Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC ENV (British Columbia Ministry of Environment and Climate Change Strategy). 2020. B.C. Source Drinking Water Quality Guidelines: Guideline Summary. Water Quality Guideline Series, WQG-01. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary*. Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture*. Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermochline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermochline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermochline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermochline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermochline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermochline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermochline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermochline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC ENV (British Columbia Ministry of Environment and Climate Change Strategy). 2020. B.C. Source Drinking Water Quality Guidelines: Guideline Summary. Water Quality Guideline Series, WQG-01. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermochline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermochline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermochline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermochline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC ENV (British Columbia Ministry of Environment and Climate Change Strategy). 2020. B.C. Source Drinking Water Quality Guidelines: Guideline Summary. Water Quality Guideline Series, WQG-01. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC ENV (British Columbia Ministry of Environment and Climate Change Strategy). 2020. B.C. Source Drinking Water Quality Guidelines: Guideline Summary. Water Quality Guideline Series, WQG-01. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermochline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermochline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.

Notes:

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within 30 days.

In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.

(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.

(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.

(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.

(d) The guideline is based on an aesthetic objective rather than a health-based objective.

(e) The guideline is a minimum value.

(f) The guideline is a working guideline.

(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (43 to 74 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.

(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.

(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.

(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.0 to 8.3). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.

(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (1.3 to 2.6 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.

(m) The guideline is for chromium VI.

(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).

(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).

(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.

(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.

(DW) = concentration is higher than the BC ENV drinking WQG.

(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.

(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.

(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.

AT = above thermocline; B = bottom; BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; BT = below thermocline; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; MID = middle; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; S = surface; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC ENV (British Columbia Ministry of Environment and Climate Change Strategy). 2020. B.C. Source Drinking Water Quality Guidelines: Guideline Summary. Water Quality Guideline Series, WQG-01. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC ENV (British Columbia Ministry of Environment and Climate Change Strategy). 2020. B.C. Source Drinking Water Quality Guidelines: Guideline Summary. Water Quality Guideline Series, WQG-01. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture - Guideline Summary.* Water Quality Guideline Series, WQG-20. Prov. B.C., Victoria B.C.
BC WLRS (British Columbia Ministry of Water, Land, and Resource Stewardship). 2025. *Working Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture.* Water Quality Guideline Series, WQG-08-01. Prov. B.C., Victoria B.C.

Notes:
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.
Water quality screening against long-term chronic guidelines is presented for reference only; long-term chronic guidelines apply to the average value of five measurements taken within
In cases where toxicity-modifying factors (e.g., DOC, chloride, hardness) were below detection limits, 0.5 times the detection limit was used to calculate the sample specific guideline.
(a) When BC WLRS WQGs for the protection of wildlife were not available or inapplicable, livestock guidelines were used for comparison purposes. If wildlife and livestock guidelines were unavailable, irrigation guidelines were applied.
(b) The guideline value is for irrigation. The water quality guidelines recommend levels of waterborne chemicals and pathogens for irrigating crops, which may be consumed.
(c) The guideline value is for livestock. The guideline is designed to ensure safe drinking water for livestock.
(d) The guideline is based on an aesthetic objective rather than a health-based objective.
(e) The guideline is a minimum value.
(f) The guideline is a working guideline.
(g) The guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (44 to 59 mg/L). The guideline is calculated based on the individual hardness value for each sample. If no hardness value was available, a monthly station average was used for guideline calculation. If no monthly station average for hardness could be calculated, a station average was used for guideline calculation.
(h) The guideline is chloride dependent. The guideline range shown is based on the chloride concentration observed in the dataset (<0.5 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.
(i) The ammonia guideline is pH and temperature dependent. Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample. If no pH or temperature value was available, monthly averages were used for guideline calculation.
(j) The total phosphorus guideline is a range, with the objective of protecting salmonid productivity. The guideline is applied only to lakes with salmonids as the predominant fish species.
(k) The guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.7 to 8.9). The guideline is calculated based on the individual pH for each sample. If no pH value was available, a monthly station average was used for guideline calculation. If no monthly station average for pH could be calculated, a station average was used for guideline calculation.
(l) The guideline is DOC dependent. The guideline range shown is based on the DOC concentration range observed in the dataset (0.67 to 4.7 mg/L). The guideline is calculated based on the individual DOC concentration in each sample. If no DOC value was available, a monthly station average was used for guideline calculation. If no monthly station average for DOC could be calculated, a station average was used for guideline calculation.
(m) The guideline is for chromium VI.
(n) The total copper drinking water screening criteria has an aesthetic objective (1.0 mg/L) and a maximum acceptable concentration for short and long-term exposure (2.0 mg/L).
(o) The total manganese drinking water screening criteria has an aesthetic objective (0.02 mg/L) and a maximum acceptable concentration (0.12 mg/L).
(p) The molybdenum guideline for wildlife is specific to wildlife physiology, ruminant (0.034 mg/L) and non-ruminant (0.284 mg/L) wildlife.
(q) The guideline is pH, hardness, DOC, and temperature dependent. Sample specific guidelines were generated using a parameter specific British Columbia Biotic Ligand Model which is available from BC WLRS. The guideline is calculated based on the individual pH, hardness and DOC concentrations in each sample. If no pH, hardness, or DOC values were available, a monthly station average was used for guideline calculation. If no monthly station averages for pH, hardness, and DOC could be calculated, a station average was used for guideline calculation.
(DW) = concentration is higher than the BC ENV drinking WQG.
(Bc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Ba) = concentration is higher than the maximum BC WLRS WQG for the protection of aquatic life or outside the recommended pH, DO, or total alkalinity range.
(Wc) = concentration is higher than the 30-day mean BC WLRS WQG for the protection of wildlife.
(Wa) = concentration is higher than the maximum BC WLRS WQG for the protection of wildlife.
(DL>Bc) = analytical detection limit is higher than the long-term chronic BC WLRS guideline.
BC ENV = British Columbia Ministry of Environment and Climate Change Strategy; BC WLRS = British Columbia Ministry of Water, Land, and Resource Stewardship; CaCO3 = calcium carbonate; °C = degrees celsius; DOC = dissolved organic carbon; NTU = nephelopmetric turbidity unit; - = no guideline or no data; m = metres; µg/L = micrograms per litre; µS/cm = microsiemens per centimetre; mg-N/L = milligrams of nitrogen per litre; mg-P/L = milligrams of phosphorus per litre; mg/L = milligrams per litre; % = percent; TCU = true colour unit; WQG = Water Quality Guidelines.

APPENDIX 3-7: SEDIMENT AND AQUATIC LIFE MONITORING REPORT

Mount Polley Mine Comprehensive Environmental Monitoring Program 2024 – Sediment and Aquatic Life

Prepared for:
Mount Polley Mining Corporation
Likely, British Columbia

Prepared by:
Minnow Environmental Inc.
Victoria, British Columbia

March 2025

Mount Polley Mine Comprehensive Environmental Monitoring Program 2024 – Sediment and Aquatic Life

Katharina Batchelar, M.Sc., R.P. Bio
Project Manager

Pierre Stecko, M.Sc., EP, R.P. Bio
Senior Advisor / Technical Reviewer

ACKNOWLEDGEMENTS

Kagan Meier, B.Sc. and Braden Gregory, Ph.D., G.I.T.
Sediment Quality

Braden Gregory, Ph.D., G.I.T.
Sediment Toxicity

Rhiannon Hodgson, M.Sc.
Periphyton Community and Productivity

Hillary Quinn-Austin, M.Sc.
Plankton Community and Productivity

Rebecca Osborne, Ph.D.
Benthic Invertebrate Community (Lakes)

Sarah Latimer, B.Sc.
Benthic Invertebrate Community (Creeks)
Fish Tissue Quality (Lakes)

Alexandra Lischka, Ph.D., P.Biol., R.P.Bio.
Periphyton and Benthic Invertebrate Tissue Quality
Fish Tissue Quality (Creeks)

TABLE OF CONTENTS

ACRONYMS AND ABBREVIATIONS XIII

1 INTRODUCTION 1
1.1 Site Description and Background 1
1.2 Regulatory Environment 4
1.3 Scope of this Report 5
1.4 Monitoring Objectives 6
1.5 Report Organization 7

2 STUDY DESIGN OVERVIEW 9
2.1 Conceptual Overview 9
2.2 Lake Habitat 11
2.3 Creek Habitat 14
2.4 Interpretive Approach 17

3 METHODS – LAKE HABITAT 20
3.1 Sediment Quality 20
3.1.1 Sample Collection 25
3.1.2 Laboratory Analysis 27
3.1.3 Data Analysis 28
3.2 Sediment Toxicity 33
3.2.1 Sample Collection 35
3.2.2 Laboratory Analysis 36
3.2.3 Data Analysis 36
3.3 Plankton Community and Productivity 39
3.3.1 Sample Collection 43
3.3.2 Laboratory Analysis 45
3.3.3 Data Analysis 48
3.4 Zooplankton Tissue Quality 52
3.4.1 Sample Collection 54
3.4.2 Laboratory Analysis 55
3.4.3 Data Analysis 55
3.5 Benthic Invertebrate Community 58
3.5.1 Sample Collection 60
3.5.2 Laboratory Analysis 61
3.5.3 Data Analysis 62
3.6 Fish Catchability, Usage, and Population Health 66
3.6.1 Overview 66
3.6.2 Spring Survey 69
3.6.3 Fall Survey 70
3.6.4 Fish Processing 70
3.6.5 Data Analysis 72
3.7 Fish Tissue Quality 74
3.7.1 Sample Collection 78
3.7.2 Laboratory Analysis 80
3.7.3 Data Analysis 81
3.8 Supporting Measures 84
3.8.1 Supporting Measures 85
3.8.2 Laboratory Analysis 86
3.8.3 Data Analysis 87

4 METHODS – CREEK HABITAT 91
4.1 Sediment Quality 91
4.1.1 Sample Collection 91
4.1.2 Laboratory Analysis 94
4.1.3 Data Analysis 94
4.2 Periphyton Community and Productivity 96
4.2.1 Sample Collection 101
4.2.2 Laboratory Analysis 103
4.2.3 Data Analysis 104
4.3 Benthic Invertebrate Community and Productivity 107
4.3.1 Sample Collection 110
4.3.2 Laboratory Analysis 111
4.3.3 Data Analysis 111
4.4 Periphyton and Benthic Invertebrate Tissue Quality 114
4.4.1 Sample Collection 115
4.4.2 Laboratory Analysis 117
4.4.3 Data Analysis 117
4.5 Fish Tissue Quality 120
4.5.1 Sample Collection 123
4.5.2 Laboratory Analysis 125
4.5.3 Data Analysis 125
4.6 Supporting Measures 127
4.6.1 Measures Collection 127
4.6.2 Laboratory Analysis 128
4.6.3 Data Analysis 129

5 RESULTS – LAKE HABITAT 130
5.1 Polley Lake 130
5.1.1 Sediment Quality 130
5.1.2 Sediment Toxicity 137
5.1.3 Plankton Community and Productivity 142
5.1.4 Zooplankton Tissue Quality 155
5.1.5 Benthic Invertebrate Community 159
5.1.6 Fish Usage and Population Health 168
5.1.7 Fish Tissue Quality 177
5.2 Quesnel Lake 204
5.2.1 Sediment Quality 204
5.2.2 Sediment Toxicity 218
5.2.3 Plankton Community and Productivity 229
5.2.4 Zooplankton Tissue Quality 244
5.2.5 Benthic Invertebrate Community 250
5.2.6 Fish Community, Catchability, and Population 259
5.2.7 Fish Tissue Quality 260

6 RESULTS – CREEK HABITAT 286
6.1 Hazeltine Creek 286
6.1.1 Sediment Quality 286
6.1.2 Periphyton Community and Productivity 299
6.1.3 Benthic Invertebrate Community and Productivity 316
6.1.4 Periphyton and Benthic Invertebrate Tissue Quality 339
6.1.5 Fish Tissue Quality 376
6.2 Edney Creek 389

6.2.1 Periphyton Community and Productivity 389
6.2.2 Benthic Invertebrate Community and Productivity 390
6.2.3 Periphyton and Benthic Invertebrate Tissue Quality 392

7 SUMMARY OF FINDINGS 406
7.1 Polley Lake 406
7.1.1 Sediment Quality 406
7.1.2 Aquatic Life 407
7.1.3 Key Findings 411
7.2 Quesnel Lake 415
7.2.1 Sediment Quality 415
7.2.2 Aquatic Life 417
7.2.3 Key Findings 420
7.3 Hazeltine Creek 424
7.3.1 Sediment Quality 424
7.3.2 Aquatic Life 425
7.3.3 Key Findings 430
7.4 Edney Creek 435
7.4.1 Aquatic Life 435
7.4.2 Key Findings 437

SPIN – Summer Profundal Index Netting

SRN – Sample Receipt Notification

TOC – Total Organic Carbon

TOR – Terms of Reference

TSF – Tailings Storage Facility

TTF – Trophic Transfer Factor

UER – Upper Edney

ug/L – Micrograms Per Litre

UHC – Upper Hazeltine Creek

USEPA – United States Environmental Protection Agency

YOY – Young-of-the-Year

WTP – Water Treatment Plant

WW – wet weight

1 INTRODUCTION

1.1 Site Description and Background

Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals, owns and operates the Mount Polley copper-gold mine (Mount Polley) located approximately 9 kilometers southwest of Likely, British Columbia (BC) and 56 km (100 km by road) northeast of Williams Lake, BC (Figure 1.1). Infrastructure at the Mount Polley Mine site includes open pits, an underground mine, a crusher, a mill and office spaces, a Tailings Storage Facility (TSF), a Water Treatment Plant (WTP), waste rock disposal areas, collection and settling ponds, a surface water collection system, haul roads, access roads, and storage facilities (Figure 1.2). The total lease area associated with the mine is 24,096 hectares (ha).

Mount Polley began operating in 1997 and operated from 1997 to 2001, when it entered care and maintenance. The discovery of new ore reserves at the site and improved commodity prices prompted MPMC to reopen the mine in 2005 (MPMC 2009). Mount Polley continued operating until August 4, 2014, when a foundation failure at the perimeter embankment of the TSF resulted in a breach (Ministry of Energy and Mines 2015; Province of British Columbia 2015). The TSF perimeter embankment breach ("the breach") resulted in the release of approximately 25 million cubic meters of water, tailings slurry, and dam construction material into nearby Polley Lake, Hazeltine Creek, Edney Creek, and Quesnel Lake (Figure 1.1).

Mount Polley ceased operations immediately after the breach to focus on impact assessment, cleanup, and remediation. Restricted operations were permitted to commence on August 5, 2015. During restricted operations, all tailings were placed under water in the Springer Pit (Figure 1.2). Approval for discharge of treated mine effluent to Quesnel Lake was granted under the BC *Environmental Management Act* (EMA) on November 29, 2015, and Mount Polley initiated discharge of treated effluent to Quesnel Lake on December 1, 2015 (Figure 1.2). Restrictions on operations were lifted on June 23, 2016, and the mine began operating at full capacity on June 27, 2016 (MPMC 2017). On January 7, 2019, MPMC announced that Mount Polley operations would be suspended in May 2019 due to declining copper prices. Mount Polley was placed under care and maintenance on May 31, 2019, and remained so until August 25, 2021, when Mount Polley resumed pit mining and initiated a transition back to active operations. Full active operations at Mount Polley, including milling, copper concentration production, and tailings deposition, resumed in June 2022. The discharge of treated effluent to Quesnel Lake has been ongoing since 2015 (including during care and maintenance) and is currently permitted until June 30, 2025.

1.2 Regulatory Environment

Mount Polley is required to comply with Permit 11678, which was first issued under the BC EMA on May 30, 1997. Conditions of the permit include criteria for effluent quality and non-lethality, water quality monitoring, and biological monitoring. Permit 11678 was amended on November 7, 2012, to allow for effluent discharge from the TSF to Hazeltine Creek, which began on April 10, 2014. Discharges were halted in response to the August 4, 2014, breach.

Following extensive clean-up and remediation efforts, the British Columbia Ministry of Environment and Climate Change Strategy (BCMOECCS; currently the British Columbia Ministry of Environment and Parks) issued an amendment to Permit 11678 on November 29, 2015, which allowed Mount Polley to discharge treated effluent into Quesnel Lake via Hazeltine Creek as part of a short-term water management strategy. Permit 11678 was amended again on April 7, 2017, allowing for the use of a pipeline to convey treated water from the WTP to diffusers in Quesnel Lake (see Figure 1.2). Permit 11678 was most recently amended on December 1, 2022, and included an update to the permitted date for the direct discharge of treated effluent to Quesnel Lake via the pipeline and diffusers, which is now allowed under Permit 11678 until June 30, 2025.

Section 3.2 of the amended Permit 11678 requires MPMC to develop and implement a Comprehensive Environmental Monitoring Plan (CEMP) for the Mount Polley site and surrounding receiving environment that combines pre-existing monitoring programs into an integrated plan:

> *3.2.1 "The Permittee must continue to develop, submit, and implement an ongoing Comprehensive Environmental Monitoring Plan to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas."*
>
> *3.2.4 "The CEMP must meet all the following requirements:*
>
> *(a) Consolidate and integrate all of the monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.*
>
> *(b) At a minimum address, a three-year time span.*
>
> *(c) At a minimum include all sampling sites, frequency of sampling, variables to be analyzed, method detection limits, sampling methods, sample analysis methods, and data analysis methods.*

(d) The updated CEMP must be approved by the Director"

In accordance with this requirement, the CEMP (MPMC 2019) covers the 2018 to 2020 period and was developed based on an approved updated Terms of Reference (TOR) provided by BCMOECCS. The 2019 CEMP (MPMC 2019) was submitted to BCMOECCS on October 31, 2019, and was approved by BCMOECCS on February 10, 2021, subject to additional monitoring requirements (BCMOECCS 2021). Monitoring in 2024 was completed in accordance with the approved CEMP (MPMC 2019) and the additional CEMP requirements (outlined in BCMOECCS 2021), although the CEMP covers the 2018 to 2020 period. Based on the requirements of Permit 11678, an updated 2023 CEMP (MPMC 2023) was submitted to BCMOECCS on March 31, 2023, and is currently under review.

The CEMP is an integrated monitoring plan that has been developed to capture, in one document, several independent and interdependent monitoring programs, including: site monitoring, water discharge monitoring, Metal and Diamond Mining Effluent Regulations (MDMER) monitoring, breach response monitoring, and monitoring following completion of remediation efforts. The CEMP has been developed through an extensive consultative process that encompasses several permitting and other regulatory processes. This integrated monitoring plan offers the additional benefit of facilitating more efficient monitoring plan review by regulatory agencies, First Nations, and other stakeholders.

1.3 Scope of this Report

This report covers a subset of the CEMP. It includes monitoring of the aquatic receiving environment adjacent to, and downstream of Mount Polley over the three-year period from 2022 to 2024. The three-year period covered in the present report (2022 to 2024) serves to meet the requirement outlined in Section 3.2.6 of the amended Permit 11678, which stipulates that the permittee (MPMC) must:

"Submit a three-year detailed monitoring program interpretive report to the Director by March 31, 2022, and every three years thereafter."

To fulfill the dual requirements of both annual reporting and three-year integrative reporting, all raw data collected in 2024 are provided within this report whereas data collected in 2022 and 2023 are discussed and presented in reference to previous reports that have provided raw data. Where relevant, data collected prior to 2022 (as far back as baseline data collected in 1995) are used in data interpretation in reference to the previous reports that provided the raw data.

This report specifically includes lakes, creeks, and rivers with the potential to have been influenced by Mount Polley through effluent discharge, the breach, or general mine operations, including Polley Lake, Hazeltine Creek, Edney Creek, Quesnel Lake, and the Quesnel River

(Figure 1.1). Additional areas were also evaluated as references for the potentially affected areas to facilitate interpretation of potential effects (as outlined in the Study Design Overview; Section 2). This report is focused on sediment, periphyton, plankton, benthic invertebrates, and fish. Additional supporting data (e.g., physical habitat characteristics, water quality) are used in the interpretation of the key monitoring components.

1.4 Monitoring Objectives

The overarching objective of the monitoring undertaken under the CEMP is to support the evaluation of the potential for effects of mine-related activities on the physical, chemical, and biological characteristics of the environment surrounding Mount Polley (i.e., the receiving environment). Monitoring under the CEMP is completed to:

1. Evaluate if pollution[1] is occurring in the receiving environment as a result of the existing water discharge or mine-related activities;
2. Evaluate the environmental impacts of the August 2014 TSF embankment breach and to evaluate the effects of mitigation measures that are implemented as part of the remediation strategy; and
3. Inform management decisions, including reclamation and closure.

General objectives of the CEMP elements reported herein (i.e., sediment, periphyton, plankton, benthic invertebrates, and fish) are to:

1. Evaluate the influence of mine activities on the receiving environments in comparison to baseline/pre-breach and/or reference conditions;
2. Determine potential implications to aquatic life; and
3. Provide data to support exposure assessment as part of Ecological Risk Assessment (ERA) and Human Health Risk Assessment (HHRA).

Specific questions being addressed under these objectives are:

1. Are there differences in conditions at exposed areas relative to baseline/pre-breach and/or reference conditions?
2. If yes, are the differences mine-related?

[1] Pollution as defined in the BC EMA (S.1(1)) means "*…the presence in the environment of substances or contaminants that substantially alter or impair the usefulness of the environment*".

3. Does the weight-of-evidence indicate that the usefulness of the aquatic environment is impaired?

Specific objectives associated with the CEMP elements herein are provided in Table 1.1.

1.5 Report Organization

This report is presented in eight sections, the first of which is this introduction (Section 1). Section 2 provides an overview of the approach and study design for the CEMP elements reported herein (i.e., sediment, periphyton, plankton, benthic invertebrates, and fish). Section 3 provides the methods used for data collection, treatment, and interpretation applicable to lake habitat. Section 4 provides the same for creek habitat. Sections 5 and 6 provide the results, assessment, and interpretation of data collected in lake and creek habitat, respectively. Section 7 provides an integrated summary of the key findings. All references cited throughout the report are provided in Section 8.

Table 1.1: Objectives of the Mount Polley CEMP Sediment and Aquatic Life Monitoring Components

Component	Objectives	Sub-Components
Sediment	1. Evaluate the influence of mine activities on depositional receiving environments (e.g., Polley Lake, Quesnel Lake, and limited locations in Hazeltine Creek) in comparison to baseline and/or reference conditions; 2. Determine potential implications to aquatic life (e.g., relative to available sediment quality guidelines); 3. Provide supporting information for benthic invertebrate community monitoring; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Sediment Quality 2. Sediment Toxicity
Periphyton[b]	1. Evaluate the influence of mine activities on erosional receiving environments (e.g., Hazeltine Creek and Edney Creek) in comparison to baseline and/or reference conditions; 2. Serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (benthic invertebrates and fish); 3. Provide supporting information for the assessment of benthic invertebrate tissue quality, benthic invertebrate community condition, and fish habitat productivity; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Community Composition 2. Productivity 3. Tissue Quality
Plankton	1. Evaluate the influence of mine activities on lake environments (Polley Lake and Quesnel Lake) in comparison to baseline and/or reference conditions; 2. Serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (fish); 3. Provide supporting information for the assessment of fish habitat productivity and fish tissue quality; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Phytoplankton Community Composition 2. Phytoplankton Productivity 3. Zooplankton Community Composition 4. Zooplankton Productivity 5. Zooplankton Tissue Quality
Benthic Invertebrates	1. Evaluate the influence of mine activities on receiving environments (e.g., Hazeltine Creek, Edney Creek, Polley Lake, and Quesnel Lake) in comparison to baseline and/or reference conditions; 2. Determine potential implications to aquatic life (e.g., through assessment of benthic invertebrate community and productivity endpoints, and comparison of benthic tissue quality results to available guidelines); 3. Provide supporting information for the assessment of potential effects to higher trophic levels (e.g., fish); and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Community Composition 2. Productivity[b] 3. Tissue Quality[b]
Fish	1. Evaluate the influence of mine activities on receiving environments (e.g., Hazeltine Creek, Edney Creek, Polley Lake, Quesnel Lake, and Quesnel River) in comparison to baseline and/or reference conditions; 2. Determine potential implications to aquatic ecosystem health and human health (e.g., relative to available fish tissue quality guidelines); 3. Document fish habitat utilization in creek and lake areas that were physically impacted by the TSF breach (most notably Hazeltine Creek and lower Edney Creek), thereby documenting the effectiveness of fish habitat rehabilitation efforts; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Fish Habitat and Usage[b] 2. Community Composition 3. Fish Population Health 4. Tissue Quality

[a] Ecological Risk Assessment (ERA) and Human Health Risk Assessment (HHRA).
[b] Denotes a component or sub-component that only applies to creeks.

2 STUDY DESIGN OVERVIEW

2.1 Conceptual Overview

The overall study design for the Mount Polley CEMP, including rationale for the design, is provided in the approved 2019 CEMP study design document (MPMC 2019). That document provides an overview of the mine site and its surrounding environment, an overview of environmental management on the mine site, and a detailed description of each monitoring component of the CEMP. The latter includes the monitoring objective, a summary of historical findings, a study design overview and rationale, and methodology associated with quality assurance/ quality control (QA/QC), sample collection, laboratory analyses, data quality review (DQR), data handling, data interpretation, and reporting (MPMC 2019).

This report covers a subset of Mount Polley's CEMP and is specifically focused on sediment and aquatic biological monitoring under the CEMP (i.e., sediment, periphyton, plankton, benthic invertebrate, and fish components of the CEMP). Briefly, sediment and aquatic biological monitoring under the CEMP was developed in consideration of:

1. Pathways of potential effects (MPMC 2019);
2. Accepted biological monitoring tools and measurement endpoints sensitive to mine-related influences (Table 2.1; MPMC 2019);
3. The availability of baseline and/or pre-breach data (MPMC 2019);
4. The findings of previous studies (MPMC 2019);
5. Statistical considerations for comparisons of exposed-area data to reference, baseline, and/or over time (MPMC 2019);
6. Needs of the ERA and HHRA (Golder 2017a,b); and
7. Consultation (MPMC 2019).

Key pathways of potential effects to the aquatic environment include diffuse influences of the mine footprint and mining operations, the direct influence of the breach on Polley Lake, Hazeltine Creek, Edney Creek, and Quesnel Lake, and the direct discharge of treated mine water to Quesnel Lake. Sediment and aquatic biological monitoring endpoints used under the CEMP include chemical tools that address key questions and biological monitoring endpoints that are typically recognized as being the most sensitive to metals and to the potential influence of mine operations in general (Table 2.1; ESG 1999; Environment Canada 2012b; British Columbia Ministry of Environment [BCMOE] 2013, 2016; Arche et al. 2016; Simpson and Batley 2016). Baseline and/or pre-breach data are available for lakes and creeks immediately adjacent to

Table 2.1: Mount Polley CEMP Sediment and Aquatic Life Monitoring Components and Measurement Endpoints, 2022 to 2024[a]

Monitoring Component	Habitat Type	Sub-Component	Measurement Endpoints
Sediment	Lake and Creek[b]	Sediment Texture	moisture particle size distribution total organic carbon

		Tissue Quality	moisture metals (CRC-ICP-MS scan[d]) mercury

[a] A number of additional supporting measures were collected to assist in the interpretation of results associated with the core measurement endpoints displayed. Not all measurement endpoints were evaluated annually between 2022 to 2024. See Minnow 2023a, 2024a for details of monitoring in 2022 and 2023, respectively.

[b] Due to the predominantly erosional habitat of the creek habitats assessed, measurement endpoints for sediment collected from these creek habitats were limited to the sub-components texture and quality.

[c] Benthic invertebrate biomass as a measure of secondary productivity was limited to creek habitats only.

[d] Metal scans by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) or Collision Reaction Cell ICP-MS (CRC-ICP-MS). "Metals" includes non-metallic parameters, such as phosphorus, which are common in CRC-ICP-MS analysis packages.

[e] Taxa reported at the lowest practicable level of taxonomy.

[f] Fish habitat and fish habitat usage were monitored in creek habitats only.

[g] Fish collection and catch-per-unit-effort using a variety of techniques: minnow trapping and backpack electrofishing in creek habitats; hoop netting, minnow trapping, angling, and gill netting in lake habitats.

[h] Fish population health was monitored in lake habitats only (Polley Lake).

the mine (Polley Lake, Hazeltine Creek, Edney Creek, Bootjack Lake, and Quesnel Lake). To the extent possible, monitoring is designed to make the best use of baseline and/or pre-breach data in interpretation. Findings of previous studies (reviewed in the CEMP; MPMC 2019) also informed the study design, with the design focused on areas of greatest potential impact and on addressing key questions of effect or of recovery.

The assessment of potential mine-related effects is predicated on the detection of differences between exposed areas and baseline, pre-breach, or reference areas, or over time. Therefore, the study design was driven by considering statistical requirements (e.g., the number of reference areas and replication [n] within each exposed and reference area) to support sufficiently powerful comparisons among areas and over time (replication level is typically n=5 to n=8). The design was also developed in consideration of data needs to support potential future iterations of ERA and HHRA.

2.2 Lake Habitat

Monitoring of lake habitat in the vicinity of the Mount Polley Mine between 2022 and 2024 focused on two lakes: Polley Lake, which is located to the immediate east of the mine and Quesnel Lake, which is located further to the east of Polley Lake and approximately 3.7 kilometers from the mine at its nearest point (Figure 2.1). As indicated above, Polley Lake was influenced by the breach in August 2014 and may be influenced by mining operations. Quesnel Lake was influenced by the breach in August 2014 (via Hazeltine Creek) and is currently also influenced by the direct discharge of treated mine water to Quesnel Lake (as of January 8, 2018[2]; Figure 2.1). Bootjack Lake serves as reference for Polley Lake, and unexposed/unimpacted areas within Quesnel Lake serve as references for exposed/impacted areas of the lake (Figures 1.2 and 2.1).

CEMP monitoring in lakes is outlined in detail in the CEMP study design document (MPMC 2019), including detailed description of each monitoring component and associated rationale for the study design and for the selected measurement endpoints. This section provides a general overview of the sediment and aquatic biological monitoring of lakes completed over the 2022 to 2024 period (see Figure 2.1, Table 2.2). Briefly, CEMP monitoring of lakes from 2022 to 2024 included the following components: sediment quality, sediment toxicity, phytoplankton community and productivity, zooplankton community and productivity, zooplankton tissue quality, benthic invertebrate community, fish community/ population, and fish tissue quality. Not all monitoring components were completed at every area each year (Figure 2.1, Table 2.2).

[2] Discharge of treated mine water to Quesnel Lake via Hazeltine Creek was initiated on December 1, 2015. Direct discharge to Quesnel Lake (via a pipe) was initiated on January 8, 2018.

Notes: Checkmarks indicate sampling was completed at the area indicated. Dashes indicate sampling was not completed at the area indicated. Quesnel River is grouped with lake habitats for this report because of its close association with Quesnel Lake monitoring.

[a] Detailed descriptions of each monitoring element and associated rationale based on historical findings are provided in the CEMP (MPMC 2019); detailed methods are provided in Section 3 of this report.

[b] Fish community / population monitoring in Bootjack Lake and Quesnel Lake is associated with sampling efforts undertaken for the purpose of fish tissue quality monitoring. In Polley Lake, fish population health monitoring is undertaken in addition to sampling efforts for the purpose of fish tissue quality monitoring.

[c] Fish tissue quality monitoring includes multiple species (rainbow trout and longnose sucker in Polley and Bootjack Lakes; lake trout, northern pikeminnow, and peamouth chub in Quesnel Lake; rainbow trout in Quesnel River).

Detailed descriptions of monitoring conducted in lake habitats from 2022 to 2024 are provided in Section 3.

2.3 Creek Habitat

Monitoring of creek habitat in the vicinity of the Mount Polley Mine between 2022 and 2024 focused on two creeks: Hazeltine Creek, which flows from Polley Lake to Quesnel Lake, and Edney Creek which conflows with Hazeltine Creek before entering Quesnel Lake (Figure 2.2). Hazeltine Creek was impacted by the breach in August 2014, has conveyed Mount Polley mine water over two periods (April 11 to August 4, 2014, and November 29, 2015, to September 30, 2017), and is influenced by mining operations. The lower 775 m of Edney Creek was also impacted by the breach. Remediation efforts of Hazeltine Creek and lower Edney Creek following the breach were initiated in 2014. Edney Creek conflowed with Hazeltine prior to the breach, but remediation efforts separated the two creeks (Edney Creek near Quesnel Lake flowed adjacent to Hazeltine Creek) from 2014 until September 2020 when the creeks were rejoined. Two creeks (Edney Creek upstream of the impacted area and Frypan Creek) serve as references for Hazeltine Creek and the impacted area of Edney Creek (Figure 2.2).

CEMP monitoring in creeks is outlined in detail in the CEMP study design document (MPMC 2019), including detailed description of each monitoring component and associated rationale for the study design and for the selected measurement endpoints. This section provides a general overview of the sediment and aquatic biological monitoring of creeks completed over the 2022 to 2024 period (see Figure 2.2, Table 2.3). Briefly, CEMP monitoring of creeks over the 2022 to 2024 period included the following components: sediment quality, periphyton community and productivity, benthic invertebrate community and productivity, periphyton and benthic invertebrate tissue quality, fish habitat usage and community, and fish tissue quality. Not all components were completed at each area in each year (Figure 2.2, Table 2.3). Fish tissue quality monitoring was completed in creeks in 2024 although this is not a monitoring requirement of the approved CEMP (MPMC 2019) nor a requirement of the 2019 CEMP approval conditions (BCMOECCS 2021). Methods and results of the fish tissue monitoring completed in creeks in 2024 are included in the present report because this monitoring is complimentary to that required under the CEMP. Fish habitat characterization and fish usage monitoring (for spawning and rearing purposes) in upper and lower Hazeltine Creek and lower Edney Creek is part of the CEMP (Table 2.3); however, this monitoring focuses on a set of objectives identified and reviewed by

Notes: Checkmarks indicate sampling was completed at the area indicated. Dashes indicate sampling was not completed at the area indicated.

[a] Detailed descriptions of each monitoring element and associated rationale based on historical findings are provided in the CEMP (MPMC 2019); detailed methods are provided in Section 4 of this report.

[b] Alternate area identifiers used for HRWG reporting are noted, where applicable.

[c] Fish habitat assessment monitoring included documentation of fish habitat conditions. Fish usage and community monitoring included documentation of the usage of fish habitat by any / all fish species for Edney and Hazeltine Creeks.

[d] Fish tissue quality monitoring was completed in association with sampling efforts undertaken for the purpose of fish usage and community monitoring.

the Habitat Remediation Working Group[3] (HRWG). As such, results of this monitoring between 2022 and 2024, and prior years, are summarized in a separate report (i.e., HRWG report, Minnow 2025). Detailed descriptions of sediment, periphyton, and benthic invertebrate, and fish tissue monitoring conducted in creek habits from 2022 to 2024 are provided in Section 4.

2.4 Interpretive Approach

The interpretation of sediment and aquatic biological data collected under the CEMP (i.e., data reported herein) is based on several key interpretive tools. The approach to data interpretation is outlined in the CEMP (MPMC 2019) and detailed methods are provided in Sections 3 and 4 of this report. Briefly, chemical data collected at potentially impacted areas are evaluated in comparison to environmental quality guidelines (as available), and based on statistical comparison to reference, to baseline and/ or pre-breach, and over time (replication [n] = 5 to 8).

Presentation of chemical data incorporates results for all analytes reported by the laboratory; however, detailed analyses and discussion are focused on "primary" and "secondary" analytes (Table 2.4).[4] Primary and secondary analytes are constituents that have been identified in previous monitoring as being indicative of a mine influence on the receiving environment. Specifically, primary analytes are those that were previously identified as strongly indicative of a mine influence for most monitoring components and for which environmental quality guidelines are available. Secondary analytes are those that were previously identified as potentially indicative of a mine influence in only a subset of monitoring components. Evaluation of primary and secondary analytes was completed for all chemical data in the present report (i.e., water, sediment, and tissue quality data). To focus the interpretation of primary and secondary analyte results, discussion was limited to those analytes for which differences were reported temporally (at the exposed areas relative to prior post-breach data and/or baseline/pre-breach data) and/ or spatially (between the exposed and reference areas in the present year). Biological data for potentially impacted areas are evaluated based on the measurement endpoints presented in Table 2.1 and are based on statistical comparison to reference, to baseline and/ or pre-breach, and over time (n = 5 to 8).

[3] The HRWG was established at the request of Fisheries and Oceans Canada (DFO; April 9, 2015), in response to regulatory requirements set out in Section 38(6) of the *Fisheries Act*. Members of the initially assembled working group included: DFO, BCMOECCS (currently British Columbia Ministry of Environment and Parks), British Columbia Ministry of Forest Lands and Natural Resource Operations and Rural Development (currently British Columbia Ministry of Water, Land, and Resource Stewardship [BCMOWLRS]), Soda Creek Indian Band, Williams Lake Indian Band, and Mount Polley Mining Company.

[4] Primary and secondary analytes are analytes that were classified as POIs (parameters of interest) and IPs (indicator parameters) for monitoring components in previous evaluations (see Minnow 2019a for details).

Table 2.4: Primary and Secondary Analytes used in the Evaluation of Chemical Data for the Mount Polley CEMP Sediment and Aquatic Life Monitoring Components, 2022 to 2024[a]

Category	Analyte
Primary	Arsenic
	Copper
	Iron
	Selenium
Secondary	Barium
	Cadmium
	Calcium
	Cobalt
	Manganese
	Mercury
	Molybdenum
	Nickel
	Phosphorus
	Silver
	Sodium
	Strontium
	Tin
	Titanium
	Uranium
	Vanadium
	Zinc

[a] See Section 2.4 and Minnow (2019a) for the rationale associated with selection of these analytes.

Relationships between chemical and physical features (e.g., sediment chemistry and particle size distribution) and relationships between biological measurement endpoints and chemistry (e.g., benthic invertebrate community taxon richness and water or sediment chemistry) are evaluated using correlation or regression analysis to enhance understanding of potential cause. Although it is recognized that a significant correlation does not indicate cause, it can be useful in identifying potential causes and/or in distinguishing among different potential causes (e.g., Shipley 2000; Suter 2015). Lastly, data interpretation includes a step to bring the sediment and aquatic biological data together to identify consistencies (or inconsistencies) in the findings and to assist in the derivation of conclusions in consideration of all lines of evidence and relationships among them.

3 METHODS – LAKE HABITAT

3.1 Sediment Quality

Sediment quality monitoring was completed at shallow and deep exposed areas of Quesnel Lake and Polley Lake (and associated reference areas) between 2022 and 2024. In deep exposed areas of Quesnel Lake and Polley Lake (and associated references), post-breach sediment quality monitoring was initiated in 2014 and has been completed at least every three years since 2018 (Figures 3.1 and 3.2, Tables 3.1 and 3.2), in accordance with the CEMP (MPMC 2019). In shallow Quesnel Lake habitats, sediment quality monitoring was initiated in 2014 and has been completed annually since 2019 (Figure 3.2, Table 3.2). In shallow Polley Lake habitats (and associated reference; Bootjack Lake), sediment quality monitoring was initiated in 2019 and has been completed every three years since then (Figure 3.1, Table 3.1). The monitoring of shallow lake habitats is in accordance with Condition 9 of the CEMP approval conditions dated February 10, 2021 (BCMOECCS 2021). Although not a requirement of the CEMP (MPMC 2019), sediment has been collected annually from the deep near-field area of Quesnel Lake (QUL-PNF) since 2018 to support the evaluation of monitored natural recovery (Table 3.2; see Section 3.5). Sediment quality monitoring in the shallow and deep lake habitats supports sediment toxicity testing (Section 3.2) and/or benthic invertebrate community monitoring (Section 3.5) that is also completed at these areas.

In Polley Lake, sediment quality monitoring in 2024 included two deep monitoring areas (POL-P1 and POL-P2) and an associated deep reference area in Bootjack Lake (BOL-B2), where sampling last occurred in 2021 (Figure 3.1, Table 3.1). Sediment quality monitoring of shallow areas (1.5 to 3.5 meters depth) located in Polley Lake (POL-S) and Bootjack Lake (BOL-S; reference) was last completed in 2022 (Figure 3.1, Table 3.1).

In Quesnel Lake, sediment quality monitoring in 2024 included three deep areas (approximately 80 to 100 meters depth), with one near-field area (QUL-PNF), one far-field area (QUL-PFF1), and one reference area (QUL-PREF1). Sediments from QUL-PNF have been monitored annually for the past seven years (2018 to 2024) for the evaluation of monitored natural recovery. Prior to 2024, the other deep areas (QUL-PREF1 and QUL-PFF1) were last monitored in 2021 (Figure 3.2, Table 3.2). Sediment quality monitoring of shallow sediments in 2024 included two areas (1 to 2 meters depth), with one near-field area (QUL-LNF1) and one reference area (QUL-LREF1); these areas have been monitored annually for the last six years (2019 to 2024; Figure 3.2, Table 3.2).

Sediment quality was also monitored in deep areas of Quesnel Lake in 2024 as part of Environmental Effects Monitoring (EEM; Phase 4) under the MDMER of the federal *Fisheries Act*.

Notes: "-" = not sampled/not applicable. Sediment Quality analyses included: metals and Total Organic Carbon (TOC) in < 63 µm fraction, moisture, particle size, pH, total nitrogen, and total sulphur for sampling completed between 2014 and 2024 (post-breach sampling).

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored between 2022 and 2024 are displayed, as well as historical data for these areas.

[b] Areas are associated with effluent discharged-related monitoring under the Metal and Diamond Mining Effluent Regulations [MDMER] Environmental Effects Monitoring [EEM]). QUL-EEMEXP represents and effluent-exposed area, QUL-EEMREF1 represents a non-breach-influenced reference area, and QUL-EEMREF2 represents a breach-influenced reference area.

Three deep areas were evaluated as part of EEM; one exposed (QUL-EEMEXP) and two reference areas (QUL-EEMREF1 [non-breach-influenced], and QUL-EEMREF2 [breach-influenced]). Results for the Phase 4 EEM are due in a separate report in October 2025, therefore methods and results for this monitoring are not included in the present report. Prior to 2024, sediment quality monitoring in support of the Phase 3 EEM was last completed in 2021 (Table 3.2; Minnow 2022c).

Sample collection and analysis methods for 2024 are described herein (excluding those related to the Phase 4 EEM) and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, including equivalent historical sampling areas, refer to the references listed in Tables 3.1 and 3.2.

3.1.1 Sample Collection

Sediment samples were collected from Polley Lake (and the associated reference, Bootjack Lake) between August 19 and August 24, 2024 (Appendix Table A.1.1). Five replicate stations were sampled to represent each monitoring area (Figure 3.1, Table 3.1). One sediment sample was collected at each replicate station, and each sample was a homogenized composite of multiple sub-samples. Sediment samples for metals[5] analysis from deep areas of Polley Lake and Bootjack Lake have historically been collected using gravity coring methods (1999 to 2021). Accordingly, gravity coring methods were employed in 2024 to collect sediments for the analysis of total organic carbon (TOC), total sulphur, total nitrogen, and metal concentrations. Gravity coring was conducted in accordance with provincial (BCMOE 2013) and federal (Environment Canada 2012b) technical guidance, the CEMP (MPMC 2019), and was consistent with previous sampling years (1999 to 2021; Table 3.1).

A Ball corer, which is a gravity corer that collects samples in 3” (7.62 cm) diameter core tubes, was used to collect sediments from each replicate station in Polley Lake and Bootjack Lake in 2024. In previous years, a Kajak-Brinkhurst (K-B) or Tech Ops corer was used for sediment core sample collection (e.g., Minnow 2022a), and use of a Ball corer in 2024 was implemented to improve sample collection efficiency and success. Consistent gravity coring methods and sample collection techniques were applied in all years regardless of which gravity corer was used (i.e., K-B, Tech Ops, or Ball). Sediment core collection relies on a combination of surface tension within the core and suction (supplied by a ball in a Ball corer or an automatic seal in a K-B or Tech Ops corer) that seals the top of the core tube after being deployed by a messenger.

Gravity coring methods were implemented at each replicate station in Polley Lake and Bootjack Lake as follows. The Ball corer was lowered to the sediment surface, taking care to control the

[5] For ease of discussion, metals, metalloids, and non-metals are collectively referred to as metals throughout this report.

rate and vertical position of the corer during deployment to minimize disturbance of the sediment-water interface. The corer was then carefully retrieved to the surface and an extruder head was inserted into the bottom of the core tube to prevent sediment slippage. Core samples were rejected if there was evidence of slippage, if the corer did not penetrate the substrate vertically, or if the sediment-water interface was disturbed within the core. The core tube was then removed from the corer and the extruder head was used to push the sediment upwards towards the top of the core tube in a controlled fashion with care taken to minimize suspension of fines. In the event of suspension, momentum was stopped, allowing the solids to re-settle. Once the sediment was extruded to near the top of the tube, an extrusion collar marked with 1 cm intervals was carefully aligned on the top of the tube and the sediment extruded upwards into the collar. A core slicer was carefully inserted between the tube and the collar at the 3 cm interval, to collect the top 3 cm of sediment. The sediment was then transferred into one or more pre-labelled 250 mL glass sampling jars. The procedure was repeated at least twice more to provide a composite sample with sufficient volume for the required analyses. All sampling equipment was rinsed between stations using site water.

Sediment samples for the analysis of particle size were collected from each replicate station in Polley Lake and Bootjack Lake using a stainless-steel Petite Ponar grab sampler (Appendix Table A.1.1). Grab sampling was completed in accordance with provincial (BCMOE 2013) and federal (Environment Canada 2012b) technical guidance, the CEMP (MPMC 2019), and was consistent with previous monitoring which has typically employed grab sampling to collect sediments for physical analysis (particle size distribution[6]) from Polley Lake and Bootjack Lake (1999 to 2021; Table 3.1). The Petite Ponar grab sampler is a 6” x 6” (15.24 cm x 15.24 cm) grab sampler with jaws that can be held open by shear-pressure on a spring-loaded pin. At each sampling station, the Petite Ponar was lowered to the substrate at which point the shear-pressure was eliminated and the pin released. As with gravity coring, care was taken to control the rate at which the ponar was lowered to allow appropriate sediment penetration and to minimize disturbance of the sediment-water interface. Surficial sediment was collected by pulling upwards on the sampler, which triggered the spring pin and caused the jaws to close. The Petite Ponar was then carefully retrieved to surface, where the sediment grab was placed in a plastic bin and observed for completeness and unusual characteristics. If the sample was deemed acceptable (i.e., the sampler was full to each end and was representative of surface sediment), material to a depth of 3 cm was transferred to a second tote using a stainless-steel spoon, and the remaining sediment was discarded. This procedure was repeated

[6] Grab sampling was also used for the collection of sediment for total organic carbon chemical analysis in 1999 (Beak 2000), 2007 (Minnow 2009), and 2014 (Minnow 2015a).

at each station for a minimum of five successful grabs. At that point, the composite material within the tote was homogenized using a stainless-steel spoon and transferred into two or more pre-labelled 250 mL glass sampling jars. All sampling equipment was rinsed between stations using site water.

Sediment samples were collected from shallow and deep areas of Quesnel Lake from August 19 to August 24, 2024 (Appendix Table A.1.1). Five replicate stations were sampled to represent each monitoring area (Figure 3.2, Table 3.2). Samples were collected using a stainless-steel Petite Ponar for the analysis of TOC, total sulphur, total nitrogen, particle size, and metal concentrations. Sampling was conducted in accordance with provincial (BCMOE 2013) and federal (Environment Canada 2012b) guidance and with previous monitoring (Table 3.2). Grab sampling at each station was completed as described above for Polley and Bootjack lakes, except that samples from deep areas (i.e., QUL-PREF1, QUL-PFF1, and QUL-PNF; Figure 3.2, Table 3.2) were collected with the assistance of a commercial line hauler (Ace Line Hauler Brutus Plus 40).

Duplicate (split) sediment samples were collected at a target frequency of 10% for QA/QC purposes. Immediately after collection, samples were stored in a cooler with ice packs until they were placed in a refrigerator at the field laboratory, where they were held until shipment (on ice) to the analytical laboratory.

Supporting measures were collected at each sampling station to support data interpretation (see Section 3.8.1 for details).

3.1.2 Laboratory Analysis

Laboratory analysis of sediment quality samples from lake habitats was completed by ALS Environmental in Burnaby BC, a laboratory that is accredited by the Canadian Association for Laboratory Accreditation (CALA). Upon receipt of the sample shipment(s), ALS Environmental measured temperature in each cooler to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique sample identification code. A sample receipt notification (SRN) was then sent to Mount Polley and Minnow for verification.

Laboratory analysis included moisture content, pH, particle size distribution, TOC, total nitrogen, total sulphur, and total metal concentrations for all samples. Analysis methods for all parameters were consistent with previous post-breach sampling years (Tables 3.1 and 3.2). Analyses of TOC and metals concentrations were completed on the silt/ clay fraction (<63 µm diameter) in accordance with recommendations (BCMOE 2016) and consistent with previous methods (2014 to 2023; Tables 3.1 and 3.2). Analyses of the remaining parameters (moisture, pH, total nitrogen, total sulphur, and particle size distribution) were completed on bulk sediment.

Analysis of pH was completed by electrode, particle size analysis was completed by sieve and pipette, TOC was completed by combustion and titration (total carbon minus total inorganic carbon), and total nitrogen and total sulphur were completed by combustion. Analysis of metals was based on the BC Strong Acid Leachable Metals digestion (SALM; BCMOE 2016), with total metals analysis completed by Collision Reaction Cell Inductively Coupled Plasma – Mass Spectrometry (CRC-ICP-MS; United States Environmental Protection Agency [USEPA] Method 6020B; USEPA 2014]), and mercury analysis completed by Cold Vapour Atomic Absorption Spectrophotometry (CVAAS; USEPA Methods EPA 200.2/1631; USEPA 1994, 2001).

QA/QC sampling completed by the laboratory included method blank (MB) samples, laboratory replicates, and laboratory accuracy measures (i.e., laboratory control samples [LCS], and/ or reference materials [RMs]). Upon completion of the analyses, a data report was provided by ALS Environmental to Mount Polley and Minnow in Adobe Acrobat Portable Document Format (PDF) and Microsoft Excel files (Appendix G).

3.1.3 Data Analysis

3.1.3.1 Data Screening and Analytes of Interests

Upon receipt of the initial analytical data, a DQR was completed, including an examination of data completeness, laboratory reporting limits (LRLs) achieved, laboratory precision, laboratory accuracy, and field precision (Appendix B). Following completion of the DQR, raw data were summarized by area by calculating mean, median, standard deviation (SD), minimum, and maximum. Summary statistics were calculated using the Kaplan-Meier (K-M) method as described in Section 3.8.3.1.

Data were evaluated in comparison to British Columbia Working Sediment Quality Guidelines for the protection of aquatic life (British Columbia Ministry of Water, Land, and Resources Stewardship [BCMOWLRS] 2024) and the British Columbia Approved Water Quality Guideline for selenium in sediment (BCMOWLRS 2024, 2025), collectively termed British Columbia Working Sediment Quality Guidelines (BCWSQG) in this report. The BCWSQGs are numerical criteria that are protective of sediment-dwelling organisms based on long-term exposure. Most BCWSQGs have been adopted from the Canadian Council of Ministers of the Environment (CCME; CCME 1999) or from Ontario (OMOE 1993) and have two levels: a lower BCWSQG and an upper BCWSQG. The lower BCWSQG is intended to represent a concentration that will protect aquatic life from adverse effects of a toxic substance in most situations. The upper BCWSQG is intended to represent a concentration that, if exceeded, will likely cause severe effects on aquatic life (BCMOWLRS 2024, 2025). However, BCWSQGs (even the

upper BCWSQGs) are often naturally exceeded in mineralized areas. In addition, BCWSQGs were developed based on co-occurring bulk surficial sediment data and biological effect data (CCME 1995), as bulk sediment chemistry can differ substantially from the <63 µm fraction. This discrepancy between measurement (<63 µm fraction) and exposure (to bulk sediment [to which BCWSQGs are most applicable]) should be considered in interpretation, as "caution should be used in interpreting the biological significance of chemical concentrations in sediments for different types based on these guidelines" (CCME 1995).

Sediment quality data from exposed areas were also evaluated relative to 1) "reference data", and 2) "pre-breach data". Reference data included all available post-breach data (2014 to 2024) from reference areas that were sampled in 2024. Reference and pre-breach data were compiled separately and used to calculate reference and pre-breach 95th percentile screening values, respectively. Reference 95th percentile screening values were calculated from each post-breach reference dataset (i.e., separately for Quesnel Lake shallow [QUL-LREF1], Quesnel Lake deep [QUL-PREF1], and Bootjack Lake [BOL-B2] reference areas). Pre-breach 95th percentile screening values were calculated from each available pre-breach dataset (i.e., Polley Lake deep areas [1989 to 2012], Bootjack Lake deep areas [1989 to 2012], and Quesnel Lake shallow area QUL-LNF1 [2007]). Pre-breach 95th percentile screening values were calculated from each available pre-breach dataset (i.e., and Quesnel Lake shallow area QUL-LNF1 [2007]). Once calculated, the 95th percentile reference and pre-breach screening values were compared, and the highest of these values for each analyte was then used to screen the associated exposed data. If pre-breach data were not available, as is the case for the deep monitoring areas of Quesnel Lake, only the 95th percentile reference values were used. The reference and pre-breach data used in the calculation of the 95th percentiles and used in data screening are presented in Appendix Tables C.2.1 to C.2.3 and C.2.9.

All analytes (including primary and secondary analytes) were screened against BCWSQGs and applicable reference and pre-breach 95th percentile values. Analytes at exposed areas with mean concentrations that exceeded all the following criteria were termed "Analytes of Interest": 1) the BCWSQG; 2) the associated reference 95th percentile value; and 3) the associated pre-breach 95th percentile value (if available). Analytes of Interest were determined separately for each monitoring area (i.e., separately for deep areas of Polley Lake, and deep and shallow areas of Quesnel Lake). Concentrations of the Analytes of Interest, along with TOC, were the focus of more detailed interpretation which included graphical plots, formal statistical contrasts of temporal and spatial differences in concentrations, and examination of relationships to physical and chemical sediment variables.

3.1.3.2 Statistical Analyses

Statistical analyses of Analyte of Interest concentrations and TOC content of lake sediments were conducted using post-breach data (i.e., 2014 to 2024) to answer one or more of the following questions:

1. Have mean analyte concentrations at the exposed area changed relative to the reference area?
2. Were there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?
3. Have mean analyte concentrations at the exposed area changed over time since the breach?

To answer these questions, data were grouped into three categories for separate tabular and graphical presentation and statistical analyses:

1. Deep Polley Lake (POL-P1 and POL-P2; exposed) compared to a deep reference area (Bootjack Lake; BOL-B2).
2. Deep exposed area of Quesnel Lake (QUL-PNF and PFF1) compared to an un-impacted deep reference area (QUL-PREF1)
3. Shallow exposed area of Quesnel Lake (QUL-LNF1) compared to an un-impacted shallow reference area (QUL-LREF1).

Questions 1 and 2 were answered by conducting a two-way Analysis of Variance (ANOVA) assessing the relative differences between exposed and reference areas, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA included all data with paired exposed and reference results. Except for TOC, the data used in the two-way ANOVA model were $\log_{10}$ transformed. As such, differences between the exposed and reference areas were multiplicative when testing the significance of the interaction between *Area* and *Year* (i.e., if the concentration in the reference area decreases by 50%, then the null hypothesis would be that the concentration in the exposed area also decreases by 50%). Values below the LRL were replaced with the highest LRL when present. If the *Area*×*Year* interaction term was significant ($\alpha = 0.05$), then the ratios of the concentrations from the exposed area to the reference area differed among years. In this case, pairwise contrasts among years were completed to compare the relative difference in means (in $\log_{10}$ units) between areas among years. The hypotheses tested were:

$$H_0: \left(\mu_{\text{Exposed}} - \mu_{\text{Reference}}\right)_i = \left(\mu_{\text{Exposed}} - \mu_{\text{Reference}}\right)_j \text{ for all years i, j, i} \neq \text{j}$$

Contrasts were completed for all pairwise comparisons among years, where paired exposed and reference data were available. The analysis for analyte (metal) concentrations assumed data were $\log_{10}$ distributed so the hypothesis of testing differences between means is equivalent to testing the ratios of exposed to reference concentrations on the untransformed scale because of the following property of logarithms:

$$log(x_{\text{Exposed}}) - log(x_{\text{Reference}}) = log\left(\frac{x_{\text{Exposed}}}{x_{\text{Reference}}}\right).$$

Comparisons of TOC were conducted on untransformed data and thus significant interactions tested for absolute rather than relative differences between reference and exposed areas.

The results of the multiple comparisons among years were displayed by assigning letters (e.g., A, B, C) to each year. Letters were assigned such that the year with the highest difference in log or untransformed (e.g., TOC) concentrations between the exposed and reference areas was assigned the letter "A" and years that do not differ significantly ($\alpha = 0.05$) share a letter. When the *Area*×*Year* interaction term was not significant ($\alpha = 0.05$), the differences between areas were consistent among years and no contrasts were conducted. For simplicity, models comparing changes in concentrations between reference and exposed areas on the transformed or untransformed scale are hereafter referred to throughout the report as changes in the relative differences between these areas.

Temporal changes in the differences between the exposed and reference areas were quantified by calculating a Magnitude of Difference (MOD), which is the difference between the value for the exposed area and the predicted value for the exposed area, assuming the same difference from the baseline year (the first year the data were collected). This MOD was expressed as a percent change on the back-transformed scale as:

$$MOD = \frac{10\text{^}\bar{x}_{Exposed\ Observed} - 10\text{^}\bar{x}_{\text{Exposed }Predicted}}{10\text{^}\bar{x}_{\text{Exposed }Predicted}} \times 100\%$$

where $\bar{x}_{Exposed\ Observed}$ is the mean for the exposed area (in $\log_{10}$ units) for the given year and $\bar{x}_{\text{Exposed }Predicted}$ is the predicted mean (log units), assuming the relative difference between the exposed area and reference area did not change from the baseline year (i.e., $\bar{x}_{\text{Exposed }Predicted} = \bar{x}_{\text{Reference}} + \left(\bar{x}_{\text{Exposed Baseline}} - \bar{x}_{\text{Reference Baseline}}\right)$). The MODs for TOC did not need to be back-transformed but were calculated using the same formula otherwise.

Question 3 was answered using the results of the same two-way ANOVA used to answer Question 1 but considered exposed and reference data independently (rather than assessing the change in the differences between these areas as outlined for Questions 1 and 2). These analyses included unpaired exposed and reference data. When the interaction term of this

two-way ANOVA was significant, spatial and temporal *post hoc* contrasts were conducted to test differences among years for each area and between reference and exposed areas in each year. The MOD between the exposed and reference areas for significant spatial comparisons was calculated in each year as:

$$MOD = \frac{10\text{^}\bar{x}_{Exposed} - 10\text{^}\bar{x}_{\text{Reference}}}{10\text{^}\bar{x}_{\text{Reference}}} \times 100\%$$

where $\bar{x}_{Exposed}$ and $\bar{x}_{Reference}$ are the exposed and reference area means (in log units), respectively. The MOD for temporal differences from the base year were similarly calculated as:

$$MOD = \frac{10\text{^}\bar{x}_{Yeari} - 10^{\bar{x}}{}_{\text{Base year}}}{10\text{^}\bar{x}_{\text{Base year}}} \times 100\%$$

where $\bar{x}_{Yeari}$ and $\bar{x}_{Baseyear}$ are the means for the selected year and base year of monitoring (in log units), respectively. For both MOD calculations, the means for TOC were not back-transformed because the model used untransformed data. When the interaction term was not significant, the differences between exposed and reference areas were consistent over time and a spatial MOD (i.e., between areas) was calculated for all years combined if the *Area* term was significant, and temporal contrasts and MODs were conducted for the pooled areas (i.e., combined reference and exposed).

Analytes of Interest concentrations and TOC content were plotted to support the two-way ANOVA results and included comparison of post-breach data (i.e., those data included in the analyses) to BCWSQG and reference and/or pre-breach 95th percentile values.

Relationships between the Analytes of Interest concentrations and sediment physical (i.e., % clay) and chemical variables (TOC, total nitrogen, and total sulphur content) were evaluated using Spearman's Rank correlation analysis. Correlation analyses were conducted separately for each of the three data groupings outlined above (1: deep Polley Lake and Bootjack Lake areas; 2: deep Quesnel Lake areas; 3: shallow Quesnel Lake areas) using all available post-breach data (i.e., 2014 to 2024) to evaluate these relationships over time. For all three areas, differing relationships were apparent for the exposed areas relative to reference. As such, correlations were run separately for the three areas using the following data groups: 1) exposed and reference areas combined (i.e., BOL-B1, POL-P1, and POL-P2 combined; QUL-PNF, QUL-PFF1, and QUL-PREF1 combined; and QUL-LNF1 and QUL-LREF1 combined), and 2) exposed areas only (i.e., POL-P1 and POL-P2; QUL-PNF and QUL-PFF1 combined; and QUL-LNF1). Metal concentrations were measured in the <63 µm fraction of sediment (see Section 3.1.2), therefore relationships between Analyte of Interest concentrations and particle size were

completed for this fraction of sediment only, with clay content used in correlations calculated as (% clay) / (% silt and clay). Following the derivation of correlation coefficients, a Bonferroni-type correction (i.e., α = 0.05 divided by the total number of independent variables) was applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected α of 0.05. Any significant correlations found at the Bonferroni-adjusted α were further investigated using scatter plots.

Sediment quality data were analysed using Principal Component Analysis (PCA) as a means of summarizing the data for use in correlation analyses to assess potential physical and/or chemical causes of differences in benthic invertebrate community condition (see Section 3.5.3.2). A PCA is a multivariate statistical ordination technique that can be used to reduce many variables and to assist in the identification of patterns in datasets. Separate PCAs were completed for sediment quality data from the two deep lake categories listed above; 1) Polley Lake (POL-P1 and POL-P2; exposed) compared to Bootjack Lake (BOL B2; reference); 2) deep exposed areas (QUL-PNF, QUL-PFF1) and a deep reference area (QUL-PREF1) of Quesnel Lake. Data included in the PCA were selected to include those years for which benthic invertebrate community data exist (i.e., 1999 to 2024 for deep Polley Lake areas [and reference], and 2014 to 2024 for deep Quesnel Lake areas). Prior to running PCA, analytes for which more than 25% of the data were below the LRL, or analytes for which an incomplete dataset existed (e.g. sulphur, mercury) were excluded from the data matrix. All concentration data were transformed using a $\log_{10}$-transformation and principal component axes were then generated. Subsequently, the correlation between each parameter and the first two principal components were tested using a Pearson's correlation coefficient and plotted to identify analytes that best explained similarities and differences in sediment chemistry among stations. All sediment statistical analyses and plots were completed using R (R Core Team 2024).

3.2 Sediment Toxicity

Sediment toxicity monitoring was completed at shallow and deep exposed areas of Quesnel Lake and Polley Lake (and associated reference areas) between 2022 and 2024 using two test organisms: *Chironomus dilutus* (benthic dipteran) and *Hyalella azteca* (an epibenthic amphipod). In deep exposed areas of Quesnel Lake and Polley Lake (and associated references), sediment toxicity monitoring using *C. dilutus* was initiated in 2014 and has been completed every three years since 2018 (Figures 3.1 and 3.2, Table 3.3), in accordance with the CEMP (MPMC 2019). Sediment toxicity testing using *C. dilutus* was completed in 2024 for the deep areas of Polley Lake (POL-P1, POL-P2) with a deep area of Bootjack Lake (BOL-B2) serving as reference, and for the deep near-field (QUL-PNF) and reference (QUL-PREF1) areas of

Notes: "-" = not sampled/not applicable. *C. dilutus* = *Chironomus dilutus*, *H. azteca* = *Hyalella azteca*. Test durations shown are for survival and growth tests (i.e., 10-day survival and growth, 14-day survival and growth, 28-day survival and growth).

[a] Values indicate the number of stations sampled per area. Values in brackets, e.g., (x), indicate the number of replicates per station. If no value in brackets is given, a single sample was collected per station. Only sampling areas that were monitored between 2022 and 2024 are displayed, as well as historical data for these areas.

[b] *Hyalella azteca* 14-day survival and growth tests were completed using two methodologies in 2021 as part of an investigation: 1) the standard static exposure methods that have been employed in all prior years; and 2) static-renewal exposure methods that differ from methods used in prior years. See Minnow (2022a) for details.

Quesnel Lake (Figures 3.1 and 3.2, Table 3.3). Prior to 2024, toxicity testing of sediments from these deep monitoring areas was last completed in 2021 (Table 3.3).

In shallow areas of Quesnel Lake, sediment toxicity using *H. azteca* monitoring was initiated in 2014 and has been completed annually since 2019 at the shallow near-field area (QUL-LNF1) and reference (QUL-LREF1) areas of Quesnel Lake (Figure 3.2, Table 3.3). This monitoring serves to satisfy Condition 9 of the CEMP approval dated February 10, 2021 (BCMOECCS 2021) which specified the following:

> *"H. azteca toxicity testing using sediment from shallow areas of Quesnel Lake must be continued as stated in the March 14, 2019 approval letter. "No effect to H. azteca" in that letter shall mean "no unacceptable response" relative to the reference area, as defined on page 37 of "Mount Polley Comprehensive Environmental Monitoring Program 2019 – Sediment and Aquatic Life".*

In shallow areas of Polley Lake (POL-S) and an associated reference (Bootjack Lake; BOL-S), sediment toxicity using *H. azteca* monitoring was initiated in 2019 and has been completed every three years since then, with monitoring last completed in 2022 (Figure 3.1, Table 3.3). This monitoring serves to satisfy Condition 9 of the CEMP approval dated February 10, 2021 (BCMOECCS 2021) which specified the following:

> *"The 14-day sediment toxicity test on H. azteca must be conducted every three years (i.e., next in 2022) using sediment of shallow habitat from Polley Lake unless MPMC can clearly show that copper concentrations in all Polley Lake shallow sediment samples are below the 95th percentile of the copper concentrations in the Bootjack Lake reference area shallow sediment samples.".*

Sample collection and analysis methods for 2024 are described herein and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, including equivalent historical sampling areas, refer to the references listed in Table 3.3.

3.2.1 Sample Collection

Sediment samples for toxicity testing using *C. dilutus* and *H. azteca* in 2024 were collected using a Petite Ponar grab sampler as described in Section 3.1.1. Toxicity testing using *C. dilutus* in 2024 was conducted with sediments from the deep areas of Polley Lake (POL-P1, POL-P2) with a deep area of Bootjack Lake (BOL-B2) serving as reference, and with sediments from the deep near-field (QUL-PNF) and reference (QUL-PREF1) areas of Quesnel Lake (Figures 3.1 and 3.2, Table 3.3). Toxicity testing using *H. azteca* was conducted with sediments from the shallow near-field area (QUL-LNF1) and reference (QUL-LREF1) areas of Quesnel Lake (Figure 3.2, Table 3.3).

Sediments were collected at a total of five replicate stations per area, with the field replicates serving as replicates in the laboratory. Sediment samples for toxicity testing were shipped to Nautilus Environmental (Nautilus) in Burnaby BC following the methods used for sediment quality samples, described in Section 3.1.1.

3.2.2 Laboratory Analysis

Upon receipt, Nautilus opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and confirmed sample receipt with Mount Polley and Minnow. Static water toxicity testing of *H. azteca* and *C. dilutus* as outlined in detail in Nautilus (2024; Appendix G) was conducted according to procedures described in the Biological Test Method for these species: 14-day survival and growth test using *H. azteca* (Environment Canada 2017) and 10-day survival and growth test using *C. dilutus* (Environment Canada 1997). Briefly, Nautilus set up five field-replicate test vessels per sampling area (i.e., with each replicate representing a sampling station) for each toxicity test (i.e., static testing for 14-day *H. azteca* and 10-day *C. dilutus*). A laboratory control (beach sand in accordance with the biological test method) was also set up with five laboratory replicates in each test.

In the toxicity test laboratory, several supporting measurements were collected within the toxicity test vessels as described by Nautilus (2024; Appendix G). Briefly, this included meter measurements of overlying water (temperature, dissolved oxygen, conductivity, and pH) and the collection of overlying water for analysis of hardness, alkalinity, Dissolved Organic Carbon (DOC), and dissolved copper by ALS Environmental (Burnaby, BC) and total ammonia and hardness by Nautilus. Collection of overlying water samples for analysis of hardness, alkalinity, and total ammonia analysis was completed at test initiation (Day 0) and test termination (Day 10 for *C. dilutus* and Day 14 for *H. azteca*). Collection of overlying water samples for analysis of hardness, alkalinity, DOC, and dissolved copper by ALS was completed at test termination (Nautilus 2024; Appendix G).

3.2.3 Data Analysis

Upon receipt of the laboratory report, a DQR was completed, including an examination of laboratory controls, reference toxicants, and hold times (Appendix B).

Statistical analyses for the tests were performed by Nautilus using CETIS software (Tidepool Scientific Software 2022) and included contrasts of the exposed area against laboratory controls and the matched reference area. Statistical contrasts were completed following guidance provided by Environment Canada (2005) and involved the use of an ANOVA with Dunnett's test for quantitative data that met parametric test assumptions. When non-parametric techniques

were required, the data were analyzed using Steel's Many-one rank sum test. For quantile data, the Fisher Exact/ Bonferroni Holm test was performed. A two-tailed Tukey-Kramer test was applied to compare results from samples that were run with organisms from different batches in error (see details below). Significant differences were determined at the significance level of $\alpha = 0.05$.

Sediment toxicity test results were interpreted based on a combination of statistical contrasts and effect size by comparing exposed area results relative to both the laboratory control and reference area results. For this evaluation, results were grouped into three categories for separate tabular and graphical presentation, statistical analyses, and interpretation:

1. Deep Polley Lake areas (POL-P1 and POL-P2; exposed) compared to a deep reference area (Bootjack Lake; BOL B2), tested using *C. dilutus*.
2. Deep near-field area of Quesnel Lake (QUL-PNF) compared to an un-impacted deep reference area (QUL-PREF1), tested using *C. dilutus.*
3. Shallow near-field area of Quesnel Lake (QUL-LNF1) compared to an un-impacted shallow reference area (QUL-LREF1), tested using *H. azteca*.

During toxicity testing, a laboratory error occurred in which toxicity tests for the deep areas of Polley Lake (POL-P1 and POL-P2; exposed) and the corresponding deep area of Bootjack Lake (BOL-B2; reference) were initiated with different batches of *C. dilutus* organisms (see Appendix G for further details). The use of different test organism batches precluded direct comparison of exposed and reference area tests for these areas. Therefore, a weight of evidence approach was adopted by Nautilus to confirm the presence or absence of effects, including:

- Visual comparison of endpoints between exposed (POL-P1 and POL-P2) and reference areas (BOL-B2);
- Comparison of endpoints to relative control samples, which were different for the deep areas of Polley and Bootjack lakes; and
- Statistical comparison of exposed (POL-P1 and POL-P2) and reference (BOL-B2) areas using a two-tailed Tukey-Kramer test.

Comparisons for each test endpoint reported by the laboratory were evaluated using a stepwise procedure similar to that of the Southern California Coastal Water Research Project (SCCWRP) California Sediment Quality Objectives (CASQO; Bay et al. 2014):

1. Mean responses of percent survival and growth (dry weight [dw] per surviving organism) were expressed as a percentage of the mean laboratory control result and the mean field reference result.

2. Results of the statistical contrasts of mean responses in tests of impacted sediment against the laboratory control and the field reference sediment were compiled (i.e., the impacted area was identified as significantly different or not significantly different from the mean laboratory control result and the mean field reference result).

3. Results were categorized as follows:

    a. No unacceptable response was identified as a mean response within 20% of the mean laboratory control result and the mean field reference result (i.e., survival or growth were ≥80% of the control and field reference);

    b. Low to moderate response was identified as a mean response of between 20% and 50% of the mean laboratory control result and the mean field reference result (i.e., survival or growth were 50% to 80% of the control and field reference);

    c. High (large) response was identified as a mean response of >50% of mean laboratory control result and the mean field reference result (i.e., survival or growth were <50% of the control and field reference);

4. Results that were in the low to moderate response category were subject to a further categorization step:

    a. If the “low to moderate” response did not differ statistically from the laboratory control and the field reference, it was categorized as a low response;

    b. If the “low to moderate” response differed statistically from the laboratory control and the field reference, it was categorized as a moderate response.

5. Where comparisons to mean laboratory control result and the mean field reference result did not fall into the same response category, the result was discussed relative to both the control and the field reference.

Application of a 20% reduction in survival relative to the field reference to define acceptability is consistent with thresholds used elsewhere (e.g., Suter et al. 1995; BCMELP 1998; Government of Canada 2010; Mebane 2010; Nautilus and Zajdlik 2011; Bay et al. 2014). The 20% threshold is the same as the acceptability threshold for laboratory control survival identified in the test method (i.e., a test is considered acceptable if fewer than 20% of organisms in the laboratory control die; Environment Canada 2017).

If a toxicity response was observed for a given results category (e.g., deep Polley Lake, deep Quesnel Lake, or shallow Quesnel Lake), relationships between control normalized survival and growth results and supporting chemical and physical variables (i.e., TOC and copper concentrations in sediment and dissolved copper concentrations in overlying water [field and

laboratory; where available]) were evaluated using a simple linear regression model. No toxicity response was observed for deep Polley Lake sediments; therefore, deep Polley Lake results were excluded from regression analysis. The regression analysis was completed separately for each of the two Quesnel Lake results categories (e.g., deep and shallow). For Quesnel Lake shallow areas, the analysis included 14-day static test data for *H. azteca* from QUL-LNF and QUL-LREF1 (2014 to 2024). For Quesnel Lake deep areas, the analysis included all available 10-day static test data for *C. dilutus* (2014 to 2024)[7]. Sediment toxicity test results from 2015 and 2016 which were treated with TOC addition or removal[8] were omitted from the regression analyses. Each linear relationship was plotted with the line of best fit. Regression plots included comparison of sediment copper and aqueous dissolved copper concentrations to applicable guidelines (BCWSQG and BCWQG, respectively; see Section 3.8.3.3 for details of dissolved copper BCWQG calculation). Data were explored for outliers based on a Cook's Distance of 6/n; an approach more conservative than the recommended Cook's distance critical value for outlier identification (>4/n; Arimie et al. 2020). When outliers were identified, correlations were run with and without outliers included in the data and results of both analyses presented. Statistically significant regressions were identified using an α of 0.05.

Control normalized survival and growth results (i.e., presented as a percentage of the average laboratory control result) were also plotted over time for each exposed and corresponding reference monitoring area. All statistical analyses and plots were completed using R (R Core Team 2024).

3.3 Plankton Community and Productivity

Plankton community and productivity monitoring was completed at exposed areas of Quesnel Lake and Polley Lake (and associated reference areas) annually between 2022 and 2024, in accordance with the CEMP (MPMC 2019)[9]. Post-breach plankton community and productivity sampling at current monitoring areas were initiated in 2016 and 2014 for phytoplankton and zooplankton in Quesnel Lake (exposed and reference areas), respectively, and in 2015 for both phytoplankton and zooplankton in Polley Lake (Figure 3.3, Tables 3.4 and 3.5). Since then,

[7] The regression analysis for Quesnel Lake deep areas included data from the following areas: QUL-PREF2, QUL-PREF1, QUL-PNF, QUL-PNF, QUL-PFFF, QUL-PFF1, QUL-PFF2, QUL-I.

[8] Some sediment samples collected in 2015 and 2016 were manipulated by either adding TOC or by removing TOC (by loss on ignition) in order to assist in interpreting the role of TOC in toxicity test response.

[9] Minnow has completed interpretive reporting for plankton community and productivity monitoring data collected since 2018 (Minnow 2019a, 2020, 2021a, 2022a, 2023a, 2024a) and has completed monitoring implementation since 2019 after providing monitoring program design modifications (Minnow 2019b) at the request of MPMC. A complete description of historic plankton sampling activities was included in Minnow (2019a) and the modified monitoring program design was included in the approved CEMP (MPMC 2019).

Notes: "-" = not sampled/not applicable. Data from 2014 to 2018 were provided in electronic form to Minnow from the Mount Polley Mine database.

[a] Values indicate the number of samples collected per area per year or month. Only sampling areas that were monitored between 2022 and 2024 are displayed, as well as historical data for these areas.

[b] Analysis of zooplankton samples from Quesnel Lake was performed using two mesh sizes (50 µm and 150 µm) to facilitate comparison to historical samples collected using 150 µm mesh size. See Minnow (2020a) for details.

plankton community and productivity monitoring continued annually in each waterbody, and in 2019 was revised to incorporate a standardized annual monitoring approach (Figure 3.3, Table 3.4) which is consistent with the CEMP (MPMC 2019). Since 2019, annual monitoring has included an exposed area in Polley Lake (POL-P2; with Bootjack Lake [BOL-B2] serving as a reference area), and exposed (QUL-ZOO-1) and reference (QUL-ZOO-7) areas of Quesnel Lake (Figure 3.3, Tables 3.4 and 3.5; Appendix Table A.1.3), in accordance with the CEMP (MPMC 2019). Annual plankton community and productivity monitoring since 2019 has been completed in three sampling events per year (June, July, and August), with each sampling event occurring at least 30 days apart (Appendix Table A.1.3). Each year, single (n=1) phytoplankton and zooplankton samples were collected in June and August at each monitoring area, and five replicate (n = 5) samples were collected in July at each monitoring area (Tables 3.4 and 3.5), in accordance with the CEMP (MPMC 2019). Phytoplankton productivity has been evaluated solely based on chlorophyll-a- concentration since 2020 (see Minnow 2021a for details).

Sample collection and analysis methods for 2024 are described herein and are largely consistent with those outlined in the CEMP (MPMC 2019; exceptions and associated rationale are outlined in the following sub-sections). For details pertaining to prior sampling years, refer to the references listed in Tables 3.4 and 3.5.

3.3.1 Sample Collection

3.3.1.1 Phytoplankton

Phytoplankton sampling was completed in June (n=1 per area), July (n=5 per area), and August (n=1 per area) 2024 and included the collection of community composition and productivity (chlorophyll-a) samples (Table 3.4).

Phytoplankton samples were collected using a depth-integrated (DI) water sampler (i.e., a length of plastic tubing that was weighted at the bottom). To collect one sample, the weighted end of the DI sampler was lowered to the required sampling depth, crimped, and pulled to the surface while remaining crimped. The weighted end of the DI sampler was then placed into a clean plastic pail and the crimped end was released allowing the water to flow into the clean bucket. The DI sampler enables collection of water and phytoplankton throughout the photic zone, which is the upper layer of the water column receiving light penetration (and was estimated at approximately twice the measured Secchi depth). DI samples were collected using nearly the full length of the tube (length ~13 m) whenever station depth was greater than 12 m, or only a portion of the tube in areas < 12 m deep (Appendix Table A.1.3) to prevent collection of sediment or water from the sediment-water interface.

Upon retrieval of the DI sample into the clean bucket, *in situ* water quality measurements were immediately taken with a handheld YSI EXO™ (see Section 3.8.1). Phytoplankton and water samples were then taken by decanting water from the bucket into appropriate sample bottle(s), and samples were preserved and stored as follows:

1. Samples for analysis of phytoplankton community composition were decanted into an opaque 250 mL plastic bottle and then preserved using Lugol's solution, which was added using an eyedropper until the sample was a weak tea colour. The sample was gently swirled to thoroughly integrate the Lugol's solution and stored in a cool dark environment prior to shipment to the laboratory for analysis.
2. Samples for analysis of aqueous chlorophyll-a concentrations were decanted into an opaque 250 mL plastic bottle and supporting water samples were decanted into water quality sample bottles and preserved as required. Supporting water quality samples were kept on ice in the field and refrigerated until being shipped (on ice) to the analytical laboratory. Duplicate (split) routine water quality and chlorophyll-a samples were collected at a target frequency of 10% for QA/QC purposes.

Water collected for chlorophyll-a analysis was kept on ice in the field until same-day filtration. In brief, a measured[10] volume (~250 mL) of sample was decanted into the vacuum filtration apparatus and filtered through 0.45 µm pore diameter Whatman mixed cellulose ester (MCE) filter paper. The filter paper (containing sample) was then folded and placed into a labeled opaque centrifuge tube and frozen until shipment (on ice) to the analytical laboratory. Filtration equipment was rinsed with distilled water between samples.

Supporting *in situ* water quality depth profiles were recorded at every area (n=1) and Secchi depth was measured at every station (n=1 per area in June and August, n=5 per area in July; see Section 3.8.1 for description of supporting measures collection).

3.3.1.2 Zooplankton

Zooplankton sampling was carried out concurrently with phytoplankton sampling in June (n=1 per area), July (n=5 per area), and August (n=1 per area) 2024 and included collection of samples for assessment of community composition and productivity (Table 3.4).

Samples were collected using a 90 cm long zooplankton haul net with a 50 cm diameter mouth opening and 50 µm Nitex mesh. Zooplankton community samples were collected by lowering the zooplankton haul net to a specific depth (see below), then hauling the net vertically through the water column using a hand-over-hand motion at a rate of about 0.5 metres per second (m/s).

[10] The chlorophyll-a concentration was determined from the precise volume of sample filtered.

Each zooplankton sample consisted of a single vertical haul.[11] Haul depths differed among lakes; hauls were conducted at 31 m depth in the much deeper Quesnel Lake, at 20 to 27 m in Polley Lake, and at 10 to 15 m in Bootjack Lake. Haul depths at Polley and Bootjack Lakes were conducted from a depth approximately 2 m less than the total station depth (Appendix Table A.1.3).

Upon retrieval, material on the inside of the net was rinsed into the cod end by lifting the net in and out of the water without submerging the mouth of the net. Sample material was then rinsed from the cod end of the net into a 250 mL plastic bottle using a squeeze bottle filled with filtered water. Samples were then preserved with buffered formalin solution to a nominal concentration of 4%. Preserved samples were stored in a dark, cool place prior to shipment to the laboratory for taxonomic analysis.

Supporting measures included those outlined above for phytoplankton (Section 3.3.1.1; see Section 3.8.1 for description of supporting measures collection).

3.3.2 Laboratory Analysis

3.3.2.1 Phytoplankton

3.3.2.1.1 Community

Phytoplankton samples were sent to Biologica Environmental Services Ltd. (Biologica) in Victoria, BC, for taxonomic identification and enumeration. Upon arrival, samples were examined and additional Lugol's preservative was added (if required) to ensure adequate preservation. A sample receipt confirmation was then sent to Minnow.

Plankton community samples were processed by first thoroughly mixing (i.e., shaking) the sample container. Sub-samples (10 to 100 mL) were then dispensed into Utermöhl settling

[11] The CEMP approval amendment letter from BCMOECCS (dated July 15, 2019; BCMOECCS 2019) stipulated that zooplankton samples must be collected using a modified horizontal tow method, which is a condition that applies to all zooplankton sample collection. This was not the intent of the plankton program recommendations provided by Minnow (dated May 28, 2019; Minnow 2019b), which included the use of different plankton tow methods for the collection of: 1) zooplankton productivity and community samples, and 2) zooplankton tissue quality samples. Minnow maintains that zooplankton productivity and community samples should be collected using a vertical tow method only (consistent with the recommendations provided by Minnow in May 2019; Minnow 2019b). A modified horizontal tow method was not recommended for the collection of zooplankton community samples for two reasons. Firstly, zooplankton samples for community analysis have previously been collected by a single vertical tow. Changing the collection method for this sample type to a modified horizontal tow would limit comparability with previously collected data. Secondly, it is difficult to ensure that the sampling net ascends through the water column at a constant speed when conducting a horizontal tow. Since zooplankton community composition differs through the water column, variability in the amount of time that the net samples a given depth during a horizontal tow could influence the community results. Use of a vertical tow method eliminates this consideration entirely. Following consultation with MPMC regarding this rationale and the best methodological approach to implement, Minnow collected zooplankton community and productivity samples using a vertical haul methodology between 2019 and 2024. For a comparison of zooplankton community and productivity samples collected using both vertical and modified horizontal haul methodologies, see Minnow (2020a).

chambers and allowed to settle for 12 to 48 hours, depending on sub-sample volume. Sub-samples were then systematically scanned using a Zeiss Axio Vert A.1 inverted phase contrast microscope at 400x magnification. All algal cells were counted in a series of randomly located field of view (FOV) until a minimum of 300 algal units were identified and enumerated. Algal units represent single cells of all algal groups, as well as colonies or filaments of blue-green algae. Given that blue-green algal colonies and filaments may contain hundreds of cells, enumerating units (rather than individual cells) allows for a more equal representation of algal groups. The mean number of cells per unit (1 for single cells, >1 for all other algal forms) were estimated for all taxa and used to calculate total densities. Only "viable" cells (those that appeared to be alive at the time of collection) were identified and enumerated. Loricas, the cellulose cups formed by some chrysophyte species, were also counted when observed (USEPA 2010).

Phytoplankton were identified to genus, where possible, following the most up-to-date taxonomic references and collaborations with international and local algal taxonomic experts. Species-level identifications were only given to identifiable taxa for which there are reliable taxonomic references available that encompass the species-level morphological diversity in North America. This approach ensures long-term consistency of data sets and is in accordance with the trend in algal taxonomic practice to be more conservative with delineation of species. Species-level identifications for some taxa are problematic due to widespread phenotypic plasticity that can artificially inflate species richness (Wehr et al. 2015). When applicable, the term "cf." (*confertim*) was used when the species being identified looked similar to a known species but did not meet all the taxonomic requirements to assign the identification with confidence, and the terms "sp.1", "sp. 2", etc. were employed to distinguish between different undetermined species in the same genus.

Taxa were grouped according to their major ecological groupings (e.g., diatoms, cyanobacteria, etc.). Data were reported as density (cells per liter) for each taxon, for each ecological grouping, and as total density at each station.

Laboratory QA/QC included evaluation of sub-sampling accuracy on at least 10% of samples. Data were provided to MPMC and Minnow as a Microsoft Excel spreadsheet along with a methods and QA/QC report as an Adobe Acrobat PDF file (Appendix G).

3.3.2.1.2 Productivity

Phytoplankton chlorophyll-a analysis was completed by ALS Environmental (Burnaby, BC). Upon receipt, ALS Environmental measured the internal temperature of shipping coolers to verify the integrity of samples, logged each sample, and assigned each sample a unique identification code. A sample receipt confirmation was then sent to Minnow and MPMC.

Chlorophyll-a analysis followed procedures adapted from USEPA Method 445.0 (USEPA 1997). Briefly, chlorophyll-a was determined by routine acetone extraction followed by fluorescence detection using a non-acidification procedure, a method that is not subject to interferences from chlorophyll-b.

Laboratory QA/QC included reagent blanks and laboratory accuracy measures (i.e., LCS). Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G).

3.3.2.2 Zooplankton

3.3.2.2.1 Community

Zooplankton community samples were sent to Biologica (Victoria, BC) for taxonomic analysis. The sample receipt procedure was as described above for phytoplankton (Section 3.3.2.1.1). Samples were transferred from their formalin solution into 70% ethanol and assigned a unique identification number.

The zooplankton community samples were processed through a 50 µm screen and analyzed in three fractions as follows:

- A “coarse” Unique, Rare, and Large fraction, in which a check of the entire sample was performed to look for such taxa. These organisms were enumerated as a whole count;
- A “coarse” fraction comprised of Cladocera, adult Copepoda, and copepodids, in which a minimum count of 200 organisms was obtained; and
- A “fine” or “micro” fraction, in which Copepod Nauplii and Rotifera were identified and enumerated. Processing of the micro fraction was completed to either a 100 count or a minimum of three sub-samples.

The coarse fraction was analyzed in a Bogorov tray through a stereo microscope at 10-40x magnification and the micro fraction was analyzed using a 1-mL Sedgewick-Rafter counting chamber. Sub-sampling for all fractions was performed using Hensen-Stempel pipettes. Generally, sub-samples were 1/10th of total sample volume for the coarse fraction and 1/100th for the micro fraction. Organisms were identified by taxonomic experts to the lowest practicable taxonomic level (LPL)[12] using a compound microscope (100–400x magnification),

[12] The term “Lowest Practical Level” is commonly used to describe the level of resolution for taxonomic identification (often relating to benthic invertebrate taxonomy; e.g., Environment Canada 2012b). However, the term “Lowest Practicable Level" (e.g., Carter and Resh 2001; Bailey et al. 2001) has been used throughout this report because it is a more accurate description of the taxonomic decision (i.e., the term “practicable” implies the level of identification that is attainable).

appropriate dissection tools, and standard taxonomic references. Zooplankton were identified to species wherever possible, although this was not possible for immature copepods that lack differentiating features required for identification beyond order (e.g., Calanoida, Cyclopoida, or Harpacticoida). For Copepoda, the stage of development was recorded as Nauplii or copepodite stages I-V, as was the sex for mature individuals (copepod stage VI). Rotifera were identified to the genus level. All identifications were performed using taxonomic references and collaborations with external experts, where necessary.

Laboratory QA/QC included evaluation of sub-sampling accuracy on at least 10% of samples. Data were provided to Minnow as a Microsoft Excel spreadsheet (Appendix G).

3.3.2.2.2 Productivity

Zooplankton productivity was evaluated as biomass values (i.e., dry weight biomass [mg/L]) derived from biovolume estimates based on cell measurements performed by Biologica. Biomass calculations were performed for the seven most dominant zooplankton taxa by measuring at least five to 10 specimens of each taxon and applying length/ weight regression formulae (USEPA 2003). Biomass estimates were presented as total wet weight (ww) and dry weight (dw) values derived from per-sample abundances. Data were provided to Minnow as a Microsoft Excel spreadsheet (Appendix G).

3.3.3 Data Analysis

3.3.3.1 Phytoplankton

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, formulae checks, and evaluation of percent agreement among laboratory sub-sampling accuracy samples (see Appendix B).

3.3.3.1.1 Community Metrics

Phytoplankton community data were evaluated in terms of total density (cells/L), taxon richness (No. of taxa), Simpson's Diversity and Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012b), and the relative densities (%) and densities (cells/L) of major ecological groups (cells/L). These endpoints were calculated at the LPL of taxonomy. Phytoplankton community results at the LPL of taxonomy can contain a mixture of taxonomic levels (e.g., species, family, order, and phylum), which can affect the calculation of metrics such as taxon richness and Simpson's Diversity and Evenness. To address this issue, a series of decision criteria were applied to the data to reassign taxon abundance across levels of taxa, while conserving the relative abundances within the higher taxonomic levels (see Appendix E.2 text for details). The taxonomic groups evaluated included one or more of the following major

ecological groups (based on the presence of these taxa at each sampling area): Diatoms, Chlorophytes (green algae), Cyanobacteria (blue-green algae), Chrysophytes (golden algae), Cryptomonads, Dinoflagellates, Euglenophytes, and Radiophytes, and the relative densities (%) densities of all groups were determined for each sample. Phytoplankton productivity was evaluated using chlorophyll-a concentrations measured in micrograms per litre (µg/L).

Phytoplankton community and productivity metrics were calculated for each monitoring area in each year and were summarized by area and year using the following statistics: sample size, mean, median, minimum, maximum, and SD (where replicate data were available).

3.3.3.1.2 Statistical Analyses

Statistical analyses of phytoplankton community and productivity data were conducted to answer the following questions:

1. Were there differences in phytoplankton community and productivity between the exposed and reference areas in 2024?
2. Have the phytoplankton community and/or productivity of exposed areas changed among years (2019 to 2024) relative to changes at reference areas over this time?

To answer these questions, data were grouped into two categories for the separate calculation of community metrics, tabular and graphical presentation, and statistical analyses:

1. Polley Lake (POL-P2) compared to reference (Bootjack Lake; BOL-B2).
2. Quesnel Lake exposed area (QUL-ZOO-1) compared to an un-impacted reference (QUL-ZOO-7).

Phytoplankton data cannot be pooled across different sampling events due to high variability among seasons. As such, statistical analyses focused on replicate samples (n=5) collected in July, as per the CEMP (MPMC 2019). Results of single samples collected in June and August were interpreted without the use of formal statistical contrasts.

Statistical comparisons of data from July 2019 to 2024 were conducted as two-way ANOVAs with *Area* and *Year* as factors and by assessing the interaction between *Area* and *Year*. If the *Area*×*Year* interaction term was significant, all pairwise contrasts were evaluated. If the interaction term was not significant but the *Area* term was significant, pairwise contrasts were conducted between areas pooling years; if the *Year* term was significant, pairwise contrasts were conducted between years pooling areas. Pairwise contrasts were evaluated using a Sidak correction to account for multiple comparisons. Regardless of which overall ANOVA terms were significant, MOD were calculated based on Measures of Central Tendency (MCT) of individual

samples described below. The results of the multiple comparisons were displayed by assigning letters (e.g., A, B, C) to each unique combination of year and method, such that years that did not differ significantly share a letter and the year with the highest mean was assigned the letter "A."

Prior to analysis, the assumptions of normality and homogeneity of variances were tested on the residuals of the two-way ANOVA model using the Shapiro-Wilk test and Levene's test, respectively, based on median values and using α=0.05. Data were transformed as necessary to satisfy assumptions of normality and homogeneity of variance (log_{10}, $log_{10}(x+1)$ when zeros were present in the data). In instances where the residuals of the ANOVA model did not meet the assumptions of normality and homogeneity of variances, the analysis was conducted on ranks (equivalent to a non-parametric test).

MOD between the exposed area and reference area was calculated as:

$$MOD = \frac{MCT_{Exposed} - MCT_{Reference}}{SD_{Pooled}}$$

MOD between years was calculated as:

$$MOD_{Year} = \frac{MCT_{Year} - MCT_{Baseline\ Year}}{SD_{Pooled}}$$

where MCT is the mean for untransformed data, geometric mean for log_{10}-transformed data and the SD is the pooled standard deviation from the ANOVA model. The effect size calculations were conducted on the transformed scale when the data were transformed for analysis. When the analysis was done on the rank-transformed scale, the observed effect size was estimated using median values instead of means, and the Median Absolute Deviation (MAD) instead of SD:

$$MAD = median(|x_i - median(dataset)|)$$

where x_i is each observation in the dataset and $|f(x)|$ is the absolute value of $f(x)$.

All statistical comparisons were conducted using R (R Core Team 2024). Statistically significant differences in phytoplankton community endpoints between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were further identified as potentially ecologically meaningful in both statistical analyses results and in data interpretation (Environment Canada 2012b[13]),

[13] Environment Canada (2012b) identifies a critical effect size (CES) of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community. This criterion has been applied here to the interpretation of phytoplankton community.

although all statistically significant differences (e.g., including those with a MOD < ±2 SD/ MAD) were discussed in the data interpretation.

Total phytoplankton density (cells/L), taxon richness (No. of taxa), and chlorophyll-a concentrations (µg/L) were plotted as time-series figures comparing sampling areas over time (including all seasonal data from baseline to present, where available). Relative densities (%) and densities of major phytoplankton groups were plotted from 2019 to 2024 as stacked bar charts of mean values. Phytoplankton community metrics from July 2019 to 2024 were also plotted to support interpretation of the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2024). Historical (pre-2019) phytoplankton proportional density data had low comparability with 2019 to 2024 data due to changes in taxonomist and were therefore excluded from plots (see Minnow 2019a for details regarding historical taxonomic efforts and data limitations that affect comparability).

3.3.3.2 Zooplankton

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, formulae checks, and evaluation of percent agreement among laboratory sub-sampling accuracy samples (see Appendix B).

3.3.3.2.1 Community Metrics

Zooplankton community data were evaluated in terms of total density (organisms/ L), taxon richness (No. of taxa), Simpson's Diversity and Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012b), and the relative densities (%) and densities (organisms/L) of major ecological groups. Zooplankton endpoints were calculated at the LPL of taxonomy. Similar to the phytoplankton community, zooplankton community results at the LPL of taxonomy can contain a mixture of taxonomic levels, which can affect the calculation of metrics such as taxon richness and Simpson's Diversity and Evenness. To address this issue, a series of decision criteria were applied to the data to reassign taxon abundance across levels of taxa, while conserving the relative abundances within the higher taxonomic levels (see Appendix E.2 text for details). Zooplankton data were converted from per-sample abundance values to volumetric density values (organisms/L) by dividing total densities by the volume of water through which the net passed (see Appendix E.2 text for details). For the calculation of relative densities (%) of major zooplankton groups, taxa were grouped as Calanoida, Cladocera, Cyclopoida, and Rotifera, with Copepoda Nauplii (the earliest juvenile stage of Copepoda) left as their own grouping. Zooplankton productivity was evaluated using dry weight biomass (mg/L).

Zooplankton community and productivity metrics were calculated for each monitoring area in each year and were summarized by area and year using the following statistics: sample size, mean, median, minimum, maximum, and SD (where replicate data were available).

3.3.3.2.2 Statistical Analyses

Zooplankton community data were evaluated to answer the following questions:

1. Were there differences in zooplankton community and productivity between exposed and reference areas in 2024?
2. Have the zooplankton community and/or productivity of exposed areas changed among years (2019 to 2024) relative to changes at reference areas over this time?

To answer these questions, data were grouped into two categories for the separate calculation of community metrics, tabular and graphical presentation, and statistical analyses:

1. Polley Lake (POL-P2) compared to reference (Bootjack Lake; BOL-B2).
2. Quesnel Lake exposed area (QUL-ZOO-1) compared to an unimpacted reference (QUL-ZOO-7).

Methods for replicate analysis, data pooling, statistical analyses, presentation of historical data, and current limitations of data for temporal statistical analyses of zooplankton data are the same as those outlined for phytoplankton in Section 3.3.3.1.2, with the one exception that dry weight biomass served as the measure of zooplankton productivity in both statistical analyses and plots.

3.4 Zooplankton Tissue Quality

Zooplankton tissue quality monitoring was completed at exposed areas of Quesnel Lake and Polley Lake (and associated reference areas) annually between 2022 and 2024, in accordance with the CEMP (MPMC 2019). Post-breach zooplankton tissue quality monitoring at current monitoring areas was initiated in 2014 in Quesnel Lake and in 2015 in Polley Lake (and reference; Bootjack Lake) and has been completed annually since then (Figure 3.3, Table 3.6). Since 2019, annual monitoring has included an exposed area in Polley Lake (POL-P2) with Bootjack Lake (BOL-B2) serving as a reference, and an exposed (QUL-ZOO-1) and reference (QUL-ZOO-7) area of Quesnel Lake (Figure 3.3, Table 3.6; Appendix Table A.1.3), in accordance with the CEMP (MPMC 2019). Annual zooplankton tissue monitoring since 2019 has been completed in three sampling events per year (June, July, and August), with each sampling event occurring at least 30 days apart (Appendix Table A.1.3). Each year, single (n=1) zooplankton tissue quality samples were collected in June and August at each monitoring area and five replicate (n = 5) samples were collected in July at each monitoring area (Table 3.6), in accordance with the CEMP (MPMC 2019).

Table 3.6: Overview of Zooplankton Tissue Quality Monitoring in Lake Habitats in the Vicinity of the Mount Polley Mine, 2014 to 2024[a]

Waterbody	Area Type	Area Code	Post-Breach																					
			2014 (Golder 2017a)	2015 (Golder 2017a)	2016 (Golder 2017a)	2017 (Golder 2017a)	2018 (Minnow 2019a)	2019 (Minnow 2020a)			2020 (Minnow 2021a)			2021 (Minnow 2022a)			2022 (Minnow 2023a)			2023 (Minnow 2024a)			2024		
			September to December	May to September	Early and Late Season	Early and Late Season	Early and Late Season	June	July	August	June	July	August	June	July	August	June	July	August	June	July	August	June	July	August
Polley Lake	Exposed	POL-P2	-	4	2	2	2	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1
Bootjack Lake	Reference	BOL-B2	-	-	-	-	-	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1
Quesnel Lake	Exposed	QUL-ZOO-1 (ZP 2, 4, 6, 9, 12, 15, 18, 21)	8	5	2	2	2	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1
	Reference	QUL-ZOO-7 (ZP 8, 11, 14, 17, 20)	5	5	2	2	2	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1	1	5	1

Notes: "-" = not sampled/not applicable. "ZP" = zooplankton. In 2014, QUL-ZOO-1 and QUL-ZOO-7 were reported as ZP stations. Data from 2014 to 2018 were provided in electronic form to Minnow from the Mount Polley Mine database.

[a] Values indicate the number of samples collected per area in the month or season identified. In 2014 to 2018, single samples were collected from each area during each sampling event. Only sampling areas that were monitored between 2022 to 2024 are displayed, as well as historical data for these areas.

Sample collection and analysis methods for 2024 are described herein and are largely consistent with those outlined in the CEMP (MPMC 2019; exceptions and associated rationale are outlined in the following subsections). For details pertaining to prior sampling years, refer to the references listed in Table 3.6.[14]

3.4.1 Sample Collection

Zooplankton tissue quality samples were collected in June (n =1 per area), July (n = 5 per area), and August (n=1 per area), 2024, using methods largely consistent with the CEMP (MPMC 2019).[15]

Zooplankton tissue samples were collected using a 90 cm long zooplankton haul net with a 50 cm diameter mouth opening and 50 µm Nitex mesh. Sampling in Polley Lake (POL-P2) and Bootjack Lake (BOL-B2) was completed using the vertical haul method described in Section 3.3.1.2, with a maximum start depth of approximately 20 to 27 m in Polley Lake and 10 to 15 m in Bootjack Lake (Appendix Table A.1.3). Vertical hauls were completed until a sufficient sample weight was obtained (minimum 1.5 g wet weight).

Zooplankton tissue quality samples were collected from Quesnel Lake (QUL-ZOO-1 and QUL-ZOO-7) by completing a single modified horizontal haul[16] at each area. Each horizontal haul was completed by lowering the net to a starting depth of 31 m and then towing the net through the water column for a set time (e.g., 5 to 5.5 minutes; Appendix Table A.1.3) while slowly retrieving the net to the surface.

Upon retrieval of each vertical or horizontal haul, the plankton net was rinsed towards the cod end to concentrate the sample. Excess water was decanted through the mesh of the cod end or

[14] Minnow has completed interpretive reporting for plankton community and productivity monitoring data collected since 2018 (Minnow 2019a, 2020a, 2021a, 2022a, 2023a, 2024a) and has completed monitoring implementation since 2019 after providing monitoring program design modifications (Minnow 2019b) at the request of MPMC. A complete description of historic plankton sampling activities was included in Minnow (2019a) and the modified monitoring program design was included in the approved CEMP (MPMC 2019).

[15] Zooplankton tissue quality samples were historically collected using multiple vertical hauls until a sufficient sample weight was obtained. Due to the low productivity in Quesnel Lake, this process was labour-intensive. Therefore, Minnow recommended substitution of the vertical tow method for a modified horizontal tow method in Quesnel Lake to decrease the time required to collect sufficient sample material. Minnow recommended the continuation of vertical haul methods in Polley Lake (Minnow 2019b). The modified horizontal tow method for the collection of zooplankton tissue quality samples from Quesnel Lake was incorporated into the CEMP approval amendment letter from BCMOECCS (dated July 15, 2019; BCMOECCS 2019). However, the letter stipulated that all zooplankton samples must be collected using the modified horizontal tow method. This methodology was only recommended for use in Quesnel Lake (not Polley or Bootjack Lakes) and specifically for zooplankton tissue quality sample collection for the reasons outlined above (Minnow 2019b). Minnow maintains that the use of a vertical tow method for the collection of zooplankton tissue quality samples is suitable for Polley and Bootjack lakes and has implemented this methodology in 2019 to 2024. The haul method used (vertical or horizontal) does not affect the characteristics of the resulting zooplankton tissue quality sample; only the time associated with sample collection.

[16] Modified horizontal tow methods were consistent with those approved in July 2019 (BCMOECCS 2019) and incorporated into the CEMP (MPMC 2019).

the net. If too much water remained in the sample, the cod end was removed from the plankton net, the stretched net was placed over a bucket, and the sample was poured out of the cod end onto the net. A scoopula was then used to facilitate drainage by pressing on the mesh of the net. The scoopula was used to transfer the sample from the cod end or net (depending on method of sample drainage) into a pre-labelled plastic scintillation vial. All sampling equipment was rinsed between stations using site water. Duplicate (split) zooplankton tissue samples were collected at a target frequency of 10% for QA/QC purposes. Immediately after collection, samples were stored in a cooler with ice packs until being frozen prior to shipment (on ice) to the analytical laboratory.

Supporting measures during each sampling event included measurement of a Secchi depth, a vertical depth profile of *in situ* water quality measures, and a supporting depth-integrated water quality sample collected at each area (see Section 3.3.1.1 for DI sample collection methods). See Section 3.8.1 for a description of supporting measures collection.

3.4.2 Laboratory Analysis

Laboratory analysis of zooplankton tissue quality samples was completed by ALS Environmental in Burnaby BC. Upon receipt of the sample shipment(s), ALS Environmental measured temperature in each cooler to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique sample identification code. A SRN was then sent to MPMC and Minnow for verification.

Laboratory analysis of zooplankton tissue quality samples included metals by CRC-ICP-MS (USEPA Method 6020B; USEPA 2014), mercury by CVAAS (USEPA Methods EPA 200.2/1631E; USEPA 1994, 2001), and moisture content. Laboratory QA/QC included MB samples, laboratory duplicates, and laboratory accuracy measures (i.e., LCSs and/or RMs). Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow (Appendix G).

3.4.3 Data Analysis

Upon receipt of the initial analytical data, a DQR was completed, including an examination of data completeness, LRLs achieved, laboratory precision, laboratory accuracy, and field precision (Appendix B).

Data analysis of zooplankton tissue quality results focused on replicate samples (n=5) collected in July of each year (2019 to 2024). Results of single (n=1) samples collected from 2014 to 2024 were interpreted without the use of formal statistical contrasts (including single samples from June and August 2019 to 2024). Zooplankton tissue quality data from each sampling event in 2024 (June, July, and August) were screened against the British Columbia selenium guideline for the protection of aquatic life (for invertebrate tissue) of 4 mg/kg dw (BCMOE 2014).

Replicated zooplankton tissue quality data from July were summarized by area by calculating sample size, mean, SD, minimum, median, and maximum. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1.

Statistical analyses of analyte concentrations in zooplankton tissues were conducted using replicated data (i.e., data from July 2019 to 2024) to answer the following questions:

1. Have mean analyte concentrations at the exposed area changed relative to the reference area?
2. Were there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?

To answer these questions, data were grouped into two categories for separate tabular and graphical presentation and statistical analyses:

1. Polley Lake (POL-P2; exposed) compared to Bootjack Lake (BOL-B2; reference).
2. Quesnel Lake exposed area (QUL-ZOO-1) compared to an un-impacted reference (QUL-ZOO-7).

Question 1 was answered by conducting a two-way ANOVA assessing the relative differences between exposed and reference areas, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year* (as described in Section 3.1.3.2). Due to the prevalence of analyte results which were below the LRL, the two-way ANOVA was completed with Maximum Likelihood Estimation (MLE) using a censored regression, assuming a lognormal distribution. If the *Area*×*Year* interaction term was significant (α = 0.05), then the concentrations from the exposed area relative to the reference area differed among years. In this case, pairwise contrasts among years were completed to compare the relative difference in means (in log-units) between areas among years. Letters were assigned such that the year with the greatest relative difference between exposed and reference areas was assigned the letter “A” and years that do not differ significantly (α = 0.05) share a letter. When the *Area*×*Year* interaction term was not significant (α = 0.05), the differences between areas were consistent among years and no relative contrasts were conducted.

Temporal changes in the relative difference between exposed and reference areas were quantified by calculating a MOD as described in Section 3.1.2.3, but back-transformation for natural logarithms (rather than $\log_{10}$).. This MOD was also expressed as a percent change as:

$$MOD = \frac{exp\hat{}\bar{x}_{Exposed\ Observed} - exp\hat{}\bar{x}_{\text{Exposed } Predicted}}{exp\hat{}\bar{x}_{\text{Exposed } Predicted}} \times 100\%$$

where $\bar{x}_{Exposed\ Observed}$ is the mean for the exposed area (in log units) for the given year and $\bar{x}_{\text{Exposed }Predicted}$ is the predicted mean (log units), assuming the relative difference between the exposed area and reference area did not change from the baseline year (i.e., $\bar{x}_{\text{Exposed }Predicted} = \bar{x}_{\text{Reference}} + \left(\bar{x}_{\text{Exposed B}aseline} - \bar{x}_{\text{Reference B}aseline}\right)$).

Question 2 was answered using the results of the two-way ANOVA. When the *Area×Year* interaction term was significant (α = 0.05), contrasts were conducted for each year to compare the exposed and reference areas. When the *Area×Year* interaction term was not significant, (i.e., the difference between areas did not depend on year) the area comparison was assessed using the *Area* term of the two-way ANOVA. For significant interactions, the MOD between the exposed area and reference area was calculated in each year as:

$$MOD = \frac{exp\hat{}\bar{x}_{Exposed} - exp\hat{}\bar{x}_{\text{Reference}}}{exp\hat{}\bar{x}_{\text{Reference}}} \times 100\%$$

where $\bar{x}_{Exposed}$ and $\bar{x}_{Reference}$ are the exposed and reference area means (in log units), respectively. When the interaction term was not significant the MOD between reference and exposed areas was calculated across all years combined.

Statistical comparisons were completed for all available analytes; however, data interpretation focused on primary and secondary analytes (see Table 2.4). Plots of data from July 2019 to 2024 that support the two-way ANOVA were presented for primary and secondary analytes that: 1) had a significant *Area×Year* interaction in the analyses and had a positive MOD for 2024 (i.e., exposed concentrations were significantly higher than reference) or negative MOD for 2024 (i.e., exposed concentrations were significantly lower than reference) ; and 2) lacked a significant *Area×Year* interaction in the analyses but had a positive overall MOD (i.e., exposed concentrations were significantly higher than reference and the difference did not depend on year). Concentrations of primary and secondary analytes from all seasons from 2014 to 2024 were also plotted to allow qualitative comparison among seasons and qualitative temporal comparison of results. Years with more than 50% of the data reported below the LRL for both the exposed and reference areas were excluded from the analysis. All statistical comparisons and plots were completed using R (R Core Team 2024).

Routine water quality monitoring data collected by Mount Polley between 2015[17] and 2024 in Polley Lake, Bootjack Lake, and Quesnel Lake were used to aid in tissue quality interpretation and to evaluate if water quality has changed temporally. The evaluation included water quality data collected at the surface of the north and south basin of Polley Lake (POL-P1 and POL-P2, respectively), and from stations QUL-18 (exposed), QUL-2a (exposed), and QUL-120a (reference) of Quesnel Lake (Figure 3.3). Post-breach trends (2015 to 2024) of total and dissolved concentrations of primary and secondary analytes (Table 2.4) were evaluated at these routinely monitored stations using a Seasonal Kendall test (as described in Section 3.8.3.4) and were also graphically compared to approved and working British Columbia Water Quality Guidelines (BCWQG; refer to Sections 3.8.3.2 and 3.8.3.3 for details). Results of depth-integrated water quality samples collected concurrently with the zooplankton tissue samples in 2024 were also compared to BCWQG (for details, refer to Section 3.8.3.2).

3.5 Benthic Invertebrate Community

Benthic invertebrate community monitoring was completed at deep exposed areas of Quesnel Lake and Polley Lake (and associated reference areas) between 2022 and 2024. In deep exposed areas of Quesnel Lake and Polley Lake (and associated references), post-breach benthic invertebrate community monitoring was initiated in 2014 and has been completed at least every three years since 2018 (Figures 3.1 and 3.2, Table 3.7), in accordance with the CEMP (MPMC 2019). Although not required by the CEMP (MPMC 2019), benthic invertebrate community has been monitored annually at the deep near-field area of Quesnel Lake (QUL-PNF) since 2018 for evaluation of monitored natural recovery (Table 3.7).

In Polley Lake, benthic invertebrate community monitoring in 2024 included two deep monitoring areas (POL-P1 and POL-P2) and an associated deep reference area in Bootjack Lake (BOL-B2); sampling at these areas last occurred in 2021 (Figure 3.1, Table 3.7). In Quesnel Lake, benthic invertebrate community monitoring in 2024 included three deep areas (approximately 80 to 100 meters depth), with one near-field area (QUL-PNF), one far-field area (QUL-PFF1), and one reference area (QUL-PREF1). The benthic invertebrate community at QUL-PNF has been monitored annually for the past seven years (2018 to 2024) for the evaluation

[17] Routine water quality data prior to 2015 are available for Polley Lake, Bootjack Lake, and Quesnel Lake but were excluded from plots and statistical analyses to distinguish between short-term effects from potential long-term effects of the breach on water quality trends analysis in these waterbodies. The exclusion of data prior to January 2015 was based on the rationale explained in Minnow (2019a). Briefly, laboratory turbidity data resulting from the suspension of fine particulate matter immediately after the breach were used to qualitatively identify a “breach” period (i.e., a period characterized by short-term effects on water quality). By late 2014, laboratory turbidity had decreased to values more similar to pre- breach. Based on these results, the 'breach” period was defined as beginning on August 4, 2014, and ending in December 2014. Therefore, use of data starting in January 2015 should be effective in excluding short-term breach effects on water quality.

Table 3.7: Overview of Benthic Invertebrate Community Monitoring in Lakes in the Vicinity of the Mount Polley Mine, 1989 to 2024[a]

Waterbody		Area Type	Area Code	Pre-Breach				Post-Breach												
				1989[b] (Imperial Metals 1990)	1995 (HKP 1996)	1996 (HKP 1997)	1999 (Beak 2000)	2014 (Minnow 2015a)	2015 (Minnow 2016a)	2016 (Minnow 2016d)	2016 (Minnow 2017a)	2018 (Minnow 2019a)	2018 (Minnow 2019c)	2019 (Minnow 2020a)	2020 (Minnow 2021a)	2021 (Minnow 2022a)	2021 (Minnow 2022c)	2022 (Minnow 2023a)	2023 (Minnow 2024a)	2024

Notes: Displayed monitoring efforts used the following sampling methodology: petite-ponar grab sampler, 5-grab composite, 250 µm sieve, LPL (Lowest Practicable Level) taxonomy, except where noted otherwise.

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored between 2022 and 2024 are displayed, as well as historical data for these areas.

[b] In 1989, each sample was a single grab sieved using 355 µm mesh (Imperial Metals 1990). In 1995 and 1996, each sample was a single grab sieved using 200 µm mesh (HKP 1996, 1997). In 1999, each sample was a composite of 3 grabs, and was sieved using 200 µm mesh (Beak 2000).

[c] Five replicate samples were collected in Spring, and five were collected in Fall (with the exception of 6 replicates collected in Fall 1995 at B1, and 4 replicates collected in Fall 1995 at B2). Data from the Fall 1996 collection are unavailable due to loss of the samples at the taxonomic laboratory (HKP 1997).

[d] Results were also reported for the 500 µm sieve fraction by the laboratory.

[e] Areas are associated with effluent discharged-related monitoring under the Metal and Diamond Mining Effluent Regulations [MDMER] Environmental Effects Monitoring [EEM]). QUL-EEMEXP represents and effluent-exposed area, QUL-EEMREF1 represents a non-breach-influenced reference area, and QUL-EEMREF2 represents a breach-influenced reference area.

of monitored natural recovery. Prior to 2024, the other deep areas (QUL-PREF1 and QUL-PFF1) were last monitored in 2021 (Figure 3.2, Table 3.7).

Benthic invertebrate community was also documented in deep areas of Quesnel Lake in 2024 as part of Phase 4 EEM under the MDMER of the federal *Fisheries Act*. Three deep areas were evaluated as part of EEM; one exposed (QUL-EEMEXP) and two reference areas (QUL-EEMREF1 [non-breach-influenced], and QUL-EEMREF2 [breach-influenced]). Results for the Phase 4 EEM are due in a separate report in October 2025, therefore methods and results for this monitoring are not included in the present report. Prior to 2024, benthic invertebrate community monitoring in support of the Phase 3 EEM was completed in 2021 (Table 3.7; Minnow 2022c).

Sample collection and analysis methods for 2024 are described herein (excluding those related to the Phase 4 EEM) and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, refer to the references listed in Table 3.7.

3.5.1 Sample Collection

Benthic invertebrate community samples were collected from deep areas of Polley Lake (and reference; Bootjack Lake) and from deep areas of Quesnel Lake between August 19 and 24, 2024 (Appendix Table A.1.1). Five replicate stations were sampled within each monitoring area (Figures 3.1 and 3.2, Table 3.7) to provide adequate statistical power to detect differences of ± two SDs at α and β of 0.10. One sample was collected at each replicate station. To ensure that the sample was representative of the station, each single sample was a composite of five sub-samples (grabs; 0.116 m^2 of bottom area in total).

Samples were collected using a stainless-steel Petite Ponar grab sampler according to methods consistent with provincial (BCMOE 2013) and federal (Environment Canada 2012b) guidance and with previous monitoring (see Table 3.7). Samples were collected from each station using the ponar sampling methods described in Section 3.1.1. Upon retrieval, grab samples were closely examined to verify that only high quality, comparable samples were retained. Each grab was placed into a tub to evaluate whether the grab was complete (i.e., that the grab captured the surface material and was full to each edge), to evaluate the depth to which the grab penetrated, and to verify consistency in terms of particle size, organic matter, and the presence or absence of plants or algae. Incomplete or unusual grabs were discarded. Acceptable grab samples were rinsed from the ponar into a plastic tub to ensure the complete removal of all material from the grab sampler. This grab sampling method was repeated until five acceptable grabs were collected at a given station.

At each replicate station, the composite sample of five grabs was placed into a 250 µm mesh sieve bag and sieved free of all material less than 250 µm in diameter. After sieving, the retained material (sample) was carefully transferred into one or more pre-labelled 1 L wide mouth plastic jars using a wash bottle. The transfer was completed while working over a plastic tub to avoid any potential loss of organisms. Any organisms that fell into the tub or adhered to the sieve bag were removed and added to the sample. Each sample was then preserved with buffered formalin solution to achieve a nominal concentration of 10% and stored at room temperature until shipment to the laboratory.

Supporting measures were collected at each sampling station, including *in situ* water measures, Secchi depth, and supporting sediment measures (see Section 3.1). Refer to Section 3.8.1 for additional details about supporting measures.

3.5.2 Laboratory Analysis

Taxonomic identification of the benthic invertebrate community samples was completed by Cordillera Consulting (lead taxonomist Scott Finlayson), in Summerland BC, using standard methods that incorporate QA/QC measures (e.g., Environment Canada 2012b, 2014). Taxonomists at Cordillera have achieved Level 2 certification by the Taxonomic Certification Program of the Society for Freshwater Science (formerly the North American Benthological Society), including certification for Group 1 (general Arthropods East/West), 2 (Ephemeroptera, Plecoptera and Trichoptera [EPT] East/West), 3 (Chironomidae East/West), and 4 (Oligochaeta) benthic organisms. Organisms were identified to the LPL (typically genus or species) using up-to-date taxonomic keys.

Upon arrival, each benthic sample was logged into proprietary software and inspected for leaks, damage, and correct preservation, before the addition of Rose Bengal dye. A sample receipt confirmation was then sent to Minnow. Sample processing was initiated with sample washing, including elutriation to remove sand and gravel (as applicable). The remaining organic material was then examined to estimate the total number of invertebrates and preserved in 70% ethanol. If the estimated number of invertebrates was greater than 600 individuals and the sample was fine and non-clumping, a sub-sample was taken using a Marchant Box (Marchant 1989) as described by Environment Canada (2014). All samples were sieved and processed in the laboratory using the same mesh size as used in during field collections (250 µm).

Samples (or sub-samples) were sorted using a gridded Petri dish under a low power stereo microscope into family/order while maintaining counts (counts excluded Porifera, Nemata, Platyhelminthes, Ostracoda, Copepoda, Cladocera, and any terrestrial drop-ins). When specimens were broken, only heads were counted towards the total, and larval and pupal exuviae were not counted. All samples were processed to a minimum 300 organism count. If the

300th organism was found part way through counting a cell, the entire cell was completed, and if 300 organisms had not been reached by the 50th cell of the Marchant Box, then the entire sample was sorted. All sorted organisms were stored in labeled vials containing 80% ethanol, separated by family/order, while debris was preserved and labeled separately.

Insects were identified to the genus/species level and non-insects were identified to, at minimum, family level and to the genus/species level where possible. Identification was completed by experienced, certified taxonomists using standard keys. Taxonomists made comparisons to an externally verified reference collection, and to Standard Taxonomic Effort lists compiled by the Canadian Aquatic Biomonitoring Network (CABIN), Southwest Association of Freshwater Invertebrate Taxonomists (SAFIT), and Pacific Northwest Aquatic Monitoring Partnership (PNAMP) to ensure accuracy. Following identification, newly identified representative specimens of each taxon were placed in separate vials to update an ongoing reference collection.

Laboratory QA/QC included an assessment of sub-sampling precision and accuracy, sorting efficiency, and taxonomic identification accuracy on at least 10% of the samples (Environment Canada 2012b, 2014). Data were entered into proprietary software (INSTAR1), which was also used to calculate benthic invertebrate community metrics and to generate the taxonomic report. Data were provided to Minnow as a Microsoft Excel spreadsheet along with a methods and QA/QC report as an Adobe Acrobat PDF file (Appendix G).

3.5.3 Data Analysis

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, organism sorting efficiency, sub-sampling precision and accuracy, and taxonomic identification error (see Appendix B). Following completion of the DQR, benthic invertebrate community results were analyzed as described below.

3.5.3.1 Metrics

Benthic invertebrate community condition was evaluated using metrics of organism density (organisms/m^2), taxon richness (No. of taxa), Simpson's Diversity and Evenness, and the relative density (%) and density (organisms/m^2) of dominant taxa groups. These endpoints were calculated at the LPL of taxonomy. Benthic invertebrate community results at the LPL taxonomy level can contain a mixture of taxonomic levels (e.g., species, family, order, and class), which can affect the calculation of metrics such as taxon richness and Simpson's diversity. To address this issue, a decision key was applied to the benthic invertebrate data to reassign taxon abundance across levels of taxa, while conserving the relative abundances within the higher taxon levels (see Appendix E.4 text and Appendix Figure E.4.1 for details). Several taxa were excluded from total organism counts by the laboratory (see Section 3.5.2) prior to application of the decision key

and endpoint calculation. Rare members of the benthic invertebrate community for which the level of identification was insufficient to determine whether the individual was a member of the aquatic or terrestrial community were also excluded.

Evaluation of the benthic invertebrate community at Polley Lake (and reference; Bootjack Lake) included comparison to samples collected at the same sampling locations in 1999 (pre-breach; Beak 2000). It should be noted that some caution must be applied to the interpretation of post-breach results relative to pre-breach results. This is due to the challenges presented using different laboratories for the taxonomic analyses of samples (i.e., different laboratories for pre-breach and post-breach sample analyses) and the large time span between data collection in 1999 versus 2024 (over which general improvements in laboratory protocols and higher-level taxonomic changes may have occurred). A major difference between the taxonomic analyses performed by the different laboratories was the use of CABIN protocol (Environment Canada 2012a) for processing of post-breach samples (2014 to 2024). CABIN protocol excludes enumeration of the taxa outlined in Section 3.5.2 while these taxa were enumerated for pre-breach (1999) samples. Therefore, these taxa were not included in the present analyses in accordance with CABIN protocol (Environment Canada 2012a). In addition, aquatic mites were not identified past Arachnida in 1999; therefore, aquatic mite data in all post-breach results were collapsed to Arachnida. The collapsed and merged pre-breach and post-breach data were used for calculation of benthic invertebrate community metrics as described above.

Following taxa exclusions, application of the decision key, and the collapsing of taxonomic data to maintain consistency among years, the metrics outlined above were calculated for all years included in the evaluation (1999 to 2024; Table 3.7): organism density, taxon richness, Simpson's Diversity and Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012b). The densities and relative densities (%) of dominant/indicator taxa were also calculated. Dominant/indicator taxa were defined as those groups representing more than 5% of total organism abundance within each set of data, or any taxon groups considered to be important indicators of environmental stress. The benthic invertebrate community metrics were calculated and summarized for each year using the following statistics: sample size, mean, median, minimum, maximum, and SD.

Correspondence Analyses (CA; a multivariate ordination method) was used to further examine spatiotemporal differences benthic invertebrate community structure in the deep lake monitoring areas. Specifically, data were evaluated in two separate CAs; one using all years of data (1999 to 2024) from deep Polley Lake areas (POL-P1, POL-P2) with Bootjack Lake serving as reference (BOL-B2), and one using all years of data (2014 to 2024) from deep exposed

(QUL-PNF, QUL-PFF1) and reference (QUL-PREF1) areas of Quesnel Lake. Correspondence Analysis is a multivariate ordination method that is used to reduce complex multivariate data into a smaller number of independent variables (Gauch 1982; Pielou 1984). The analysis extracts theoretical values (CA axis scores) that capture the variation in the abundance of benthic invertebrate taxa. The CA produces axis scores for each deep station in each year (with available data) as the sum of a weighted average of $ln_{(x+1)}$-transformed species densities (#/m^2). Taxa scores are also produced as the sum of weighted averages of their densities across stations and years. The structure of the data can then be depicted in scatter plots of one CA axis against another, showing both taxa and station scores. Taxa that tend to co-occur plot together and those that rarely co-occur plot farther apart. Similarly, years at the deep areas that share many taxa plot closer to one another, while those with few in common plot further apart. Thus, CA can be used to describe which benthic invertebrate taxa best accounts for observed differences in the overall benthic invertebrate community between years and/or areas. The CA analysis was conducted at the LPL of taxonomic organization using $ln_{(x+1)}$-transformed density data. CA is sensitive to the presence of rare taxa (Legendre and Legendre 1983; Poos and Jackson 2012). Taxa occurring in fewer than 1% of samples or those that made up less than 1% of the total abundance of each dataset were excluded from the analysis (Dolédec and Chessel 1991). The ordination was conducted using the cca() function in the vegan package (Oksanen et al. 2020) of R statistical software (R Core Team 2024). Results of the CA were summarized by sampling station and year using the following statistics: sample size, mean, median, minimum, maximum, and SD. Taxa with the highest magnitude weights on the CA axes were identified and used in interpretation of the separation of stations on the CA axes.

3.5.3.2 Statistical Analysis

Statistical analyses of benthic invertebrate community data were conducted using pre-breach data (where available) and post-breach data (i.e., 2014 to 2024) to answer the following questions:

1. Were there differences between the benthic invertebrate community of exposed and reference areas in 2024?
2. Has the benthic invertebrate community of exposed areas changed among years relative to changes at reference areas over this time, and where pre-breach data exist, has the community recovered to pre-breach conditions?

To answer these questions, data were grouped into two categories for the separate calculation of community metrics, tabular and graphical presentation, and statistical analyses:

1. Polley Lake (POL-P1, POL-P2) compared to reference (Bootjack Lake; BOL-B2).

2. Quesnel Lake exposed areas (QUL-PNF, QUL-PFF1) compared to an un-impacted reference (QUL-PREF1).

The statistical analyses were completed following the methods outlined in Section 3.3.3.1.2. For Polley Lake (and reference; Bootjack Lake), this included evaluation of post-breach results from 2014 to 2024 as well as pre-breach data (1999; Table 3.7). For Quesnel Lake, this included evaluation of post-breach results from 2014 to 2024 since no pre-breach data exist (Table 3.7).

Interpretation of benthic invertebrate community metrics was enhanced by inspection of raw data and taxonomic proportions to detect patterns of ecologically relevant spatial and temporal differences. Ecological and habitat requirements of benthic invertebrates, as outlined in standard references (Clarke 1981; Edmunds et al. 1976; Weiderholm 1983; Wiggins 1996; Vieira et al. 2006; Merritt et al. 2008) were also used in data interpretation. All statistical comparisons were conducted using R (R Core Team 2024). Statistically significant differences in benthic invertebrate community between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were identified as potentially ecologically meaningful in statistical analyses results and in data interpretation (Environment Canada 2012b[18]), although all statistically significant differences (e.g., including those with a MOD < ±2 SD/MAD) were discussed in the data interpretation. Densities and relative densities (%) of major benthic invertebrate groups were plotted as stacked bar charts. Benthic invertebrate community metrics were plotted to support the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2024).

Potential relationships between benthic invertebrate community metrics and physical and chemical conditions of the monitoring areas were explored using correlation analysis as part of causal assessment. Correlation analyses were completed separately for the two data categories outlined above: 1) deep areas of Polley and reference (Bootjack Lake; 1999 to 2024) and 2) deep areas of Quesnel Lake (2014 to 2024). Although correlation is not causation, it is a fundamental tool applied for exploring data and generating evidence of causation (Shipley 2000, Suter 2015). Benthic invertebrate community metrics (including CA axis scores) were compared to environmental variables including physical measures (station depth), bottom *in situ* water quality measures (temperature, dissolved oxygen, pH, and specific conductance), physical/ chemical sediment measures (% fines and TOC content), sediment Analyte of Interest concentrations (see Section 3.1.3.1 for details), and sediment chemistry PCA axis scores (see Section 3.1.3.2 for details). Following derivation of correlation coefficients using Spearman's

[18] Environment Canada (2012b) identifies a CES of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community.

Rank correlation, a Bonferroni-type correction (i.e., α [0.05] divided by the total number of independent variables) was applied to minimize the risk of declaring false positive correlations.

Statistically significant correlations found at the Bonferroni-adjusted p-value were further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were leveraged by outlying points (or groups of points). The effects of leverage were carefully considered because any differences in benthic community attributes observed at the exposed areas relative to reference, or temporal differences at the exposed area, might be correlated with breach-related differences in water or sediment quality regardless of cause. Leverage is a particularly important consideration in cases where substantially impacted areas are compared to unimpacted reference areas, because physical, chemical, and biological features may all be impacted and relationships among them may not actually indicate a cause other than "they were all impacted." Statistically significant correlations, coupled with careful examination of scatterplots, were used to identify the factors that most contribute to temporal and spatial variability in benthic invertebrate community endpoints. These factors were then evaluated with consideration of known physical and chemical influences on benthic invertebrate communities (e.g., limitation due to low nutrient availability, toxicity by exposure to high analyte concentrations).

3.6 Fish Catchability, Usage, and Population Health

3.6.1 Overview

Fish population health monitoring in Polley Lake was completed annually from 2022 to 2024, consistent with the CEMP (MPMC 2019). This monitoring was initiated in 2014, revised to incorporate a standardized monitoring approach in 2019 (Minnow 2020a), and has continued annually from 2019 to 2024 (using the standardized monitoring approach), in accordance with the CEMP (MPMC 2019). The objective of fish population health monitoring is to continue to document population structure and abundance, provide an estimate of Young-of-the-Year (YOY) survival in Polley Lake, and to assess the success of remediation efforts in Hazeltine Creek. A brief background and summary of historical findings of this monitoring is provided below.

Historically, the majority of Polley Lake rainbow trout (*Oncorhynchus mykiss*) recruitment was supported by spawning and rearing in Hazeltine Creek and lower Bootjack Creek, downstream of Polley Lake (Bruce and Slaney 1991). Following the breach, both Hazeltine Creek and Bootjack Creek were inaccessible to Polley Lake fish and spawning and juvenile rearing habitat for the Polley Lake rainbow trout population was limited to Frypan Creek and a few unnamed intermittent tributaries around the lake (Figure 3.4). Production of rainbow trout fry from these creeks was insufficient to sustain the historical rainbow trout population within Polley Lake (Minnow 2018d).

Post-breach monitoring in Polley Lake was initiated in 2014 to assess the impact of the breach and monitor the health of fish populations (particularly rainbow trout and longnose sucker [*Catostomus catostomus*]) over time. Notably, age- and size-frequency distributions for rainbow trout caught in 2016 indicated that far fewer age-1 and age-2 individuals were captured than in 2014 (Minnow 2017c) and an absence and near absence of age-1, age-2, and age-3 fish was reported in 2017 and 2018, respectively (Minnow 2018d, Minnow 2019a). This is indicative of limited recruitment associated with Hazeltine Creek being inaccessible for spawning and rearing from 2014 to 2017.

After remediation efforts in Hazeltine Creek were completed in the fall of 2017, fish from Polley Lake were allowed access to the upper two reaches of Hazeltine Creek (Reach 1: HAC-R1, and Reach 2: HAC-U [HAC-R2]) on April 26, 2018, and subsequently to the entire length of Hazeltine Creek on October 7, 2020 (Minnow 2019b, 2020b, 2021b).[19] Following re-establishment of fish access to upper Hazeltine Creek in 2018, fish population monitoring has been completed twice a year in Polley Lake (spring and fall). Sampling efforts in spring target adult fish aggregating before spawning (also targeted for tissue quality sample collection), whereas fall fishing efforts are randomized using standard effort to provide interannual comparisons of fish population structure and abundance in Polley Lake. Monitoring conducted in the spring in Polley Lake showed that rainbow trout catch-per-unit-effort (CPUE) was higher in 2019 than in 2018 and 2017 but substantially lower than in 2016. Rainbow trout CPUE in the spring subsequently decreased from 2019 to 2021 (consistent with loss of recruitment and natural mortality of older fish since the breach) before increasing in 2022 and 2023 to the highest point since 2016 suggesting that most of the remaining 2018 and a portion of the 2019 cohort had reached maturity.

Monitoring conducted in the fall in Polley Lake, when fishing is randomized, showed rainbow trout CPUE that was higher from 2019 to 2021 than in 2016 and 2018 (with the highest CPUE documented in 2021; Minnow 2023a). This was driven mostly by the higher relative abundance of smaller rainbow trout in catches (YOY to age-2 based on predicted length-at-age from a linear model) resulting from successful recruitment of rainbow trout to Polley Lake and overwintering survival. In 2022 and 2023, CPUE declined relative to the previous three years,

[19] High water levels associated with the spring freshet in May 2020 caused flooding that enabled adult rainbow trout to bypass the fish fence located at the downstream extent of HAC-U and access the creek downstream (Minnow 2021b). In response, MPMC extended monitoring to include Reach 3 of Hazeltine Creek (HAC-R3) in the 2020 Hazeltine Creek Monitoring Program (Minnow 2021b). On July 4, 2020, the fish fence at the downstream extent of HAC-U was moved to lower Hazeltine Creek (in the vicinity of HAC-D). On October 7, 2020, the fish fence in lower Hazeltine Creek was removed (following completion of remediation works in this area), and fish were allowed access to the entire length of Hazeltine Creek. The entirety of Hazeltine Creek remained accessible to fish from October 2020 until present, except for a brief period (July to August 2021) when lower Hazeltine Creek was inaccessible during the completion of final instream remediation works in this area (Minnow 2022b).

but rainbow trout catches included a higher relative frequency of age-2 and older (age-2+) fish and a size class distribution more closely resembling 2016, signaling the successful recruitment of older age classes. Further, since 2019 when catches provided strong evidence of successful recruitment of the 2018-year class, annual monitoring data has been characterized by good year to year survival of this cohort as well as the successful recruitment of subsequent cohorts through to 2022 and 2023 (Minnow 2023a, 2024a).

Sampling methodologies for fish surveys completed in 2024 are described herein and were consistent with fish surveys conducted annually since 2018, and consistent with the CEMP (MPMC 2019). The methods associated with monitoring of fish population structure and abundance in Polley Lake prior to 2018 are described elsewhere (MPMC 2019; Minnow 2019a). In 2024, the spring survey was completed in April/May in Polley Lake with Bootjack Lake serving as reference (April 23 to May 2, 2024; Appendix Table C.6.1), and the fall survey was completed in Polley Lake in September (September 24 to 29, 2024; Appendix Table C.6.2). The spring survey served two purposes: 1) to provide data for the evaluation of fish population structure and abundance in Polley Lake; and 2) to provide data for the evaluation of fish tissue quality in Polley Lake compared to reference (Bootjack Lake; see Section 3.7). The fall survey served to provide complementary interannual comparisons of fish population structure and abundance in Polley Lake.

Fish sampling described herein was conducted under BCMOWLRS Fish Permit WL24-846725.

3.6.2 Spring Survey

The spring survey was initiated shortly after ice-out in Polley and Bootjack lakes (i.e., April 16, 2024) in Polley Lake (and a similar date in Bootjack Lake). Ice cover, water temperature, and/or fish “homing” to natal streams (e.g., Hazeltine Creek or Bootjack Creek which is currently diverted directly into the south-west end of Polley Lake; Figure 3.4) were closely monitored by mine staff to support the timing of program commencement. Initial fish aggregation in Hazeltine Creek was observed by mine staff on April 9, 2024.

Spring fishing was conducted from April 23 to May 2, 2024 using seven hoop net sets in Polley Lake and twenty in Bootjack Lake (2.5-foot diameter, 1.5-inch stretched mesh; Appendix Table C.6.1). Hoop nets were set for one to two nights and targeted key spawning areas such as the outflow to Hazeltine Creek (for Polley Lake) and small tributary streams of Bootjack Lake to capture individuals that were ready to spawn (Figure 3.4).

For each hoop net set, the level of sampling effort was recorded (i.e., set duration), along with supporting Global Positioning System (GPS) coordinates. Supporting measures also included vertical depth profiles of *in situ* water quality measures at the two deep basins of each lake

(Polley and Bootjack Lakes; see Section 3.8.1 for details). Captured fish were identified and enumerated to characterize the fish community.

3.6.3 Fall Survey

Fall fishing was conducted in Polley Lake from September 24 to 29, 2024 using seven hoop nets (three 2.0-foot diameter nets [0.8-inch stretched mesh] and four 2.5-foot diameter nets [1.5-inch stretched mesh]). Net set locations were determined *a priori* by dividing Polley Lake into 28 sampling areas (Figure 3.5) and using a random number table to select the sampling area where any given net would be set on a given day. All seven hoop nets were set at the pre-determined locations in Polley Lake and left overnight. The next day, all seven nets were lifted, fish enumerated and/or measured (see Section 3.6.4 for details) and reset at a new pre-determined locations in Polley Lake. This continued for a total of five nights of effort (Appendix Table C.6.2).

For each hoop net, sampling effort (i.e., set duration, configuration), and supporting GPS coordinates were recorded. Supporting measures also included vertical depth profiles of *in situ* water quality measures at the two deep basins of Polley Lake and supporting habitat data (see Section 3.8.1 for details).

3.6.4 Fish Processing

Target species that were captured during the spring and fall surveys were retained for non-lethal evaluation of fork length, total length and weight. Target sample sizes for non-lethal measures were n ≥ 30 per lake (Polley and Bootjack lakes) for rainbow trout and longnose sucker in the spring. In the fall, non-lethal measurements were completed for rainbow trout, longnose sucker, and redside shiner (*Richardsonius balteatus*) from Polley Lake, with target sample sizes of n ≥ 100 fish for longnose sucker and redside shiner. The target sample size was achieved for redside shiner (n = 106) and nearly achieved for longnose sucker (n = 94). For rainbow trout, physical measurements during fall monitoring were targeted from n ≥ 100 of each juvenile and adult fish to ensure collection of measurements from a relatively large sample size across the entire size range of rainbow trout captured. The sample size achieved for rainbow trout (n = 64) was limited by catch results. Prior to the collection of physical measurements, rainbow trout were assigned as juvenile or adult in the field based on the presence (juvenile) or absence (adult) of observable parr marks. This approximation was for field-based determination of maturity only.

Incidental mortalities were disposed of in an approved manner. All other fish were released live immediately following capture. Fish selected for non-lethal sampling were retained in an aerated holding container until the collection of fork length, total length, and body weight measures, then were immediately released. A measuring board was used to measure fork and total length to the

nearest millimeter. Fresh body weight was measured using Pesola™ spring scales (depending on fish weight). The Pesola™ scales were demarcated at intervals of 1 to 2% of the total scale range, providing an accuracy of ± 0.3% of the fish mass. The Pesola™ spring scale for individual weight measurement was selected so that the fish weight was near the top of the scale's range to ensure that measurements achieved a resolution near 1%.

In April/May, a subset of eight female rainbow trout and longnose sucker from each lake (Polley Lake and Bootjack Lake) were sacrificed for the assessment of condition, tissue quality, and age distribution. See Section 3.7.1 for details of the processing methods for these fish.

3.6.5 Data Analysis

Three endpoints were used to evaluate the health of rainbow trout, longnose sucker, and redside shiner populations from Polley Lake over time (2014 to 2024). First, cumulative relative frequency distributions (CRFD) of fork lengths were used as an indicator of recruitment for each of these three species. Second, weight-at-age was used as an indicator of energy use for rainbow trout and longnose sucker. Third, condition (weight-at-length) was used as an indicator of energy storage for rainbow trout and longnose sucker. The calculation of CRFD included data from the randomized fall surveys only, when fish are not aggregating for spawning (which could influence the CFRD results). Condition and weight-at-age were analyzed separately for spring and fall sampling events (for years and seasons in which the necessary data were collected) and were analyzed for males and females separately (if data on sex was available) or for both sexes combined. For rainbow trout and longnose sucker, condition analyses of data from spring and fall surveys were initially conducted using all fish captured; condition was then analyzed again using only fish with the greatest overlap in size (i.e., fork length) among years. Interpretation of condition analysis results was focused on the tests which included individuals with the greatest overlap in fork length (i.e., those tests that only included fish larger than a given fork length) to ensure interpretation of temporal contrasts were based on the analyses with the most robust and temporally comparable data sets.

Summary statistics (sample size, mean, SD, minimum and maximum value) were calculated separately by area and species for each measurement variable recorded in 2024 (weight, length, and age where available).

3.6.5.1 Weight-at-Age and Condition

Rainbow trout and longnose sucker condition and weight-at-age (females in spring only) were compared among years (i.e., 2016 to 2024 for spring surveys and 2014 to 2024 for fall surveys) using an Analysis of Covariance (ANCOVA) with $\log_{10}$-transformed body weight as the response, Year as a factor, and $\log_{10}$-transformed age or fork length as a covariate.

Significant interactions between the covariate and year (i.e., the assumption of homogeneity of regression slopes among years) in the ANCOVA were assessed using α = 0.1.

When the interaction term was significant, the coefficients of determination (R^2) of the interaction model and parallel slope model were compared to assess whether the slopes were practically significant. Briefly, if the R^2 was >0.8 and within 0.02 between the two models, then the conclusion was that the interaction model and parallel slope models were practically the same (Environment Canada 2012b) and the ANCOVA proceeded with the parallel slope model. Statistical outliers were defined to be observations with Studentized residuals with magnitude > 4 (Environment Canada 2012b) and statistical analyses were completed with these outliers excluded and an inventory of excluded outliers was provided with the analyses results. If the interaction could not be removed by comparison of R^2 values or removal of outliers, the conclusion was that the difference in the response variable between areas was dependent on the covariate values. When the interaction term was not significant it was removed from the model and the parallel slope ANCOVA model was fit.

Statistical comparisons were run as all pairwise contrasts over time. Statistically significant *post hoc* contrasts were identified at α = 0.1 using Tukey's Honestly Significant Difference. The results of the pairwise comparisons among years were expressed using a compact letter system. Capital letters were assigned to years (e.g., A, B, and C) such that years that did not differ significantly share a letter, and the year with the highest mean was assigned the letter "A."

A MOD was calculated for each endpoint in each year relative to the baseline year (defined as the minimum year used in the statistical comparison) as:

$$\text{MOD} = \frac{\bar{x}_{\text{i}} - \bar{x}_{\text{baseline}}}{\bar{x}_{\text{baseline}}} \times 100\% \text{ ,}$$

where $\bar{X}_i$ is the mean of a given year, and $\bar{X}_{Baseline}$ is the mean of the baseline (earliest) year (for ANOVA), or the covariate-adjusted mean (for ANCOVA, without interaction). When an interaction was observed, the MOD was estimated for small and large fish at the minimum and maximum values of the overlap in covariate values between areas using the predicted values of the response variables from the interaction ANCOVA regression model (Environment Canada 2012b). When response variables were $\log_{10}$-transformed, means were reported in the original data units (i.e., anti-logged), equivalent to geometric means.

Weight-at-age and condition were plotted using scatterplots with regression lines separated by year. The statistical analyses and regression model fitting for these endpoints were completed with the outliers excluded (as outlined above) and outliers were identified in plots as symbols with

an "×" through them. All statistical analyses and plots were conducted using R (R Core Team 2024).

3.6.5.2 Length Frequency Distributions

Length frequency distributions of data from the randomized sampling efforts conducted in the fall were plotted using histograms and CRFD. The CRFD is a plot of the proportion of fish on the y-axis and length on the x-axis and shows the proportion of fish that have a length less than the length value on the x-axis. Statistical comparisons of length frequency distribution between years were conducted using the two-sample Kolmogorov-Smirnov (K-S) test. The two-sample K-S test compares the maximum difference in the CRFDs between areas and evaluates whether this maximum difference varies significantly among years ($p < 0.1$). Estimated fork length for fish at a given age were estimated using a Von Bertalanffy function and plotted above the histograms for reference.

3.7 Fish Tissue Quality

Fish tissue quality monitoring was completed annually between 2022 and 2024 in Polley Lake (with Bootjack Lake serving as a reference), in Quesnel Lake (exposed and reference areas) and in Quesnel River, in accordance with the CEMP (Figures 3.4 and 3.6; MPMC 2019). Post-breach fish tissue quality in Polley Lake (with Bootjack Lake as reference) and Quesnel Lake (exposed and reference areas) was initiated in 2015 and has continued annually since then (Table 3.8). In 2018 the sampling approach was standardized, consistent with the CEMP (MPMC 2019). Since 2018, two fish tissue quality monitoring surveys have been completed annually: a spring survey in Polley and Bootjack lakes and a fall survey in Quesnel Lake and Quesnel River. The spring survey completed annually since 2018 in Polley and Bootjack lakes has targeted one sport-fish species (rainbow trout) and one small home range species (longnose sucker; Figure 3.4, Tables 3.8 and 3.9). The annual fall survey (late September to early October) completed annually since 2018 has targeted two small home-range species (northern pikeminnow [*Ptychocheilus oregonensis*] and peamouth chub [*Mylocheilus caurinus*]) from Quesnel Lake, and one sport fish species from each of Quesnel Lake and Quesnel River (lake trout [*Salvelinus namaycush*] and rainbow trout, respectively; Figure 3.6, Tables 3.8 and 3.9).

Sample collection and analysis methods specific to 2024 are described herein and are consistent with the CEMP (MPMC 2019). For details pertaining to prior sampling years, refer to the references listed in Table 3.8.

Table 3.8: Overview of Fish Tissue Quality Monitoring in Lakes in the Vicinity of the Mount Polley Mine, 2015 to 2024

Time Period	Waterbody or Area	Fish Species (Species Code)	Target Sample Size	Target Tissue(s)[b]
Spring 2015 (Minnow 2017e)	Polley Lake Tributary (Frypan Creek; Exposed)	rainbow trout (RB)	8[a]	muscle, ovary, liver, kidney,
	Bootjack Lake Tributary (Reference)		8[a]	
Fall 2015 (Minnow 2017e)	Quesnel Lake near Hazeltine Creek (Exposed)	burbot (BB), lake trout (LT), largescale sucker (CSU), northern pikeminnow (NSC), peamouth chub (PCC), redside shiner (RSC)	8	muscle, ovary, liver, kidney, or whole-body
	Quesnel Lake near Grain Creek (Reference)	largescale sucker (CSU), peamouth chub (PCC), redside shiner (RSC)	8	muscle or whole-body
	Quesnel Lake East Arm near Blue Lead Creek (Reference)	burbot (BB), lake trout (LT)	8	muscle, ovary, liver, kidney
	Quesnel Lake near Poquette Creek (Exposed)	kokanee (KO)	8	muscle, liver, kidney
	Quesnel River (Exposed)	rainbow trout (RB)	8	muscle, liver, kidney
	Trio Lake (Reference)	rainbow trout (RB)	8	muscle, liver, kidney
Spring 2016	Polley Lake (Exposed)	longnose sucker (LSU), rainbow trout (RB), redside shiner (RSC)	8[a]	muscle, ovary, liver
	Quesnel Lake near Hazeltine Creek (Exposed)	largescale sucker (CSU), northern pikeminnow (NSC), peamouth chub (PCC)	8	muscle and liver, or whole-body
	Quesnel Lake near Grain Creek (Reference)			
Spring 2017 (Minnow 2018e)	Polley Lake (Exposed)	longnose sucker (LSU), rainbow trout (RB)	8	muscle, ovary, liver
	Bootjack Lake (Reference)	longnose sucker (LSU), rainbow trout (RB)	8	muscle, ovary, liver
Fall 2017 (Minnow 2018e)	Quesnel River (Exposed)	rainbow trout (RB)	8	muscle, liver, kidney
	Quesnel Lake near Hazeltine Creek (Exposed)	northern pikeminnow (NSC)	8	whole-body
Spring 2018 to 2024 (Annually; Minnow 2019a, 2020a, 2021a, 2022a, 2023a, 2024a)	Polley Lake (Exposed)	longnose sucker (LSU), rainbow trout (RB)	8	muscle, ovary, liver, kidney
	Bootjack Lake (Reference)	longnose sucker (LSU), rainbow trout (RB)	8	muscle, ovary, liver, kidney
Fall 2018 (Minnow 2019a)	Quesnel Lake near Poquette Creek (Exposed)	kokanee (KO)	8	muscle, ovary (if present), liver, kidney
	Quesnel Lake North Arm near Mitchell River (Reference)	kokanee (KO)	8	muscle, ovary (if present), liver, kidney
Fall 2018 to 2024 (Annually; Minnow 2019a, 2020a, 2021a, 2022a, 2023a, 2024a)	Quesnel Lake near Hazeltine Creek (Exposed)	northern pikeminnow (NSC)	8	whole-body
		peamouth chub (PCC)	8	muscle, ovary (n=2), liver, kidney
	Quesnel Lake near Cedar Point (Exposed)	lake trout (LT)	8[c]	muscle, ovary (n=2), liver, kidney
	Quesnel Lake near Grain Creek (Reference)	northern pikeminnow (NSC)	8	whole-body
		peamouth chub (PCC)	8	muscle, ovary, liver, kidney (n=5 for each tissue type)
	Quesnel Lake East Arm near Blue Lead Creek (Reference)	lake trout (LT)	8	muscle, ovary (n=1), liver, kidney
	Quesnel River (Exposed)	rainbow trout (RB)	8	muscle, ovary (n=5), liver, kidney

Grey shading indicates fish tissue sampling completed in 2024.

[a] The target for these collections was n = 8 ovary samples. For the spring 2015 and 2016 data set, this resulted in more than 8 muscle and liver samples.

[b] The target sample size was achieved in 2024 for each species and tissue unless otherwise indicated. Actual sample sizes that differed from the target sample size in 2024 are indicated in parentheses (e.g., n=5) following each tissue type listed.

[c] The target for these collections was n = 8 samples of each tissue type. For the fall 2019 data set, this resulted in collection of more than 8 muscle, liver, and kidney samples for lake trout.

Table 3.9: Life History and Habitat Preferences of Target Fish Species in Lakes in the Vicinity of the Mount Polley Mine[a]

	Lake Trout (LT)	Longnose Sucker (LSU)	Northern Pikeminnow (NSC)	Peamouth Chub (PCC)	Rainbow Trout (RB)
	Salvelinus namaycush	*Catostomus catostomus*	*Ptychocheilus oregonensis*	*Mylocheilus caurinus*	*Oncorhynchus mykiss*
Home Range	move within lake to spawning sites.	move to spring spawning sites, but tagged fish have often been re-captured close to where they were originally captured.	move to spring spawning sites, but and considered to have small home range (tagged fish in the Columbia River were generally found within 3 km of the tagging location).	move to spawn in spring. Movement limited to diel inshore movement in evening and offshore in morning.	move from lake habitat to spawning creeks (generally tributaries to, or outlets of, their native lake).
Spawning	in the fall (September-November), usually at night, when water temperatures drop below 10 °C , usually in lakes over boulder or rubble bottom from depths ranging from 0.3 to 12 m, although some populations spawn in rivers.	in spring shortly after ice-out at a threshold temperature of 5 °C, although some populations in the Peace and Cariboo regions delay to a water temperature of 15 to 16 °C. Usually spawn in streams over gravel substrates in moderate currents.	in the spring at a threshold temperature of 12 °C (April to July), typically in gravel or cobble of inlet streams, generally close to the lake.	in spring/early summer (April-July) at water temperatures between 9 and 15 °C. Typically in lake inlet or outlet streams in areas of flowing water over gravel substrate. Rarely more than a few hundred metres from the lake.	in spring (April-June) at water temperatures between 8 and 15 °C. Triggered by rising water temperature above 5 °C. In fine gravel of riffle areas of tributary streams, typically at depths of 0.15 to 2.5 m and water velocity of 0.3 to 0.9 m/s. Can also spawn on gravel beaches in lakes.
Growth	growth is highly variable; in some lakes 2+ fish were in the 20 cm range.	3 to 6 cm by end of first growing season.	3.5 to 6.5 cm by end of first growing season.	3.5 to 6.0 cm by end of first growing season.	growth is highly variable depending on habitat type, productivity and food chain structure.
Maximum Age and Size	>20 years is common; oldest aged was 62 years; 75 cm.	19 years (probable under-estimate); 50 cm.	20 years; 50+ cm; females live longer and grow larger than males.	males live up to 8 years and females live up to 19 years; 25 cm.	8 years; maximum size is highly variable depending on habitat type, productivity and food chain structure.
Age at Maturity	between 5 and 13 years; males 1 to 2 years before females.	males - 5 to 6 years females - 6 to 7 years	males - 3 to 4 years females - 5 to 6 years	males - 3 years females - 4 years	3 to 5 years; as early as 1 year by males and as late as 6 years by females.
Food	young-of-year forage on plankton and aquatic insect larvae, adding larger benthic organisms as they grow. At a length of 35 to 40 cm, switch to piscivore if an appropriate prey species is available.	are benthivores as adults, but early stages forage in shallow water for a variety of prey, most commonly zooplankton. Mouth shifts from terminal to ventral with development. As adults, most common food is chironomid larvae and pupae.	mostly aquatic insects when small; diets include fish after 10 cm size. Are mostly piscivorous when larger than 30 cm (although they will eat almost any prey of suitable size).	juveniles consume a wide variety of prey (planktonic crustaceans, chironomid pupae, benthic invertebrates). Consume larger prey as they grow; adults primarily eat invertebrates, but occasionally eat fish.	in creeks, fry and juveniles forage on drifting aquatic insects. In lakes, fry forage on bottom and water column invertebrates; juveniles and adults have similar diets, but adults take larger prey and more adult insects. Large adults (> 40 cm) in large lakes often become piscivorous.
Habitat - Early Life Stages	young seek out deeper water within a month of being hatched, and prefer deeper water than adults (possibly due to cannibalism). When surface waters are cool, juveniles can also be found in shallow water about 1 to 2 m offshore.	young-of-year stay near shore near cover (vegetation or woody debris). Fry transition to deeper water.	young-of-year are typically found around lake margins in shallow water close to cover. Juveniles tend to move offshore into deeper water in the fall.	young-of-year are typically found in shallow water, and tend to move offshore at night. Juveniles also occupy shallow water, but generally deeper than young-of-year.	alevins take 1 to 4 weeks to emerge. Fry may move immediately to lakes, or reside in the stream as many as 3 years. Fry staying in the stream are territorial, and initially occupy slow, shallow areas (shallower than other species), moving to deeper and faster water as they get older.
Habitat - Adults	prefer cool water (below approximately 10 °C); during warmer summer months adults inhabit the hypolimnion (below the thermocline) and disperse throughout the lake during the winter months.	habitat generalists, found in lakes and rivers. In lakes, tend to forage inshore at night, but remain below the thermocline in the day.	often in the littoral zone about 1 m off the bottom and at the offshore side of weed beds. Move into deeper water in the fall.	habitat use changes seasonally. Generally near bottom in the winter. Move inshore in the spring and after spawning, exhibit a diel migration, moving inshore in the evening and offshore in the morning.	in lakes, prefer cool (7 to 18 °C) temperatures and high dissolved oxygen; tend to stay below the 18 °C isotherm. Spend most of the time within 3 m of surface and are often in cover in the lower littoral zone.

Notes: km = kilometres, °C = degrees Celsius, m = metres, m/s = metres per second, cm = centimetres, + = plus, > = greater than.

[a] Based on information in Scott and Crossman (1998), Roberge et al. (2001, 2002), McPhail (2007) and Barrett and Munkittrick (2010).

3.7.1 Sample Collection

Spring fishing in Polley and Bootjack lakes was completed from April 23 to May 2, 2024, under BCMOWLRS Fish Permit WL24-846725, using hoop nets to capture rainbow trout and longnose sucker (Figure 3.4), as described in Section 3.6.2. Fishing was completed in the spring to support collection of ripe ovary tissue from these two species, which is a key tissue for selenium monitoring (see Section 3.7.3.1).

Fall fishing in Quesnel Lake and Quesnel River was completed from October 16 to 26, 2024, under BCMOWLRS Fish Permit WL24-846725 and Department of Fisheries and Oceans Canada (DFO) Permit XR 145 2024. Hoop nets were primarily used to target small home-range species (i.e., northern pikeminnow and peamouth chub) in the exposed (West Arm [near Hazeltine Creek]) and reference areas (North Arm [near Grain Creek]) of Quesnel Lake (Figure 3.6, Table 3.8). Hoop netting was completed from October 16 to 26, 2024, with hoop nets set for one to three nights. The small home-range species (i.e., northern pikeminnow and peamouth chub) were also targeted using angling at the Quesnel Lake reference area (North Arm [near Grain Creek]) on October 27, 2024, and using minnow trapping at the exposed (West Arm [near Hazeltine Creek]) and reference (North Arm [near Grain Creek]) areas of Quesnel Lake from October 23 to 26, 2024 (Figure 3.6). Gill nets were used to target lake trout in the exposed (West Arm [near Cedar Point]) and reference (East Arm [near Blue Lead Creek]) areas of Quesnel Lake (Figure 3.6) during the daylight hours of October 16 to 21, 2024. The mesh sizes of the gill nets ranged from 3 to 5 inches (stretched mesh) and gill nets were deployed using Summer Profundal Index Netting (SPIN) methods (Sandstrom and Lester 2009) to specifically target lake trout. Angling was used to target rainbow trout in the Quesnel River (Figure 3.6, Table 3.8) on October 19 and 20, 2024. Fall fish collection methods in 2024 were largely consistent with those employed in previous years (i.e., 2018 to 2023).[20] Fish tissue samples collected in 2024 satisfied both the CEMP (MPMC 2019) and the MPMC Phase 4 EEM (Minnow 2024c) fish tissue selenium study monitoring requirements.

For each sampling area, the target sample size for each species (e.g., rainbow trout) and tissue type (e.g., muscle, ovary, liver, and kidney, or whole-body)[21] was n=8 to facilitate meaningful statistical comparison of fish tissue quality between exposed and reference areas (Table 3.8). The target sample size was met for each species from each sampling area in 2024, except for peamouth chub from the reference area (North Arm [near Grain Creek]) of Quesnel Lake where the achieved sample size was n=5. Despite extensive hoop netting effort at this area

[20] Gill netting was not approved under the DFO permit in 2023 due to concerns about salmon bycatch. As such, lake trout were targeting using angling in 2023 (see Minnow 2024a for details).

[21] The tissue types collected varied by species and location; see Table 3.8.

in 2024 (33 trap days; Appendix Table C.6.12) and additional effort via minnow trapping and angling (Appendix Tables C.6.14 and C.6.15), only nine peamouth chub were captured. In an effort to satisfy the requirement for collection of female peamouth chub for the MPMC Phase 4 EEM (i.e., for ovary tissue collection for selenium analysis), only female peamouth chub captured from this area (n = 5) were retained for tissue quality sampling.

Supporting data recorded for the 2024 fish tissue monitoring in lake habitats included GPS coordinates of each fishing location (net set or angling effort), level of effort (net deployment and retrieval times, angling duration), *in situ* water quality measurements (i.e., a depth profile of temperature, pH, dissolved oxygen, conductivity, and specific conductance collected at each fishing area), and habitat data (see Section 3.8.1; for details).

Upon retrieval of fishing gear, captured fish were identified to species. Target species that were captured and were of an appropriate size (relative to historical fish size range data) were retained for processing. Incidental mortalities were disposed of in an approved manner. Non-target fish species were enumerated and released live immediately following capture. Fish retained for lethal sampling were euthanized with a decisive blow to the head and placed in a cooler with ice prior to processing within <12 hours.

Fish retained for lethal sampling were processed as follows. Each fish was measured for fork length, total length, and body weight (as described in Section 3.6.4), then cut open using dissecting scissors and any internal abnormalities were noted. Each dissected fish was examined internally to confirm sex. Internal tissues (liver, kidney, and ovary if available[22]) were then removed using dissecting tweezers and scissors, weighed to the nearest 0.001 g (±1% precision) using an analytical balance and placed in labelled Whirl-Pak™ bags. A boneless, skinless muscle sample was also collected using a filet knife and placed in a clean, labeled Whirl-Pak™ bag. Tissue samples were collected using clean implements (cutting boards, filet knives, and tweezers) which were cleaned between fish. Duplicate (split) samples were collected at a target frequency of 10% for QA/QC purposes and were evenly distributed among fish species and tissue types (excluding whole-body northern pikeminnow samples which could not be split). Whirl-Pak™ bags containing whole carcasses (northern pikeminnow) or individual tissue samples (all other species) were stored frozen until shipment (on ice) to the analytical laboratory.

Aging structures from lethally sampled fish were collected for age determination as follows:

- Otoliths (rainbow trout, lake trout) or whole heads (peamouth chub);

[22] Ovary tissue was only sampled when available (i.e., when fully developed in mature females). Additional fish were not targeted and sacrificed to achieve the target sample size (n = 8) for ovary tissues, except in the case of peamouth chub in 2024.

- Scales (northern pikeminnow)[23];
- Pectoral fins (longnose sucker)[24]; and
- Scales as a secondary age structure (rainbow trout, lake trout, peamouth chub, longnose sucker).

Aging structures (i.e., otoliths, pectoral fins, and/or scales, as above) were removed, wrapped in waxed paper, placed in labelled coin envelopes, and frozen until shipment to the laboratory for aging analyses. For peamouth chub, whole heads were removed, placed in labeled Whirl-Pak™ bags, and frozen prior to shipment (on ice) to the aging laboratory for otolith extraction and age determination.

3.7.2 Laboratory Analysis

Laboratory analysis of fish tissue quality samples was completed by ALS Environmental (Burnaby, BC) using the same methods and QA/QC measures outlined in Section 3.4.2.

Determination of fish ages using aging structures was completed by AAE Tech Services in La Salle, Manitoba. Prior to aging, samples were thawed, and otoliths were extracted from fish heads (i.e., peamouth chub), as required. Otoliths for each relevant fish (rainbow trout, lake trout, and peamouth chub) were examined under magnification for any issues related to structural integrity (e.g., cracks, fractures, etc.) and deformation (e.g., crystallization or misshapen lobes). Based on this evaluation, one otolith from each pair (if a pair of otoliths was collected, otherwise the single available otolith was used) was selected for processing and embedded in Cold Cure epoxy resin and cured for 48 hours before sectioning and polishing. Age estimation was carried out by submerging the otolith section in water under magnification with the polished surface facing up.

Pectoral fin rays from longnose sucker were processed and analyzed using a sectioning method similar to that used for the otoliths. Fin rays were embedded in Cold Cure epoxy resin to increase the structural integrity of the sample and prevent damage or degradation of the sample during processing. Samples were cured for 48 hours before sectioning. A minimum of three sections were taken to compensate for misalignment or staggering of the rays, due to shifting

[23] Aging structures collected for northern pikeminnow have historically (i.e., 2018 to 2023) included whole heads (for laboratory otolith extraction) and scales, consistent with the CEMP (MPMC 2019). In 2024, fish tissue quality samples served to satisfy both CEMP (MPMC 2019) and MPMC Phase 4 EEM (Minnow 2024c) monitoring requirements. As such, scales were the only aging structure collected for northern pikeminnow in 2024 in accordance with the approved MPMC Phase 4 EEM Study Design (Minnow 2024c) to allow for the submission of whole heads with the whole-body northern pikeminnow samples for tissue quality analysis, as stipulated by Environment and Climate Change Canada (ECCC 2024).

[24] Catostomidae (sucker) species are known to have low-quality otoliths for aging, therefore fin rays are the preferred structure with which to derive age estimates.

during the embedding process, or the inherent shape of the structure. The analysis of multiple rays enables age verification and improves the reliability of the age estimate, especially in the case of heavy checking or faint/ thin annuli. The three sections were then submerged in a dish of water under magnification with the ageing surface facing up. Orientation was matched across all three sections to ensure accurate comparison.

Scales from northern pikeminnow were processed for age determination as follows. Scales were isolated, examined for completeness, and placed between two dry standard microscope slides. Between six and twelve scales from each sample were prepared in this manner, then examined under magnification to determine an age estimation by identifying annuli.

For all aging methods (otoliths, pectoral fin rays, or scales), ages were recorded with a corresponding Confidence Index value based on the aging structure condition, annuli assessment, and the likelihood of the age estimate to be reconfirmed by the reader. Scales that were collected as backup structures for age analysis were processed (following the methods outlined above) only if an otolith or pectoral fin was damaged or otoliths were not collected successfully during sample processing. Data reports were provided to Minnow and Mount Polley as an Adobe Acrobat PDF file (methods) and Microsoft Excel spreadsheet (age results; Appendix G).

3.7.3 Data Analysis

Fish catch data were compiled and summarized to provide a catch list for each sampling area and gear type. The catch compilations, along with data on fishing efforts completed in April/May and October 2024, were used to calculate CPUE for each species and sampling area. For hoop netting, gill netting, minnow trapping, and angling efforts, CPUE was expressed as number of fish per day. For angling, CPUE was calculated as the number of fish per angler day. Fish length, weight, and age data were also compiled and summarized by calculating the mean, median, SD, and total range (minimum and maximum) by species and area.

Upon receipt of the fish tissue quality data from ALS and the fish aging data from AAE, a DQR was performed. For the fish tissue quality data, this included the assessment of field precision, laboratory precision, and laboratory accuracy against data quality objectives (DQOs) established at the outset of the project. For the fish aging data, this included the assessment of laboratory precision through evaluation of original and reassessed age estimates. Following the DQR, summary statistics for tissue quality data were calculated for each analyte, species, tissue type (i.e., muscle or whole-body, liver, ovary, and kidney), and area. Summary statistics included the sample size, % of samples less than the LRL, mean, SD, minimum, median, and maximum. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1.

3.7.3.1 Data Screening

Fish muscle and whole-body data were evaluated in comparison to tissue quality guidelines for human health and/or for aquatic ecosystem health (available for mercury and selenium) and the tissue quality of fish collected from reference areas. Tissue quality guidelines included the Canadian Food Inspection Agency/ Health Canada (CFIA) mercury guideline for the protection of human health (0.5 mg/kg ww; CFIA 2015) and the BC selenium guidelines (BCMOE 2014). British Columbia selenium guidelines for the protection of human health for subsistence consumers (7.3 mg/kg dw) and for the general population (14.5 mg/kg dw) were selected as most relevant for evaluation of Polley Lake, Quesnel Lake, and Quesnel River fish tissue quality and applied in data screening. Selenium guidelines for BC also exist for the protection of aquatic life, with guidelines of 4 mg/kg dw in muscle tissue and whole-body samples, and 11 mg/kg dw in egg/ ovary tissues (BCMOE 2014).

Scientific consensus is that the best tissues for evaluating the potential adverse effects of selenium to fish (which are considered the most selenium sensitive organisms) are ripe ovaries or eggs (Luoma and Presser 2009; Janz et al. 2010; Stewart et al. 2010; DeForest et al. 2012; Janz 2012). Therefore, ovary tissues were used as the primary basis for evaluating potential effects of selenium on aquatic life. The BC guideline for selenium in egg/ ovary tissue (11 mg/kg dw) includes a two-fold uncertainty factor that may not be justified given a very steep dose-response curve (DeForest et al. 2012), therefore selenium concentrations in fish ovaries were also compared to the threshold (5th percentile of the distribution of 10th percentile Effect Concentrations [EC10]) for reproductive effects in eggs and ovaries (20 mg/kg dw; DeForest et al. 2012).

3.7.3.2 Statistical Analyses

Statistical analyses of analyte concentrations in fish tissues were conducted using post-breach data (i.e., 2015 to 2024) to answer the following questions:

1. Have mean analyte concentrations at the exposed area changed over time relative to the reference area?
2. Were there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?

To answer these questions, data were grouped into two categories for separate tabular and graphical presentation and statistical analyses:

1. Polley Lake (exposed) compared to reference (Bootjack Lake).

2. Quesnel Lake exposed (near Hazeltine Creek or near Cedar Point) compared to an un-impacted reference (near Grain Creek or East Arm).[25]

Questions 1 and 2 were answered by conducting a two-way ANOVA assessing the relative differences between exposed relative to reference areas, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA was completed as detailed in Section 3.1.3.2 (for Questions 1 and 2) to address the same questions. Similar statistical comparisons were also completed for fish ages, lengths, and weights to answer the question: is there a difference in mean fish length between exposed and reference areas, and does the difference depend on year? The comparisons of lengths, weights and age followed the two-way ANCOVA methods detailed in Section 3.6.5.1 with log10(fork length) as a covariate and data were analyzed as $\log_{10}$-transformed (length and weight) or untransformed (Age) response variables.

When reference area data were not collected concurrently with the exposed area in 2024 or over time (i.e., 2018 to 2024), or when sample sizes were insufficient for a two-way ANOVA approach (i.e., < 2 samples from either the exposed or reference area), statistical comparisons of concentrations of analytes in fish tissues were conducted to answer the following question:

Are there differences in mean analyte concentrations at the exposed area over time?

In 2024, this applied to rainbow trout from Quesnel River (all tissues) for which no reference area exists, and to lake trout from Quesnel Lake (ovary tissue only) for which there were insufficient reference ovary samples collected in 2024 for a two-way ANOVA approach (n = 1). The question was answered by conducting a one-way ANOVA with *Year* as a factor, excluding any years in which there were insufficient samples (i.e., n < 2). Due to the prevalence of analyte results which were below the LRL (i.e., censored data), analyses of tissue analyte concentration data were completed using a censored regression one-way ANOVA fit with MLE and assuming a lognormal distribution. Length, weight, and age data did not contain censored data and thus were analyzed as $\log_{10}$-transformed (length and weight) or untransformed (age) response variables. The MOD between the exposed area in each year relative to the first year of data collection was estimated as:

$$MOD = \frac{MCT_{Year} - MCT_{First\ Year}}{MCT_{First\ Year}} \times 100\%$$

[25] Data for rainbow trout from Quesnel River and lake trout ovary tissues from Quesnel Lake were considered separately since these datasets either do not have an associated reference for comparison (i.e., Quesnel River) or the number of samples collected in 2024 was insufficient for a two-way ANOVA (i.e., Quesnel Lake exposed [near Cedar Point] and reference [East Arm]), and statistical contrasts can be temporal only.

where MCT is calculated as back-transformed marginal means.

R software (R Core Team 2024) was used to conduct all statistical analyses. Censored regressions (i.e., MLE) were completed using the *survreg* function in the survival package (Therneau 2017) in R and contrasts were completed using the methods described in Oehlert (2010). Marginal means were estimated using the *emmeans*() function in R and were used to calculate MODs for the one-way and two-way ANOVA analyses. These estimates of the mean are equivalent to geometric means because the ANOVA analyses were completed on log-transformed concentrations. Consequently, the means used for the MOD calculations were not the same as the K-M mean concentrations reported in Appendix C.7 (see Section 3.8.3.1 for description of the K-M method).

Mercury concentrations were analyzed using units of mg/kg ww, in keeping with the reporting units for mercury guidelines. Mercury analyses were completed using ANCOVA with mean $\log_{10}$(fork length) as a covariate when the covariate was a significant predictor of mercury concentration, since mercury is known to bioaccumulate (i.e., larger fish have higher tissue mercury concentrations; Kidd and Batchelar 2012).

Statistical comparisons were completed for all available analytes; however, data interpretation focused on primary and secondary analytes (see Table 2.4). Plots of data that support the two-way ANOVA were presented for primary and secondary analytes that: 1) had a significant *Area*×*Year* interaction in the analyses and had a positive MOD (i.e., exposed concentrations were significantly higher than reference) for 2024 or negative MOD (i.e., exposed concentrations were significantly lower than reference) for 2024; and 2) lacked a significant *Area*×*Year* interaction in the analyses but had a positive overall MOD (i.e., exposed concentrations were significantly higher than reference and the difference did not depend on year). Plots of data that support the one-way ANOVA were presented for primary and secondary analytes that had a significant *Year* effect. Years with more than 50% of the data reported below the LRL for both the exposed and reference areas (for two-way ANOVAs) or from the exposed area only (for one-way ANOVAs) were excluded from the analyses.

3.8 Supporting Measures

A variety of supporting physical and chemical information was used to support the interpretation of sediment and aquatic biological data collected from lakes as part of the CEMP. This information falls into two categories: 1) supporting information that was collected by Minnow during field collections of sediment, plankton, benthic invertebrates, and fish; and 2) supporting information that was collected routinely by MPMC as part of ongoing CEMP monitoring and provided to Minnow. Unless otherwise specified, the supporting measures outlined below belong to the

first category (measures collected by Minnow). Data analysis approaches for supporting information are also detailed below.

Supporting measures collection and analysis methods specific to 2024 are described herein and are consistent with the CEMP (MPMC 2019). For details pertaining to prior sampling years, refer to the references listed in Tables 3.1 to 3.8.

3.8.1 Supporting Measures

Supporting spot water samples were collected from specific depths using a water sampling device (Beta bottle) in support of data interpretation of the sediment toxicity monitoring. Prior to sediment sampling, spot water samples were collected from just above the sediment water interface (~0.5 m above) at each shallow exposed (QUL LNF; n=5 per area) and reference (QUL LREF1; n=5 per area) sediment sampling station (Figure 3.2) as follows. The sampling bottle was rinsed with site water and then lowered to the desired depth. Once at the appropriate depth, the sampling bottle was moved side to side gently without disturbing the substrate (to ensure a representative sample was collected) prior to tripping the closure mechanism with a steel messenger. Upon retrieval, water samples were collected from a spigot fitted to the bottle. Samples were collected into laboratory provided bottles and preserved immediately (as required). Duplicate (split) water samples were collected at a target frequency of 10% for QA/QC purposes. Water samples were kept on ice in the field and refrigerated until being shipped (on ice) to ALS Environmental (Burnaby, BC). Duplicate (split) depth-integrated water quality samples were collected at a target frequency of 10% for QA/QC purposes.

One depth-integrated water sample was collected at each plankton monitoring area, during each sampling event, to support the interpretation of zooplankton tissue quality results. Samples were collected using a depth-integrated tube sampler (length ~13 m) as described in Section 3.3.1.1. Upon retrieval of the sampler, the water from the tube was emptied into a clean bucket to collect *in situ* measures. Following collection of *in situ* measures, a clean measuring cup was used to fill laboratory provided bottles, which were preserved (as required). Samples were kept on ice in the field and refrigerated until being shipped (on ice) to the analytical laboratory as described above. Duplicate (split) depth-integrated water quality samples were collected at a target frequency of 10% for QA/QC purposes.

In addition to the spot water quality samples collected in 2024 by Minnow, water quality samples were collected routinely by MPMC staff as part of their ongoing water quality monitoring program (MPMC 2019) and were used to support data interpretation (see routine water quality monitoring station locations in Figures 3.1 to 3.3). These data were subjected to an internal DQR by MPMC, including screening of laboratory QA/QC data, sample integrity issues, detection limits achieved,

data accuracy, as well as potential outliers/extreme values. As such their quality was not further assessed in this report. Data were provided to Minnow by MPMC as a Microsoft Excel file.

Additional supporting information collected at each lake monitoring station in 2024 included GPS coordinates, date and time of sampling efforts, sampling depth, *in situ* field meter measurements of temperature, specific conductance, dissolved oxygen, and pH (at mid-column for shallow areas and at surface and bottom for deep areas)[26] and sample photographs (Appendix Tables A.1.1 to A.1.3). For sediment, plankton, and fish monitoring areas, a minimum of one vertical depth profile of *in situ* water quality measures was recorded at one station per area per monitoring event (Appendix Figures A.1.1 to A.1.7), as well as at least one Secchi depth measure. *In situ* water quality measures were collected using a YSI EXO™ handheld portable field meter equipped with a YSI EXO™ sonde which was calibrated at least every second day. Field notes that would aid interpretation were also recorded. For sediment quality and benthic invertebrate sampling these included notes on the presence or absence of aquatic vegetation in sediment and additional physical observations of sediment texture, colour, density, etc. For fish monitoring programs, these included notes on the habitat present (Appendix Tables A.1.4 and A.1.5).

3.8.2 Laboratory Analysis

Upon receipt of water samples, ALS opened the coolers, measured temperature to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique identification code. A SRN was then sent to MPMC and Minnow for verification.

Laboratory analyses included the parameters in the CEMP routine surface water quality monitoring program (MPMC 2019): dissolved organic carbon (DOC), total metals, dissolved metals, anions (nitrate, nitrite, sulphate, chloride, and fluoride), ammonia, total nitrogen, total phosphorus, dissolved phosphorus, orthophosphate, alkalinity, hardness, turbidity, total suspended solids, total dissolved solids, pH, and conductivity. Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow as an Adobe Acrobat PDF file and Microsoft Excel spreadsheet (Appendix G)[27].

[26] Mid-column or surface and bottom *in situ* water quality measures were collected at each monitoring station sediment and benthic invertebrate community sampling stations only.

[27] Data reports for spot water quality sampling are included in Appendix G. Data from routine water quality monitoring completed by MPMC were provided to Minnow in Microsoft Excel format from the MPMC database and these are not included in Appendix G.

3.8.3 Data Analysis

3.8.3.1 Summary Statistics

Summary statistics (means, percentiles, and SDs) were calculated for select chemical parameters using the K-M method (Helsel 2012). Additional information about the application of this summary statistic calculation method (i.e., which monitoring components and analytes this method was applied to) are found within the methods sections for analysis of chemical data above (Sections 3.1.3, 3.4.3, and 3.7.3).

The K-M method (Helsel 2012) involves transforming left-censored data (i.e., data prefaced with a "<" symbol) to right-censored data (i.e., values prefaced with a greater than [>] symbol), and then using the K-M estimator (used to estimate the mean survival time in survival analysis) to estimate the mean. The calculation was completed using the *survfit*() function in the survival package (Therneau 2017) in R software (R Core Team 2024) and involves calculating the area under the K-M survival curve.

The K-M method is non-parametric and can accommodate multiple LRLs. This method of estimating the mean is equivalent to using the distribution of detected values below the maximum LRL to represent values that are <LRL. For example, the mean of the data set {1, 2, <4, 5} is estimated as the mean of 1, 2, [½×1 + ½×2], and 5 which is 2.375. The value <4 is replaced by the distribution of values below 4 (i.e., 1 and 2 with equal weight of ½). Similarly, the mean of the data set {1, 1.6, 2, 2.1, <4, 5} is estimated as the mean of 1, 1.6, 2, 2.1, [¼×1 + ¼×1.6 + ¼×2 + ¼×2.1], and 5 which is 2.229. Again, the value <4 is replaced by the distribution of values below 4 (i.e., 1, 1.6, 2, and 2.1 with equal weight of ¼). If the minimum value in the data set is <LRL, it is replaced with the LRL. Therefore, if there is only one LRL and no detected values <LRL, the K-M estimate of the mean is equivalent to replacing the value <LRL with the LRL (i.e., the best guess for the values <LRL is the LRL). If a SD could not be estimated (e.g., all data <LRL), then one was not reported.

For percentiles, estimates were first calculated using K-M estimator based on survival analyses. The percentiles were calculated using the quantile() function for a survival model generated in the survival package in R software (R Core Team 2024). Estimates of percentiles cannot be generated for highly censored data using the K-M method, and so a second method was used to provide practical estimates of the percentiles. For example, for the data set: <2, <2, <2, <2, 5; the K-M method will not produce an estimate of the median. However, the median value of this data set is clearly <2. The second method of estimating percentiles was used whenever the K-M method could not generate an estimate. This method involved calculating the percentile after

substitution with the LRL, then identifying the value in the dataset equal to this value (or the next detected value in the dataset that is below this value).

Summary statistics for biological endpoints (sediment toxicity, plankton community and productivity, benthic invertebrate community, and fish community and population health; Sections 3.2.3, 3.3.3, 3.5.3, and 3.6.5) were calculated using standard methods and formulae.

3.8.3.2 Water Quality Guideline Screening

Results of spot and routine water quality samples were screened against available approved or working BCWQGs (collectively termed "BCWQGs;" Appendix Table C.1.1; BCMOWLRS 2024, 2025). For guidelines that are dependent on other water quality parameters (e.g., hardness based, pH, temperature), concurrent water quality parameter values were used in their calculation (BCMOWLRS 2024, 2025). If concurrent data were not available, the conservative values were chosen using the historical data for that station (e.g., the minimum hardness recorded for that station was used). If hardness was outside the accepted range, then the bound of that range (either upper or lower) was used to calculate the guideline (BCMOWLRS 2024, 2025). Spot water quality samples collected in 2024 were screened against BCWQG in tabular form. Surficial water quality samples collected by MPMC staff from Polley, Bootjack, and Quesnel Lake routine water quality stations (Figures 3.1 and 3.2) from 2015 to 2024 were screened against BCWQG in plots of total and dissolved concentrations of primary and secondary analytes (Table 2.4). In addition, temperature and nutrient results (total phosphorus, dissolved phosphorus, orthophosphate, total nitrogen, and nitrate) were plotted for Polley, Bootjack, and Quesnel Lake routine water quality stations (Figures 3.1 and 3.2) to help support the interpretation of plankton community results. Tabular and graphical screening against BCWQG was completed using R (R Core Team 2024).

3.8.3.3 Biotic Ligand Model-derived BCWQG

The BCWQG Biotic Ligand Model (BLM) guideline lookup tables were used to calculate acute (short-term) and chronic (long-term) guidelines for dissolved copper and nickel (BCMOWLRS 2025). This was used to support interpretation of zooplankton tissue quality by evaluating surface waters of Polley Lake and Quesnel Lake.

The BLM integrates exposure and toxicity modifying factors that are known to modify copper and nickel bioavailability. Using this approach, the BLM defines concentrations below which chronic adverse effects would not be expected under the specific water quality that co-occurs with the copper or nickel concentration. Specifically, the BCWQG BLM guideline lookup tables produce acute and chronic guidelines based on the three required modifying water chemistry inputs for

dissolved copper (pH, DOC, and hardness) and four water chemistry inputs (pH, DOC, hardness and temperature) for dissolved nickel (BCMOWLRS 2025).

If required input parameters for the BCWQG BLM were missing for a data set, these data were replaced to increase the sample size, when possible. This was done using professional judgement to replace the missing data as closely as possible or by using a conservative replacement value. Data missing for the parameters pH, and DOC were replaced by substituting the mean value from sampling events conducted in close temporal proximity to the missing data or using the most conservative values (e.g., using the minimum value collected at a station).

3.8.3.4 Water Quality Trends

Temporal trends in surface water quality data were evaluated to support interpretation of chemical monitoring components. Specifically, surface water quality data collected routinely by MPMC post-breach (i.e., 2015[28] to 2024) in Polley Lake and Quesnel Lake were evaluated to support the interpretation of zooplankton tissue quality from these areas (refer to Section 3.4.3). This evaluation was completed using the Seasonal Kendall test detailed below and included evaluation of aqueous total and dissolved concentrations of primary and secondary analytes (Table 2.4), and acute and chronic Guideline Exceedance Factors (GEFs) for copper (the ratio of observed dissolved copper concentrations divided by BCWQG BLM-derived guidelines).

The non-parametric Seasonal Kendall test described by Hirsch et al. (1982) was used to evaluate temporal trends in surface water quality data from the north and south basins of Polley Lake (P1 and P2, respectively) and from three stations in Quesnel Lake (QUL-18 and QUL-2a [exposed], and QUL-120a [reference]; Figures 3.1 to 3.3). The Seasonal Kendall test assesses temporal trends separately for each season (or month in this case, for routine water quality samples collected throughout the year) and combines the results for each season into an overall test for trend. The test is non-parametric and assesses whether there is a monotonic increasing or monotonic decreasing trend over time. The test is conducted by calculating the test statistic S_i which is equal to the sum of the number of increases and decreases from a time period t_i to all time periods after t for each observation in season i. The overall test statistic S is computed as the sum of S_i for all seasons. The significance of the observed S is determined by comparing it

[28] Routine water quality data prior to 2015 are available for Polley Lake, Bootjack Lake, and Quesnel Lake but were excluded from plots and statistical analyses to distinguish between short-term effects from potential long-term effects of the breach on water quality trends analysis in these waterbodies. The exclusion of data prior to January 2015 was based on the rationale explained in Minnow (2019a). Briefly, laboratory turbidity data resulting from the suspension of fine particulate matter immediately after the breach were used to qualitatively identify a “breach” period (i.e., a period characterized by short-term effects on water quality). By late 2014, laboratory turbidity had decreased to values more similar to pre- breach. Based on these results, the 'breach” period was defined as beginning on August 4, 2014, and ending in December 2014. Therefore, use of data starting in January 2015 should be effective in excluding short-term breach effects on water quality.

to a critical value of S (at the significance level α = 0.05) determined from the exact sampling distribution of S (calculated by determining all possible permutations and combinations of S based on the increases and decreases from the number of pairwise comparisons made; Hirsch et al. 1982). If more than 45 pairwise comparisons are made (equivalent to the number of pairwise comparisons for n = 10 in a single season), then the normal approximation is used to calculate a p-value and to assess significance (Hirsch et al. 1982). The standard normal deviate Z is calculated as:

$$Z = \begin{cases} \frac{S-1}{\sqrt{\sigma_S}} if\ S > 0 \\ 0 \quad if\ S = 0 \\ \frac{S+1}{\sqrt{\sigma_S}} if\ S < 0 \end{cases}$$

where $\sigma_S = \sum_{i=1}^{k} \frac{n_i(n_i-1)(2n_i+5)-\sum_{T_i} t_i(t_i-1)(2t_i+5)}{18}$ and n_i is the number of samples in month i, t_i is the number of tied values for each tied value T_i, and k is the number of seasons (Hirsch et al. 1982).

An estimate of the trend slope over time was calculated by computing the median of all slopes between data pairs within the same month (Helsel and Hirsch 2002). The slope was reported as a change in concentration per year and as a percentage change in concentration per year. The intercept of a line through the time series was estimated as the median intercept of all lines through each point with the estimated slope (Pohlert 2016). The trend analysis was only conducted with a minimum number of five pairwise comparisons, the minimum number required for all consecutive increases or decreases to be significant at α = 0.05.

4 METHODS – CREEK HABITAT

4.1 Sediment Quality

Sediment quality monitoring was completed at exposed areas of Hazeltine Creek (and associated reference areas) annually between 2022 and 2024, in accordance with the CEMP (MPMC 2019). Post-breach sediment quality monitoring was initiated in Hazeltine Creek in 2014, then completed annually from 2018 to 2024 in accordance with the CEMP (MPMC 2019; Table 4.1). Since 2018, annual sediment quality monitoring in creek habitats has included areas of upper (HAC-U [HAC-R2]) and lower (HAC-D [HAC-R5]) Hazeltine Creek, with areas of upper and lower Edney Creek serving as reference (EDC-U and EDC-D [EDC-REF], respectively; Figure 4.1, Table 4.1)[29]. Channel remediation works in the vicinity of HAC-U (HAC-R2) and HAC-D (HAC-R5) were completed in 2017 and 2021, respectively.

Sample collection and analysis methods for 2024 are described herein and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, including equivalent historical sampling areas, refer to the references listed in Table 4.1.

4.1.1 Sample Collection

Sediment samples were collected from Hazeltine Creek and Edney Creek (upper and lower areas) from August 8 to 13, 2024. Five replicate stations were sampled to represent each monitoring area (Figure 4.1, Table 4.1; Appendix Table A.2.1). One composite sediment sample was collected at each replicate station.

Hazeltine Creek has historically been predominantly erosional with limited locations of true sediment deposition (HKP 1996, 1997a; Minnow 2007). As conditions in Hazeltine Creek stabilize following remediation works, sediment accumulation has occurred in upper and lower Hazeltine Creek areas and continues to occur. The flow of water in Hazeltine Creek has been modified from 2018 to 2024 by controlling the discharge of water to the creek from Polley Lake (using a weir), and by pumping water from below the thermocline in Polley Lake into the creek for the specific purpose of maintaining conditions that support the use of upper Hazeltine Creek as fish habitat. As such, sediment deposition in Hazeltine Creek differs from that in Edney Creek (i.e., reference), with thicker deposition of fines in pool areas of Hazeltine Creek than occurs in Edney Creek. Within Edney Creek, which is subject to a natural flow regime, the limited sediments tend to wash through during spring freshet and deposit as a thin layer of fines in quiescent areas on the lowering hydrograph (i.e., non-uniform sediment deposition). Due to this non-uniform

[29] HAC-R2, HAC-R5, and EDC-REF are the alternate names used for the HAC-U, HAC-D, and EDC-D sampling areas, respectively, for HRWG reporting (Minnow 2025).

Table 4.1: Overview of Sediment Quality Monitoring in Creeks in the Vicinity of the Mount Polley Mine, 1995 to 2024[a]

Waterbody		Area Type	Area Code[b]	Baseline			Pre-Breach					Post-Breach								
				1995 (HKP 1996)	1996 (HKP 1997a)	1999 (Beak 2000)	2007 (Minnow 2009)	2009 (Minnow 2011)	2010 (Minnow 2011)	2012 (Minnow 2013a)	2013 (Minnow 2013b)	2014 (Minnow 2015a)	2015 (Minnow 2015b)	2018 (Minnow 2019a)	2019 (Minnow 2020a)	2020 (Minnow 2021a)	2021 (Minnow 2022a)	2022 (Minnow 2023a)	2023 (Minnow 2024a)	2024

Sediment quality samples collected in 1996 had unusually high concentrations for some parameters. Values are suspect and were not used in data analyses, presentation, or interpretation.

Notes: "-" = not sampled/not applicable. Sediment Quality analyses included: metals and Total Organic Carbon (TOC) in <63 µm fraction, moisture, particle size, pH, total nitrogen, and total sulphur, for sampling completed between 2014 and 2024 (post-breach).

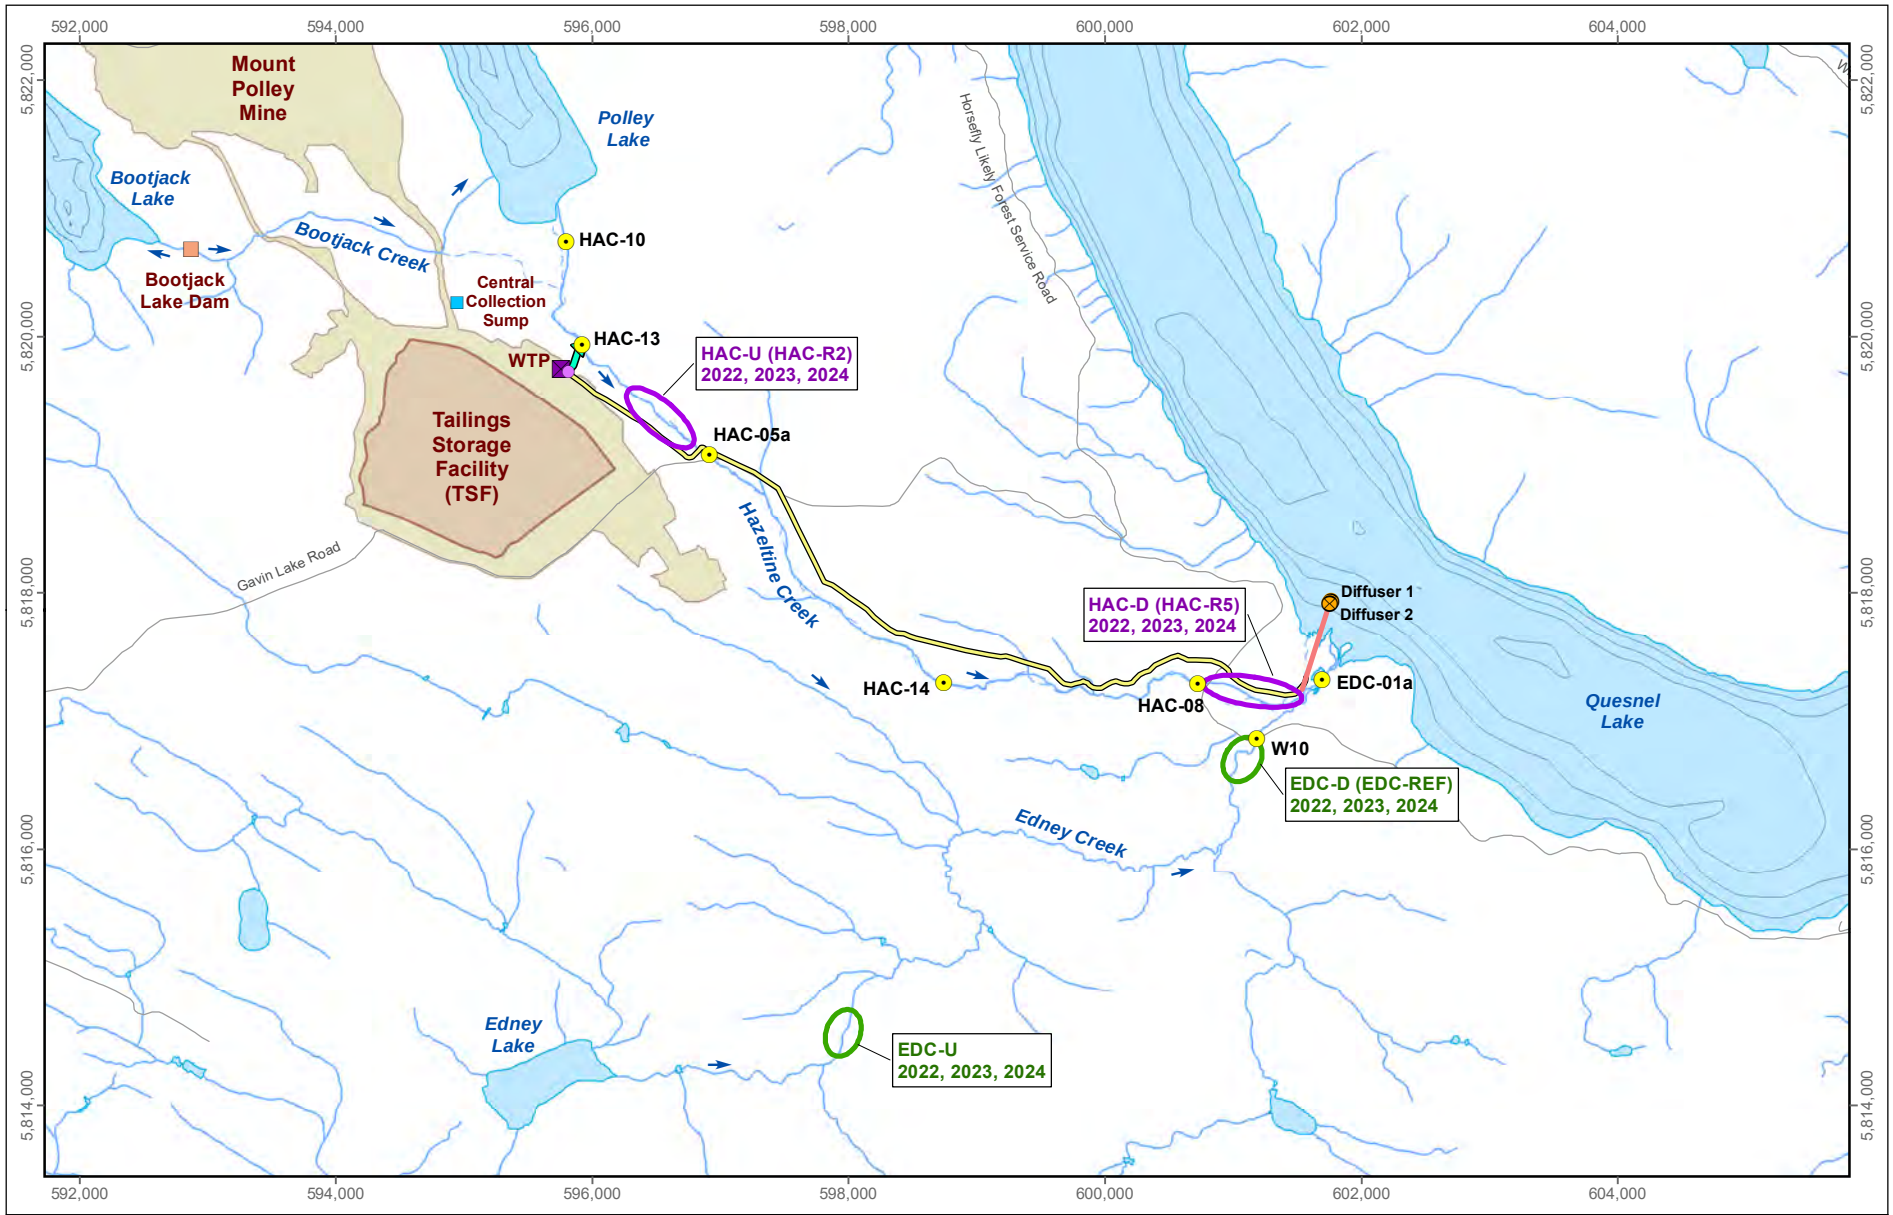
[a] Numbers indicate the number of stations sampled per area. Where multiple areas were sampled in a given year, the area is identified in parentheses after the number of stations. Only sampling areas that were monitored between 2022 and 2024 are displayed, as well as historical data for these areas.

[b] Alternate area identifiers used for HRWG reporting are noted, where applicable.

[c] Eight samples were collected in separate spring and fall sampling events.

[d] Selenium was the only parameter reported.

[e] Sediment quality data for EDC-D in 2015 were not used in the calculation of post-breach summary statistics in Minnow (2015b). See Minnow (2019a) for presentation of raw data.



Sediment Quality Monitoring Areas, Hazeltine and Edney Creeks, 2022 to 2024

Date: March 2025
Project 247202.0004

Figure 4.1

Document Path: C:\Users\MLaPalme\Trinity Consultants, Inc\Imperial Metals - 247202.0004 - 2024 MPMC\D - GIS\1-2024 CEMP\Task 6\24-04 Figure 4.1 Sediment Creeks.mxd

nature of sediment deposition, wetted locations that support some accumulation of fine materials (i.e., pools, backwaters, or interstices between boulders) were selected opportunistically for sample collection in Edney Creek. Collection of true sediment (i.e., fines in the silt and clay size category) could not be completed by conventional grab sampling in all areas (particularly the Edney Creek reference areas) due to the dominant presence of sand, gravel, and cobble in some of the areas. Therefore, sediment fines were therefore targeted at all areas using a clean stainless-steel spoon.

At each sampling station selected, the location was approached by foot in a manner that did not disturb the sediment prior to sampling. Surficial sediment was then collected carefully by slowly inserting the spoon into the sediment (to minimize disturbance), with collection targeting up to 3 cm.[30] The spoon was then moved horizontally until full, and slowly retrieved to the surface to avoid sample washout.

The contents of each spoonful were inspected to ensure that it was predominantly fine sediment (i.e., silt and clay), and, if acceptable, was placed into two or more pre-labelled 250 mL glass sampling jars. This procedure was repeated approximately >20 times at each station to form a composite sample representative of the sampling station and to collect sufficient sample material for analysis. Sampling equipment was rinsed between all stations using site water. Duplicate sediment samples were collected at a target frequency of 10% for QA/QC purposes. Samples were kept on ice in the field then stored in a refrigerator until shipment (on ice) to the analytical laboratory. Supporting information was collected at each sampling station to support data interpretation (see Section 4.6.1 for details).

4.1.2 Laboratory Analysis

Laboratory analysis of sediment quality samples from creek habitats was completed by ALS Environmental (Burnaby, BC) using the same methods and QA/QC measures described for sediment quality samples from lakes (Section 3.1.2).

4.1.3 Data Analysis

4.1.3.1 Data Screening and Analytes of Interests

Upon receipt of the analytical data, a DQR was completed, including an examination of data completeness, LRLs achieved, laboratory precision, laboratory accuracy, and field precision. Following completion of the DQR, raw data were summarized by area by calculating mean,

[30] Collection depth was often less than 3 cm, as fines often settle in a thin layer over coarser material (and sampling seeks to avoid coarse material).

median, SD, minimum, and maximum. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1.

Sediment quality data were evaluated relative to BCWSQG (BCMOWLRS 2024, 2025) and relative to reference and pre-breach 95th percentile concentrations (as described for lake sediment quality samples in Section 3.1.3.1). Guidelines and pre-breach and reference values were used in a two-way screening to identify analytes at exposed areas with mean concentrations that exceeded BCWSQG as well as reference and pre-breach 95th percentile values. Reference and pre-breach data used for screening values were compiled and calculated separately. Reference data included all available post-breach results from Edney Creek (excluding data from 2015), and pre-breach data included all results from Hazeltine Creek prior to 2014 (excluding data from 1996; Table 4.1). The reference and pre-breach data used in the calculation of the 95th percentiles and used in data screening are presented in Appendix Tables D.1 to D.5.

The screening of sediment quality data against BCWSQG and reference and pre-breach 95th percentile values included all analytes (including primary and secondary analytes; as described in Section 3.1.3.1). Analytes at exposed areas with mean concentrations that exceeded all the following criteria were termed “Analytes of Interest”: 1) the BCWSQG, 2) the associated reference 95th percentile value, and 3) the associated pre-breach 95th percentile value. Analytes of Interest were determined separately for each monitoring area (i.e., separately for upper [HAC-U] and lower [HAC-D] areas of Hazeltine Creek). Concentrations of the Analytes of Interest, along with TOC, were the focus of more detailed interpretation which included graphical plots, formal statistical contrasts of temporal changes in concentrations, and examination of relationships to physical and chemical sediment variables.

4.1.3.2 Statistical Analyses

Statistical analyses of Analyte of Interest concentrations and TOC content of creek sediments were conducted using post-breach data from 2018 to 2024 to answer the following questions:

1. Have mean analyte concentrations at the exposed area changed relative to the reference area?
2. Were there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?
3. Have mean analyte concentrations at the exposed area changed over time since the breach?

To answer these questions, data were grouped into two categories for separate tabular and graphical presentation and statistical analyses:

1. Upper Hazeltine Creek (HAC-U [HAC-R2]) compared to an upper creek reference area (Upper Edney Creek; EDC-U).
2. Lower Hazeltine Creek (HAC-D [HAC-R5]) compared to a lower creek reference area (Lower Edney Creek; EDC-D [EDC-REF]).

Questions 1 to 3 were answered by using the same statistical approach (i.e., two-way ANOVA with *Area* and *Year* as factors) described for lake sediments in Section 3.1.3.2. Sediment concentrations from 2014 were excluded from temporal comparisons because this sediment represented freshly deposited breach-material that was removed during remediation efforts in 2015.

Analytes of Interest concentrations and TOC content were plotted to support the two-way ANOVA results and included comparison to BCWSQG and reference and pre-breach 95th percentile values.

Relationships between the Analytes of Interest concentrations and physical variables (particle size) and other chemical variables (TOC, total nitrogen, and total sulphur content) were evaluated using Spearman's rank correlation analysis described for lake sediment (Section 3.1.3.2). Correlation analysis was completed using data from 2018 to 2024 combined from upper and lower areas of Hazeltine and Edney Creeks. In these correlations, differing relationships were apparent for the exposed areas relative to reference. As such, correlations were run separately for two groups of data: 1) the paired exposed and reference areas combined (i.e., HAC-U [HAC-R2], EDC-U, HAC-D [HAC-R5], and EDC-D [EDC-REF]); 2) exposed areas only (i.e., HAC-U and HAC-D). All sediment statistical analyses and plots were completed using R (R Core Team 2024).

4.2 Periphyton Community and Productivity

Periphyton community and productivity monitoring was completed at exposed areas of Hazeltine Creek (and associated reference areas) between 2022 and 2024, in accordance with the CEMP (MPMC 2019). Post-breach periphyton community and productivity monitoring were initiated in 2017 in upper and lower areas of Hazeltine Creek (and associated reference areas; Table 4.2). Since 2018, periphyton community monitoring has been completed annually at two exposed areas of upper Hazeltine Creek areas (HAC-R1 and HAC-U [HAC-R2]) with an area of upper Edney Creek (EDC-U) serving as reference (Figures 4.2 and 4.3, Table 4.2)[31], in accordance with the CEMP (MPMC 2019). In accordance with the CEMP (MPMC 2019),

[31] HAC-R2 is the alternate name used for the HAC-U sampling area for HRWG reporting (Minnow 2025).

Periphyton and Benthic Invertebrate Monitoring Areas, Frypan Creek, 2022 to 2024[a]

Date: March 2025
Project 247202.0004

minnow environmental inc.

Figure 4.3

Document Path: C:\Users\MLaPalme\Trinity Consultants, Inc\Imperial Metals - 247202.0004 - 2024 MPMC\D - GIS\1-2024 CEMP\Task 6\24-04 Figure 4.3 Periphyton and BI, Frypan Creek.mxd

periphyton productivity monitoring has also been completed annually since 2018 at the upper Hazeltine Creek areas (HAC-R1 and HAC-U [HAC-R2]), the upper Edney Creek reference area (EDC-U) and at a reference area in Frypan Creek (FPC-R3). Although not a requirement of the CEMP (MPMC 2019), periphyton productivity monitoring was initiated at an additional exposed area of upper Hazeltine Creek (HAC-R3) in 2020 and has been completed annually since then. The upper reference areas EDC-U and FPC-R3 serve as the reference areas for HAC-R3 (Table 4.2). In lower creek areas, periphyton community and productivity monitoring has been completed biennially since 2019 in accordance with the CEMP (MPMC 2019). This biennial monitoring has been completed at an exposed area of lower Hazeltine Creek (HAC-D [HAC-R5]) and an exposed area of lower Edney Creek (E1), with an unimpacted area of lower Edney Creek (EDC-D [EDC-REF]) serving as reference for both exposed lower creek areas (Figure 4.2, Table 4.2).[32] Monitoring at these lower creek areas was last completed in 2023 (Table 4.2).

In addition to satisfying CEMP (MPMC 2019) monitoring requirements, periphyton productivity monitoring in Hazeltine Creek (and associated reference areas) serves to support the evaluation of fish habitat in upper Hazeltine Creek as part of HRWG monitoring objectives (e.g., Minnow 2025). Supporting the evaluation of fish habitat is the sole purpose of the annual periphyton productivity monitoring completed at areas HAC-R3 and FPC-R3 since 2020 and 2018, respectively. As such, previous CEMP Sediment and Aquatic Life reports (e.g., Minnow 2024a) have presented periphyton productivity data from HAC-R3 and FPC-R3 in tabular form only, with analyses and interpretation of data from these two areas presented in a separate report focused on the assessment of fish habitat in Hazeltine Creek (i.e., HRWG report; Minnow 2024b). In the present report, periphyton productivity results from both HAC-R3 and FPC-R3 from all years of monitoring have been incorporated throughout data tabulation, analyses, and interpretation for the purposes of improving reporting clarity and efficiency.

Channel remediation works at HAC-R1, HAC-U (HAC-R2), and HAC-R3 were completed in 2016, 2017, and 2019, respectively. Channel remediation works in the vicinity of HAC-D (HAC-R5) and E1 were initiated in 2015 and completed in 2021. Initial remediation works in the breach-impacted areas of lower Hazeltine and Edney creeks (i.e., near HAC-D [HAC-R5] and E1) included reconstruction of the two creeks as separate watercourses in 2015. Edney Creek conflowed with Hazeltine prior to the breach, and remediation works undertaken in summer 2020 rejoined the two waterbodies. Further remediation works were completed in August 2021 and encompassed the entirety of the established HAC-D (HAC-R5) monitoring area (Minnow 2022a).

[32] HAC-R5 and EDC-REF are the alternate names used for the HAC-D and EDC-D sampling areas, respectively, for HRWG reporting (Minnow 2025).

In 2021, HAC-D (HAC-R5) monitoring stations were therefore relocated as far upstream in lower Hazeltine Creek as possible (Minnow 2022a).[33] Final remediation works in lower Edney Creek were also completed in August 2021 but were undertaken after the 2021 biological sampling had been completed (Minnow 2022a). Given the rejoining of lower Edney and Hazeltine creeks in 2020, the E1 monitoring area was relocated in 2021 to upstream of the confluence of the two creeks (Figure 4.2) to ensure that stations were not influenced by Hazeltine Creek.[34] The HAC-D (HAC-R5) and E1 monitoring areas sampled in 2023 were consistent with those established in 2021 following the completion of final remediation works in these areas.

Sample collection and analysis methods for 2024 are described herein and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, including equivalent historical sampling areas, refer to the references listed in Table 4.2.

4.2.1 Sample Collection

Periphyton samples for the assessment of community and productivity (chlorophyll-a and ash free dry mass [AFDM]) were collected between August 11 and August 15, 2024. Five stations were sampled in each area (Figures 4.2 and 4.3, Table 4.2), and one chlorophyll-a and one AFDM sample were collected at each replicate station. Periphyton sampling stations were established at a minimum distance of approximately three bankfull widths from adjacent stations and coincided with those for benthic invertebrate community monitoring. Sampling was completed at each station by selecting five representative submerged rocks (excluding those that were too small, highly angular, or uncharacteristic in surface texture). Selected rocks were taken to shore for processing as described below for productivity and community sample collection (Sections 4.2.1.1 and 4.2.1.2, respectively).

A concerted effort was made to ensure that habitat characteristics (water depth, velocity, and substrate characteristics) were comparable among sampling stations and areas to minimize natural influences on the variability of productivity and community endpoints. As outlined in Section 4.1.1, the discharge of water in Hazeltine Creek from 2018 to 2024 was modified by controlling the discharge of water to the creek from Polley Lake (using a weir), and by pumping water from below the thermocline in Polley Lake into the creek to decrease water temperatures

[33] HAC-D monitoring stations were relocated in 2021 with the intention of completing sampling in areas that had been allowed some recovery following the completion of remediation works weeks prior to monitoring. Specifically, stations were relocated upstream into areas with noticeably greater periphyton coverage (indicative of some established biological growth) relative to areas further downstream that were either actively undergoing remediation during biological sampling or where remediation had been completed within days prior to biological sampling efforts (and therefore had lower periphyton coverage; Minnow 2022a).

[34] The monitoring area E1 sampled up to and including 2019 was located downstream of the future confluence of Hazeltine and Edney Creeks (Minnow 2022a).

in the creek. This supplemental pumping increased water depth and velocity in Hazeltine Creek relative to natural conditions which made matching habitat conditions between the exposed (Hazeltine Creek) and reference (Edney Creek and Frypan Creek) areas particularly challenging. Despite these challenges, exposed and reference sampling locations were matched for habitat as closely as possible in 2024. The flow augmentation to Hazeltine Creek also presented challenges for matching exposed and reference area conditions in previous years of monitoring (2018 to 2023; Table 4.2).

Supporting measures were collected at each periphyton sampling station to support data interpretation. Refer to Section 4.6.1 for additional details about supporting measures.

4.2.1.1 Productivity

Periphyton samples were collected for chlorophyll-a analysis using methods consistent with technical guidance (BCMOE 2013, 2016) and the CEMP (MPMC 2019). Briefly, samples were collected at each station by firmly placing a thin acetate template with a 2x2 cm (4 cm²) opening in the middle of each selected rock and scraping off the periphyton within this area using a stainless steel razor blade or scalpel. This was completed for the five rocks selected at each sampling station. Sample material scraped from each of the five rocks was then transferred from the razor blade or scalpel to a large MCE filter paper (filter diameter 47 mm, pore diameter 0.45 µm) until a single composite sample was obtained per station. The total area scraped at each station was recorded (0.002 m²: 4 cm² x 5 rocks) to allow calculation of chlorophyll-a concentration per-unit area for comparison to the BCWQG (100 mg/m²; BCMOWLRS 2025). The filter paper was then folded and placed into a pre-labeled opaque centrifuge tube. This process was repeated for each of the five stations per monitoring area.

The same five rocks sampled for chlorophyll-a analysis were used to collect separate scrapings for analysis of AFDM. Sampling methods for AFDM followed those outlined above for chlorophyll-a (0.002 m² per station); however, material on the razor blade or scalpel from scraping of each rock was rinsed into a pre-labelled plastic scintillation vial with site water added to cover the tissue (as necessary).

Immediately after collection, all chlorophyll-a and AFDM samples were stored in a cooler with ice packs until being frozen prior to shipment (on ice) to the analytical laboratory.

4.2.1.2 Community

Periphyton community samples were collected from the same five rocks used for productivity sampling whenever possible, or from rocks of a similar size collected from the same general location and habitat (i.e., depth and velocity). Sample collection methods were similar to those outlined for AFDM (Section 4.2.1.1). Periphyton was collected from a 2x2 cm (4 cm²) area on five

rocks at each station to form a single composite sample representing 0.002 m² surface area (4 cm² x 5 rocks). The periphyton was removed from each rock using a razor blade or scalpel, then rinsed into a pre-labelled plastic scintillation vial using site water, with additional site water (as necessary) to ensure the sample was fully immersed. (BCMOE 2013, 2016; Stevenson and Bahls 2006). This process was repeated for each of the five stations per monitoring area. Immediately after collection, the sample was preserved with Lugol's iodine solution until the sample was the colour of weak tea (approximately 1 mL of Lugol's per 250 mL of sample; BCMOE 2013, 2016) and was mixed gently by inverting the sampling jar. All periphyton community samples were stored at room temperature prior to shipment to the laboratory for taxonomic analyses.

4.2.2 Laboratory Analysis

4.2.2.1 Productivity

Laboratory analysis of periphyton productivity (chlorophyll-a and AFDM) was completed by ALS Environmental (Burnaby, BC). Upon receipt, laboratory staff opened the coolers, measured temperature to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique sample identification code. A SRN was then sent to MPMC and Minnow for verification.

Analysis of chlorophyll-a followed procedures outlined in Section 3.3.2.1.2. Determination of total AFDM followed procedures adapted from American Public Health Association (APHA) Method 10200 I (APHA 2010). Total AFDM was calculated as the difference between the dried sample weight and the ash weight, both determined gravimetrically. Dry weight was determined following drying at 105°C. The remaining sample was subsequently ignited at 500°C, rewetted to hydrate clays and minerals and brought to a constant weight at 104°C to determine ash weight.

Laboratory QA/QC included reagent blanks and laboratory control samples. Upon completion of the analyses, data reports were provided by ALS Environmental to MPMC and Minnow electronically as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G).

4.2.2.2 Community

Taxonomic identification and enumeration of periphyton community samples was completed by Biologica in Victoria, BC. Briefly, sample volumes were standardized by adding distilled water. Samples were then homogenized by sonication, settled in Ütermohl chambers for three hours, and all cells within randomly selected FOV were enumerated until a minimum count of 300 algal units (1 unit = >1 cell for colonial or filamentous taxa) were enumerated or until 80 FOV were scanned. Cell units were enumerated rather than individual cells, due to colonial/filamentous algae species containing hundreds of cells per unit. Identification was

performed using an inverted phase contrast microscope at 400x magnification, and algal taxa were identified to a minimum of genus-level (whenever possible) according to the most up-to-date taxonomic references (see laboratory methods description in Appendix G). Periphyton density (cells/cm^2) was determined using the number of units counted, number of cells per unit, proportion sub-sampled, and the total area of the selected FOV.

Laboratory QA/QC included a re-analysis of at least 10% of samples and a calculation of percent agreement among results. Upon completion of the analyses, the data and quality control reports were provided by Biologica to MPMC and Minnow electronically as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G).

4.2.3 Data Analysis

Upon receipt of the 2024 analytical data, a DQR was performed, including assessments of laboratory internal quality control checks, data completeness, calculations and unit conversions, and laboratory precision. Following completion of the DQR for the periphyton productivity endpoints, productivity results were analyzed as described below. In 2021, the DQR of periphyton community resulted in a request for an investigation of the data by the laboratory that ultimately led to the reissuing of periphyton cell density data from 2018 to 2021 (see Minnow 2022a for details). Once the quality of the 2024 periphyton community data were confirmed through the DQR process, periphyton community results were analyzed as described below, with the corrected periphyton community results from 2018 to 2021 used for all analyses (Minnow 2022a).

4.2.3.1 Metrics

The periphyton community was evaluated using the metrics of organism density (cells/cm^2), taxon richness (No. of taxa), Simpson's Evenness and Diversity, diatom richness, and the relative densities (%) and densities (cells/cm^2) of dominant taxa groups. These metrics were calculated using LPL taxonomy as outlined in Section 3.3.3.1.1. Taxonomic groups evaluated included one or more of the following major ecological groups (based on the presence of these taxa at each sampling area): Diatoms, Chlorophytes (green algae), Chrysophytes (golden algae), Cyanobacteria (blue-green algae), Dinoflagellates, Phaeophytes (brown algae), and Rhodophytes (red algae)[35].

[35] Periphyton data were classified as "Other" taxa in laboratory results issued in 2018 and although the taxonomic groups contained in this category were unknown (i.e., unknown taxonomic identification of these organisms), they were suspected to include Phaeophytes, Chrysophytes, and Rhodophytes. Temporal statistical contrasts therefore excluded 2018 data for these taxa (Phaeophytes, Chrysophytes, and Rhodophytes) which were reported as absent from all samples in 2018 data. See Minnow 2019a for detailed laboratory results for 2018. Data reported in 2018 for this "Other" category was therefore excluded from data presentation and analyses in the present report. Periphyton taxonomy results have not been reported in an "Other" category by the laboratory since 2018.

Periphyton productivity was evaluated using chlorophyll-a and AFDM data, which were converted to standard area-based measurements (mg/m^2 and g/m^2, respectively). Chlorophyll-a measurements were compared to water quality guidelines for eutrophic conditions (BCWQG = 100 mg/m^2; BCMOWLRS 2025) and a classification for moderately enriched streams (21 mg/m^2; Biggs 1996). Periphyton and community endpoints were summarized by area and year, including sample size, mean, median, minimum, maximum, and SD.

Total richness, diatom richness, Simpson's Evenness, and Diversity were calculated under the assumption that each taxonomic group identified by the lab was unique. As a result, richness values reported herein differ slightly from those reported directly by the laboratory (see Appendix G), which only considers taxa that are certainly unique. For example, for the purposes of this report, the taxa Pennate Diatoms and *Diatoma* species were considered as two separate taxa, whereas the richness calculations completed by the laboratory were considered as one taxon. Although this approach may slightly overestimate richness, this is consistent across data sets.

Evaluation of the periphyton community and productivity included comparison to baseline and pre-breach samples collected at the same areas as post-breach samples, where possible. However, the comparability of 2018 to 2024 periphyton community data with historical (1995, 1996, and 2011) datasets is limited due to differences in taxonomic practices and sampling effort across these years. Specifically, the use of multiple taxonomic laboratories since 1995 may have resulted in problems related to misidentifications and/or the use of multiple naming conventions for a single taxon (see Minnow 2019a for details). Furthermore, the taxonomic resolution of historic data was lower than 2018 to 2024 taxonomic analysis, limiting the potential for comparison. The periphyton community data from 2018 to 2024 has greater taxonomic resolution and is considerably more reliable than the historic datasets. The use of varying degrees of qualitative taxonomic analysis (categorizing the degree to which taxa were present as opposed to enumerating them) in 1995 (HKP 1996), 1996 (HKP 1997a), and 2011 (Minnow 2012), substantially limited comparisons that could be made with these data.[36] Due to these data limitations, periphyton metrics for baseline (1995 and 1996) and pre-breach (2011) data excluded Simpson's Evenness and Diversity, and excluded baseline results (but included

[36] Periphyton taxonomy data from 1995, 1996, and 2011 were qualitative, mostly consisting of characterization of presence/absence ("predominant", "common", "abundant," etc.) as opposed to discrete density values. In 1995 and 1996, proportions were reported for some dominant genera and groupings, however the degree to which those data represent quantitative data is unknown without density data. Even in 2011, when data were presented as density, many taxa were presented with "less than" values because the methodology employed by the taxonomist (Fraser Environmental Services) involved some qualitative elements.

pre-breach results) for density based metrics. Statistical comparisons that included baseline and pre-breach data were limited to chlorophyll-a results only.

4.2.3.2 Statistical Analyses

Statistical comparisons of periphyton community and productivity metrics were conducted using baseline (1995, 1996) and pre-breach (2011) data (for chlorophyll-a only) and post-breach data (i.e., 2017 to 2024) to answer the following questions:

1. Were there differences in periphyton community and productivity between exposed and reference areas in 2024?
2. Have the periphyton community and productivity of exposed areas changed among years relative to changes at the reference area over this time, and where pre-breach data exist, has the community recovered to pre-breach conditions?

To answer these questions for community endpoints, results from upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]) were compared to reference (EDC-U). For productivity endpoints, results from upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], and HAC-R3) were each compared to two reference areas (EDC-U and FPC-R3) and to pre-breach results for upper Hazeltine Creek (W7; 1995, 1996, 2011, for chlorophyll-a only). Comparisons for periphyton community and productivity included calculation of community metrics, tabular and graphical presentation, and statistical analyses.

Statistical comparisons of community endpoints and AFDM were completed using two-way ANOVAs with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year*. The analyses were completed using the two-way ANOVA methods and pairwise contrasts described in Section 3.3.3.1.2 with exposed and reference post-breach data from the creeks (2018 to 2024 for community endpoints; 2017 to 2024 for AFDM).

Statistical comparisons of chlorophyll-a were completed using a two-way ANOVA with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year* (as described in Section 3.3.3.1.2), and included baseline, pre-breach, and post-breach (exposed and reference) chlorophyll-a data. Specifically, periphyton chlorophyll-a results from post-breach monitoring (i.e., 2017 to 2024) were compared to baseline data from 1995 (HKP 1996) and 1996 (HKP 1997a), and pre-breach data from 2011 (Minnow 2012) where possible (see Table 4.2). In addition, baseline data (1995 and 1996) were compared between upper Hazeltine (W7) and upper Edney (W9) creeks to evaluate the baseline condition in these areas. Pre-breach data from upper Hazeltine Creek (W7; 2011) were treated as a separate area from HAC-R1, HAC-U (HAC-R2), and HAC-R3 in the two-way ANOVA of chlorophyll-a because baseline and pre-breach data from W7 (2011) were used in comparison to each of the HAC-R1, HAC-U (HAC-R2),

and HAC-R3 areas. The pairwise contrasts for chlorophyll-a differed from those described in Section 3.3.3.1.2. If the *Area* term was significant for the ANOVA, temporal pairwise contrasts were completed among the areas (FPC-R3, EDC-U, W9, W7, HAC-R1, HAC-U [HAC-R2], and HAC-R3; as though a significant interaction had been detected) due to the inherent temporal contrasts of the *Area* term (i.e., baseline and prebreach data for W7 compared to post breach data for HAC-R1, HAC-U [HAC-R2], and HAC-R3). Results of the contrasts of chlorophyll-a from HAC-R1 and HAC-U [HAC-R2] to data from W7 were shown on plots with an "*" for 1995, a "†" for 1996, and a "‡" for 2011. Pairwise comparisons to pre-breach data in tables are shown using the standard letter display (years that share a letter were not significantly different).

All statistical comparisons were conducted using R (R Core Team 2024). Statistically significant differences in periphyton community and productivity between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were identified as potentially ecologically meaningful in both statistical analyses results and in data interpretation (Environment Canada 2012b[37]), although all statistically significant differences (e.g., including those with a MOD < ±2 SD/MAD) were discussed in the data interpretation. Densities and relative densities (%) of major periphyton taxon groups were plotted as stacked bar charts.[38] Periphyton community and productivity metrics were plotted to support the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2024). As outlined above, periphyton community endpoints for baseline and pre-breach were excluded from statistical contrasts due to data quality limitations but were included in plots for visualization purposes only.

4.3 Benthic Invertebrate Community and Productivity

Benthic invertebrate community and productivity monitoring was completed at exposed areas of Hazeltine Creek (and associated reference areas) between 2022 and 2024, in accordance with the CEMP (MPMC 2019). Post-breach benthic invertebrate community and productivity monitoring at two upper Hazeltine Creek areas (HAC-R1 and HAC-U [HAC-R2]) and at associated reference areas (upper Edney Creek [EDC-U] and Frypan creek [FPC-R3]) was initiated in 2018

[37] Environment Canada (2012b) identifies a CES of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community. This criterion has been applied here to the interpretation of periphyton community.

[38] In 2018 and earlier, Chrysophytes, Phaeophytes, and Rhodophytes were grouped into an 'Other' category in stacked bar charts. Periphyton data were classified as "Other" taxa in laboratory results issued in 2018 but the taxonomic groups contained in this category were unknown (i.e., unknown taxonomic identification of these organisms), but suspected to include Phaeophytes, Chrysophytes, and Rhodophytes. See Minnow 2019a for detailed laboratory results for 2018. Periphyton taxonomy results have not been reported in an "Other" category by the laboratory since 2018."

(Figures 4.2 and 4.3, Table 4.3)[39] and has continued annually since then, in accordance with the CEMP (MPMC 2019). Although not a requirement of the CEMP (MPMC 2019), benthic invertebrate community and productivity monitoring was initiated at an additional exposed area of upper Hazeltine Creek (HAC-R3) in 2020 and has been completed annually since then. The upper reference areas EDC-U and FPC-R3 serve as the reference areas for HAC-R3 (Table 4.3). In lower creek areas, post-breach benthic invertebrate community (but not productivity) monitoring was initiated in 2016 at exposed (E1) and unimpacted (EDC-D [EDC-REF]) areas of lower Edney Creek only. Post-breach monitoring of both community and productivity of benthic invertebrates was initiated in 2017 at an exposed area of lower Hazeltine Creek (HAC-D [HAC-R5]), an exposed area of lower Edney Creek (E1), and an unimpacted reference area in lower Edney Creek (EDC-D [EDC-REF]; Figure 4.2, Table 4.3).[40] Benthic invertebrate community and productivity monitoring at these three lower creek areas has continued biennially since 2017 in accordance with the CEMP (MPMC 2019) and was last completed in 2023 (Table 4.3).

Benthic invertebrate community and productivity monitoring in Hazeltine Creek (and associated reference areas) serves to satisfy the CEMP (MPMC 2019) as well as supporting the evaluation of fish habitat in upper Hazeltine Creek as part of HRWG monitoring objectives (e.g., Minnow 2025). Supporting the evaluation of fish habitat is the sole purpose of the annual benthic invertebrate community and productivity monitoring completed at areas HAC-R3 and FPC-R3 since 2020 and 2018, respectively. As described in Section 4.2 (for periphyton productivity monitoring), a different approach to reporting results from HAC-R3 and FPC-R3 has been used in the present report compared to previous years, with the objective of improving reporting clarity and efficiency with the HRWG report. In the present report, benthic invertebrate community, and productivity results from both HAC-R3 and FPC-R3 from all years of monitoring have been incorporated throughout data tabulation, analyses, and interpretation (rather than tabular data presentation only).

Channel remediation works at HAC-R1 and HAC-U (HAC-R2) were completed in 2016 and 2017, respectively, and at HAC-R3 were completed in 2019. Channel remediation works in the vicinity of HAC-D (HAC-R5) and E1 were initiated in 2015 and completed in 2021; see Section 4.2 for

[39] HAC-R2 is the alternate name used for the HAC-U sampling area for HRWG reporting (Minnow 2025). Post-breach benthic invertebrate community and productivity at the Frypan Creek reference area (FPC-R3) was initiated in 2017 (Table 3.4) but monitoring results from this monitoring event are excluded from consideration in the present report (including data analysis; Section 4.3.3) because a single sample was collected in 2017 (n=1).

[40] HAC-R5 and EDC-REF are the alternate names used for the HAC-D and EDC-D sampling areas, respectively, for HRWG reporting (Minnow 2025).

Table 4.3: Overview of Benthic Invertebrate Community and Productivity Monitoring in Creeks in the Vicinity of the Mount Polley Mine, 1995 to 2024[a]

Waterbody		Area Type	Area Code[b]	Baseline[c]			Pre-Breach											
				1995 (HKP 1996)	1996 (HKP 1997a)	1999 (Beak 2000)	2002 (Morrow/ Azimuth 2003)	2007 (Minnow 2009)	2016[d] (Minnow 2017a)	2017 (Minnow 2018a)	2018 (Minnow 2019a)	2019 (Minnow 2020a)	2020 (Minnow 2021a)	2021 (Minnow 2022a)	2022 (Minnow 2023a)	2023 (Minnow 2024a)	2024

Laboratory analysis did not include determination of total wet and dry biomass.

Notes: "-" = not applicable, LPL = Lowest Practicable Level taxonomy. Only monitoring efforts that used the following methodology are displayed: Surber/ Hess sampler, 3-grab composite, 250 µm sieve, LPL. Prior to 2019, alternate sampling methodologies were employed. See Minnow 2019a for a detailed list of these alternate sampling methods.

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored between 2022 and 2024 are displayed, as well as historical data for these areas. Collection of benthic invertebrate biomass data was initiated in 2017.

[b] Alternate area identifiers used for HRWG reporting are noted, where applicable.

[c] In 1995 and 1996, each sample was a single grab collected by Surber with 243 µm mesh (HKP 1996, 1997a). In 1999, each sample was a composite of 3 Surber grabs with a 250 µm mesh (Beak 2000).

[d] Monitoring was not completed at the upper Edney Creek reference area (EDC-U) in 2020 due to differences in habitat variables (water depth and velocity) relative to the remediated areas of upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], and HAC-R3) for which it is a reference.

details of the remediation timeline and monitoring station placement in these monitoring areas during remediation activities.

Sample collection and analysis methods for 2024 only are described herein and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Table 4.3.

4.3.1 Sample Collection

Benthic invertebrate community samples were collected between August 7 and 15, 2024. Five stations were sampled in each area (Figures 4.2 and 4.3, Table 4.3) to provide adequate statistical power to detect differences of ± two SDs at α and β of 0.10. One sample was collected at each station, and each sample was a composite of three sub-samples to ensure that each sample was representative of the sampling station. Each sampling station was established at a minimum distance of approximately three bankfull widths from adjacent stations and coincided with those for periphyton monitoring. Sampling methods were in accordance with technical guidance (BCMOE 2013, 2016) and the CEMP (MPMC 2019).

Samples were collected using a Hess sampler (0.1 m^2 cylinder) in upper Hazeltine Creek (HAC-R1, HAC-U, HAC-R3) and a Surber sampler (30.5 x 30.5 cm square; 0.093 m^2) in Edney Creek (EDC-U), and Frypan Creek (FPC-R3). The samplers were each equipped with 250 µm mesh, which was selected to allow comparability to pre-breach data (Minnow 2009). Each sub-sample was collected by carefully inserting the base of the sampler into undisturbed substrate. Cobble and gravel contained within the sampler was carefully washed to remove debris and organisms, allowing the current to carry dislodged organisms and debris into the collection net. Once the organisms were rinsed into the collection net, the sampler was moved to the next sub-sampling location within a station. This procedure was repeated until three sub-samples were collected from each station, forming a single sample (i.e., approximately 0.300 m^2 and 0.279 m^2 of total creek surface area for a Hess and Surber sampler, respectively). Material and organisms retained in the collection net were then carefully transferred to one or more pre-labelled 1 L wide mouth plastic jars. This transfer was completed using a wash bottle over a plastic tub to avoid any potential loss of organisms. Any organisms that fell into the tub or adhered to the sieve bag were removed and added to the sample. Each sample was preserved with buffered formalin solution to achieve a nominal concentration of 10% and stored at room temperature until shipment to the laboratory.

A concerted effort was made to ensure that water depth, water velocity, and substrate characteristics were comparable among sub-samples, stations, and sampling areas, to minimize the influence of natural variability on benthic invertebrate community and productivity endpoints. As outlined for periphyton (see Section 4.2.1 for details), the pumping of water from below the

thermocline in Polley Lake into Hazeltine Creek presented challenges for matching habitat conditions between Hazeltine Creek and reference (Edney Creek and Frypan Creek) areas in 2024 similar to previous years of monitoring (2018 to 2023; Table 4.3).

Supporting measures were collected at each sampling station to support data interpretation. Refer to Section 4.6.1 for additional details about supporting measures.

4.3.2 Laboratory Analysis

Taxonomic identification of benthic invertebrate community samples from creek habitats was completed by Cordillera Consulting using the standard methods and QA/QC measures described in Section 3.5.2 for benthic invertebrate community samples from lakes.

Following taxonomic identification, the wet and dry biomass of each sample was determined as follows[41]. For wet biomass, a piece of fine mesh was weighed, and the weight recorded in an Excel template. The identified organisms were split into the pre-determined groups for weighing and then placed onto the mesh. Excess liquid was absorbed by blotting gently with absorbent paper. The mesh and organisms were then weighed to the nearest 0.0001 g using a digital balance, with weights entered in the Excel spreadsheet. The total sample wet weight was determined by subtracting the weight of the mesh from the total weight. For dry biomass, glass fiber filters were labeled and dried in an oven at 150°F for four hours, then stored until use. Just before use, filters were weighed, and the mesh weight was entered in an Excel template. Organisms were placed on the filter and dried at 150°F for four hours. Following a standardized short period of cooling, samples were weighed as described above, and total sample dry weight was calculated in Excel.

Laboratory QA/QC measures and the delivery of data were completed as described in Section 3.5.2 for lake benthic invertebrate community samples.

4.3.3 Data Analysis

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, organism sorting efficiency, sub-sampling precision and accuracy error, and taxonomic identification error (see Appendix B). Following completion of the DQR, benthic invertebrate community results were analyzed as described below.

[41] Total wet and dry biomass analysis was initiated in 2017; benthic invertebrate biomass data do not exist prior to 2017 (Table 4.3).

4.3.3.1 Metrics

Benthic invertebrate community condition was evaluated using metrics of organism density (organisms/m^2), taxon richness (No. of taxa), Simpson's Diversity and Evenness, and the relative density (%) and density of dominant taxa groups. These endpoints were calculated at the LPL of taxonomy, following taxa exclusions, application of the decision key, and the collapsing of taxonomic data to maintain consistency among years as outlined in Section 3.5.3.1. The benthic invertebrate community composition was further examined using CA, using the methods detailed in Section 3.5.3.1. Benthic invertebrate productivity was evaluated using total wet and dry biomass, which was converted to a standard area-based measurement (g/m^2). Benthic invertebrate community metrics (including CA station scores) were calculated for each monitoring area in each year and were summarized by area and year using the following statistics: sample size, mean, median, minimum, maximum, and SD.

Evaluation of the benthic invertebrate community of upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], and HAC-R3) included comparison of post-breach results to samples collected from a similar area of upper Hazeltine Creek during pre-breach monitoring in 2007 (UHC; Minnow 2009; Table 4.3). Methods employed in post-breach monitoring were consistent with those used during pre-breach sampling in 2007, enabling comparisons to pre-breach conditions (Table 4.3). Post-breach results from HAC-U (HAC-R2) and EDC-U in were not compared to baseline results 1995, and 1996 (from W7 and W9, respectively; Table 4.3) because differences in sample collection methods and in taxonomic resolution precluded comparison. Adequate baseline for comparison to post-breach results is provided by the 2007 results.

Despite the consistencies between pre-breach and post-breach data collection methods, comparison of these results is still challenging due to the use of different laboratories for the taxonomic analyses, and the large time span between data collection for the two studies (over which general improvements in laboratory protocols have occurred). A major difference between the pre-breach and post-breach data is that aquatic mites were not identified to a taxonomic level more specific than Subclass (Acari) in 2007 but were identified to genus in post-breach data, and springtails were identified to Class (Collembola) in 2007 but were identified to Family in post-breach data. Therefore, to keep data consistent and comparable to the pre-breach (2007) results, the aquatic mite and spring-tail data were collapsed to Class (Arachnida and Collembola, respectively). These reassignments were all completed prior to calculation of benthic community endpoints described above.

4.3.3.2 Statistical Analyses

Statistical analyses of benthic invertebrate community and productivity metrics were conducted using pre-breach (2007) and post-breach (2018 to 2024) to answer the following questions:

1. Were there differences in benthic invertebrate community and productivity between exposed and reference areas in 2024?
2. Have the benthic invertebrate community and productivity of exposed areas changed among years relative to changes at reference areas over this time, and where pre-breach data exist, has the community recovered to pre-breach conditions?

To answer these questions, results from upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], and HAC-R3) were each compared to the two reference areas (EDC-U and FPC-R3) and to pre-breach results for upper Hazeltine Creek (UHC; 2007). Comparisons for benthic invertebrate community and productivity included calculation of community metrics (including CA), tabular and graphical presentation, and statistical analyses.

Statistical comparisons were completed using two-way ANOVAs with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year*. The analyses were completed using the two-way ANOVA methods described in Section 3.3.3.1.2 with pre-breach and post-breach (exposed and reference) data from the creeks. Comparisons of benthic invertebrate community and productivity endpoints were completed between exposed and reference areas for each year that paired exposed and reference data were available for an endpoint, including pre-breach (see Table 4.3).

Within the two-way ANOVAs, the post-breach data (i.e., HAC-R1, HAC-U [HAC-R2], and HAC-R3; 2018 to 2024) were compared to pre-breach data (i.e., UHC; 2007) as separate areas (as described in Section 4.2.3.2). Pairwise contrasts were conducted as described in section 3.3.3.1.2, except that If the *Area* term was significant for the ANOVA, temporal pairwise contrasts were completed among all the areas (FPC-R3, EDC-U, UHC, HAC-R1, HAC-U [HAC-R2], and HAC-R3; as though a significant interaction had been detected). This approach for pairwise contrasts was used due to the inherent temporal contrasts of the *Area* term (i.e., pre-breach data for UHC compared to post-breach data for HAC-R1, HAC-U [HAC-R2], and HAC-R3). In addition, pre-breach data (2007) were compared between upper Hazeltine (UHC) and upper Edney (UER) creeks to evaluate the pre-breach condition in these areas. Pairwise comparisons to pre-breach data in tables are shown using the standard letter display (years that share a letter were not significantly different). Results of the contrasts of HAC-R1, HAC-U [HAC-R2], and HAC-R3 to pre-breach data from UHC (2007) are shown on figures with an asterisk "*" indicating a significant difference relative to pre-breach.

Interpretation of benthic invertebrate community metrics was enhanced by inspection of raw data and taxonomic proportions to detect patterns of ecologically relevant differences between the exposed and pre-breach areas. Ecological and habitat requirements of benthic invertebrates, as outlined in standard references (Clarke 1981; Edmunds et al. 1976; Weiderholm 1983; Wiggins 1996; Vieira et al. 2006, Merritt et al. 2008) were used in data interpretation. All statistical comparisons were conducted using R (R Core Team 2024). Statistically significant differences in benthic invertebrate community between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were identified as potentially ecologically meaningful in statistical analyses results and in data interpretation (Environment Canada 2012b[42]). Densities and relative densities (%) of major benthic invertebrate groups were plotted as stacked bar charts. Benthic invertebrate community metrics were plotted to support the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2024).

Correlation analyses were completed to investigate the relationships between benthic invertebrate community metrics and supporting measures of physical and chemical conditions in these areas since initial remediation. The correlation analyses included pre-breach data from upper Hazeltine and Edney creeks (UHC and UER respectively; 2007) and post-breach data (2018 to 2024) from upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], HAC-R3), Upper Edney Creek (EDC-U), and Frypan Creek (FPC-R3). Benthic invertebrate community metrics were compared to the environmental variables water depth, velocity, temperature, dissolved oxygen (concentration and %), pH, specific conductivity, and substrate size using Spearman's Rank correlation (as described in Section 3.5.3.2). A Bonferroni-type correction (i.e., α [0.05] divided by the total number of independent variables) was applied to minimize the risk of declaring false positive correlations. Statistically significant correlations found at the Bonferroni-adjusted p-value were further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were leveraged by outlying points (or groups of points).

4.4 Periphyton and Benthic Invertebrate Tissue Quality

Periphyton and benthic invertebrate tissue quality monitoring was completed at exposed areas of Hazeltine Creek and Edney Creek (and associated reference areas) annually between 2022 and 2024, in accordance with the CEMP (MPMC 2019). Post-breach benthic invertebrate tissue quality monitoring was initiated in 2015 at exposed areas of upper (HAC-U [HAC-R2]) and lower (HAC-D [HAC-R5]) Hazeltine Creek, and at an unimpacted reference area of lower Edney Creek

[42] Environment Canada (2012b) identifies a CES of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community.

(EDC-D [EDC-REF]; Figure 4.3, Table 4.4).[43] Tissue quality monitoring in creek habitats was expanded in 2017 to include the initiation of periphyton tissue quality sampling and the inclusion of another exposed area of upper Hazeltine Creek (HAC-R1; Figure 4.3, Table 4.4). Periphyton and benthic invertebrate tissue quality monitoring was initiated at the upper Edney Creek reference area (EDC-U) and at the exposed lower Edney Creek area (E1) in 2018 and 2019, respectively. Monitoring of periphyton and benthic invertebrate tissue quality has continued annually at exposed areas of upper and lower Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], HAC-D [HAC-R5]) and unimpacted reference areas of Edney Creek (EDC-U, EDC-D [EDC-REF]) since 2018, and has continued annually at the exposed area of lower Edney Creek (E1) since 2019 (Table 4.4). This annual periphyton and benthic invertebrate tissue quality monitoring since 2018/2019 has been in accordance with the CEMP (MPMC 2019).

Some temporal differences exist in the composition of benthic invertebrate samples, including the collection of composite-taxa and/ or single taxon (caddisfly) sample types (Table 4.4). Composite-taxa samples are representative of the range of taxa present at a sampling area and are reflective of dietary exposure for fish, therefore may be used in assessment of fish habitat. Single-taxon samples represent one taxon group and were collected to decrease the potential variability in results related to differences among benthic invertebrate taxa in tissue quality. Both single taxon (caddisfly) and composite-taxa samples have been collected at each sampling area from 2018 to 2024, consistent with the CEMP (MPMC 2019). Prior to 2018, either composite-taxa (2009 to 2015) or single taxon (2016 and 2017) benthic invertebrate tissue quality samples were collected (see Table 4.4 and Minnow 2018c, 2019a for details).

Sample collection and analysis methods for 2024 are described herein and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Table 4.4.

4.4.1 Sample Collection

Periphyton and benthic invertebrate tissue samples were collected from eight replicate stations within each area (n=8; Figure 4.2, Table 4.4) between August 8 and 15, 2024. Three tissue quality samples were collected at each replicate station: one periphyton sample, one single taxon (caddisfly) benthic invertebrate sample, and one composite-taxa benthic invertebrate sample (Table 4.4).

A periphyton tissue sample was collected at each station by scraping periphyton from the surface of at least five rocks using a scalpel until a sufficient sample weight (i.e., more than 0.5 g

[43] HAC-R2, HAC-R5, and EDC-REF are the alternate names for HAC-U, HAC-D, and EDC-D for HRWG reporting (Minnow 2025).

Table 4.4: Overview of Periphyton and Benthic Invertebrate Tissue Quality Monitoring in Creeks in the Vicinity of the Mount Polley Mine, 2009 to 2024[a]

Shading indicates only selenium was monitored.
Shading indicates areas were exposed to effluent being conveyed by Hazeltine Creek to Quesnel Lake.

Notes: "-" = not applicable/not sampled.

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored in 2023 are displayed, as well as historical data for these areas.

[b] Alternate area identifiers used for HRWG reporting are noted, where applicable.

[c] Composite-taxa benthic invertebrate samples were collected from 2009 to 2015. In 2016 and 2017, stoneflies and caddisflies were sampled at reference and exposed areas, respectively. In 2018 to 2023, both composite-taxa samples and single taxon (caddisfly) samples were collected at all areas.

[d] Eight samples for stoneflies and eight samples for caddisflies were sampled at a total of 12 stations.

wet weight) was attained for analysis. The periphyton scrapings were then placed into a pre-labeled plastic scintillation vial without the addition of site water.

Benthic invertebrate tissue samples were collected at each station using a combination of kick-and-sweep and hand picking. The kick-and-sweep method involved a field technician moving upstream and across the stream channel (in a zig-zag pattern) while holding a kick net (a net with a triangular opening and a 400 µm mesh bag) immediately downstream and disturbing the substrate with their feet to dislodge benthic organisms into the net. The net was then rinsed with water to move all debris and invertebrates to the collection cup at the bottom of the net. The collection cup was removed and the contents (i.e., invertebrates and debris) were poured into a white tub. Benthic invertebrates were then picked free of debris and transferred into pre-labelled plastic scintillation vials without the addition of site water. Hand picking entailed overturning rocks in the streambed and collecting any benthic invertebrates observed. Both kick-and-sweep and hand-picking methods were employed at each erosional sampling station to collect benthic invertebrate samples. Two types of benthic invertebrate tissue samples were collected from each station: composite-taxa and single taxon (caddisfly).

Duplicate (split) samples were collected at a target frequency of 10% for QA/QC purposes and were evenly distributed among sampling areas and tissue types. Following collection, samples were stored in a cooler with ice packs until being frozen prior to shipment (on ice) to the analytical laboratory.

4.4.2 Laboratory Analysis

Laboratory analysis of periphyton and benthic invertebrate tissue quality samples was completed by ALS Environmental (Burnaby, BC) using the same methods and QA/QC measures outlined in Section 3.4.2.

4.4.3 Data Analysis

Upon receipt of periphyton and benthic invertebrate tissue quality data, a DQR was completed, including an examination of data completeness, LRLs achieved, laboratory precision, laboratory accuracy, and field precision (Appendix B).

Benthic invertebrate tissue quality data from 2024 were screened against the British Columbia selenium guideline for the protection of aquatic life (for invertebrate tissue) of 4 mg/kg dw (BCMOE 2014). Summary statistics for 2024 were calculated for each analyte by area and tissue type, including mean, SD, minimum, median, and maximum values. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1. Data analysis and interpretation of periphyton and benthic invertebrate tissue quality focused on primary and secondary analytes (Table 2.4).

4.4.3.1 BCF and TTF Calculation

Concentrations of the primary and secondary analytes in periphyton and benthic invertebrate tissues were evaluated relative to concentrations in water. The ratio of ([tissue sample concentration]/ [dissolved water concentration]) is referred to as a Bioconcentration Factor (BCF). These ratios are often used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes other than diet (i.e., Arnot and Gobas 2006) and are applicable to erosional areas where sediments are generally rare. The BCFs were calculated using mean tissue analyte concentrations (dry weight) and mean aqueous dissolved analyte concentrations from routine water quality monitoring stations near each tissue sampling area (Figure 4.2). Mean aqueous analyte concentrations were calculated as described in Section 3.8.3.1 using data from the one-year period prior to sampling (i.e., September 2023 to August 2024). Mean values at the LRL were replaced with the LRL for the calculation of the BCF ratios. For EDC-U, routine water quality data were not collected by MPMC, and so BCFs were calculated using data from the spot water samples collected during tissue collection.

Concentrations of primary and secondary analytes in benthic invertebrate tissue were also evaluated relative to concentrations in periphyton tissue. These ratios of concentrations are referred to as Trophic Transfer Factors (TTFs) and can be estimated for benthic invertebrates assuming they inhabit a single trophic level above periphyton (i.e., TTF = [benthic invertebrate sample] / [periphyton sample]). TTFs can be used to describe the extent to which analyte concentrations increase between lower and higher trophic levels (e.g., Presser and Luoma 2010). Paired observations of benthic invertebrate and periphyton tissue quality were used to calculate TTFs for each replicate station in 2024 (i.e., eight replicate TTFs per area in 2024). In addition, data collected pre-breach (2010), and in prior post-breach years (i.e., 2017 to 2023; years when both periphyton and benthic invertebrate tissue samples were collected) were also used to calculate TTFs in Hazeltine Creek (refer to previous reports outlined in Table 4.4). If an analyte concentration for either the nominator (benthic invertebrate tissue analyte concentration) or denominator (periphyton tissue analyte concentration) in the TTF calculation was censored (i.e., < LRL), the TTF was not calculated. The calculated TTFs were then summarized by year and area calculating the mean, SD, median, minimum, and maximum.

4.4.3.2 Statistical Analyses

Statistical analyses of analyte concentrations in 1) periphyton tissue, 2) caddisfly tissue, and 3) composite-taxa benthic invertebrate tissue samples and associated TTFs (for caddisfly and composite-taxa benthic invertebrate tissues) were conducted using pre-breach (2010) and

post-breach (2015 to 2024 for tissue analyte concentrations; 2017 to 2024 for TTFs)[44] data to answer the following questions:

1. Have mean analyte concentrations or TTFs at the exposed area changed over time relative to the reference area?
2. Were there differences in mean analyte concentrations or TTFs between exposed and reference areas, and does the difference depend on year?
3. Do mean analyte concentrations or TTFs at exposed areas differ from pre-breach conditions?

To answer these questions, data were grouped into three categories for separate tabular and graphical presentation and statistical analyses:

1. The exposed areas of upper Hazeltine Creek (HAC-R1 and HAC-U [HAC-R2]; 2018 to 2024 for periphyton and composite and single-taxon benthic invertebrates) compared to reference (EDC-U; 2018 to 2024 for periphyton and composite and single-taxon benthic invertebrates).
2. The exposed area of lower Hazeltine Creek (HAC-D [HAC-R5]; 2017 to 2024 for periphyton, 2015 and 2018 to 2024 for composite-taxa and 2018 to 2024 for single-taxon benthic invertebrates) compared to reference (EDC-D [EDC-REF]; 2017 to 2024 for periphyton, 2015 and 2018 to 2024 for composite-taxa and 2018 to 2024 for single-taxon benthic invertebrates).
3. The exposed area of lower Edney Creek (E1; 2019 to 2024 for periphyton and composite and single-taxon benthic invertebrates) compared to reference (EDC-D [EDC-REF]; 2019 to 2024 for periphyton and composite and single-taxon benthic invertebrates).

Questions 1 and 2 were answered by conducting a two-way ANOVA assessing the relative differences between exposed and reference areas, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA was completed *as* detailed in Section 3.1.3.2 (for Questions 1 and 2) to address the same questions.

To answer Question 3, post-breach results (2015 to 2024) were statistically contrasted to pre-breach data, where possible. Pre-breach data were collected for periphyton and composite-taxa benthic invertebrate tissue quality from HAC-U (HAC-R2) and HAC-D (HAC-R5) in 2010 (W7 and

[44] Paired periphyton and benthic invertebrate tissue quality monitoring during the post-breach period was initiated in 2017; post-breach periphyton tissue quality results do not exist prior to this. Therefore, TTFs cannot be calculated prior to 2017.

W11, respectively; Table 4.4).[45] The comparisons to pre-breach were conducted using a censored one-way ANOVA with *Year* as the factor as described in Section 3.7.3.2 and were used to contrast post-breach results for periphyton tissue quality, composite-taxa benthic invertebrate tissue quality, and TTFs to pre-breach conditions. The TTF data (calculated as described in Section 4.4.3.1) did not contain censored (i.e., < LRL) values, therefore the ANOVA models for comparison of TTFs were fit with least-squares estimation (i.e., not MLE) and $\log_{10}$ transformed response variables. Data used in these comparisons included the following:

1. Post-breach periphyton tissue quality, composite-taxa benthic invertebrate tissue quality, and TTF results from HAC-R1 and HAC-U (HAC-R2) compared to pre-breach results from HAC-U (HAC-R2; W7); and
2. Post-breach periphyton tissue quality, composite-taxa benthic invertebrate tissue quality, and TTF results from HAC-D (HAC-R5) compared to pre-breach results from HAC-D (HAC-R5; W11).

Although statistical analyses were conducted for all analytes detected in the chemical analyses, data presentation, interpretation, and discussion were focused on the identified primary and secondary analytes (see Table 2.4). Plots of data that support the two-way ANOVA were presented for primary and secondary analytes that: 1) had a significant *Area×Year* interaction in the analyses and had a positive MOD for 2024 (i.e., exposed concentrations were significantly higher than reference) or negative MOD for 2024 (i.e., exposed concentrations were significantly lower than reference); and 2) lacked a significant *Area×Year* interaction in the analyses but had a positive overall MOD (i.e., exposed concentrations were significantly higher than reference and the difference did not depend on year). Results of the contrasts to pre-breach (2010) were shown on the two-way ANOVA figures with an "*" indicating a significant difference relative to pre-breach.

All statistical analyses were conducted using R software (R Core Team 2024). A significance level $\alpha = 0.05$ was used for statistical comparisons, as was used for the evaluation of all chemical data in this report.

4.5 Fish Tissue Quality

Fish tissue quality monitoring was completed at exposed areas of Hazeltine Creek (and associated reference areas) in 2024. In upper Hazeltine Creek (HAC-R1 and HAC-U [HAC-R2]; exposed) and an associated reference area (Frypan Creek; FPC-R2), post-breach fish tissue quality monitoring was initiated in 2018 and occurred again in 2024 (Figure 4.4, Table 4.5).

[45] Pre-breach periphyton and composite-taxa benthic invertebrate tissue quality samples were also collected in 2011 to 2013 at HAC-U and HAC-D, and from HAC-U in 2009. Reported data for these samples included selenium as the only analyte, therefore these results were not included in statistical contrasts to pre-breach data.

				coho salmon (CO)	Whole-body	-	8
Edney Creek	Lower	EDC-D (EDC-REF)	Reference	rainbow trout (RB)	Whole-body	-	8
				coho salmon (CO)	Whole-body	-	8
Frypan Creek		FPC-R2 (Reach 2)	Reference	rainbow trout (RB)	Whole-body	8	8

Notes: "-" = no data/ no samples collected. Juvenile fish tissue samples were collected as whole-body samples. In 2024, rainbow trout were targeted from upper creek areas (n= 8 per area), while rainbow trout and coho salmon were targeted from lower creek areas (n = 8 per area). Coho salmon are not present in the upper creek areas.

[a] Alternate area identifiers used for HRWG reporting are noted, where applicable.

[b] Rainbow Trout from upper Hazeltine Creek in 2018 were captured from two stations in HAC-R1 and two stations in HAC-U (HAC-R2). See Appendix Table D.6.1 and Minnow (2019d) for details of sampling locations within these two areas.

[c] The target sample size (n = 8) for rainbow trout in lower Hazeltine Creek (HAC-D [HAC-R5]) was not be achieved as only one (n=1) rainbow trout was captured in this area during fishing efforts.

Fish tissue quality monitoring completed in upper creek areas in 2018 and 2024 targeted whole-body samples of juvenile rainbow trout. In lower Hazeltine Creek (HAC-D [HAC-R5]; exposed) and an associated reference area (unimpacted lower Edney Creek; EDC-D [EDC-REF]), post-breach fish tissue quality monitoring was initiated in 2024 (Figure 4.4, Table 4.5). Fish tissue quality monitoring completed in the lower creek areas in 2024 targeted whole-body samples of juvenile rainbow trout and juvenile coho salmon (*Oncorhynchus kisutch*; Table 4.5). Whole-body juvenile fish tissue quality data do not exist for the lower creek areas prior to 2024 (Table 4.5).

Fish tissue quality monitoring in creek habitats is not a requirement of the CEMP (MPMC 2019). The primary purpose of implementing fish tissue quality monitoring in exposed areas of upper and lower Hazeltine Creek (and associated reference areas) in 2024 was to investigate tissue selenium concentrations in juvenile fish species (i.e., rainbow trout and coho) as it relates to dietary exposure to benthic invertebrate tissue selenium concentrations. The fish tissue monitoring completed in creek habitats in 2024 is consistent with Condition 3(g) of the draft CEMP approval conditions dated May 16, 2024 (BCMOECCS 2024), which specified the following:

> *"Conduct annual juvenile fish tissue chemistry sampling in upper and lower Hazeltine creek and corresponding reference locations."*

4.5.1 Sample Collection

Fish collections in upper Hazeltine Creek (exposed; HAC-U [HAC-R2]) and Frypan Creek (reference; FPC-R2) were completed from August 8 to 12, 2024, under BCMOWLRS Fish Permit WL24-846725. Closed-station backpack electrofishing was used to target juvenile rainbow trout at HAC-U (HAC-R2; exposed) and FPC-R2 (reference) as follows. Electrofishing stations were enclosed using 3/8" mesh stop nets installed at the upstream and downstream extent of the station. An electrofishing team, consisting of an electrofishing unit operator and a netter, employed a multiple pass removal method at each station whereby one upstream pass (or "sweep") of the enclosed reach was repeated three or more times. Fish captured during each closed station sweep were placed in buckets of aerated water prior to processing and/or release.

Fish collections in lower Hazeltine Creek (exposed; HAC-D [HAC-R5]) and an unimpacted area of lower Edney Creek (reference; EDC-D [EDC-REF]) were completed from August 7 to 14, 2024 and from October 21 to 25, 2024 under BCMOWLRS Fish Permit WL24-846725 and DFO Fish Permit XR 145 2024 (Appendix Tables D.6.1 to D.6.3). Minnow trapping was used to target juvenile rainbow trout and coho from HAC-D (HAC-R5; exposed) and EDC-D (EDC-REF; reference) because electrofishing was prohibited in the presence of juvenile salmonids (e.g., coho), in accordance DFO Fish Permit XR 145 2024 conditions, and

average water depth in the creeks was too low to effectively implement other fish collection methods (e.g., hoop nets). As such, minnow trapping efforts were completed using standard “Gee Style” traps with 1/8” mesh body that were baited with a suitable attractant in a mesh container. Minnow traps were deployed in sets of two to four for a duration ranging from 22 to 50 hours. Fish captured upon retrieval of each minnow trap were placed in buckets of aerated water prior to processing and/or release.

The closed-station electrofishing efforts in upper Hazeltine Creek (and reference; FPC-R2) and minnow trapping efforts in lower Hazeltine Creek (and reference; EDC-D [EDC-REF]) in 2024 were completed to satisfy fish and fish habitat evaluation objectives of the HRWG. The collections of rainbow trout and coho tissue quality samples in August and October 2024 were coordinated with the HRWG fish collections to maximize efficiency of fishing efforts and minimize fish handling. The fish collection efforts and methods presented herein are a subset of those completed to satisfy HRWG evaluation objectives; see Minnow (2025) for details of the entire fish and fish habitat monitoring program completed in 2024.

The target sample size for each species (e.g., rainbow trout or coho) at each area was n=8 to facilitate meaningful statistical comparison of fish tissue quality between exposed and reference areas (Table 4.5). The target sample size was met for each species from each sampling area in 2024, except for rainbow trout from the exposed lower Hazeltine Creek area (HAC-D [HAC-R5]). A single rainbow trout was captured at HAC-D (HAC-R5) during fishing efforts in August and October (Appendix Table D.6.3) and was retained for tissue quality sampling (n = 1 for this area; Table 4.5).

Supporting data recorded for the 2024 fish tissue monitoring in creek habitats included GPS coordinates of each fishing location (minnow trap set or closed-station electrofishing station), level of effort (deployment and retrieval times for minnow trapping, seconds of fishing effort for electrofishing), and habitat data (e.g., water depth for minnow trapping, mean station length and wetted with for closed-station electrofishing).

Upon retrieval of minnow traps or completion of closed-station electrofishing efforts, captured fish were identified to species. Target species that were captured were retained for processing (up to the target sample size; n = 8 per area). Incidental mortalities were disposed of in an approved manner. Non-target fish species were enumerated and released live immediately following capture. Fish retained for lethal sampling were euthanized with a decisive blow to the head, placed in a cooler, and processed within <12 hours as follows. Each fish was measured for fork length, total length, and body weight (as described in Section 3.6.4). Scales for aging were removed, wrapped in waxed paper, placed in labelled coin envelopes, and frozen until shipment to the laboratory for aging analyses. The whole-body carcass of each fish was then

placed in a pre-labelled Whirl-Pak™ bag and stored frozen until shipment (on ice) to the analytical laboratory. Duplicate (split) samples were not collected since fish tissue quality samples were whole-body samples which could not be split.

4.5.2 Laboratory Analysis

Laboratory analysis of fish tissue quality samples was completed by ALS Environmental (Burnaby, BC) using the same methods and QA/QC measures outlined in Section 3.4.2

4.5.3 Data Analysis

Fish catch data were compiled and summarized to provide a catch list for each sampling area and gear type.[46] The catch compilations, along with data on fishing efforts completed in August and October 2024, were summarized by species and sampling area. Fish length, weight, and age data were also compiled and summarized by calculating the mean, median, SD, and total range (minimum and maximum) by species and area.

Upon receipt of the fish tissue quality data from ALS and the fish aging data from AAE, a DQR was performed. For the fish tissue quality data, this included the assessment of field precision, laboratory precision, and laboratory accuracy. For the fish aging data, this included the assessment of laboratory precision through evaluation of original and reassessed age estimates.

Whole-body fish tissue quality data from 2024 were screened against the BC selenium guideline for the protection of aquatic life (for whole-body fish tissue) of 4 mg/kg dw (BCMOE 2014). Fish tissue quality guidelines for the protection of human health (mercury and selenium; see Section 3.7.3.1) were also applied in the data screening of whole-body juvenile fish samples although human consumption of whole-body juvenile fish is improbable.

Summary statistics for whole-body fish tissue quality data were calculated for each analyte, species, and area. Summary statistics included the sample size, % of samples less than the LRL, mean, SD, minimum, median, and maximum. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1.

[46] Fish collections were completed in creek habitats in 2024 for the purpose of HRWG reporting (Minnow 2025); only fish collection (minnow trapping or electrofishing) stations and events associated with fish tissue quality sample collection are include in the present report. See Minnow (2025) for fishing effort and catch records for all stations sampled in August and October 2024.

4.5.3.1 Statistical Analyses

Statistical analyses of analyte concentrations in whole-body juvenile rainbow trout were conducted using available post-breach data (i.e., 2018 and 2024 for exposed and reference areas) to answer the following questions:

1. Have mean analyte concentrations at the exposed area changed over time relative to the reference area?
2. Were there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?

To answer these questions, results from the exposed area of upper Hazeltine Creek (HAC-U [HAC-R2]) were compared to the Frypan Creek reference area (FPC-R2) using available whole-body tissue quality data for juvenile rainbow trout from 2018 and 2024. Tissue quality data for whole-body juvenile rainbow trout do not exist for these areas prior to 2018 (i.e., pre-breach tissue quality data for juvenile rainbow trout from Hazeltine Creek and Frypan Creek do not exist).

Questions 1 and 2 were answered by conducting a two-way ANOVA assessing the relative difference between the exposed and reference areas, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA was completed as detailed in Section 3.1.3.2 (for Questions 1 and 2) to address the same questions. Similar statistical comparisons were also completed for fish lengths, and weights to answer the question: is there a difference in mean fish length between exposed and reference areas, and does the difference depend on year? The comparisons of lengths, weights followed the two-way Analysis of Covariance (ANCOVA) methods detailed in Section 3.7.3.2.

Statistical analyses of analyte concentrations in whole-body juvenile coho were conducted using available post-breach data (i.e., 2024 for exposed and reference areas) to answer the following question:

Are there differences in mean analyte concentrations at the exposed area over time?

To answer this question, results from the exposed area of lower Hazeltine Creek (HAC-D [HAC-R5]) was compared to the unimpacted lower Edney Creek reference area (EDC-D [EDC-REF]) using whole-body tissue quality data for juvenile coho from 2024. Tissue quality data for whole-body juvenile coho from these areas do not exist prior to 2024. The question was answered by conducting a censored one-way ANOVA with *Year* as a factor as described in Section 3.7.3.2. Statistical analyses of analyte concentrations in whole-body juvenile rainbow trout from HAC-D (HAC-R5) and EDC-D (EDC-REF) in 2024 were not completed because the sample size achieved (n = 1) at HAC-D (HAC-R5) was insufficient for the analyses.

Tissue quality data for whole-body juvenile rainbow trout do not exist for lower creek areas prior to 2024.

Statistical comparisons were completed for all available analytes; however, data interpretation focused on primary and secondary analytes (see Table 2.4). Plots of data that support the two-way ANOVA were presented for primary and secondary analytes that: 1) had a significant *Area×Year* interaction in the analyses and had a positive MOD (i.e., exposed concentrations were significantly higher than reference) for 2024 or negative MOD (i.e., exposed concentrations were significantly lower than reference) for 2024; and 2) lacked a significant *Area×Year* interaction in the analyses but had a positive overall MOD (i.e., exposed concentrations were significantly higher than reference and the difference did not depend on year). Plots of data that support the one-way ANOVA were presented for primary and secondary analytes that had a significant *Year* effect.

Whole-body fish tissue selenium concentrations (2018 and 2024 for rainbow trout; 2024 for coho) from exposed and reference areas were plotted relative to selenium concentrations in composite-taxa and single-taxon (caddisfly) benthic invertebrate tissue samples collected at or near the same time and location as the fish tissue samples. A line representing a one-to-one relationship between fish and benthic invertebrate tissue selenium concentrations was presented on the plot. This one-to-one line represents a TTF, or ratio of consumer (i.e., fish) to dietary (i.e., benthic invertebrate) tissue selenium concentrations, and a TTF ratio of one usually observed in fish tissues relative to dietary exposure concentrations in aquatic food webs (e.g., Presser and Luoma 2010).

All statistical analyses were conducted using R software (R Core Team 2024). A significance level $\alpha = 0.05$ was used for statistical comparisons, as was used for the evaluation of all chemical data in this report.

4.6 Supporting Measures

A variety of supporting physical and chemical information was used to support the interpretation of sediment and aquatic biological data collected from creeks as part of the CEMP. This information falls into two categories: 1) supporting information that was collected by Minnow during field collections; and 2) supporting information that was collected routinely by MPMC as part of ongoing CEMP monitoring components. Unless otherwise specified, the supporting measures outlined below belong to the first category (measures collected by Minnow).

4.6.1 Measures Collection

Supporting single spot water samples were collected from creek stations concurrent with periphyton community, benthic invertebrate community, and tissue quality sampling for

comparison to BCWQG. These samples were collected on August 12, 2024 (not concurrent with biological sample collection) to ensure sample arrival at the laboratory was within the recommended hold times. Water samples were collected by wading into a mid-channel area, moving from downstream to upstream, so as not to collect water downstream of disturbed substrates, and collecting the samples from approximately half of the total water depth. Water quality data collected routinely by Mount Polley staff at stations near to the biological monitoring areas were also used in support of data interpretation (Figure 4.2). Spot and routine water sampling of creek areas in 2024 both included the collection of samples for selenium speciation analysis, which is the first occurrence of this sampling type and analysis at MPMC. These data were subjected to an internal DQR by Mount Polley and were not further assessed for data quality in this report (for details refer to Section 3.8.1). Immediately after collection, both spot and routine water quality samples were placed into a cooler with ice packs before being stored in a refrigerator until shipment (on ice) to the analytical laboratory (as detailed in Section 3.8.1).

Supporting measures and sampling information were collected at each of the creek monitoring stations to support data interpretation (Appendix Figures A.2.1 to A.2.4, Appendix Tables A.2.1 to A.2.5). These included those described in Section 3.8.1 (excluding vertical depth profiles and Secchi depth) as well as the following: water velocity, substrate size (20 randomly selected substrate pieces measured per station), and general habitat characteristics assessed once for each monitoring area (channel measures, canopy cover, instream cover, periphyton coverage, and substrate characteristics) using methods adapted from Environment Canada (2012a).

4.6.2 Laboratory Analysis

Laboratory analyses of supporting spot and routine water quality samples were completed as described in Section 3.8.2 and included the parameters outlined in the CEMP routine surface water quality monitoring program (MPMC 2019) as well as analysis of selenium speciation parameters (selenate, selenite, selenocyanate, and unknown selenium species). Upon completion of the analyses, a data report was provided by ALS to Mount Polley and Minnow as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G)[47].

[47] Data reports for spot water quality sampling are included in Appendix G. Data from routine water quality monitoring completed by MPMC were provided to Minnow in Microsoft Excel format from the MPMC database and are these not included in Appendix G.

4.6.3 Data Analysis

4.6.3.1 Summary Statistics

Summary statistics were calculated for water, sediment, and tissue quality parameters following the K-M methods described in Section 3.8.3.1. Additional information on specific parameters and applications of the summary statistics for chemical data are found within the methods sections for analysis of these data above (Sections 4.1.3 and 4.4.3 above). Summary statistics for biological endpoints (periphyton and benthic invertebrate community and productivity) were calculated using standard methods and formulae.

4.6.3.2 Water Quality Guideline Screening

Results of spot water quality sampling were screened against BCWQG (Appendix Table D.1.1; BCMOWLRS 2024, 2025) as outlined in Sections 3.8.3.2 and 3.8.3.3. Results of creek water quality sampling completed routinely by Mount Polley staff in the year preceding monitoring (i.e., September 2023 to August 2024) were also screened against BCWQG (see Sections 3.8.3.2 and 3.8.3.3 for details). These routine water quality data were also summarized by calculating sample size, mean, SD, minimum, maximum, and % LRL values as described in Section 3.8.3.1. Plots comparing total and dissolved aqueous concentrations of primary and secondary analytes (Table 2.4) to BCWQG were prepared for routinely collected water quality samples from 2015 to 2024. Aqueous selenium speciation concentrations were also plotted for routinely collected water quality samples in 2024 (the first year of aqueous selenium speciation monitoring), although BCWQG do not exist for these parameters. Tabular screening against BCWQG was completed using Microsoft Excel and plots were generated using R (R Core Team 2024).

4.6.3.3 Water Quality Trends

Temporal trends in routine surface water quality data from Hazeltine Creek and Edney Creek from 2015 to 2024 were evaluated to support interpretation of periphyton and benthic invertebrate tissue quality results from these areas (refer to Section 4.4.3). This evaluation was completed using the Seasonal Kendall test detailed in Section 3.8.3.4 and included evaluation of aqueous total and dissolved concentrations of primary and secondary analytes (Table 2.4), and acute and chronic GEFs for copper (the ratio of observed dissolved copper concentrations divided by BCWQG BLM-derived guidelines). Aqueous selenium speciation results were excluded from the evaluation of temporal trends because 2024 represents the first year of sample collection for these parameters (i.e., aqueous selenium speciation monitoring was initiated in 2024).

5 RESULTS – LAKE HABITAT

5.1 Polley Lake

5.1.1 Sediment Quality

Sediment quality monitoring in 2024 was completed at POL-P1 and POL-P2 of Polley Lake (Figure 3.1, Table 3.1) with BOL-B2 of Bootjack Lake serving as reference. Prior sediment quality monitoring within the 2022 to 2024 period included monitoring at a shallow area in Polley Lake (POL-S) and the corresponding reference area in Bootjack Lake (BOL-S) in 2022 (Figure 3.1, Table 3.1).

A review of 2024 sediment quality results (Appendix B) indicated that the data met the established data quality objectives. Specifically, the data were characterized by good detectability, negligible analyte concentrations in method blank samples, good laboratory and field precision, and excellent laboratory accuracy. Measurement uncertainty for particle size analysis was higher in all sediment samples from Polley and Bootjack Lakes due to high moisture content. However, particle size results were similar among replicate samples and were comparable to those from previous years. Future monitoring efforts will implement strategies to try and avoid the uncertainty associated with particle size analysis (e.g., collection of additional sample material if available, or alternate laboratory processing approaches; see Appendix B for details). Overall, the sediment quality data can be used with a high level of confidence for interpretation.

5.1.1.1 Deep Areas

Sediment collected from the deep monitoring areas of Polley Lake in 2024 were composed almost entirely of silt and clay at both POL-P1 (mean = 74.5% and 24.8%, respectively) and POL-P2 (mean = 74.7% and 24.6%, respectively), which was similar to sediments from the reference lake (mean = 80.5% and 18.8%, respectively; Table 5.1; Appendix Tables C.2.4 and C.2.5). The particle size distribution of sediments from Polley and Bootjack Lakes were also similar to those collected in previous post-breach monitoring years (2014 to 2021; Table 5.1).

The mean TOC content of both POL-P1 (mean = 9.74%) and POL-P2 sediment (mean = 8.16%) in 2024 was lower than 2021 but higher than all remaining post-breach years; however this difference was not statistically significant (Figure 5.1, Table 5.1; Appendix Tables C.2.4 and C.2.5). The relative (exposed-reference) difference of TOC content in Polley Lake sediments (POL-P1 and POL-P2) has not changed significantly between 2014 and 2024 (Figure 5.1; Appendix Table E.1.1), and the slight temporal increase in mean concentrations in Polley Lake sediments may be early evidence of recovery that is not yet statistically significant. Similar to TOC, total nitrogen content of both POL-P1 (mean = 1.06%) and POL-P2 sediment

Table 5.1: Summary of Sediment Quality Data for Polley Lake (POL-P1, POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Deep Monitoring Areas, 2014 to 2024

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: "-" = no current BC Working Sediment Quality Guidelines/ no data. "SD" = Standard Deviation. ***Bold/ Italics*** indicates exposed value (Polley Lake) is > pre-breach (for Polley Lake) and reference 95th percentile values (<5th percentile value for pH) or reference value (Bootjack Lake) is > pre-breach (for Bootjack Lake) and reference 95th percentile values (<5th percentile value for pH).

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] The 5th percentile is reported and screened for the pH reference data. Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. For calculation of pre-breach 95th percentile values for Bootjack Lake and Polley Lake see Appendix Tables C.2.1 and C.2.2, respectively. For calculation of reference 95th percentile values (2014 to 2024) see Appendix Table C.2.3. Pre-Breach sediment metal concentrations are based predominantly on bulk sediment rather than the fines fraction (<63 µm).

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Tables C.2.1 and C.2.2).

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: "-" = no current BC Working Sediment Quality Guidelines/ no data. "SD" = Standard Deviation. ***Bold/ Italics*** indicates exposed value (Polley Lake) is > pre-breach (for Polley Lake) and reference 95th percentile values (<5th percentile value for pH) or reference value (Bootjack Lake) is > pre-breach (for Bootjack Lake) and reference 95th percentile values (<5th percentile value for pH).

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] The 5th percentile is reported and screened for the pH reference data. Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. For calculation of pre-breach 95th percentile values for Bootjack Lake and Polley Lake see Appendix Tables C.2.1 and C.2.2, respectively. For calculation of reference 95th percentile values (2014 to 2024) see Appendix Table C.2.3. Pre-Breach sediment metal concentrations are based predominantly on bulk sediment rather than the fines fraction (<63 µm).

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Tables C.2.1 and C.2.2).

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Table 5.1: Summary of Sediment Quality Data for Polley Lake (POL-P1, POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Deep Monitoring Areas, 2014 to 2024

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: "-" = no current BC Working Sediment Quality Guidelines/ no data. "SD" = Standard Deviation. ***Bold/ Italics*** indicates exposed value (Polley Lake) is > pre-breach (for Polley Lake) and reference 95th percentile values (<5th percentile value for pH) or reference value (Bootjack Lake) is > pre-breach (for Bootjack Lake) and reference 95th percentile values (<5th percentile value for pH).

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] The 5th percentile is reported and screened for the pH reference data. Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. For calculation of pre-breach 95th percentile values for Bootjack Lake and Polley Lake see Appendix Tables C.2.1 and C.2.2, respectively. For calculation of reference 95th percentile values (2014 to 2024) see Appendix Table C.2.3. Pre-Breach sediment metal concentrations are based predominantly on bulk sediment rather than the fines fraction (<63 µm).

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Tables C.2.1 and C.2.2).

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

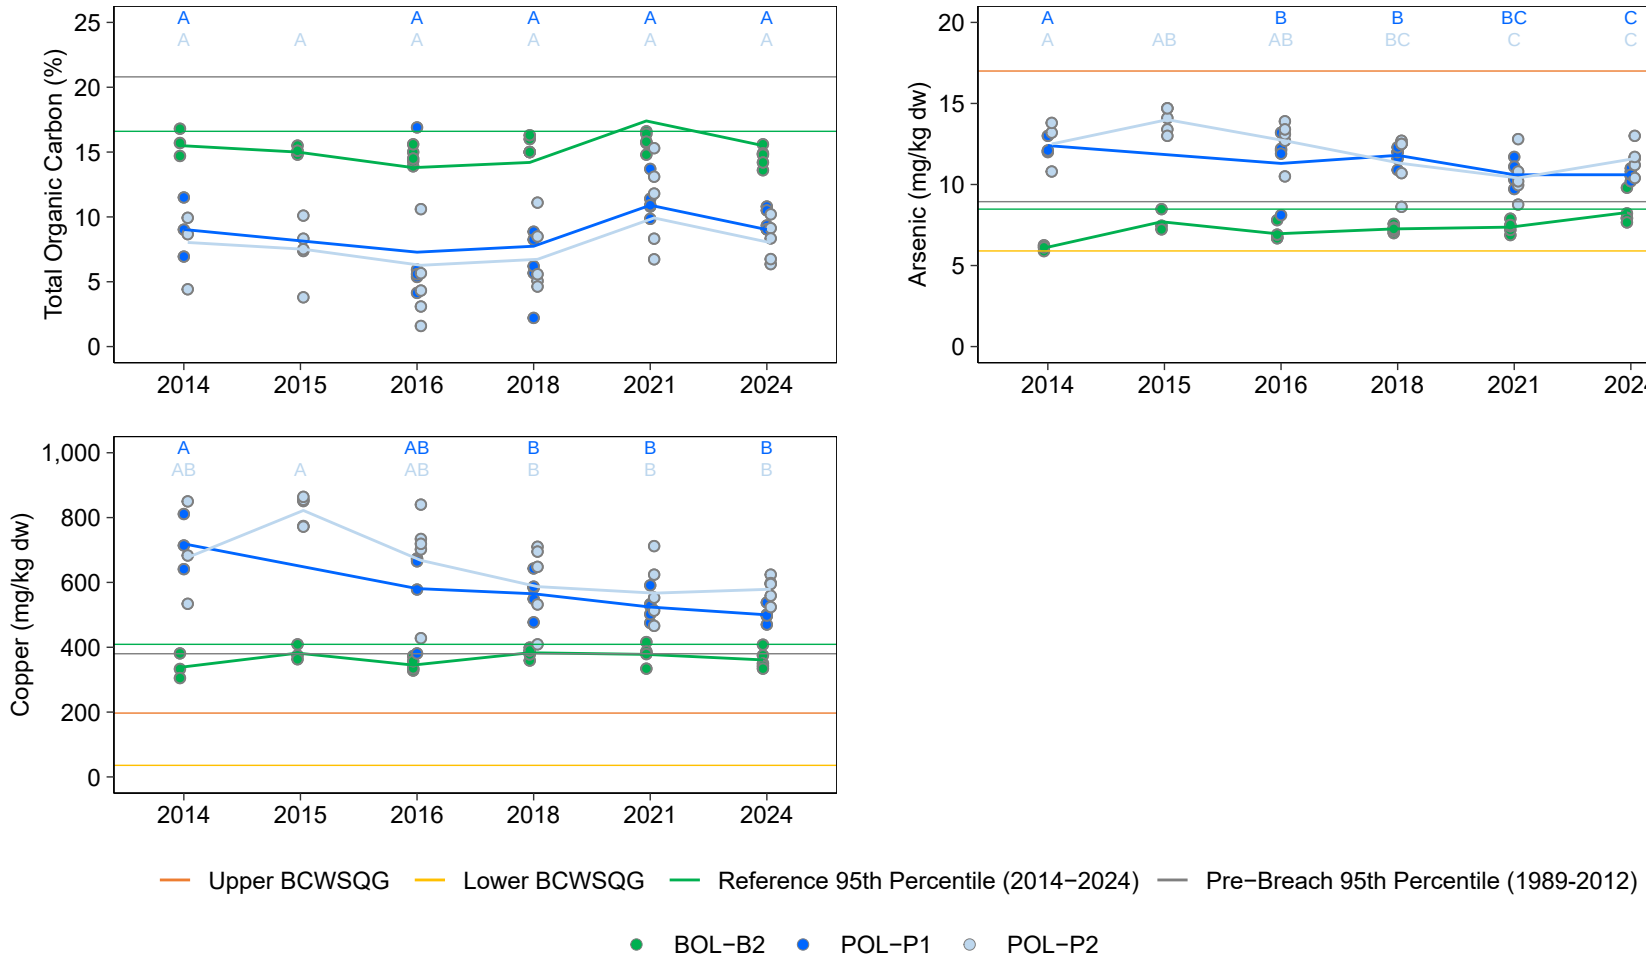

Figure 5.1: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for the Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025). Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences − TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

(mean = 0.965%) in 2024 were higher than in most previous post-breach monitoring years (2014 to 2018), but slightly lower than 2021 (mean = 1.12% and 1.13% for POL-P1 and POL-P2, respectively; Table 5.1; Appendix Tables C.2.4 and C.2.5).

Mean analyte concentrations in the sediments (<63 µm fraction) collected from POL-P1 and POL-P2 in 2024 exceeded the reference and pre-breach 95th percentile values for 11 and 14 analytes, respectively (Table 5.1; Appendix Tables C.2.4 and C.2.5). Among these analytes, arsenic and copper also exceeded the BCWSQG values in 2024. Mean arsenic concentrations in sediments from POL-P1 and POL-P2 exceeded the lower BCWSQG by 1.8- and 2.0-times, respectively, and exceeded the reference 95th percentile value by 1.3- and 1.4-times, respectively (Figure 5.1, Table 5.1). However, mean arsenic concentrations were naturally elevated in Bootjack Lake and exceeded the lower BCWSQG by 1.4-times in 2024 (Figure 5.1, Table 5.1; Appendix Tables C.2.4 and C.2.5). The mean copper concentrations in sediments from POL-P1 and POL-P2 exceeded the upper BCWSQG by 2.5- and 2.9-times, respectively, and exceeded the reference 95th percentile value by 1.2- and 1.4-times, respectively (Figure 5.1, Table 5.1). However, mean copper concentrations were naturally elevated in Bootjack Lake and exceeded the upper BCWSQG by 1.8-times in 2024 (Table 5.1; Appendix Tables C.2.4 and C.2.5). Although concentrations of arsenic and copper in Polley Lake sediments were higher in 2024 than pre-breach conditions[48], pre-breach concentrations of arsenic and copper in both Polley Lake and Bootjack Lake (reference) sediments also exceeded the BCWSQG (Table 5.1). This pre-breach exceedance of BCWSQG indicates that arsenic and copper are naturally elevated in sediments from both Polley and Bootjack lakes.

Analysis of temporal changes in the relative (exposed-reference) differences in sediment arsenic and copper concentrations over time indicated that arsenic concentrations at POL-P1 did not change significantly between 2021 and 2024 (i.e., were temporally stable), but were significantly lower in 2024 than all remaining prior years (2014 to 2018; Figure 5.1; Appendix Table E.1.1). At POL-P2, the relative difference in arsenic concentrations was lower in 2018 to 2024 compared 2014 and has not changed significantly over that period (i.e., 2018 to 2024; Figure 5.1; Appendix Table E.1.1). Arsenic concentrations at the reference area (BOL-B2) were significantly higher in 2024 compared to 2014 (when considered separately from the exposed areas; Appendix Table E.1.2), indicating that the temporal relative differences in arsenic at Polley Lake may be in part due to changes at the reference area. The relative difference of copper concentrations at both POL-P1 and POL-P2 have been temporally stable from 2018 to 2024

[48] TOC and analyte concentrations reported for pre-breach sediments were based predominantly on bulk sediment but were reported for the <63 µm fraction of sediments collected post-breach. This difference in the fraction of sediment evaluated (i.e., bulk sediments for pre-breach and <63 µm fraction for post-breach) should be considered when making comparisons of TOC and analyte concentrations between the two time periods.

(Figure 5.1; Appendix Table E.1.1). At POL-P1, the relative difference of copper concentrations was significantly lower in 2018 to 2024 compared to 2014, while at POL-P2 results were similar among all years except 2015 which was significantly higher than other years (Figure 5.1; Appendix Table E.1.1). Copper concentrations at the reference area (BOL-B2) have not changed significantly since 2014 (Appendix Table E.1.2). In all post-breach monitoring years, arsenic and copper have remained significantly higher than corresponding reference sediment concentrations (Appendix Table E.1.2).

Arsenic and copper concentrations were positively correlated with the clay content of fine sediment (% clay in the silt and clay fraction) and were negatively correlated with TOC and total nitrogen content (Appendix Figure E.1.1, Appendix Table E.1.3). These relationships are consistent with a breach-related influence defined by the input of inorganic sediments with elevated Analyte of Interest concentrations to Polley Lake.

The results of a PCA of sediment quality data from POL-P1, POL-P2, and BOL-B2 between 1999 and 2024 were included in correlations with benthic invertebrate community endpoints from these areas and sampling years (Appendix Figure E.1.2; Appendix Tables E.1.4 to E.1.5; see Section 5.1.5).

Overall, the 2024 sediment quality results indicate that temporal changes in the physical and chemical characteristics of sediments in both the Northwest and Southeast basins of Polley Lake have been limited since the breach in 2014, and no significant changes in sediment characteristics or analyte concentrations have occurred since at least 2021, but there is evidence that recovery is occurring slowly. This is consistent with the low rate of sediment deposition observed, with an average rate of 4.7 mm/yr of fresh sediment deposition in Polley Lake (Minnow 2019a).

5.1.1.2 Shallow Areas

Sediment quality monitoring in 2022 was completed in a shallow exposed area of Polley Lake (POL-S) with a similar shallow area of Bootjack Lake (BOL-S) serving as reference. The results of this monitoring are summarized briefly herein, with detailed methods and results presented in Minnow (2023a).

Sediments from the exposed (POL-S) area in 2022 was composed primarily of silt and sand (mean = 53.7% and 38.5%, respectively), while the reference (BOL-S) sediments had higher sand and lower silt content (mean = 50.7% and 41.9%, respectively). The mean TOC content of Polley Lake shallow sediments in 2022 (1.03%) was significantly lower than reference (8.80%) and did not change from 2019 to 2022, relative to reference. Sediments from the shallow areas of Polley Lake (POL-S) were characterized by concentrations of arsenic, copper, and iron greater than reference 95th percentile concentrations and BCWSQG. Copper had the most substantially

elevated mean concentrations in exposed sediments (3.4-times the upper BCWSQG), followed by iron (1.5-times the upper BCWSQG), and arsenic (2.4-times the lower BCWSQG). Copper was the only Analyte of Interest with concentrations that also exceeded the lower BCWSQG in reference sediments, which it exceeded by approximately 2.5-times. Arsenic, copper, and iron concentrations in shallow Polley Lake sediments in 2022 were similar to those reported in the previous sampling event (i.e., 2019), relative to reference, indicating temporal stability of these analyte concentrations. Overall, the 2022 sediment quality results from the shallow area of Polley Lake indicated temporal stability in the physical and chemical characteristics of these sediments since initiation of monitoring in 2019.

Arsenic, copper, and iron concentrations were significantly negatively correlated with TOC and total nitrogen content, although results were highly leveraged by the highest analyte concentrations and lowest TOC content occurring in POL-S sediments and highest TOC and total nitrogen content occurring in BOL-S sediments. These relationships are consistent with a breach-related influence defined by the input of inorganic sediments with elevated analyte concentrations to Polley Lake.

5.1.2 Sediment Toxicity

Sediment toxicity testing using *C. dilutus* in 2024 (10-day standard test using static methods) was completed at two deep exposed areas of Polley Lake (POL-P1 and POL-P2), with a deep area of Bootjack Lake (BOL-B2) serving as reference (Figure 3.1, Table 3.3). Prior sediment toxicity monitoring within the 2022 to 2024 period included testing of *H. azteca* (14-day standard test using static methods) in 2022 at a shallow area in Polley Lake (POL-S) and a corresponding reference area in Bootjack Lake (BOL-S; Figure 3.1, Table 3.3).

A review of 2024 sediment toxicity results (Appendix B) indicated that all sediment toxicity tests met control acceptability criteria, and all water quality parameters were within acceptable ranges throughout the tests, except for pH in the shallow Quesnel Lake samples (QUL-LNF1 and QUL-LREF1), which marginally exceeded a pH of 8.0 for most tests (Nautilus 2024; Appendix G). Reference toxicant test results fell inside the acceptable range and therefore the sensitivity of organisms used in the tests was considered appropriate (see the DQR for details; Appendix B). All ammonia concentrations were at levels that are not expected to cause adverse effects to *H. azteca* (Appendix G). Examination of laboratory bench sheets indicated that temperature, dissolved oxygen, conductivity, and pH were all stable over the course of the toxicity tests (Appendix G). During sediment toxicity testing, organisms from different test batches were used for the deep exposed and reference area sediments. This laboratory error did not affect test acceptability but did affect the approach for data analysis and interpretation, which is discussed in more detail below (Section 5.1.2.1).

5.1.2.1 Deep Areas

A laboratory error occurred resulting in a different batch of test organisms (*C. dilutus*) being used for the toxicity tests of sediments from the deep basins of Polley Lake (POL-P1 and POL-P2) compared to the batch of test organisms used for toxicity tests of sediments the associated reference area (deep basin of Bootjack Lake [BOL-B2]; see Section 3.2.3). The use of different batches of test organisms for exposed versus reference sediments precluded the direct comparison of exposed test results (i.e., POL-P1 and POL-P2) to reference results (i.e., BOL-B2), which is a key part of the data analysis and interpretation approach used in the present report (see Section 3.2.3). As such, a weight-of-evidence approach was used to assess the toxicity test results of exposed sediments (Nautilus 2024; Appendix G).

Multiple lines of evidence indicated no negative effects on the survival or growth responses in 10-day *C. dilutus* toxicity tests of Polley Lake deep sediments (POL-P1 and POL-P2) both independently of, and relative to, reference sediments (BOL-B2). These lines of evidence are detailed below. First, there was no response of *C. dilutus* to sediments from Polley Lake basins (POL-P1 and POL-P2) compared to test controls. Specifically, the control-normalized survival and dry weight of *C. dilutus* showed no unacceptable survival or growth responses for sediments from either of the Polley Lake basins (POL-P1 and POL-P2; Table 5.2). Second, the survival of *C. dilutus* exposed to deep Polley Lake sediments were within control acceptance criteria (>70% survival), indicating no negative effect (Nautilus 2024). Third, a visual assessment of the survival and dry weight of *C. dilutus* exposed to deep Polley Lake sediments indicated no negative impact relative to the reference sample from deep Bootjack Lake (BOL-B2; Nautilus 2024). Fourth, the mean dry weight of organisms exposed to deep Polley Lake sediments was greater than for reference (Bootjack Lake) sediments and greater than for test control samples used in the testing of Bootjack and Polley Lake sediments (Control A and Control B, respectively; Nautilus 2024). Finally, a statistical comparison showed no differences in test results for reference (Bootjack Lake) sediments and the Control B (control sample from Polley Lake sediment test) despite using different organism batches, and the test also showed no significant adverse effects on survival or dry weight of *C. dilutus* exposed to deep Polley Lake sediments compared to reference sediments (Bootjack Lake; Nautilus 2024). Based on these multiple lines of evidence, there was no unacceptable response of survival or growth of *C. dilutus* exposed to Polley Lake deep sediments in 2024.

Temporal evaluation of sediment toxicity test results at deep areas of Polley Lake (POL-P1 and POL-P2) between 2014 and 2024 indicate that both survival and growth of *C. dilutus*

Table 5.2: Summary of *Chironomus dilutus* 10-day Survival and Growth Responses for Sediment Toxicity Testing of Polley Lake (POL-P1, POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Deep Monitoring Areas, 2024

Results and Classification	POL-P1		POL-P2	
	Survival	Growth[a]	Survival	Growth[a]
	%	mg	%	mg
Raw Area Result	96 ± 5.5	2.34 ± 0.20	90 ± 17.3	2.32 ± 0.23
Raw Laboratory Control Result [b]	88 ± 11.0	1.77 ± 0.19	88 ± 11.0	1.77 ± 0.19
Raw Laboratory Control Result [c]	100 ± 0.0	1.66 ± 0.12	100 ± 0.0	1.66 ± 0.12
Raw Reference Result (BOL-B2)	98 ± 4.5	2.05 ± 0.22	98 ± 4.5	2.05 ± 0.22
Control Normalized Response	109%	132%	102%	131%
Reference Normalized Response	98%	114%	92%	113%
Statistical Difference from Control	n	n	n	n
Statistical Difference from Reference[d]	n	n	n	n
CLASSIFICATION	**NR**	**NR**	**NR**	**NR**

No unacceptable response (<20% reduction) - **NR**.
Low response (20-50% reduction) and not significantly different than control and reference - **LR**.
Moderate response (20-50% reduction) and significantly different than control and reference - **MR.**
High response (>50% reduction) - **HR**.

Notes: y = yes, n = no.

[a] Growth = dry weight per surviving organism (mg).

[b] Laboratory control data for the control treatment associated with the POL-P1 and POL-P2.

[c] Laboratory control data for the control treatment associated with BOL-B2.

[d] Reference (BOL-B2) samples were run in a different batch than exposed samples (POL-P1, POL-P2). However, statistical analyses comparing exposed results (POL-P1, POL-P2) to reference results (BOL-B2) indicate no statistically significant difference (see Appendix G for details).

have consistently shown no unacceptable responses among all years (excluding one moderate growth response at POL-P1[49]; Figure 5.2; Minnow 2017e, 2019a).

5.1.2.2 Shallow Areas
