question was addressed by comparing the results of sediment toxicity testing conducted in 2015 to those conducted in 2014.

Sampling

Sediment samples were collected from five exposed (tailings-impacted) stations (PNF) and five reference stations (PREF1) in Quesnel Lake at an approximate depth of 100 meters between August 13th and 26th 2015 (Figure 1). The sampling stations were the same as the Quesnel Lake profundal near-field and reference stations in 2014 (Minnow 2015a). Sediments were collected using a stainless steel petite ponar (15.24 cm x 15.24 cm; 0.023 m² sampling area) or a stainless steel standard ponar (22.86 cm x 22.86 cm; 0.052 m² sampling area) in accordance with technical guidance outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for EEM (Environment Canada 2012). Samples were collected with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). At each station, composite samples of the top three centimeters of surficial sediment of three to ten acceptable grabs (i.e., full to each edge of the sampler) were collected. Each grab was collected into a plastic tote and observed for completeness and any unusual characteristics. If the sample was deemed acceptable, surficial material to a depth of 3 centimeters was transferred to a second tote using a stainless steel spoon. Remaining sediment was discarded. The procedure was then repeated for all subsequent grabs. The material within the tote was homogenized using a stainless steel spoon and transferred into 500 mL glass sampling jars labeled with the project number, sample location and collection date. All sampling equipment was rinsed between stations using site water. Sediment samples were shipped to the toxicity testing laboratory (Nautilus Environmental) and to the analytical laboratory (ALS Environmental) at completion of the sampling program. Prior to shipment, samples were placed in a cooler with frozen ice packs and a chain-of custody form was prepared and packed with the samples. Coolers were shipped overnight for next day delivery.

Toxicity Testing

Upon receipt, Nautilus Environmental opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and confirmed sample receipt with MPMC and Minnow. Toxicity testing of *C. dilutus* and *H. azteca* are outlined in detail in Nautilus 2016 (Appendix B). Briefly, Nautilus set up five field-replicate test vessels (i.e., with each replicate representing a sampling station) with each of nine treatments (Table 1). The TOC treatments (control+TOC, kaolin clay+TOC, field reference+TOC, and exposed+TOC) were created by amending the original sediments with a 50:50 mixture of peat moss and ground Tetramarin fish flakes to yield a

nominal TOC concentration of 2%. A treatment made up of a 1:1 mixture of exposed sediment and field reference sediment was also prepared and tested. The pH of the kaolin clay controls was low after adding the overlying water (~pH 4.5), and was adjusted to neutral pH using sodium hydroxide prior to addition of test organisms. Toxicity testing was conducted according to procedures described by Environment Canada (1997 and 2013). Statistical analyses for the tests were performed using CETIS (Tidepool Scientific Software 2013).

Data Analysis

In addition to the statistical analyses completed by Nautilus (2016), toxicity test results were evaluated using Analysis of Variance (ANOVA) and Kruskal-Wallis (the non-parametric equivalent test) to test for overall differences among treatment means, followed by post-hoc multiple contrasts. Due to small sample size (i.e., five replicates in accordance with the test methods), data could not be evaluated for normality. Therefore, the choice of transformation was evaluated based on homogeneity of variance. This resulted in a logit transformation being applied to survival data of both *H. azteca* and *C. dilutus* and a log_e transformation being applied to growth data for *H. azteca*. All transformations resulted in unequal variance of the *C. dilutus* growth dataset. ANOVA followed by either Bonferroni (equal variance) or Tamhane's (unequal variance) multiple contrast tests were performed using raw and transformed data. In addition, the non-parametric Kruskal-Wallis test followed by Mann-Whitney multiple contrast tests were also performed using raw data. Significance of all tests was established as a p-level of 0.05. Although parametric and non-parametric tests generally agreed, the non-parametric tests results were used for data interpretation when the two approaches did not yield the same result. This is consistent with recent recommendations for testing when the assumptions of parametric testing cannot be definitively demonstrated (e.g., Sawilowsky 2005). In addition, magnitudes of difference were calculated for all multiple contrast pairs as the mean of Treatment 2 minus the mean of Treatment 1 all divided by the mean of Treatment 1. It was then relativized by dividing by the standard deviation of Treatment 1. The minimum detectable effect size was calculated as per EEM guidance (Environment Canada 2012) and expressed in units of Treatment 1 standard deviations.

Relationships between toxicity test results and TOC concentrations were explored using plots, and simple linear regression was performed using SPSS statistical software and application of an uncorrected significance level $p=0.05$ and Bonferroni-corrected significance level of 0.0125 ($p=0.05/4$ endpoints). The latter p-value was applied to

minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected p-value of 0.05.

Results

Sediment Chemistry

Sediment chemistry data have been reported under separate cover (Minnow 2015b) and are also included in Appendix C. Briefly, sediments collected in 2015 were very similar to those collected in 2014 (Appendix Tables C.1 and C.2). Quesnel Lake profundal reference sediments were composed primarily of silt (70%), with only 11% clay and 20% sand (Appendix Table C.1). Quesnel Lake profundal near-field exposed sediments were also composed primarily of silt (58%), but the remainder was mostly clay (36%; Appendix Table C.2). TOC content of the exposed sediments (0.29%) was much lower than the reference sediment (1.82%; Appendix Tables C.1 and C.2) and lower than the TOC content observed by Suedel and Rodgers (1994a) to significantly reduce survival of *C. dilutus* (i.e., less than approximately 0.76% to 0.91%; see above). Sediment metal concentrations in the profundal near-field area in 2015 were very similar to those observed in 2014, with mean concentrations of arsenic, copper, iron, and manganese greater than both reference and the lower guidelines of the British Columbia working sediment quality guidelines (BCMOE 2015). Average concentrations of copper and manganese, and 95th percentile concentrations of iron, also exceed upper guidelines of the British Columbia working sediment quality guidelines (BCMOE 2015). However, previous investigations of Mount Polley tailings and tailings-influenced sediment have indicated that mobility and bioavailability of tailings-associated metals is low (SRK 2015a,b; Minnow 2015a), and the most recent geochemical investigation of tailings material indicates that non-sulphide copper is likely present as chlorite and is considered to be non-reactive (SRK 2015b).

Sediment Toxicity

***C. dilutus* Survival**

Survival of *C. dilutus* was $\geq 80\%$ in all treatments, indicating limited response overall (Table 2; Figure 2). A reduction of 20% is often applied as a threshold for a meaningful reduction in survival (e.g., Suter et al. 1995; Mebane 2010; Nautilus and Zajdlik 2011). Survival of *C. dilutus* in the exposed (failure-influenced) sediment (PNF; $86 \pm 11.4\%$) did not differ from the reference sediment, indicating no significant tailings-associated effect on survival (Table 2; Figure 2; Appendix Table D.2). This result differs from 2014 when *C. dilutus* survival in exposed sediment was significantly lower than reference (Minnow 2015a). Survival of *C.*

Table 2: Summary of sediment toxicity testing results, with statistical comparison to laboratory control and field reference

Sample ID	<i>Chironomus dilutus</i>			<i>Hyalella azteca</i>		
	Survival ± SD (%)	Average Dry Wt. ± SD (mg)		Survival ± SD (%)	Average Dry Wt. ± SD (mg)	
Control ¹	100.0 ± 0.0	2.15 ± 0.14		94.0 ± 5.5	0.24 ± 0.02	
Control + 2% TOC ^{1,2}	90.0 ± 10.0	3.11 ± 0.25		68.0 ± 13.0 ^{a,b}	0.13 ± 0.03 ^a	
Kaolin Clay Control	82.0 ± 4.5 ^a	1.88 ± 0.57 ^b		62.0 ± 8.4 ^{a,b}	0.06 ± 0.01 ^{a,b}	
Kaolin Clay Control + 2% TOC ²	80.0 ± 10.0 ^a	2.87 ± 0.63		90.0 ± 14.1	0.15 ± 0.02	
Field Reference	92.0 ± 4.5	2.65 ± 0.23		100.0 ± 0.0	0.22 ± 0.06	
Field Reference + 2% TOC ²	84.0 ± 20.7 ^a	4.49 ± 0.59		95.0 ± 5.5	0.24 ± 0.06	
Exposed	86.0 ± 11.4 ^a	1.61 ± 0.22 ^{a,b}		80.0 ± 15.8 ^b	0.09 ± 0.03 ^{a,b}	
Exposed + 2% TOC ²	92.0 ± 4.5	3.45 ± 0.19		90.0 ± 10.0	0.19 ± 0.04	
Exposed + Reference (50:50)	92.0 ± 4.5	2.25 ± 0.21		82.0 ± 19.2 ^b	0.16 ± 0.05	

^a indicates a treatment mean that is significantly different from the laboratory control (sand)

^b indicates a treatment mean that is significantly different from the field reference sediment

¹ standard control sediment = sand

² total organic carbon - as a combination of peat and fish food

Figure 2: Survival of *Chironomus dilutus* in field and control sediments (mean \pm standard deviation)¹

¹ Letters above bars indicate significant differences

Note: Con = Laboratory Sand Control, Kao = Kaolin Clay, Ref = Reference, Exp = Exposure, and Ref:Exp = 50:50 ratio of Reference and Exposure

dilutus in the exposed sediment was significantly lower than in the laboratory control sediment, but this was true of most other treatments due to an absence of variability in the sand control, and suggests a potential influence of particle size on survival (and that the sand control alone is not appropriate for deriving conclusions of effect for this endpoint under these sediment physical characteristics).

Survival of *C. dilutus* in the exposed sediment ($86 \pm 11.4\%$) did not differ significantly from the kaolin clay control ($82 \pm 4.5\%$) nor the kaolin clay control with added TOC ($80 \pm 10\%$), but survival in kaolin clay tests were significantly lower than in laboratory control and field reference (Figure 2 and Appendix Table D.2). This suggests reduced survival in clay-sized particles, although an influence of pH (which drifted lower as also observed by Suedel and Rodgers [1994b] but was adjusted in the laboratory prior to organism addition) cannot be ruled out.

Amendment with 2% TOC resulted in an increase in *C. dilutus* survival in exposed sediment from $86 \pm 11.4\%$ to $92 \pm 4.5\%$, although the difference was not statistically significant (Figure 2 and Appendix Table D.2). Addition of TOC did not increase survival in any other treatment, although Nautilus (2016) indicated that TOC did not mix well with the control sediment nor with the kaolin clay. The 50:50 mix of exposed and reference sediment (intermediate, nominally 1% TOC) returned exactly the same survival as the exposure sediment + 2% TOC ($92 \pm 4.5\%$; Figure 2 and Appendix Table D.2).

C. dilutus Growth

Dry weight of *C. dilutus* was more variable among treatments than survival, indicating an apparent growth response (Table 2; Figure 3). Dry weight of *C. dilutus* in the exposed (i.e., failure-influenced) sediment (PNF; 1.61 ± 0.22 g) was significantly lower than in both the sand control (2.15 ± 0.14 g) and the field reference sediment (2.65 ± 0.23 g; Table 2; Figure 3; Appendix D.2), indicating an effect on growth as also observed in 2014 (Minnow 2015a). Dry weight in the exposed sediment (1.61 ± 0.22 g) did not differ significantly from the kaolin clay control (1.88 ± 0.57 g), the latter of which was also significantly lower than the field reference (Figure 3 and Appendix Table D.2). This suggests an effect of particle size and/or TOC. The fact that dry weight of the organisms exposed to the kaolin clay control was lower than those exposed to the field reference sediment but not the sand control suggests that TOC is the more likely cause of growth differences.

Amendment with 2% TOC resulted in statistically significant increases in *C. dilutus* growth in every sediment type (Figure 3 and Appendix Table D.2). This indicates a clear influence

Figure 3: Dry weight (mg) growth of *Chironomus dilutus* in field and control sediments (mean \pm standard deviation)¹

¹ Letters above bars indicate significant differences

Note: Con = Laboratory Sand Control, Kao = Kaolin Clay, Ref = Reference, Exp = Exposure, and Ref:Exp = 50:50 ratio of Reference and Exposure

of TOC on *C. dilutus* growth even as organisms are fed daily in the tests. Importantly, the addition of 2% TOC to the low TOC exposure sediment resulted in a substantial increase in organism dry weight (from 1.61 ± 0.22 g to 3.45 ± 0.19 g) and resulted in a significantly greater dry weight relative to the control sediment and the field reference sediment. This strongly indicates that low TOC is a likely cause of growth differences in tests using *C. dilutus*. However, the addition of TOC can potentially reduce effects by two mechanisms: 1) the provision of additional food; and 2) the provision of additional binding for metals, rendering them unavailable (e.g., Sposito 1987; Campbell and Tessier 1996; Strom et al. 2011). Similar growth stimulation with TOC addition in exposed sediment, control sand, and kaolin clay suggest that provision of food is the dominant mechanism. This is also consistent with the geochemical finding that the tailings were relatively inert (SRK 2015a,b). The 50:50 mix of exposed and reference sediment caused intermediate growth stimulation relative to the 2% TOC addition, which is generally consistent with the hypothesis that growth rate is proportional to sediment TOC content over the range of conditions tested.

H. azteca Survival

Survival of *H. azteca* was more variable among treatments than survival of *C. dilutus*, indicating an apparent response, which was greatest in the laboratory control with added TOC and in the kaolin clay control (Table 2; Figure 4). Survival of *H. azteca* in the exposed (i.e., failure-influenced) sediment (PNF; $80 \pm 15.8\%$) was not reduced by more than 20% nor was it significantly lower than in the control sediment (clean sand; $94 \pm 5.5\%$; Table 2; Figure 4; Appendix Table D.2). However, it was significantly lower than in the field reference sediment ($100 \pm 0.0\%$), but this was true of most other treatments due to an absence of variability in the field reference. As with *C. dilutus*, the absence of a significant tailings-associated effect on survival of *H. azteca* differs from 2014 when survival in exposed sediment was significantly lower than reference (Minnow 2015a).

Survival of *H. azteca* in the exposed sediment ($80 \pm 15.8\%$) did not differ significantly from the kaolin clay control ($62 \pm 8.4\%$) nor the kaolin clay control with added TOC ($90 \pm 14.1\%$), but survival in the kaolin clay treatment was significantly lower than in the laboratory control and the field reference (Figure 4 and Appendix Table D.2). As noted for *C. dilutus*, this suggests reduced survival in clay-sized particles, although an influence of pH (which drifted lower as also observed by Suedel and Rodgers [1994b] but was adjusted in the laboratory prior to organism addition) cannot be ruled out.

Amendment with 2% TOC resulted in an increase in survival in exposed sediment from $80 \pm 15.8\%$ to $90 \pm 10\%$ (from significantly lower than the field reference sediment to

Figure 4: Survival of *Hyalella azteca* in field and control sediments (mean \pm standard deviation)¹

¹ Letters above bars indicate significant differences

Note: Con = Laboratory Sand Control, Kao = Kaolin Clay, Ref = Reference, Exp = Exposure, and Ref:Exp = 50:50 ratio of Reference and Exposure

statistically similar; Table 2) and in kaolin clay from $62 \pm 8.4\%$ to $90 \pm 14.1\%$, although only the latter difference was statistically significant (Figure 4 and Appendix Table D.2). Addition of TOC did not increase survival in laboratory control sediment or in the field reference sediment, although Nautilus (2016) indicated that TOC did not mix well with the control sediment nor with the kaolin clay. The improvement in survival with the addition of TOC to the low TOC sediment suggests that the influence of TOC supplementation on the survival of *H. azteca* may be restricted to conditions of very low TOC. This is consistent with the literature assessment that *H. azteca* is insensitive to TOC over normal test conditions (i.e., typical ranges of TOC), while still indicating a potential sensitivity under extremes of TOC that are not well studied in the literature.

H. azteca Growth

As observed with *C. dilutus*, dry weight of *H. azteca* was more variable among treatments than survival, indicating an apparent growth response (Table 2; Figure 4). Dry weight of *H. azteca* in the exposed (i.e., failure-influenced) sediment (PNF; 0.09 ± 0.03 g) was significantly lower than in both the sand control (0.24 ± 0.02 g) and the field reference sediment (0.22 ± 0.06 g; Table 2; Figure 5; Appendix Table D.2). This is the same as observed in 2014 (Minnow 2015a) and is also similar to the observations for *C. dilutus*, suggesting an effect on growth relative to control/reference sediments with moderate TOC and sand/silt substrate. Dry weight in the exposed sediment (0.09 ± 0.03 g) was significantly greater than in the kaolin clay control (0.06 ± 0.01 g), the latter of which was also significantly lower than in all other treatments (Figure 5 and Appendix Table D.2). This suggests an effect of substrate type as an important confounding factor; the lower dry weight of the kaolin clay control relative to the field reference and the sand control suggests particle size as a potential cause of growth differences.

Amendment with 2% TOC resulted in statistically significant increases in *H. azteca* growth in exposed sediment and kaolin clay, similar results in field reference sediment, and a statistically significant decrease in growth in the sand control (Figure 5 and Appendix Table D.2). As noted previously, Nautilus (2016) indicated that TOC did not mix well with the control sediment nor with the kaolin clay. The positive influence of TOC supplementation in the low TOC tests (exposure sediment and kaolin clay) indicates that low TOC is a likely cause of effects to the growth of *H. azteca*. As noted above, the addition of TOC can potentially reduce effects by two mechanisms (food availability, chemical bioavailability). However, the growth stimulation with TOC addition in both exposed sediment and kaolin clay suggest that provision of food is the dominant mechanism. The 50:50 mix of exposed

Figure 5: Dry weight (mg) growth of *Hyalella azteca* in field and control sediments (mean \pm standard deviation)¹

¹ Letters above bars indicate significant differences

Note: Con = Laboratory Sand Control, Kao = Kaolin Clay, Ref = Reference, Exp = Exposure, and Ref:Exp = 50:50 ratio of Reference and Exposure

and reference sediment (nominally 1% TOC) caused intermediate growth stimulation of the 2% TOC addition, which is generally consistent with the hypothesis that growth rate is proportional to TOC content over the range of conditions tested.

Regression Relationships

Sediment TOC content had a strong and statistically significant positive effect on the growth of *C. dilutus*, with TOC explaining approximately 91% of the variance in *C. dilutus* growth (Table 3; Figure 6). Statistically significant positive effects of sediment TOC content on the growth of *H. azteca* were not observed based on analysis of treatment means (Table 3; Figure 6), but strong and statistically significant positive effects on growth of *H. azteca* were observed when individual replicate/station results were evaluated (Table 3; Appendix Figures E.1 and E.2). No statistically significant effects of sediment copper (the primary POI representing the impact of the failure on sediment) on *C. dilutus* or *H. azteca* were observed based on analysis of treatment means (Table 3; Figure 7). However, weak negative effects of copper on *C. dilutus* growth and *H. azteca* survival and growth were observed in correlations that only included natural sediments (Table 3; Appendix Figures E.3 and E.4).

The absence of any strong relationships for survival of *C. dilutus* and *H. azteca* (Table 3; Figures 6 and 7) is consistent with the limited survival response. The strong positive relationships between sediment TOC and growth of both test organisms, coupled with weak negative relationships between sediment copper and test endpoints (present only when the controls were removed from the analysis), suggests that TOC is the dominant influence on the observed test organism growth. The fact that strong influences on growth were observed in TOC-deficient sediments and that the responses to TOC supplementation were similar in reference clay and failure-impacted sediment suggests that the influence of TOC was as a nutrition source.

Summary

Both the scientific literature and the results of this site-specific investigation indicate the importance of sediment physical characteristics in the interpretation of sediment toxicity tests. The effects to toxicity test organisms observed in 2014 were of uncertain cause, with the candidate mechanisms including both physical and chemical factors (both of which were identified as related to the tailings dam failure; Minnow 2015a; Golder 2015). The uncertainty identified following the testing in 2014 is consistent with observations from other studies (including the test method document for *C. tentans*) and is summed up by Suedel

and Rodgers (1994a) statement that “sediment toxicity may be due to physical and biological characteristics as well as chemical contamination of sediments, and the ability to distinguish between these effects would reduce the probability of concluding a sediment is chemically toxic when it is not.” Accordingly, additional testing was conducted in 2015 to elucidate the respective roles of these factors, as well as to confirm the general patterns of toxicity observed in Quesnel Lake sediments in the 2014 testing program.

This additional investigation of toxicity of Quesnel Lake failure-impacted sediments indicated no effect to the survival of either test organism (*C. tentans* and *H. azteca*), which differs from 2014. In contrast, effects on growth of both test organisms were confirmed in 2015, with growth apparently being the more sensitive test endpoint in the impacted sediment tested. Effects on growth of *C. tentans* and *H. azteca* were eliminated with the addition of TOC to concentrations similar to reference conditions, and comparisons of exposed sediments to a clay control indicated either no difference from the clay control (*C. dilutus*) or slightly greater growth than the clay control (*H. azteca*). This is consistent with previous findings that *C. dilutus* is intolerant of sediment with TOC lower than approximately 1% despite feeding of the test organisms (Suedel and Rodgers 1994a). The consistent positive response to TOC amendment in both exposed sediment and reference clay (uncontaminated but with high fines content) suggests that the response to TOC was through provision of food resources rather than through additional metal binding capacity. Strong positive relationships were observed between growth of both organisms and TOC whereas there were no strong relationships with copper. These observations are consistent with geochemical investigations of both Mount Polley tailings and tailings-influenced sediment, which indicated that mobility of tailings-associated metals is low (SRK 2015a,b).

APPENDIX A

**EXCERPTS FROM THE
BIOLOGICAL TEST METHOD
DOCUMENTS**

APPENDIX A – Excerpts for the Biological Test Method Documents for Sediment Toxicity Tests of *Chironomus* (Environment Canada 1997) and *Hyaella* (Environment Canada 2013) on the Influence of Sediment Particle Size Distribution and Sediment Organic Matter Content on Toxicity Test Results

1) Excerpt from Biological Test Method: Test for Survival and Growth in Sediment Using the Larvae of Freshwater Midges (*Chironomus tentans* or *Chironomus riparius*) (Environment Canada 1997)

Larval *C. tentans* and *C. riparius* can tolerate a wide range of substrates. Ingersoll and Nelson (1990) reported that *C. riparius* could be reared in the laboratory in clean sediment with particle sizes ranging from >90% silt and clay to 100% sand, without detrimental effects on survival or growth. Bedard (1989) noted that growth of larval *C. tentans* was enhanced in the laboratory by coarser substrates with >80% sand. Results for 10-day tests with larval *C. tentans* held in 50 samples of uncontaminated Great Lakes sediment having particle sizes ranging from 95% clay to 100% sand and an organic carbon content from 0.3 to 8.1% suggested that growth might have been slightly influenced by grain size, with some improvement in growth in the coarser sediments (Ankley et al. 1994). Ten-day tests using larval, *C. riparius* held in samples of uncontaminated sediment with an organic carbon content ranging from 0.6 to 8.8% indicated that, within this range, the concentration of organic carbon did not influence survival or growth to a significant extent (Milani et al. 1996). In life cycle studies with laboratory formulated sediments, Suedel et al. (1993) found that *C. tentans* was tolerant of all particle size regimes examined (i.e., 0 to 100% sand, 0 to 100% silt, and 0 to 60% clay), but was intolerant of formulated control sediment with low (<1.0%) organic content. In 10-day studies with formulated control sediment, Suedel and Rodgers (1994a) found that larval *C. tentans* survived well if the organic content was 3 to 5%, whereas organics of 0.5% caused a significant reduction in percent survival and only 33% of larvae survived in formulated control sediment with 0.0% organics. Similar findings are reported in Suedel and Rodgers (1994b), together with results showing adequate (>80%) survival for fed *C. tentans* when held for 10 days in formulated sediment with 2.5% organics and particle sizes ranging from 100% sand to 100% silt. Suedel and Rodgers (1994b) also found poor (10 to 50%) survival rates for *C. tentans* fed daily during a 10-day exposure to several samples of field-collected sediment from "relatively pristine areas" which were low (0.12 to 0.19%) in organic content.

2) Excerpt from Biological Test Method: Test for Survival and Growth in Sediment and Water Using the Freshwater Amphipod *Hyalella azteca* (Environment Canada 2013)

The influence of natural physicochemical properties of sediments on the performance of *H. azteca* in sediment toxicity tests has been examined. Ingersoll and Nelson (1990) found that this species has an extremely wide tolerance of sediment grain size. In long-term exposures to clean sediments ranging from >90% silt- and clay-sized particles to 100% sand-sized particles, no detrimental effects on either survival or growth were noted. Similarly, Ankley et al. (1994) conducted 10-day *H. azteca* sediment assays using 50 uncontaminated samples of lake sediment with particle sizes ranging from 95% clay to 100% sand, and organic carbon content from 0.3 to 8.1%. These researchers found no correlation between amphipod survival rates and sediment characteristics including particle size, organic carbon content, or mineralogical composition, provided the animals were fed during the tests. In 10-day survival tests with laboratory-formulated or clean field-collected sediments, Suedel and Rodgers (1994a) determined that *H. azteca* was tolerant of all of the sediment particle size distributions (0 to 100% sand, 0 to 100% silt, and 0 to 60% clay) and ranges of organic carbon content (0.1 to 8.0%) examined. In 48-h tests with sediment spiked using a range of concentrations of alkylbenzene sulphonate, Cano et al. (1996) found that enriching the sediment with peat moss increased the acute lethal tolerance of *H. azteca* to this surfactant when total organic carbon content was >1.5%.

This report has been prepared by Nautilus Environmental Company Inc. based on data and/or samples provided by our client and the results of this study are for their sole benefit. Any reliance on the data by a third party is at the sole and exclusive risk of that party. The results presented here relate only to the samples tested.

1.0 INTRODUCTION

Nautilus Environmental conducted freshwater sediment toxicity tests for Mount Polley Mining Corp. on samples identified as PREF1 and PNF. The samples were collected between August 14 to 24, 2015 and delivered to the laboratory in Burnaby, BC on August 28, 2015. Each sample was collected as five field replicates and transported in five 1-L glass jars; samples were received at temperatures ranging between 5.5 and 11.8°C. The samples were stored in the dark at $4 \pm 2^\circ\text{C}$ prior to testing. An aliquot of each of the samples was amended with total organic carbon (TOC), as described in Section 2 and both the amended and unamended samples were tested. A mixture of samples PREF1 and PNF was also tested.

14-d *Hyalella azteca* and 10-d *Chironomus dilutus* survival and growth sediment toxicity tests were conducted on the samples. This report describes the results of these toxicity tests. Copies of laboratory data sheets and printouts of statistical analyses for the tests are provided in Appendices A and B. The chain-of-custody form is provided in Appendix C.

2.0 METHODS

Aliquots of samples PREF1 and PNF were amended with total organic carbon (TOC), which consisted of a 50:50 mixture of peat moss and ground Tetramarin fish flakes. One gram of this mixture was stirred into 100 mL of sediment in each test vessel, prior to addition of the overlying water; this amendment rate was estimated to reflect 2% TOC (assuming a 50% moisture content). Amended samples were identified as PREF1 + 2% TOC and PNF + 2% TOC. Both amended and unamended samples were tested for toxicity. A 1:1 mixture of PREF1 and PNF was also prepared and tested without amendment of TOC; this treatment was identified as PREF1+PNF.

A TOC amended control was prepared similarly to that described for the samples using control sediment (which is a fine beach sand). In addition, Kaolin clay, which is comprised of very fine grain size, was also tested with and without TOC amendment to determine whether the test organisms could tolerate sediments with very fine grain size. The pH of the kaolin clay controls was low after adding the overlying water (~pH 4.5), and was adjusted to neutral pH using NaOH prior to addition of test organisms.

Methods for the toxicity tests are summarized in Tables 1 and 2. Testing was conducted according to procedures described by Environment Canada (1997 and 2013). Statistical analyses for the tests were performed using CETIS (Tidepool Scientific Software, 2013).

Ammonia concentrations were monitored three times per week on the reference sample PREF1 to ensure that concentrations did not exceed 0.2 mg/L N of un-ionized ammonia. The ammonia concentrations in the overlying water of the samples and control were measured by ALS Environmental (Burnaby, BC) and are provided in Appendices A and B.

Table 1. Summary of test conditions: *Hyalella azteca* survival and growth test.

Test organism	<i>Hyalella azteca</i>
Test organism source	Aquatic Research Organisms, NH
Test organism age	2 - 9 days old
Test type	Static
Test duration	14 days
Test vessel	375 mL glass container
Test volume	100 mL sediment; 175 mL overlying water
Test replicates	5 field replicates per sample
Number of organisms	10 per replicate
Control water	Moderately-hard synthetic water prepared from dechlorinated municipal water (recipe from Environment Canada [2013])
Test solution renewal	None
Test temperature	23 ± 1°C
Feeding	0.75 mL of YCT and 1.35 mg Tetramin per replicate daily
Light intensity	500 to 1000 lux at water surface
Photoperiod	16 hours light/8 hours dark
Aeration	Gentle aeration throughout test
Test protocol	Environment Canada (2013), EPS 1/RM/33
Statistical software	CETIS
Test endpoint	Survival and dry weight
Test acceptability criteria for controls	Mean control survival of ≥80% survival and ≥0.1 mg/amphipod dry weight
Reference toxicant	Sodium chloride

Table 2. Summary of test conditions: *Chironomus dilutus* survival and growth test.

Test organism	<i>Chironomus dilutus</i>
Test organism source	Aquatic BioSystems, Fort Collins, CO
Test organism age	3 rd Instar
Test type	Static
Test duration	10 days
Test vessel	375-mL glass containers
Test volume	100 mL sediment; 175 mL overlying water
Test replicates	5 field replicates per treatment
Number of organisms	10 per replicate
Control water	Moderately-hard synthetic water prepared from dechlorinated municipal water (recipe from Environment Canada [2013])
Test solution renewal	None
Test temperature	23 ± 1°C
Feeding	6.0 mg Tetramin in 1.5 mL suspension per replicate daily
Light intensity	500 – 1000 lux at water surface
Photoperiod	16 hours light/8 hours dark
Aeration	Gentle aeration throughout test
Test protocol	Environment Canada (1997), EPS 1/RM/32
Statistical software	CETIS
Test endpoint	Survival and dry weight
Test acceptability criteria for controls	Mean control survival ≥70% survival and ≥0.6 mg/worm dry weight
Reference toxicant	Potassium chloride

3.0 RESULTS

Results of the toxicity tests using *H. azteca* are provided in Table 3 and associated ammonia measurements are provided in Table 5. The TOC-amended control exhibited survival and growth that was significantly lower than the control. The added TOC did not mix well into the sandy control sediment, resulting in accumulation of the TOC on the surface of the sediment, where signs of degradation, such as apparent growth of mould, were noted. Ammonia concentrations in this treatment were elevated (34.8 mg/L, compared with 0.3 mg/L in the control), and likely contributed to the adverse effects that were observed; Borgman (1994) reported that ammonia above 1 mM (i.e., 14 mg/L) resulted in mortality to this species. The kaolin clay control also performed poorly relative to the control; however, amending the kaolin clay with TOC produced survival that was not statistically different from the control, although growth was still impaired in this treatment relative to the control. The kaolin clay treatments produced low pH throughout the test (~pH 5), which may have contributed to effects observed in these treatments.

Sample PREF1 did not exhibit adverse effects on survival or growth of *H. azteca* relative to the control in either unamended or TOC-amended samples. One of the replicates of the TOC-amended PREF1 samples produced no survival; however, this appears to have been an anomalous response in this replicate, since the remaining replicates produced an average of 95.0% survival. Consequently, this replicate was removed prior to calculating the mean and standard deviation response reported in Table 3.

Sample PNF exhibited a significant reduction in growth of *H. azteca* relative to the control and both survival and growth relative to the reference sediment, PREF1; however, PNF amended with TOC did not produce survival or growth that was significantly reduced relative to either the control or reference sediment. The mixture of PREF1 and PNF exhibited survival that was significantly reduced relative to the PREF1; growth in this sample was greater than that observed in the PNF sample and was not statistically different from the control or the reference sample.

Results of the toxicity tests using *C. dilutus* are provided in Table 4 and associated ammonia measurements are provided in Table 6. The kaolin clay controls (both with and without amended TOC) exhibited statistically significantly reduced survival relative to the control. The PNF sample and PREF1 with amended TOC also exhibited a statistically significant reduction in

survival relative to the control. However, none of the samples exhibited a statistically significant reduction in survival relative to the reference sediment, PREF1.

Growth of *C. dilutus* was reduced relative to the control in sample PNF, but not in PNF sample amended with TOC, or in any of the other samples. Growth was also reduced in sample PNF relative to the PREF1 sample.

Table 3. Results: *Hyalella azteca* survival and growth test.

Sample ID	Mean ± SD	
	Survival (%)	Dry Weight (mg)
Control Sediment	94.0 ± 5.5	0.24 ± 0.02
Control Sediment + 2% TOC	68.0 ± 13.0 *+	0.13 ± 0.03 *

PREF1 + PNF	0.329	0.065

4.0 QA/QC

The health histories of the test organisms used in the exposures were acceptable and met the requirements of the Environment Canada protocols. The tests met all control acceptability criteria and water quality parameters remained within ranges specified in the protocols throughout the tests, with the exception of the kaolin clay samples, which required a pH adjustment prior to addition of the test organisms, as described in Section 2.0. Uncertainty associated with these tests is best described by the standard deviation (SD) around the mean.

The TOC did not mix well into the laboratory control sediment and formed clumps on the surface of the sediment, which then started to grow what appeared to be mould or fungus. This growth was associated with a drop in dissolved oxygen in the 24 hours prior to addition of the test organisms. A water change was conducted at test initiation to remove most of the clumps before the organisms were added into the test vessels.

Kaolin clay samples (with and without amended TOC) had low pH values (4.3 – 5.3) and were pH adjusted with 0.1M NaOH to a pH of 7.5 prior to addition of the test organisms. The pH had decreased by the following day but was not adjusted again.

Results of the reference toxicant tests conducted during the testing program are summarized in Table 7. Results of the *H. azteca* and *C. dilutus* tests fell within the range for acceptable organism performance (mean and two standard deviation range, based on historical results obtained by the laboratory with these tests). Thus, the sensitivity of the organisms used in the tests were appropriate. The *C. dilutus* reference toxicant test produced 80% survival in the control, which is lower than the ≥90% threshold for this test. However, the LC50 result fell within the acceptable range, and the survival in the control associated with the test itself was 100%. Consequently, the health of the test organisms was considered to be acceptable.

Table 7. Reference toxicant results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
<i>H. azteca</i>	Survival (LC50): 5.3 g/L NaCl	5.2 (4.3 – 6.3)	10	September 18, 2015
<i>C. dilutus</i>	Survival (LC50): 6.7 g/L NaCl	4.5 (2.4 – 8.2)	35	September 18, 2015

SD = Standard Deviation, LC = Lethal Concentration, CV = Coefficient of Variation.

APPENDIX B - *Chironomus dilutus* Toxicity Test Data

Chironomus dilutus Sediment Test Summary Sheet

Client: Mount Polley
 Work Order No.: 15670

Start Date: 18-Sep-15
 Set up by: KJL/KL

Sample Information:

Sample ID: Various - See Below
 Sample Date: Aug 14-19, 24, 2015
 Date Received: 28-Aug-15
 Sample Volume: 5x 500mL per sample

Test Organism Information:

Species: C. dilutus
 Supplier: Aquatic Biosystems, CO
 Date received: 18-Sep-15
 Age or size (Day 0): 3rd in-star

KCI Reference Toxicant Results:

Reference Toxicant ID: n/a
 Stock Solution ID: n/a
 Date Initiated: 18-Sep-15

96-h LC50 (95% CL): 6.7 (6.1 - 7.4)

96-h LC50 Reference Toxicant Mean and Range: 4.5 (2.4 - 8.2) CV (%): 35

Test Results:

Value is > British Columbia Working Sediment Quality Guideline - Lower Guideline.

¹ Reported moisture, pH, and total nitrogen data are based on bulk sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

² British Columbia Working Sediment Quality Guidelines (BCMOE 2015)

Table C.2: Raw sediment quality data for Quesnel Lake profundal exposed sampling area, Mount Polley Mine, 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment ¹.

Re: Summary and Interpretation of Water Toxicity Tests

This memorandum provides a brief summary and interpretation of toxicity test results associated with water samples collected in initial response to the Mount Polley Mine tailings dam breach (which occurred on August 4th 2014). This toxicity testing was conducted on samples collected from Polley Lake, the Hazeltine Discharge (Polley Lake water piped to Hazeltine Creek), Quesnel Lake, and the Quesnel River in August and September 2014 (Figure 1). Based on the results and interpretation of these tests, recommendations for additional toxicity testing are also provided.

Methods

Toxicity testing included lethal and sub-lethal tests recommended under the federal Metal Mining Effluent Regulations (MMER; Government of Canada 2014). All tests were conducted by a laboratory (Nautilus Environmental) accredited by the Canadian Association for Laboratory Accreditation (CALA). Tests were conducted under standard protocols (Environment Canada's Biological Test Methods). Tests of lethality included 96-hour acute lethality to rainbow trout (Environment Canada 2007a) and 48-hour acute lethality to *Daphnia magna* (Environment Canada 2000). Sublethal tests included the test of fathead minnow larval survival and growth (Environment Canada 2011), the test of *Ceriodaphnia dubia* (invertebrate) survival and reproduction (Environment Canada 2007b), the test of *Lemna minor* (plant) growth (Environment Canada 2007c) and the test of *Pseudokirchneriella subcapitata* (algae) growth (Environment Canada 2007d). Samples were collected using grab techniques in accordance with provincial and federal guidance (BCWLAP 2003; BCMOE 2012; Environment Canada 2012) and were supported by field meter measurements and concurrent water samples, which were submitted to a CALA accredited analytical laboratory (ALS Environmental) for chemical analysis.

Results

A total of 53 toxicity tests were conducted on water samples collected by the Mount Polley Mining Corporation (MPMC) between August 9th and September 30th 2014 (Table 1; Appendix A). No acute toxicity was observed, no effects to invertebrate survival were observed (in sublethal tests), and no effects on growth of plants or algae were observed. In a small number of tests (9 of 53), some biological responses were indicated. All toxicity test results are discussed below, by test type, including an examination of the reported responses in relation to concurrent water quality (Table 2).

Acute Toxicity Testing - Rainbow trout and Daphnia magna

Acute testing of rainbow trout (*Oncorhynchus mykiss*) and *Daphnia magna* (a copper-sensitive [USEPA 2007] microcrustacean of the Order Cladocera, often referred to as a water flea) indicated no lethality in any of the waters tested (Table 1).

Survival and Growth - Fathead minnow

Tests of survival and growth of fathead minnow (*Pimephales promelas*) indicated an effect on survival in one test out of 12 tests in total; an LC50 (median lethal concentration) of 84.1% at HAD-2 (the outlet of the second pipe conveying water from Polley Lake to Hazeltine Creek) on September 3, 2014 (Table 1). All other tests of fathead minnow indicated median lethal concentrations (LC50s) and median concentrations causing growth inhibition (IC50s) of greater than 100%. Growth inhibition, as evaluated using total biomass, was observed with the 25th percentile endpoint (IC25; Table 1) in two tests of the Hazeltine Discharge (of Polley Lake water discharged to Hazeltine Creek) and in one test of Quesnel River water. Examination of the toxicity test data (Appendix A) indicated that these apparent inhibitions were associated with low level mortality (fewer organisms result in lower total biomass per test chamber) and that consideration of individual dry weight data indicated no inhibition of individual biomass (Table 1). Examination of water quality data associated with the tests (i.e., from samples collected at the same location and time as the test water) did not indicate water quality conditions that would be expected to adversely affect aquatic life. Total copper was the only analyte that was elevated relative to the applicable BCWQG for the protection of aquatic life in waters where effects to fathead minnow were observed (i.e., total copper was elevated at HAD-1 and HAD-2 but not at QUR-1; Table 2; see Appendix B for reference values supporting applicable BCWQG). However, total metals do not effectively represent bioavailable metals (Allen 1993; Bergman et al 1997; Markich et al. 2001; ICMM and Eurometaux 2005). Dissolved

¹ effect concentration; in instances where an effect was observed, 95% confidence limits are also provided (where calculable)

² in instances where an effect to fathead minnow growth is reported, IC25 values are provided for both total biomass (first number) and individual dry weight (second number)

³ na = not applicable; could not be calculated

highlight indicates a reported effect

copper (which is better characterized as “filtered” [$<0.45 \mu\text{m}$] copper) better represents bioavailable copper and was below corresponding guideline levels. In fact, the dissolved copper concentration associated with the test for which an effect on survival was reported would have been $2.59 \mu\text{g/L}$ (84.1% v/v effect concentration [Table 1] x $3.08 \mu\text{g/L}$ dissolved copper [Table 2]), which is well below the corresponding guideline and would not explain acute lethality to fathead minnow, suggesting that the test result may be an anomaly. Furthermore, dissolved copper may remain an overestimate of bioavailable copper due to the presence of small particles, colloids and complexation with dissolved ligands such as dissolved organic carbon (e.g., Morel 1983; Pagenkopf 1983; Markich et al. 2001; Grosell 2012). Biotic ligand modeling (BLM), which combines a geochemical model, a metal-organic matter binding model and a toxicological model to account for the key factors that influence the bioavailability and toxicity of a number of metals (DiToro et al. 2001; Niyogi and Wood 2004; USEPA 2007; Erickson 2013; Smith 2014) indicated that:

- 1) copper-associated lethality to fathead minnow would only be expected at dissolved copper concentrations greater than approximately $680 \mu\text{g/L}$ in the Hazeltine Discharge and $166 \mu\text{g/L}$ in the Quesnel River (actual toxic units of 0.003 and 0.004, respectively; see Appendix C); and
- 2) lowest chronic effects associated with dissolved copper (i.e., effects to the most sensitive species and life stage) would not be expected at concentrations below $9.3 \mu\text{g/L}$ in the Hazeltine Discharge and $6.9 \mu\text{g/L}$ in the Quesnel River (see Appendix C).

Due to a lack of concordance between the toxicity test results and water chemistry, there is no apparent cause of the effects observed in three fathead minnow tests. Nevertheless, because biological responses were observed, it is appropriate to undertake confirmatory testing (see recommendation section below).

Survival and Reproduction - Ceriodaphnia dubia

Tests of survival and reproduction of *C. dubia* (also a copper-sensitive cladoceran; USEPA 2007) indicated no lethality. However, all Quesnel Lake deep water samples were observed to impair *C. dubia* reproduction (Table 1). The Quesnel Lake deep water samples are characterized by turbidity and total suspended solids (47.5 to 111 NTU and 20.7 to 40.6 mg/L , respectively; Table 2) greater than applicable BCWQG, which in turn, result in elevated total concentrations of a number of metals (total chromium, total copper, total iron, and total vanadium were greater than BCWQG in three or more samples; Table

2). However, as previously indicated, total metals do not effectively represent bioavailable metals. Concentrations of dissolved chromium, dissolved iron and dissolved vanadium were all below the corresponding BCWQG, whereas concentrations of dissolved copper were greater than the 30-d (chronic) guideline for total copper (but lower than the maximum [acute] guideline), with concentrations in samples accompanying the toxicity tests ranging from 5.01 to 6.20 µg/L (at 100% v/v; Table 2). To investigate the potential that copper was responsible for the observed reproductive impairment, BLMs were applied and indicate that risk ratios (the concentration of dissolved copper relative to predicted no-effect concentrations) are near unity (1.0) for the Quesnel Lake deep water samples (up to 1.09; Appendix C). This comparison is somewhat conservative because dissolved copper concentrations include copper associated with particles and colloids smaller than 0.45 µm in diameter whereas the BLM does not account for small particulates and colloids. However, this comparison does not explain impairment at the low concentrations observed (i.e., IC25s of <1.6% to 3.9% v/v and IC50s of 2.5% to 13.6% v/v; Table 1). Additional testing is recommended to verify the response and further explore potential cause (if the response is verified), including the possible influence of suspended solids on this filter feeding organism (see recommendation section below). Verification is partially justified due to the potential for false positive results, which are not uncommon in tests of *C. dubia* (USEPA 2001, 2002).

The only other observation of impaired reproduction in *C. dubia* was for the Polley Lake deep water sample (14 meter depth collected on September 16th, 2014; Table 1). Concentrations of most analytes in this sample were below applicable BCWQGs, with the exception of low dissolved oxygen (0.2 mg/L), elevated nitrite (0.22 mg/L, which was greater than the maximum [acute] guideline of 0.06 mg/L applicable to low chloride water such as those of Polley Lake) and slightly elevated total copper (but not dissolved copper; Table 2). The elevated nitrite concentration is consistent with reduced conditions evident based on low dissolved oxygen concentrations. Although toxicity tests are conducted on oxygenated waters (Appendix A), nitrite is generally considered to oxidize to nitrate at a rate sufficiently slow that the majority of nitrite initially present in the test water would remain through testing (e.g., Kroupova et al. 2008). To investigate the potential that nitrite was responsible for the observed reproductive impairment, a search of nitrite toxicity to cladoceran reproduction was undertaken (using the United States Environmental Protection Agency's ECOTOX database and other online resources) and yielded few results. A recent evaluation of the effects of nitrite to aquatic animals indicated reproductive impairment (25th percentile effective concentration) in *C. dubia* at 1.9 mg/L

(USEPA 2010). Given that this concentration is well above the nitrite concentration in the Polley Lake sample of September 16th 2014 (i.e., 0.22 mg/L at 100% v/v), nitrite does not explain impairment at the low concentrations observed (i.e., IC25 of 3.8% v/v and IC50 of 5.3% v/v; Table 1).

Plant Growth Inhibition - Lemna minor and Pseudokirchneriella subcapitata

Testing of the growth of the aquatic plant *L. minor* and the algae *P. subcapitata* indicated no impairment of growth in any water, even the deep, turbid waters collected in Quesnel Lake (Table 1).

Summary

Overall, toxicity testing conducted in waters affected by the Mount Polley tailings dam breach indicated few adverse effects. No acute toxicity was observed, no effects to *C. dubia* survival were observed, and no effects on growth of plants or algae were observed. However, some biological responses were observed and it is therefore recommended that those samples are retested to confirm whether these were true toxic responses or potential artifacts of the testing procedures.

Reported effects to fathead minnow did not corroborate well with water chemistry results. Impaired reproduction of *C. dubia* was only observed when exposed to waters collected from depth in Quesnel Lake and Polley Lake. These waters were of the poorest quality of any samples collected. The Quesnel Lake samples had elevated turbidity (47.5 to 111 NTU), suspended solids (20.7 to 40.6 mg/L), total metals, and dissolved copper (5.01 to 6.20 µg/L). In Polley Lake, water collected from depth (14 meters) had low dissolved oxygen concentrations (0.2 mg/L) and elevated concentrations of nitrite (0.22 mg/L). It is noted that the oxygen levels in Polley Lake have been restored since testing. Neither copper concentrations in the Quesnel Lake deep samples, nor nitrite in the Polley Lake deep sample were sufficient to explain the reproductive inhibition of *C. dubia* observed at low sample concentrations (IC25s of <1.5% to 3.9% v/v) and additional testing is recommended to verify the responses and explore potential causes.

Recommendations for Toxicity Testing

Based on the toxicity data collected in August and September 2014 as part of initial response monitoring, the following recommendations are provided to verify responses, optimize testing, and reduce or eliminate uncertainties (Table 3):

Table 3: Recommended Water Toxicity Testing Program for Mount Polley, Fall and Winter 2014/2015

A) Surveillance Monitoring

Location	Tests	Frequency ¹
Polley Lake or Hazeltine Discharge	7-d fathead minnow survival and growth ²	bi-monthly ³
	7-d <i>Ceriodaphnia dubia</i> survival and reproduction	bi-monthly ³
Quesnel Lake	7-d fathead minnow survival and growth ²	bi-monthly ³
	7-d <i>Ceriodaphnia dubia</i> survival and reproduction	bi-monthly ³
Quesnel River	7-d fathead minnow survival and growth ⁴	monthly
	7-d <i>Ceriodaphnia dubia</i> survival and reproduction	monthly

¹ frequency to be re-evaluated in spring of 2015 following receipt and interpretation of results from November 2014 to March 2015

² on the first month of testing, augment with 7-d test of rainbow trout survival and growth

³ every second month, as permitted by safety considerations

⁴ on the first two months of testing, augment with 7-d test of rainbow trout survival and growth and rainbow trout embryo-alevin (EA) test

B) Investigations

Investigation	Tests	Location	Timing
inhibition of <i>Ceriodaphnia dubia</i> reproduction	7-d <i>Ceriodaphnia dubia</i> survival and reproduction	Quesnel Lake QUL-66 at a minimum of 3 vertical strata ¹	as soon as possible
lethality and growth inhibition of fathead minnow	7-d fathead minnow survival and growth and 7-d rainbow trout survival and growth	Polley Lake and Quesnel River	as soon as possible

¹ minimum of 3 vertical strata corresponding with high, medium and low turbidity (near bottom, middle and near surface, but actual depth will change with lake mixing); test both the whole sample and filtered sample (0.45 µm)

- Discontinue acute lethality testing (rainbow trout and *D. magna*) as well as the sub-lethal testing of *L. minor* (plant) and *P. subcapitata* (algae) as no effects have been observed in these tests. Consideration should be given to developing a trigger by which the plant and algae tests would be conducted (e.g., based on confirmed effects to fish or invertebrates);
- Augment the fish tests (of fathead minnow) with testing of rainbow trout early life stages when high quality rainbow trout of appropriate life stage are available. Recommended tests are the 7-day survival and growth test (Lazorchak and Smith 2007) at all proposed surveillance monitoring locations (Table 3) and the embryo-alevin test (Environment Canada 1998) in the Quesnel River (Table 3).
- Investigate the equivocal results of the fathead minnow testing using the new sublethal toxicity test data for both fathead minnow and rainbow trout.
- Verify reproductive inhibition of *C. dubia* in turbid waters and investigate the cause of any observed effects with a view to determining apparent thresholds if the response is verified. Test *C. dubia* under a range of total suspended solids/turbidity (as occurs in Quesnel Lake and which may be lower than in August and September 2014) and initially in both unfiltered and filtered samples to potentially allow the characterization of site-specific thresholds.
- Continue to collect water quality samples from at least one deep location in Polley Lake to characterize seasonal cycling of dissolved oxygen and nitrite concentrations. Data should be carefully examined to determine if/when elevated nitrite concentrations occur.

This report has been prepared by Nautilus Environmental Company Inc. based on data and/or samples provided by our client and the results of this study are for their sole benefit. Any reliance on the data by a third party is at the sole and exclusive risk of that party. The results presented here relate only to the samples tested.

1.0 INTRODUCTION

Nautilus Environmental Company Inc. conducted a toxicity test for Mount Polley Mining Corporation on a sample identified as QUR-1. The sample was collected on August 6, 2014 and delivered to the laboratory in Burnaby, BC on August 7, 2014. The sample was transported in two 20-L plastic carboys and coolers. The sample was received at a temperature of 9.7°C and was stored in the dark at $4 \pm 2^\circ\text{C}$ prior to testing.

This report describes the results of the toxicity test conducted on sample QUR-1 using *Ceriodaphnia dubia*. Copies of laboratory data sheets and printouts of statistical analyses for the test are provided in Appendix A. The chain of custody form is provided in Appendix B.

2.0 METHODS

Methods for the toxicity test using *C. dubia* are summarized in Table 1. Testing was conducted according to procedures described by Environment Canada (2007). Statistical analyses for the test were performed using CETIS (Tidepool Scientific Software, 2013).

Table 1. Summary of test conditions: *Ceriodaphnia dubia* survival and reproduction test.

Test organism	<i>Ceriodaphnia dubia</i>
Test organism source	In-house culture
Test organism age	<24 h old neonates produced within 12 h
Test type	Static-renewal
Test duration	7 ± 1 day
Test vessel	20 mL test tube
Test volume	15 mL
Test replicates	10 test replicates per treatment
Number of organisms	1 per replicate
Control water	20% Perrier water
Test solution renewal	Daily
Test temperature	25 ± 1°C
Feeding	<i>Pseudokirchneriella subcapitata</i> and YCT
Light intensity	100 to 600 lux at water surface
Photoperiod	16 hours light/8 hours dark
Aeration	None
Test protocol	Environment Canada, (2007) EPS 1/RM/21
Statistical software	CETIS (2013)
Test endpoint	Survival and reproduction
Test acceptability criteria for controls	≥80% survival; ≥15 young per surviving control producing three broods; ≥60% of controls producing three or more broods
Reference toxicant	Sodium chloride

3.0 RESULTS

Results of the toxicity test conducted on sample QUR-1 using *C. dubia* are provided in Table 2. No adverse effects on survival or reproduction were observed, resulting in LC50, IC25 and IC50 values of >100%.

Table 2. Results: *Ceriodaphnia dubia* survival and reproduction test.

Concentration (% v/v)	Survival (%)	Reproduction (Mean ± SD)
Control	100	18.8 ± 4.0
1.56	100	19.6 ± 3.4
3.12	100	18.8 ± 4.3
6.25	100	20.6 ± 2.2
12.5	100	18.7 ± 3.3
25	100	20.7 ± 2.7
50	100	21.9 ± 2.8
100	100	23.1 ± 3.8
Test endpoint		
LC50	>100	--
IC25	--	>100
IC50	--	>100

SD = Standard Deviation, LC = Lethal Concentration, IC = Inhibition Concentration.

4.0 QA/QC

The health history of the test organisms used in the exposure was acceptable and met the requirements of the Environment Canada protocol. The test met all control acceptability criteria and water quality parameters remained within ranges specified in the protocol throughout the test. There were no deviations from the test methodology. Uncertainty associated with this test is best described by the standard deviation around the mean and/or the confidence limits around the point estimates.

Results of the reference toxicant test conducted during the testing program are summarized in Table 3. Results for this test fell within the range for organism performance of mean and two standard deviation range, based on historical results obtained by the laboratory with this test. Thus, the sensitivity of the organisms used in this test was appropriate.

Table 3. Reference toxicant test results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
<i>C. dubia</i>	LC50 = 1.8 g/L NaCl	1.8 (1.2 - 2.7) g/L NaCl	22	August 8, 2014
	IC50 = 1.4 g/L NaCl	1.3 (0.9 - 1.9) g/L NaCl	19

APPENDIX A - Toxicity Test Data

Ceriodaphnia dubia Summary Sheet

Client: Mount Pooley
 Work Order No.: 14521

Start Date/Time: Aug 9/14 @ 1045h
 Set up by: ALD

Sample Information:

Sample ID: QUR-1
 Sample Date: Aug 6/14
 Date Received: Aug 7/14
 Sample Volume: 2x20L

Test Validity Criteria:

- 1) Mean survival of first generation controls is $\geq 80\%$
- 2) At least 60% of controls have produced three broods within 8 days
- 3) An average of ≥ 15 live young produced per surviving female in the control solutions during the first three broods.
- 4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T ($^{\circ}$ C) = 25 ± 1 ; DO (mg/L) = 3.3 to 8.4; pH = 6.0 to 8.5

Test Organism Information:

Broodstock No.: 073114
 Age of young (Day 0): <24-h (within 12-h)
 Avg No. young in first 3 broods of previous 7 d: 20
 Mortality (%) in previous 7 d: 5
 Individual female # used ≥ 8 young on test day: 2, 3, 5, 6, 7, 8, 9, 10

This report has been prepared by Nautilus Environmental Company Inc. based on data and/or samples provided by our client and the results of this study are for their sole benefit. Any reliance on the data by a third party is at the sole and exclusive risk of that party. The results presented here relate only to the samples tested.

1.0 INTRODUCTION

Nautilus Environmental Company Inc. conducted a toxicity test for Mount Polley Mining Corporation on a sample identified as POL-2. The sample was collected on August 9, 2014 and delivered to the laboratory in Burnaby, BC on August 11, 2014. The sample was transported in two 20-L plastic carboys and coolers. The sample was received at a temperature of 17.6°C and was stored in the dark at $4 \pm 2^\circ\text{C}$ prior to testing.

This report describes the results of the toxicity test conducted on sample POL-2 using *Ceriodaphnia dubia*. Copies of laboratory data sheets and printouts of statistical analyses for the test are provided in Appendix A. The chain of custody form is provided in Appendix B.

2.0 METHODS

Methods for the toxicity test using *C. dubia* are summarized in Table 1. Testing was conducted according to procedures described by Environment Canada (2007). Statistical analyses for the test were performed using CETIS (Tidepool Scientific Software, 2013).

Table 1. Summary of test conditions: *Ceriodaphnia dubia* survival and reproduction test.

Test organism	<i>Ceriodaphnia dubia</i>
Test organism source	In-house culture
Test organism age	<24 h old neonates produced within 12 h
Test type	Static-renewal
Test duration	7 ± 1 day
Test vessel	20 mL test tube
Test volume	15 mL
Test replicates	10 test replicates per treatment
Number of organisms	1 per replicate
Control water	20% Perrier water
Test solution renewal	Daily
Test temperature	25 ± 1°C
Feeding	<i>Pseudokirchneriella subcapitata</i> and YCT
Light intensity	100 to 600 lux at water surface
Photoperiod	16 hours light/8 hours dark
Aeration	None
Test protocol	Environment Canada, (2007) EPS 1/RM/21
Statistical software	CETIS (2013)
Test endpoint	Survival and reproduction
Test acceptability criteria for controls	≥80% survival; ≥15 young per surviving control producing three broods; ≥60% of controls producing three or more broods
Reference toxicant	Sodium chloride

3.0 RESULTS

Results of the toxicity test conducted on sample POL-2 using *C. dubia* are provided in Table 2. No adverse effects on survival or reproduction were observed, resulting in LC50, IC25 and IC50 values of >100%.

Table 2. Results: *Ceriodaphnia dubia* survival and reproduction test.

Concentration (% v/v)	Survival (%)	Reproduction (Mean ± SD)
Control	100	19.9 ± 2.9
1.56	100	17.6 ± 3.9
3.12	100	19.8 ± 3.2
6.25	90	18.0 ± 4.9
12.5	100	21.3 ± 4.9
25	100	20.8 ± 2.6
50	100	19.5 ± 7.3
100	100	20.6 ± 4.1
Test endpoint		
LC50	>100	--
IC25	--	>100
IC50	--	>100

SD = Standard Deviation, LC = Lethal Concentration, IC = Inhibition Concentration.

4.0 QA/QC

The health history of the test organisms used in the exposure was acceptable and met the requirements of the Environment Canada protocol. The test met all control acceptability criteria and water quality parameters remained within ranges specified in the protocol throughout the test. There were no deviations from the test methodology. Uncertainty associated with this test is best described by the standard deviation around the mean and/or the confidence limits around the point estimates.

Results of the reference toxicant test conducted during the testing program are summarized in Table 3. Results for this test fell within the range for organism performance of mean and two standard deviation range, based on historical results obtained by the laboratory with this test. Thus, the sensitivity of the organisms used in this test was appropriate.

Table 3. Reference toxicant test results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
<i>C. dubia</i>	LC50 = 1.8 g/L NaCl	1.8 (1.2 - 2.7) g/L NaCl	22	August 8, 2014
	IC50 = 1.4 g/L NaCl	1.3 (0.9 - 1.9) g/L NaCl	19

APPENDIX A - Toxicity Test Data

Ceriodaphnia dubia Summary Sheet

Client: Mt Polley
 Work Order No.: 14524

Start Date/Time: Aug 11/14 @ 0930h
 Set up by: EMM

Sample Information:

Sample ID: ROL-2
 Sample Date: August 9/14
 Date Received: August 11/14
 Sample Volume: 2x20L

Test Validity Criteria:

- 1) Mean survival of first generation controls is $\geq 80\%$
- 2) At least 60% of controls have produced three broods within 8 days
- 3) An average of ≥ 15 live young produced per surviving female in the control solutions during the first three broods.
- 4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T ($^{\circ}$ C) = 25 ± 1 ; DO (mg/L) = 3.3 to 8.4 ; pH = 6.0 to 8.5

Test Organism Information:

Broodstock No.: 073114
 Age of young (Day 0): <24-h (within 12-h)
 Avg No. young in first 3 broods of previous 7 d: 25
 Mortality (%) in previous 7 d: 5
 Individual female # used ≥ 8 young on test day: 1, 2, 8, 9, 13, 17, 19

NaCl Reference Toxicant Results:

Reference Toxicant ID: cd116

This report has been prepared by Nautilus Environmental Company Inc. based on data and/or samples provided by our client and the results of this study are for their sole benefit. Any reliance on the data by a third party is at the sole and exclusive risk of that party. The results presented here relate only to the samples tested.

1.0 INTRODUCTION

Nautilus Environmental Company Inc. conducted toxicity tests for Mount Polley Mining Corporation on a sample identified as HAD-1. The sample was collected on August 13, 2014 and delivered to the laboratory in Burnaby, BC on August 14, 2014. The sample was transported in three 20-L plastic carboys and coolers. The sample was received at a temperature of 15.5°C and was stored in the dark at $4 \pm 2^\circ\text{C}$ prior to testing. The following sub-lethal toxicity tests were performed on the sample:

- *Ceriodaphnia dubia* survival and reproduction
- 7-d fathead minnow (*Pimephales promelas*) survival and growth
- 72-h algal (*Pseudokirchneriella subcapitata*) growth inhibition

This report describes the results of these toxicity tests. Copies of laboratory data sheets and printouts of statistical analyses for each test are provided in Appendices A to C. The chain-of-custody form is provided in Appendix D. This report was revised from an earlier version to incorporate data for dry weight of fathead minnows, in addition to biomass.

2.0 METHODS

Methods for the toxicity tests are summarized in Tables 1 to 3. Testing was conducted according to procedures described by the Environment Canada protocols (2007a, 2007b and 2011). Statistical analyses for all tests were performed using CETIS (Tidepool Scientific Software, 2013).

Table 1. Summary of test conditions: *Ceriodaphnia dubia* survival and reproduction test.

Test organism	<i>Ceriodaphnia dubia</i>
Test organism source	In-house culture
Test organism age	<24 h old neonates produced within 12 h
Test type	Static-renewal
Test duration	7 ± 1 day
Test vessel	20 mL test tube
Test volume	15 mL
Test replicates	10 test replicates per treatment
Number of organisms	1 per replicate
Control water	20% Perrier water
Test solution renewal	Daily
Test temperature	25 ± 1°C
Feeding	<i>Pseudokirchneriella subcapitata</i> and YCT
Light intensity	100 to 600 lux at water surface
Photoperiod	16 hours light/8 hours dark
Aeration	None
Test protocol	Environment Canada, (2007a) EPS 1/RM/21
Statistical software	CETIS (2013)
Test endpoint	Survival and reproduction
Test acceptability criteria for controls	≥80% survival; ≥15 young per surviving control producing three broods; ≥60% of controls producing three or more broods
Reference toxicant	Sodium chloride

Table 2. Summary of test conditions: fathead minnow (*Pimephales promelas*) survival and growth test.

Test organism	<i>Pimephales promelas</i>
Test organism source	Aquatic BioSystems, Fort Collins, CO
Test organism age	<24 hours
Test type	Static renewal
Test duration	7 days
Test vessel	375-mL glass containers
Test volume	250 mL
Test replicates	3 per treatment
Number of organisms	10 per replicate
Control water	Moderately-hard water (hardness 80-100 mg/L CaCO ₃)
Test solution renewal	Daily
Test temperature	25 ± 1°C
Feeding	Twice a day with newly hatched brine shrimp (<i>Artemia nauplii</i>)
Light intensity	100 – 500 lux
Photoperiod	16 hours light / 8 hours dark
Aeration	None
Test protocol	Environment Canada (2011), EPS 1/RM/22
Statistical software	CETIS (2013)
Test endpoint	Survival and biomass
Test acceptability criteria for controls	≥80% survival, ≥250 µg mean dry weight
Reference toxicant	Sodium Chloride

Table 3. Summary of test conditions: *Pseudokirchneriella subcapitata* growth inhibition test.

Test organism	<i>Pseudokirchneriella subcapitata</i> , strain UTCC #37
Test organism source	In-house culture, obtained from Canadian Phycological Culture Center, and originally isolated from Nitelva River, Norway.
Test organism age	3- to 7-day old culture in logarithmic growth phase
Test type	Static
Test duration	72 hours
Test vessel	Microplate
Test volume	220 µL
Test replicates	4 replicates per treatment; 8 replicates for control
Number of organisms	10,000 cells/mL
Control water	Deionized water with supplemented nutrients
Test solution renewal	None
Test temperature	24 ± 2°C
Feeding	None
Light intensity	3600 to 4400 lux
Photoperiod	24 hours light
Aeration	None
Test protocol	Environment Canada (2007b), EPS1/RM/25
Statistical software	CETIS (2013)
Test endpoint	Algal cell growth inhibition
Test acceptability criteria for controls	≥ 16-fold increase in number of algal cells; CV ≤ 20%; no trend when analyzed using Mann-Kendall test
Reference toxicant	Zinc

3.0 RESULTS

There were no adverse effects observed on survival and reproduction of *C. dubia* (Table 4), survival and growth of fathead minnow (Table 5), or cell yield of *P. subcapitata* (Table 6). The LC and IC values were therefore greater than the highest concentration tested for each of these endpoints in all toxicity tests. In addition, stimulation was observed in the *C. dubia* and *P. subcapitata* tests. For *C. dubia*, reproduction enhancement was observed in the four highest concentrations and ranged from 2.6 to 21.1%. For *P. subcapitata*, algal stimulation was observed in most concentrations and ranged from 9.6 to 282.2%.

Table 4. Results: *Ceriodaphnia dubia* survival and reproduction test.

Concentration (% v/v)	Survival (%)	Reproduction (mean ± SD)	Stimulation (%)
Control	100	19.4 ± 3.6	--
1.56	100	19.2 ± 4.9	--
3.12	90	16.9 ± 8.3	--

25	93.3 ± 5.8	801.7 ± 36.8	859.6 ± 22.4
50	90.0 ± 10.0	815.0 ± 91.3	906.0 ± 31.8
100	90.0 ± 10.0	811.7 ± 68.9	904.4 ± 49.1
Test endpoint (% v/v)			
LC50	>100	--	
IC25	--	>100	>100
IC50	--	>100	>100

SD = Standard Deviation, LC= Lethal Concentration, IC= Inhibition Concentration.

Table 6. Results: *Pseudokirchneriella subcapitata* growth inhibition test.

Concentration (% v/v)	Cell Density (x 10 ⁴ cells/mL) (Mean ± SD)	Stimulation (%)
Control	36.5 ± 4.0	--
1.5	30.2 ± 3.9	--
3.0	46.8 ± 5.0	28.1
6.0	40.0 ± 3.2	9.6
11.9	73.0 ± 7.0*	100.0
23.8	112.8 ± 12.8*	208.9
47.6	139.5 ± 20.5*	282.2
95.2	125.0 ± 12.4*	242.5
Test endpoint (% v/v)		
IC25	>95.2	--
IC50	>95.2	--

SD = Standard Deviation, IC= Inhibition Concentration.

*Indicates cell yield that were significantly greater than the control.

4.0 QA/QC

The health history of the test organisms used in the exposures was acceptable and met the requirements of the Environment Canada protocols. The tests met all control acceptability criteria and water quality parameters remained within ranges specified in the protocols throughout the tests. There were no deviations from the test methodologies. Uncertainty associated with these tests is best described by the standard deviation around the mean and/or the confidence limits around the point estimates.

Results of the reference toxicant tests conducted during the testing program are summarized in Table 7. Results for these tests fell within the range for organism performance of mean and two standard deviation range, based on historical results obtained by the laboratory with these tests. Thus, the sensitivity of the organisms used in these tests was appropriate.

Table 7. Reference toxicant results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
<i>C. dubia</i>	Survival (LC50): 1.8 g/L NaCl	1.8 (1.2 - 2.7)	22	August 8, 2014
	Reproduction (IC50): 1.4 g/L NaCl	1.3 (0.9 - 1.9)	19	
<i>P. promelas</i>	Survival (LC50): 4.0 g/L NaCl	4.6 (3.4 - 6.3)	17	August 15, 2014
	Biomass (IC50): 3.1 g/L NaCl	4.2 (3.1 - 5.8)	17	
<i>P. subcapitata</i>	Growth (IC50) 28.9 µg/L Zn	25.1 (14.8 - 42.7)	30	August 14, 2014

SD = Standard Deviation, CV = Coefficient of Variation, IC = Inhibition Concentration, LC = Lethal Concentration.

APPENDIX B - Fathead Minnow (*Pimephales promelas*) Toxicity Test Data

Fathead Minnow Test Summary Sheet
(7-d *Pimephales promelas* Survival and Growth Test)

Client: Mount Polley
Work Order No.: 14538

Start Date/Time: Aug 15/14 @ 1800h
Test Species: P. promelas

Sample Information:

Sample ID: HAD-1
Sample Date: Aug 13/14
Date Received: Aug 14/14
Sample Volume: 3x 20L

Dilution Water (initial water quality):

Type: Moderately Hard water
Temperature (°C): 24.0
pH: 8.1
Dissolved Oxygen (mg/L): 7.9
Hardness (mg/L CaCO₃): 92
Alkalinity (mg/L CaCO₃): 58

Test Validity Criteria:

The test is invalid if:

- 1) for the control solutions, the combined and cumulative incidence of any mortalities, or fish showing loss of equilibrium or other signs of atypical swimming behavior, is >20%
- 2) the average dry weight of the surviving control fish does not attain 250 ug when the fish are dried and weighed.

WQ Ranges:

T (°C) = 25 ± 1; DO (mg/L) = 3.3 to 8.4; pH = 6.5 to 8.5

Test Organism Information:

Batch No.: 081514
Source: Aquatic Biosystems, CO
Age: 24hr

NaCl Reference Toxicant Results:

Reference Toxicant ID: PP89
Stock Solution ID: n/a
Date Initiated: Aug 15/14
7-d EC50 (95% CL): 3.9 (3.4-5.4) 5.0L 3.9 (2.4-4.5) 4.0 (3.5-4.6) g/L NaCl
7-d IC50 (95% CL): 3.1 (2.9-3.4) g/L NaCl

Survival:

Reference Toxicant Mean and Historical Range: 4.6 (3.4-6.3) g/L NaCl CV(%): 17

Biomass:

Reference Toxicant Mean and Historical Range: 4.2 (3.1-5.8) g/L NaCl CV(%): 17

Test Results:

	Survival	Biomass
LC25 % (v/v) (95% CL)	>100	
LC50 % (v/v) (95% CL)	>100	
IC25 % (v/v) (95% CL)		>100
IC50 % (v/v) (95% CL)		7(00)

This report has been prepared by Nautilus Environmental Company Inc. based on data and/or samples provided by our client and the results of this study are for their sole benefit. Any reliance on the data by a third party is at the sole and exclusive risk of that party. The results presented here relate only to the samples tested.

1.0 INTRODUCTION

Nautilus Environmental Company Inc. conducted toxicity tests for Mount Polley Mining Corporation on a sample identified as HAD-1. The sample was collected on August 20, 2014 and delivered to the laboratory in Burnaby, BC on August 21, 2014. The sample was transported in three 20-L plastic carboys and coolers. The sample was received at a temperature of 10.8°C and was stored in the dark at $4 \pm 2^\circ\text{C}$ prior to testing. The following sub-lethal toxicity tests were performed on the sample:

- *Ceriodaphnia dubia* survival and reproduction
- 7-d fathead minnow (*Pimephales promelas*) survival and growth
- 7-d duckweed (*Lemna minor*) growth inhibition
- 72-h algal (*Pseudokirchneriella subcapitata*) growth inhibition

This report describes the results of these toxicity tests. Copies of laboratory data sheets and printouts of statistical analyses for each test are provided in Appendices A to D. The chain-of-custody form is provided in Appendix E. This report was revised from an earlier version to incorporate data for dry weight of fathead minnows, in addition to biomass.

2.0 METHODS

Methods for the toxicity tests are summarized in Tables 1 to 4. Testing was conducted according to procedures described by the Environment Canada protocols (2007a, 2007b, 2007c and 2011). Statistical analyses for all tests were performed using CETIS (Tidepool Scientific Software, 2013).

Table 1. Summary of test conditions: *Ceriodaphnia dubia* survival and reproduction test.

Test organism	<i>Ceriodaphnia dubia</i>
Test organism source	In-house culture
Test organism age	<24 h old neonates produced within 12 h
Test type	Static-renewal
Test duration	7 ± 1 day
Test vessel	20 mL test tube
Test volume	15 mL
Test replicates	10 test replicates per treatment
Number of organisms	1 per replicate
Control water	20% Perrier water
Test solution renewal	Daily
Test temperature	25 ± 1°C
Feeding	<i>Pseudokirchneriella subcapitata</i> and YCT
Light intensity	100 to 600 lux at water surface
Photoperiod	16 hours light/8 hours dark
Aeration	None
Test protocol	Environment Canada, (2007a) EPS 1/RM/21
Statistical software	CETIS (2013)
Test endpoint	Survival and reproduction
Test acceptability criteria for controls	≥80% survival; ≥15 young per surviving control producing three broods; ≥60% of controls producing three or more broods
Reference toxicant	Sodium chloride

Table 2. Summary of test conditions: fathead minnow (*Pimephales promelas*) survival and growth test.

Test organism	<i>Pimephales promelas</i>
Test organism source	Aquatic BioSystems, Fort Collins, CO
Test organism age	<24 hours
Test type	Static renewal
Test duration	7 days
Test vessel	375-mL glass containers
Test volume	250 mL
Test replicates	3 per treatment
Number of organisms	10 per replicate
Control water	Moderately-hard water (hardness 80-100 mg/L CaCO ₃)
Test solution renewal	Daily
Test temperature	25 ± 1°C
Feeding	Twice a day with newly hatched brine shrimp (<i>Artemia nauplii</i>)
Light intensity	100 – 500 lux
Photoperiod	16 hours light / 8 hours dark
Aeration	None
Test protocol	Environment Canada (2011), EPS 1/RM/22
Statistical software	CETIS (2013)
Test endpoint	Survival and biomass
Test acceptability criteria for controls	≥80% survival, ≥250 µg mean dry weight
Reference toxicant	Sodium Chloride

Table 3. Summary of test conditions: *Lemna minor* growth inhibition test.

Test organism	<i>Lemna minor</i>
Test organism source	In-house culture, obtained from Canadian Phycological Culture Centre, and originally isolated from Wainfleet, Stinking Barn, Niagara Peninsula, Ontario, Canada
Test organism age	7 to 10 day old
Test type	Static
Test duration	7 days
Test vessel	250 mL glass containers
Test volume	100 mL
Test replicates	4 test replicates per treatment
No. of organisms	Two 3-frond plants per replicate
Control water	Deionized water with nutrients added
Test solution renewal	None
Test temperature	25 ± 2°C
Feeding	None
Light intensity	4000 to 5600 lux full spectrum light
Photoperiod	24 hours light
Aeration	None
Test protocol	Environment Canada (2007b), EPS 1/RM/37
Statistical software	CETIS (2013)
Test endpoint	Number of fronds and dry weight
Test acceptability criteria for controls	≥ 8-fold increase in number of fronds
Reference toxicant	Potassium chloride

Table 4. Summary of test conditions: *Pseudokirchneriella subcapitata* growth inhibition test.

Test organism	<i>Pseudokirchneriella subcapitata</i> , strain UTCC #37
Test organism source	In-house culture, obtained from Canadian Phycological Culture Center, and originally isolated from Nitelva River, Norway.
Test organism age	3- to 7-day old culture in logarithmic growth phase
Test type	Static
Test duration	72 hours
Test vessel	Microplate
Test volume	220 µL
Test replicates	4 replicates per treatment; 8 replicates for control
Number of organisms	10,000 cells/mL
Control water	Deionized water with supplemented nutrients
Test solution renewal	None
Test temperature	24 ± 2°C
Feeding	None
Light intensity	3600 to 4400 lux
Photoperiod	24 hours light
Aeration	None
Test protocol	Environment Canada (2007c), EPS1/RM/25
Statistical software	CETIS (2013)
Test endpoint	Algal cell growth inhibition
Test acceptability criteria for controls	≥ 16-fold increase in number of algal cells; CV ≤ 20%; no trend when analyzed using Mann-Kendall test
Reference toxicant	Zinc

3.0 RESULTS

There were no adverse effects observed on survival and reproduction of *C. dubia* (Table 5), survival and growth of fathead minnow (Table 6), frond count and dry weight of *L. minor* (Table 7) or cell yield of *P. subcapitata* (Table 8). The LC and IC values were therefore greater than the highest concentration tested for each of these endpoints in all toxicity tests. In addition, a stimulatory effect was observed for *P. subcapitata* cell yield; percent stimulation ranged from 18.9 to 114.9%.

Table 5. Results: *Ceriodaphnia dubia* survival and reproduction test.

Concentration (% v/v)	Survival (%)	Reproduction (mean ± SD)
Control	100	20.5 ± 1.6
1.56	100	20.6 ± 2.8
3.12	100	17.9 ± 3.9
6.25	100	20.0 ± 3.7
12.5	90	18.4 ± 7.3
25	100	20.6 ± 5.0
50	100	21.2 ± 2.6
100	100	21.8 ± 2.2
Test endpoint (% v/v)		
LC50	>100	--
IC25	--	>100
IC50	--	>100

SD = Standard Deviation, LC = Lethal Concentration, IC = Inhibition Concentration.

Table 6. Results: fathead minnow (*Pimephales promelas*) survival and growth test.

Concentration (% v/v)	Mean ± SD		
	Survival (%)	Biomass (µg)	Dry Weight (µg)
Control	83.3 ± 11.6	502.7 ± 113.2	598.3 ± 61.4
1.56	96.7 ± 5.8	646.3 ± 51.0	668.8 ± 38.3
3.1	93.3 ± 11.6	587.7 ± 82.4	629.1 ± 25.9
6.25	96.7 ± 5.8	672.0 ± 35.1	696.5 ± 47.9
12.5	100.0 ± 0.0	700.3 ± 39.2	700.3 ± 39.2
25	83.3 ± 15.3	604.0 ± 89.3	729.2 ± 57.3
50	80.0 ± 10.0	551.7 ± 42.1	693.5 ± 58.0
100	76.7 ± 20.8	518.3 ± 142.7	675.5 ± 11.9
Test endpoint (% v/v)			
LC50	>100	--	--
IC25	--	>100	>100
IC50	--	>100	>100

SD = Standard Deviation, LC = Lethal Concentration, IC = Inhibition Concentration.

Table 7. Results: *Lemna minor* growth inhibition test.

Concentration (% v/v)	Frond Growth (No. of Fronds)	Dry Weight (mg)
	(Mean ± SD)	(Mean ± SD)
Control	51.0 ± 5.7	4.7 ± 0.6
1.5	55.2 ± 10.8	5.1 ± 1.0
3.0	53.8 ± 7.9	5.0 ± 0.7
6.1	54.2 ± 6.9	5.0 ± 0.9
12.1	57.2 ± 6.8	5.0 ± 0.5
24.2	57.5 ± 7.7	5.2 ± 1.0
48.5	57.5 ± 1.3	5.6 ± 0.3
97	62.0 ± 6.5	5.8 ± 0.6
Test endpoint		
IC25	>97	>97
IC50	>97	>97

SD = Standard Deviation, IC = Inhibition Concentration.

Table 8. Results: *Pseudokirchneriella subcapitata* growth inhibition test.

Concentration (% v/v)	Cell Density (x 10 ⁴ cells/mL) (Mean ± SD)	Stimulation (%)
Control	40.4 ± 3.9	--
1.5	48.0 ± 5.1	18.9
3.0	50.2 ± 5.7*	24.5
6.0	55.2 ± 5.1*	36.8
11.9	66.0 ± 8.0*	63.5
23.8	72.2 ± 9.5*	79.0
47.6	74.0 ± 7.8*	83.3
95.2	86.8 ± 6.6*	114.9
Test endpoint (% v/v)		
IC25	>95.2	--
IC50	>95.2	--

SD = Standard Deviation, IC = Inhibition Concentration.

*Indicates cell yield that were significantly greater than the control.

4.0 QA/QC

The health history of the test organisms used in the exposures was acceptable and met the requirements of the Environment Canada protocols. The tests met all control acceptability criteria and water quality parameters remained within ranges specified in the protocols throughout the tests. There were no deviations from the test methodologies. Uncertainty associated with these tests is best described by the standard deviation around the mean and/or the confidence limits around the point estimates.

Results of the reference toxicant tests conducted during the testing program are summarized in Table 9. Results for these tests fell within the range for organism performance of mean and two standard deviation range, based on historical results obtained by the laboratory with these tests. Thus, the sensitivity of the organisms used in these tests was appropriate.

Table 9. Reference toxicant results.

Test Species	Endpoint	Historical Mean (2 SD Range)	CV (%)	Test Date
<i>C. dubia</i>	Survival (LC50): 1.8 g/L NaCl	1.8 (1.2 - 2.7)	22	August 26 , 2014
	Reproduction (IC50): 1.3 g/L NaCl	1.4 (1.0 - 1.9)	19	
<i>P. promelas</i>	Survival (LC50): 5.2 g/L NaCl	4.5 (3.4 - 6.1)	16	August 22, 2014
	Biomass (IC50): 3.9 g/L NaCl	4.1 (3.0 - 5.6)	17	
<i>L. minor</i>	No. Fronds (IC50) 3.8 g/L KCl	4.2 (3.1 - 5.7)	16	September 5, 2014
<i>P. subcapitata</i>	Growth (IC50) 28.9 µg/L Zn	25.1 (14.8 - 42.7)	30	August 14, 2014

SD = Standard Deviation, CV = Coefficient of Variation, IC = Inhibition Concentration, LC = Lethal Concentration.

APPENDIX A - *Ceriodaphnia dubia* Toxicity Test Data

Ceriodaphnia dubia Summary Sheet

Client: AT Mount Polley
 Work Order No.: 14561

Start Date/Time: Aug 22/14 @ 1030h
 Set up by: EMM

Sample Information:

Sample ID: HA0-1
 Sample Date: Aug 20/14
 Date Received: Aug 21/14
 Sample Volume: 3x20L

Test Validity Criteria:

- 1) Mean survival of first generation controls is $\geq 80\%$
- 2) At least 60% of controls have produced three broods within 8 days
- 3) An average of ≥ 15 live young produced per surviving female in the control solutions during the first three broods.
- 4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T ($^{\circ}$ C) = 25 ± 1 ; DO (mg/L) = 3.3 to 8.4 ; pH = 6.0 to 8.5

Test Organism Information:

Broodstock No.: 081514B
 Age of young (Day 0): <24-h (within 12-h)
 Avg No. young in first 3 broods of previous 7 d: 20
 Mortality (%) in previous 7 d: 0
 Individual female # used ≥ 8 young on test day: 21, 22, 23, 24, 25, 26, 27, 28, 29, 30

NaCl Reference Toxicant Results:

Reference Toxicant ID: cd117
 Stock Solution ID: 14Na02
 Date Initiated: Aug 20/14

7-d LC50 (95% CL): 1.8 (1.5-2.2) g/L NaCl
 7-d IC50 (95% CL): 1.3 (1.1-1.5) g/L NaCl

7-d LC50 Reference Toxicant Mean and Historical Range: 1.9 (1.2-2.7) g/L NaCl CV (%): 22
 7-d IC50 Reference Toxicant Mean and Historical Range: 1.4 (1.0-1.9) g/L NaCl CV (%): 19

Test Results:

	Survival	Reproduction
LC50 % (v/v) (95% CL)	7100	
IC25 % (v/v) (95% CL)		7100
IC50 % (v/v) (95% CL)		7100

APPENDIX B - Fathead Minnow (*Pimephales promelas*) Toxicity Test Data

Fathead Minnow Test Summary Sheet
(7-d *Pimephales promelas* Survival and Growth Test)

Client: Mount Polley
Work Order No.: 14562

Start Date/Time: Aug 22/14 @ 1500h
Test Species: P. promelas

Sample Information:

Sample ID: HAD-1
Sample Date: Aug 20/14
Date Received: Aug 21/14
Sample Volume: 3x20L

Dilution Water (initial water quality):

Type: Moderately Hard
Temperature (°C): 24.0
pH: 8.0
Dissolved Oxygen (mg/L): 8.1
Hardness (mg/L CaCO₃): 92
Alkalinity (mg/L CaCO₃): 58
