Toxicity testing was conducted in the shallow area of Polley Lake (POL-S) in 2022 using *H. azteca* (14-day standard test using static methods), with a corresponding shallow area in Bootjack Lake (BOL-S) serving as reference (Minnow 2022a). The results of this monitoring are summarized briefly herein with detailed methods and results presented in Minnow (2023a).

Sediment toxicity testing in shallow areas indicated no unacceptable response (<20% reduction) for survival relative to the reference area or the test control, with a control-normalized survival rate of 97% and a reference-normalized survival rate of 104%. Similarly, *H. azteca* growth in tests of shallow exposed (POL-S) sediment showed no unacceptable response, with growth 14% greater than reference (BOL-S) sediments and 26% greater than the laboratory control. The survival and growth responses observed in 2022 were similar to those in 2019 when sampling was initiated at these shallow areas of Polley and Bootjack lakes.

Aqueous concentrations of dissolved copper in overlying waters of the toxicity test vessels of exposed sediments (POL-S; mean = 0.028 mg/L) were approximately 8-times higher at test conclusion (day 14) than dissolved copper concentrations in field-collected (*in situ*) water from POL-S (mean = 0.0036 mg/L). This difference in aqueous dissolved copper concentrations in toxicity test and *in situ* field-collected overlying water suggests some copper mobilization in the toxicity test set-up that has either not occurred in the field or has attenuated over time.

Condition 9 of the CEMP approval dated February 10, 2021 (BCMOECCS 2021) specified that "*The 14-day sediment toxicity test on H. azteca must be conducted every three years (i.e., next in 2022) using sediment of shallow habitat from Polley Lake unless MPMC can clearly show that copper concentrations in all Polley Lake shallow sediment samples are below the 95th percentile of the copper concentrations in the Bootjack Lake reference area shallow sediment samples.*" This condition was not met in 2022 in Polley Lake shallow sediments (see Section 5.1.1.2), indicating that toxicity testing of these shallow sediments must be completed in three years (in 2025) in accordance with the CEMP conditions.

[49] A moderate growth response was observed at POL-P1 (the Northwest basin) relative to the field reference (BOL-B2) in 2018. However, the same was not observed relative to the laboratory control. This response (21%) was only marginally greater than the specified acceptability criterion (20%).

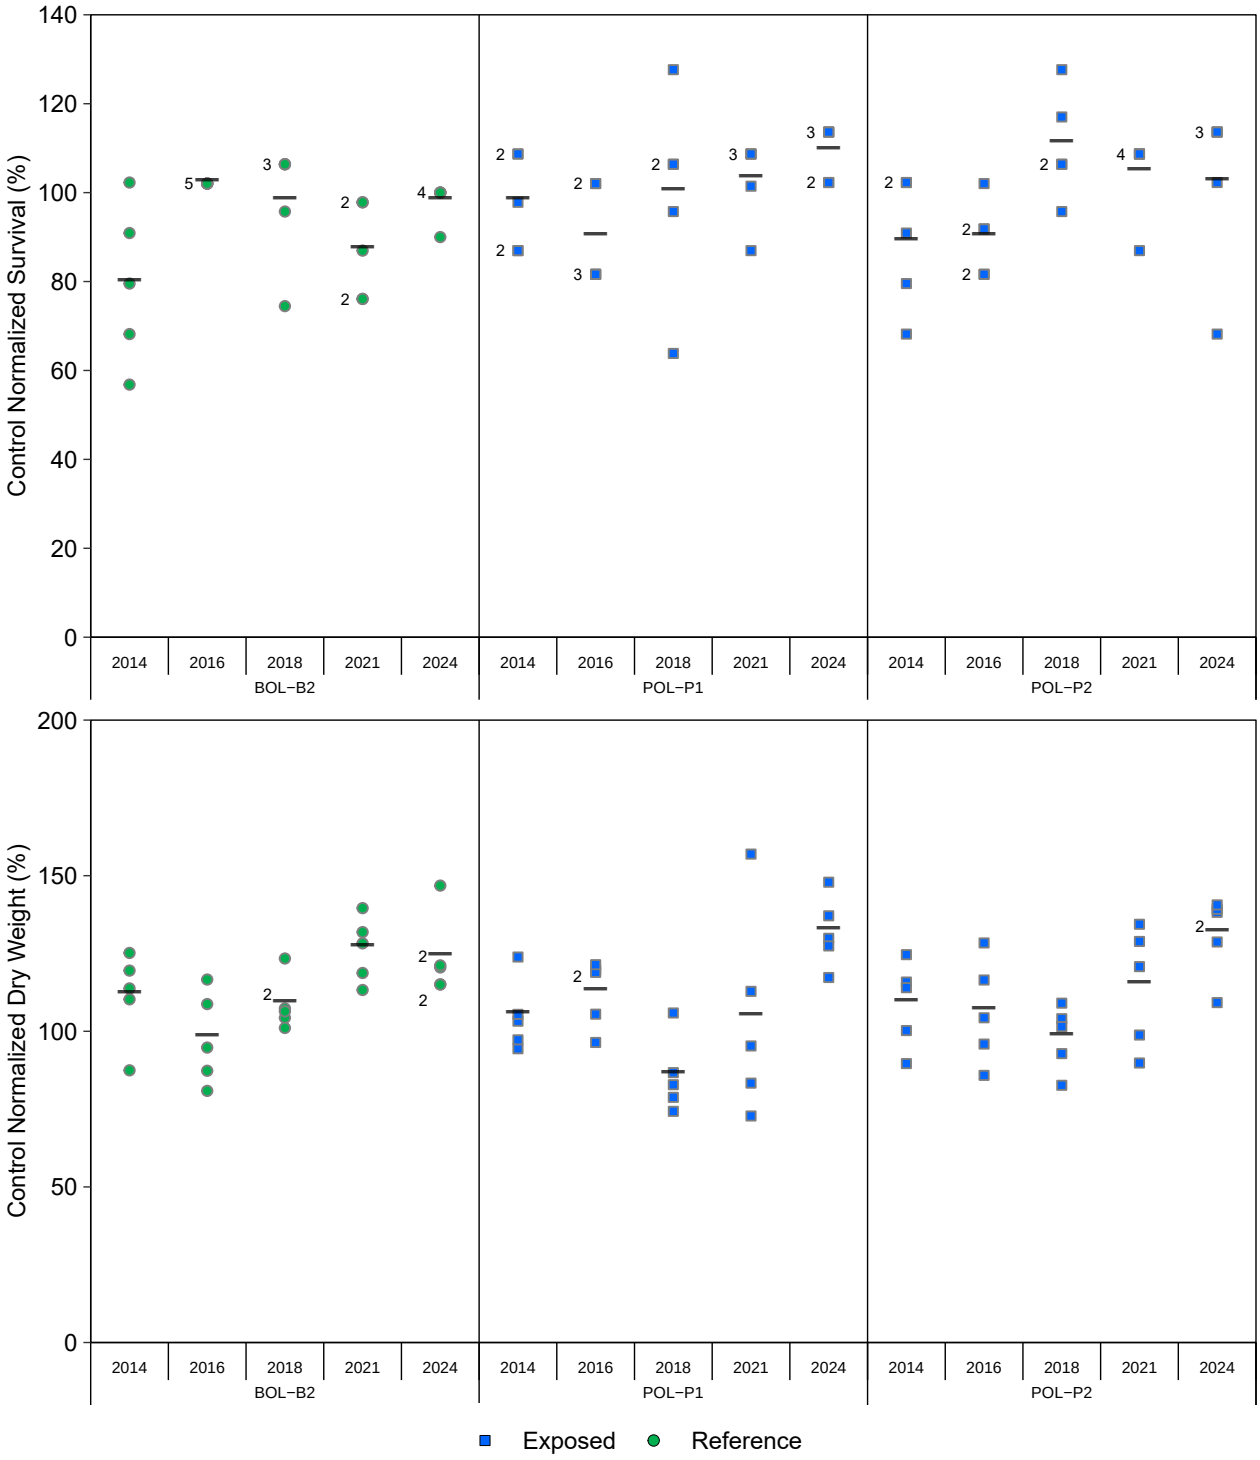

Figure 5.2: *Chironomus dilutus* Survival and Growth Responses (10−day) for Sediment Toxicity Testing at the Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: Green represents reference areas and blue represents exposed areas. Survival and growth data were normalized as a percentage of control performance for the same test batch. Numbers beside points on the plot indicate the number of overlapping results plotted. In 2024, different control sediment was used for Bootjack and Polley Lake; data were normalized to results from the associated control sample.

5.1.3 Plankton Community and Productivity

Plankton community and productivity monitoring was completed annually between 2022 and 2024 with three sampling events per year (June, July, and August) in Polley Lake (POL-P2) and a corresponding reference area in Bootjack Lake (BOL-B2; Figure 3.3, Tables 3.4 and 3.5). Single phytoplankton and zooplankton samples were collected in June and August, whereas replicate samples were collected in July of each year (n = 5 per area; see Section 3.3.1 for details).

A review of the 2024 plankton community and productivity results (Appendix B) indicated that the data met the established laboratory DQOs. Phytoplankton and zooplankton community samples had good laboratory precision and accuracy, and phytoplankton productivity (chlorophyll-a) results had good detectability, high laboratory accuracy, and no evidence of laboratory contamination. Laboratory precision could not be evaluated as the chlorophyll-a analysis required consumption of the entire sample; however, field sampling precision was excellent. Recommended hold times were exceeded by one day in three samples; however, results remained within historic range. Overall, the plankton community and productivity data for Polley Lake can be used with a good level of confidence for data interpretation.

A review of the 2024 supporting spot water quality data collected by Minnow (Appendix B) indicated results were characterized by good detectability, negligible analyte concentrations in laboratory blank samples, field and trip blanks, and good laboratory precision and accuracy. Recommended hold times were exceeded for pH (0.25 hour hold time) in all samples as well as turbidity, dissolved orthophosphate, nitrite, and nitrate (36 hour hold time) in most samples. For pH field measures were used in data analyses, so impacts were negligible. Results for dissolved orthophosphate, nitrite, and nitrate were similar to those that did not exceed hold times in prior years, suggesting that hold time exceedances had a negligible impact on analyte results. Total copper, iron, cadmium, and dissolved manganese and cadmium exceeded the recommended DQO for variation within field duplicate samples of >30% relative percent difference (RPD) in one or more samples (Appendix B). The exceedances were not consistent across all duplicate sets, suggesting water quality data had generally good field precision that was not consistently influenced by collection methods. Overall, the water quality data was of acceptable quality and can be used with a good level of confidence for interpretation.

5.1.3.1 Phytoplankton

5.1.3.1.1 Community

Qualitative evaluation of seasonal data from 2024 indicated that phytoplankton densities were highest in July and August at the exposed (POL-P2) and reference (BOL-B2) areas, with comparatively lower densities occurring in June. In contrast, taxon richness at POL-P2 was

lowest in July compared to June and August 2024 but was similar among months at BOL-B2 (Appendix Figure E.2.1, Appendix Table C.3.1). Statistical analyses of replicated data (from July sampling events) indicated that phytoplankton density and taxon richness at POL-P2 in 2024 were both significantly lower compared to BOL-B2. In contrast, Simpson's Diversity and Evenness at POL-P2 in 2024 were both significantly higher compared to BOL-B2 (Figure 5.3, Table 5.3; Appendix Tables C.3.1 and C.3.2).

Temporal analyses indicated some variability in density, taxon richness, Simpson's Diversity, and Simpson's Evenness at POL-P2 from 2019 to 2024 (Figure 5.3, Table 5.3). Mean phytoplankton density at POL-P2 decreased over time between 2019 to 2022, increased significantly in 2023 to densities similar to 2019, and then decreased significantly in 2024 to densities similar to 2020 and 2021 (Figure 5.3, Table 5.3). Mean densities at POL-P2 have been similar to (2019), significantly lower (2020 and 2024), and significantly higher (2021 to 2023) than those at the reference area, while the densities at BOL-B2 have also varied significantly between 2019 and 2024. This temporal variability in mean phytoplankton densities at both the exposed and reference areas has been driven primarily by significant changes in the densities of Cyanobacteria (Figure 5.3, Table 5.3; Appendix Figures E.2.2 and E.2.3). Taxon richness at POL-P2 in 2024 was similar to prior years except for being significantly lower than 2023 and was significantly lower than the reference in all years except 2020 (Figure 5.3, Table 5.3). However, taxon richness at POL-P2 remained within the range of post-breach results (2015 onward) for the same area, but was lower than baseline (1996) at both exposed and reference areas (Appendix Figure E.2.1). Some variability in taxon richness among the baseline (1996), early post-breach (2015 to 2018), and recent post-breach (2019 to 2023) results may be attributed to changes in phytoplankton taxonomists (see Minnow 2020a for details). Although phytoplankton density and taxon richness at POL-P2 have been significantly different than at the reference area in most years, the lack of a directionally consistent change in either of these endpoints (i.e., consistent increase or decrease over time) compared to the reference area, suggested that the observed temporal variability was likely related to changes and/or differences in local environmental factors (e.g., light exposure, water temperature, nutrient availability) between the lakes. Simpson's Diversity and Evenness at POL-P2 were similar to or significantly higher than at BOL-B2 in all years. Simpson's Diversity at both POL-P2 and BOL-B2 was higher in 2022 to 2024 compared to 2019 to 2021 while Simpson's Evenness was highest in 2022 and 2024 at POL-P2 and was highest in 2022 at BOL-B2 compared to other years (Figure 5.3, Table 5.3).

Qualitative evaluation of seasonal data from 2024 indicated that the phytoplankton community at both POL-P2 and BOL-B2 was dominated by Cyanobacteria throughout the growing season (June, July, and August). At both POL-P2 and BOL-B2, the relative densities (%) of Diatoms, Chlorophytes, Chrysophytes, and Cryptomonads were slightly higher in June compared to later

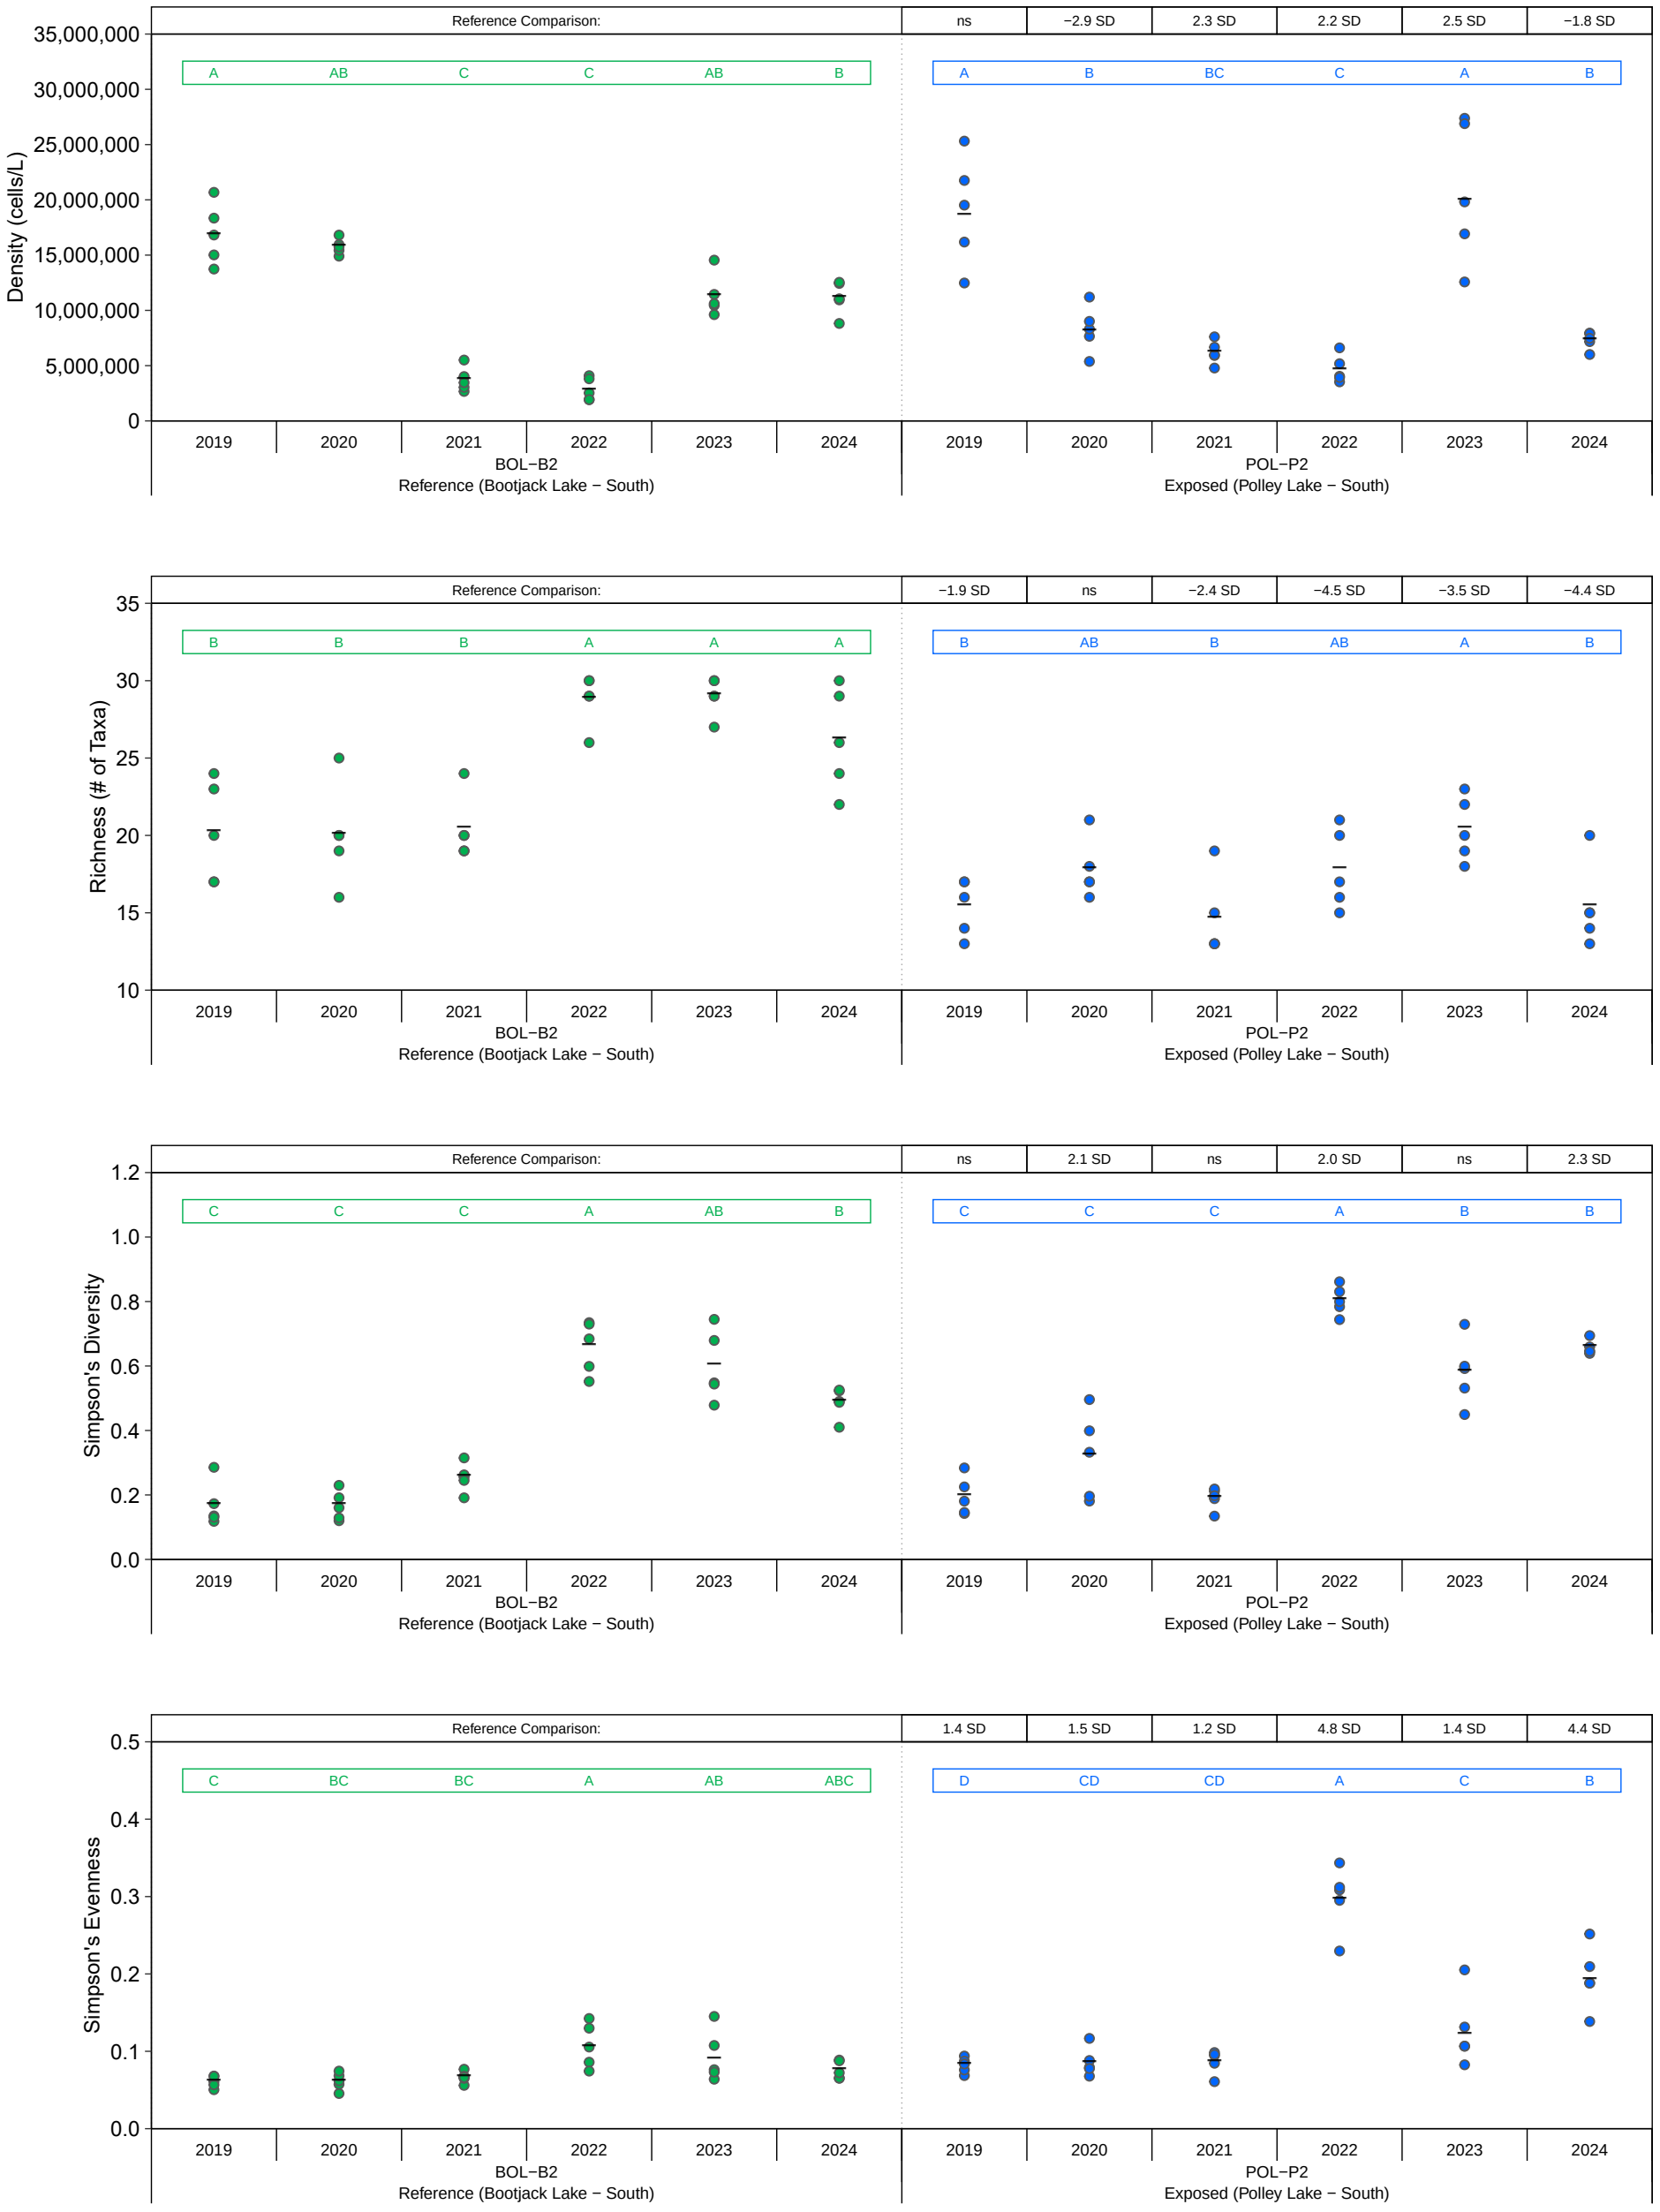

Figure 5.3: Phytoplankton Community Metrics for the Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Monitoring Areas in July, 2019 to 2024

Notes: Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value<0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD) relative to reference. 'ns' indicates a non−significant contrast. For plots of phytoplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single phytoplankton samples collected in June and August 2024, see Appendix Table C.3.1

Magnitude of Difference (MOD) < -2.

Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available, ns = non significant, µg/L = micrograms per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, $\log_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

in the summer (July and August) when Cyanobacteria (%) were more dominant in both lakes (Figure 5.4, Appendix Figure E.2.3, Appendix Table C.3.1). The pattern of increasing dominance of Cyanobacteria as the summer progressed from June to August was similar to that observed in previous years and was likely related to higher water temperatures which occurred later in the growing season, and which promoted Cyanobacteria growth (Appendix Figures A.1.2 and C.1.1; Schnurr and Allen 2015). Statistical analyses of replicated data (from July sampling events) indicated that the community composition at POL-P2 in 2024 differed from that at BOL-B2 in terms of significantly higher relative densities (%) of Chrysophytes, and significantly lower relative densities of Diatoms, Cryptomonads. Cyanobacteria, the dominant taxa in both lakes, had relative densities (%) that were similar between POL-P2 and BOL-B2 in 2024, as were Chlorophytes (%; Appendix Figure E.2.2, Appendix Table E.2.1). Dinoflagellates, Euglenophytes, and Radiophytes represented < 5% of the phytoplankton community in each year, thus changes in the relative densities of these taxa were less likely to be ecologically meaningful and were not considered further (Appendix Tables C.3.2 and E.2.1).

Temporal analyses indicated that the relative densities (%) of Cyanobacteria (the dominant taxa in both Polley and Bootjack lakes) at POL-P2 have been similar to or significantly lower than at the reference area throughout the monitoring period (2019 to 2024). The temporal variability in the differences in Cyanobacteria (%) between POL-P2 and BOL-B2 were driven mainly by temporal changes at BOL-B2 since Cyanobacteria (%) has been largely temporally stable at POL-P2 (except for a significant decrease in 2022 compared to all other years; Appendix Figure E.2.2, Appendix Table E.2.1). The relative densities (%) of Chrysophytes at POL-P2 have consistently been significantly higher than at the reference area from 2020 to 2024, and Cryptomonads (%) at POL-P2 have been significantly lower than at BOL-B2 in most years from 2021 to 2024 (except 2022 when there was no difference; Appendix Figure E.2.2, Appendix Table E.2.1). For the less dominant taxa (Chlorophytes and Diatoms), the results at POL-P2 have been more temporally variable compared to BOL-B2, but these taxa represented < 3% of the phytoplankton community in 2024 (Appendix Figure E.2.2, Appendix Table E.2.1).

Overall, the phytoplankton community in Polley Lake in 2024 was characterized by total density and taxon richness that were significantly lower, and Simpson's Diversity and Evenness that were significantly higher, than at the reference area (Bootjack Lake). Phytoplankton density has varied temporally, both within Polley Lake and relative to the reference area, and this variability is attributable to significant changes in Cyanobacteria densities in both Polley and Bootjack lakes which were likely driven by natural changes in environmental parameters (e.g., light exposure, water temperature, nutrient availability). Taxon richness in Polley Lake has consistently been significantly lower than at the reference area (except in 2020), while Simpson's Diversity and Evenness have been similar to or significantly higher than at the reference area in all years.

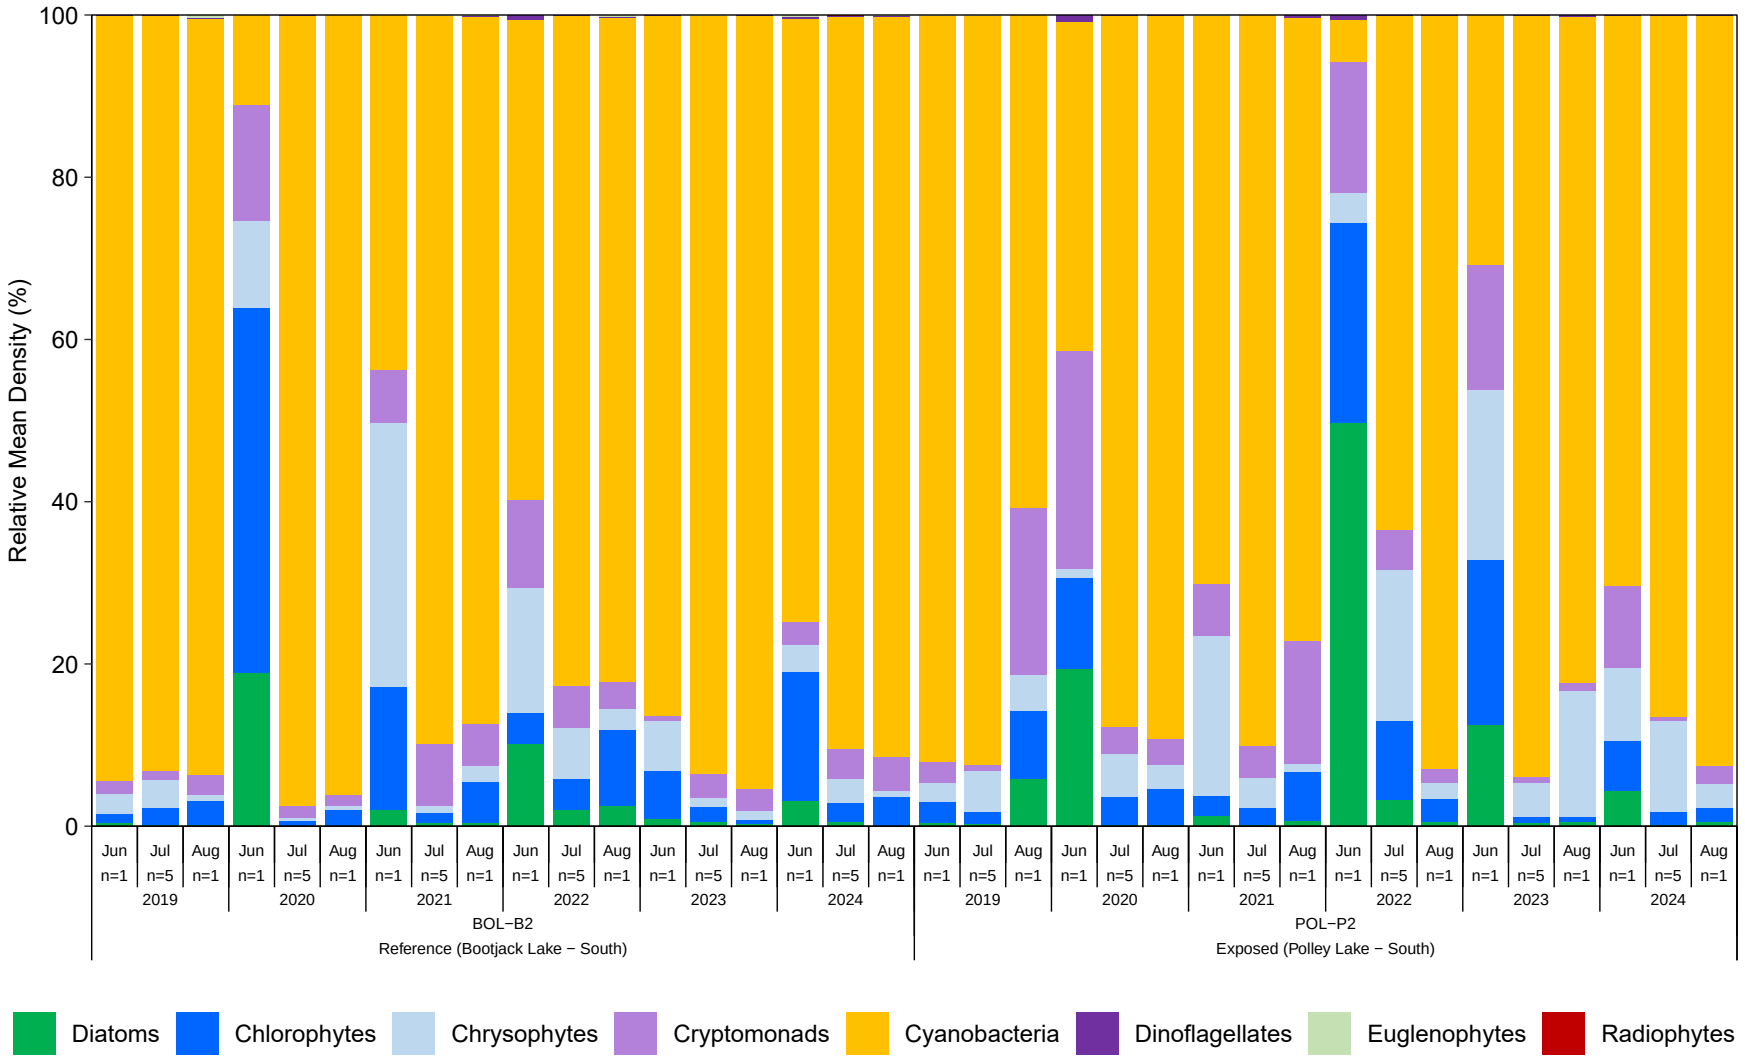

Figure 5.4: Relative Mean Densities of Major Phytoplankton Taxa for the Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Monitoring Areas, 2019 to 2024

Cyanobacteria were the dominant taxonomic group in both Polley and Bootjack Lakes from June to August in all years, with succession to greater Cyanobacteria dominance in late summer (July and August) of each year, and the relative densities of Cyanobacteria in Polley Lake have been similar to or significantly lower than in Bootjack Lake in all years. The less dominant taxa in Polley Lake have consistently shown significantly higher and lower relative densities (%) of Chrysophytes and Cryptomonads compared to Bootjack Lake, respectively, in most years since 2021. Collectively, the lack of a directionally consistent change in the differences of the Polley Lake community endpoints, relative to the reference area (i.e., no obvious consistent increasing or decreasing patterns), suggested that the observed differences were likely related to environmental factors (e.g., light exposure, water temperature, nutrient availability).

5.1.3.1.2 Productivity

Qualitative evaluation of seasonal data from 2024 indicated chlorophyll-a concentrations were lowest in June and highest in July and August at both POL-P2 (exposed) and BOL-B2 (reference; Appendix Figure E.2.1, Appendix Table C.3.1).

Statistical analyses of replicated data (from July sampling events) indicated that chlorophyll-a concentrations at POL-P2 in 2024 were significantly lower compared to BOL-B2, consistent with results observed in 2021. Chlorophyll-a concentrations at POL-P2 in 2024 were significantly lower than the remaining prior years (i.e., excluding 2021) when results at POL-P2 were similar to or significantly higher than at BOL-B2 (Figure 5.5, Table 5.3). The pattern of significant temporal changes in chlorophyll-a concentrations at POL-P2 from 2019 to 2024 was similar to those observed at BOL-B2, however, the magnitude of these differences was larger at POL-P2 (Figure 5.5, Table 5.3). The similarity in the pattern of temporal changes in chlorophyll-a concentrations between Polley Lake and Bootjack Lake suggests that natural variability in physical variables (e.g., light exposure, water temperature, nutrient availability) affected phytoplankton productivity similarly in both lakes, despite the temporal variability in the significant differences in chlorophyll-a concentrations between the lakes (Appendix Figure C.1.1 and Appendix Table C.1.2). The chlorophyll-a concentrations for Polley Lake from 2019 to 2024 were generally within the range of baseline conditions (1995 and 1996) and early post-breach years (i.e., 2015 to 2018), indicating that there has not been an obvious increase in phytoplankton productivity over the long-term (Appendix Figure E.2.1).

A lake's trophic status classification corresponds to its overall productivity in terms of sestonic algal biomass (chlorophyll-a concentrations) and nutrient concentration (Wetzel 2001). In 2024, Polley Lake and Bootjack Lake were classified as oligotrophic (<2.5 µg/L; Vollenweider and Kerekes 1982) based on mean July chlorophyll-a concentrations (1.32 µg/L for POL-P2 and 2.20 µg/L for BOL-B2; Figure 5.5; Appendix Table C.3.2). This was consistent with the trophic

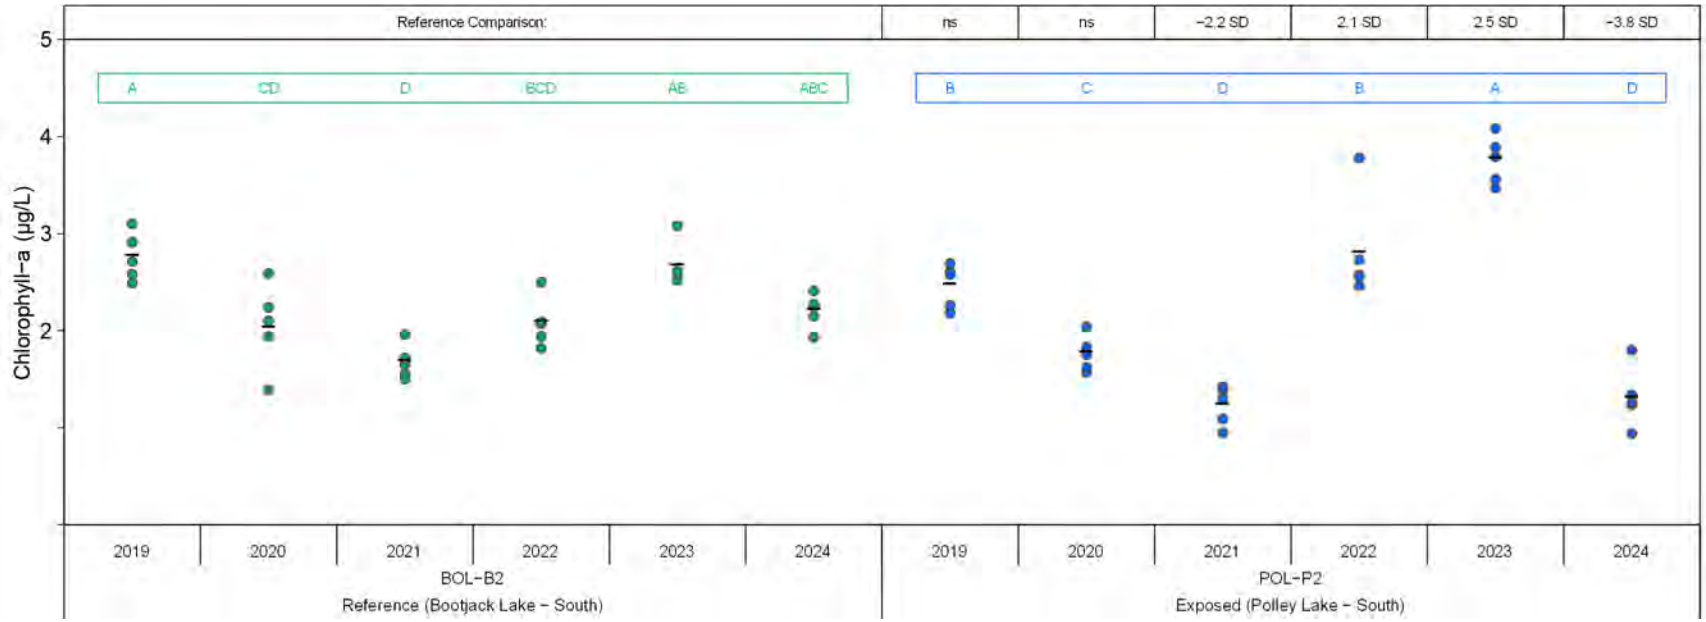

Figure 5.5: Phytoplankton Chlorophyll−a Concentrations for the Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Monitoring Areas in July, 2019 to 2024

Notes: µg/L = micrograms per litre. Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD). 'ns' indicates a non−significant contrast. For plots of phytoplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single phytoplankton samples collected in June and August 2024, see Appendix Table C.3.1.

status of the lakes in 2020 and 2021, but not in 2019, 2022, and 2023, when both lakes were classified as mesotrophic (Minnow 2020a, 2021a, 2022a, 2023a, 2024a).

5.1.3.2 Zooplankton

5.1.3.2.1 Community

Qualitative evaluation of seasonal data from 2024 indicated that zooplankton densities at POL-P2 (exposed) and BOL-B2 (reference) in 2024 were the highest in June and lowest in August in both lakes. In contrast, taxonomic richness in 2024 was highest in August in both lakes (Appendix Figure E.2.4, Appendix Table C.3.3). Statistical analyses of replicated data (from July sampling events) indicated that zooplankton density, Simpson's Diversity, and Simpson's Evenness in July 2024 were significantly lower at POL-P2 compared to BOL-B2, whereas taxon richness did not differ significantly between lakes in 2024 (Figure 5.6, Table 5.4; Appendix Tables C.3.3 and C.3.4). The significantly lower mean density at POL-P2 compared to BOL-B2 in 2024 was driven by significantly lower mean densities of Rotifera and Cladocera at POL-P2 (Appendix Figures E.2.5 and E.2.6, Appendix Table E.2.2). The 2024 results for both Simpson's Diversity and Evenness suggested differences in zooplankton community composition between POL-P2 and BOL-B2.

Temporal analyses indicated significant year-over-year decreases in zooplankton density at POL-P2 between 2022 and 2024, with the mean density in 2024 being significantly lower than all previous years (2019 to 2023; Figure 5.6, Table 5.4). However, a similar pattern was observed at BOL-B2 with significantly lower mean zooplankton density in 2024 compared to all previous years (except 2019). The similar temporal pattern in densities at POL-P2 and BOL-B2 was reflected in the MODs between the two areas that were smaller in 2024 (-2.0 SD) than in 2023 (-2.9 SD) despite the significant decrease in density at POL-P2, and suggests that natural regional environmental factors (e.g., air temperature) influenced zooplankton density at both lakes (Appendix Figures A.1.2 and C.1.1, Appendix Table C.1.2). Zooplankton densities at POL-P2 were similar to reference in 2022, then decreased to densities that were significantly lower than reference in 2023 and 2024. While the decrease in total density from 2022 to 2024 at POL-P2 was primarily driven by significantly decreased densities of Calanoida, Cladocera, and Copepod Nauplii in 2023 and 2024 compared to 2022, Cladocera and Rotifera were the only taxa at POL-P2 in 2024 with densities that were significantly lower than at the reference area (Appendix Figures E.2.5 and E.2.6, Appendix Table E.2.2). Zooplankton taxon richness and Simpson's Diversity at POL-P2 in 2024 were both similar to most prior years but were significantly lower than in 2023 (Figure 5.6, Table 5.4). Taxon richness at POL-P2 was similar to or significantly higher than the richness at BOL-B2 in all years except 2020. Simpson's Diversity at POL-P2 was significantly lower than BOL-B2 in 2019, 2002, and 2024 but similar to or significantly higher than at BOL-B2

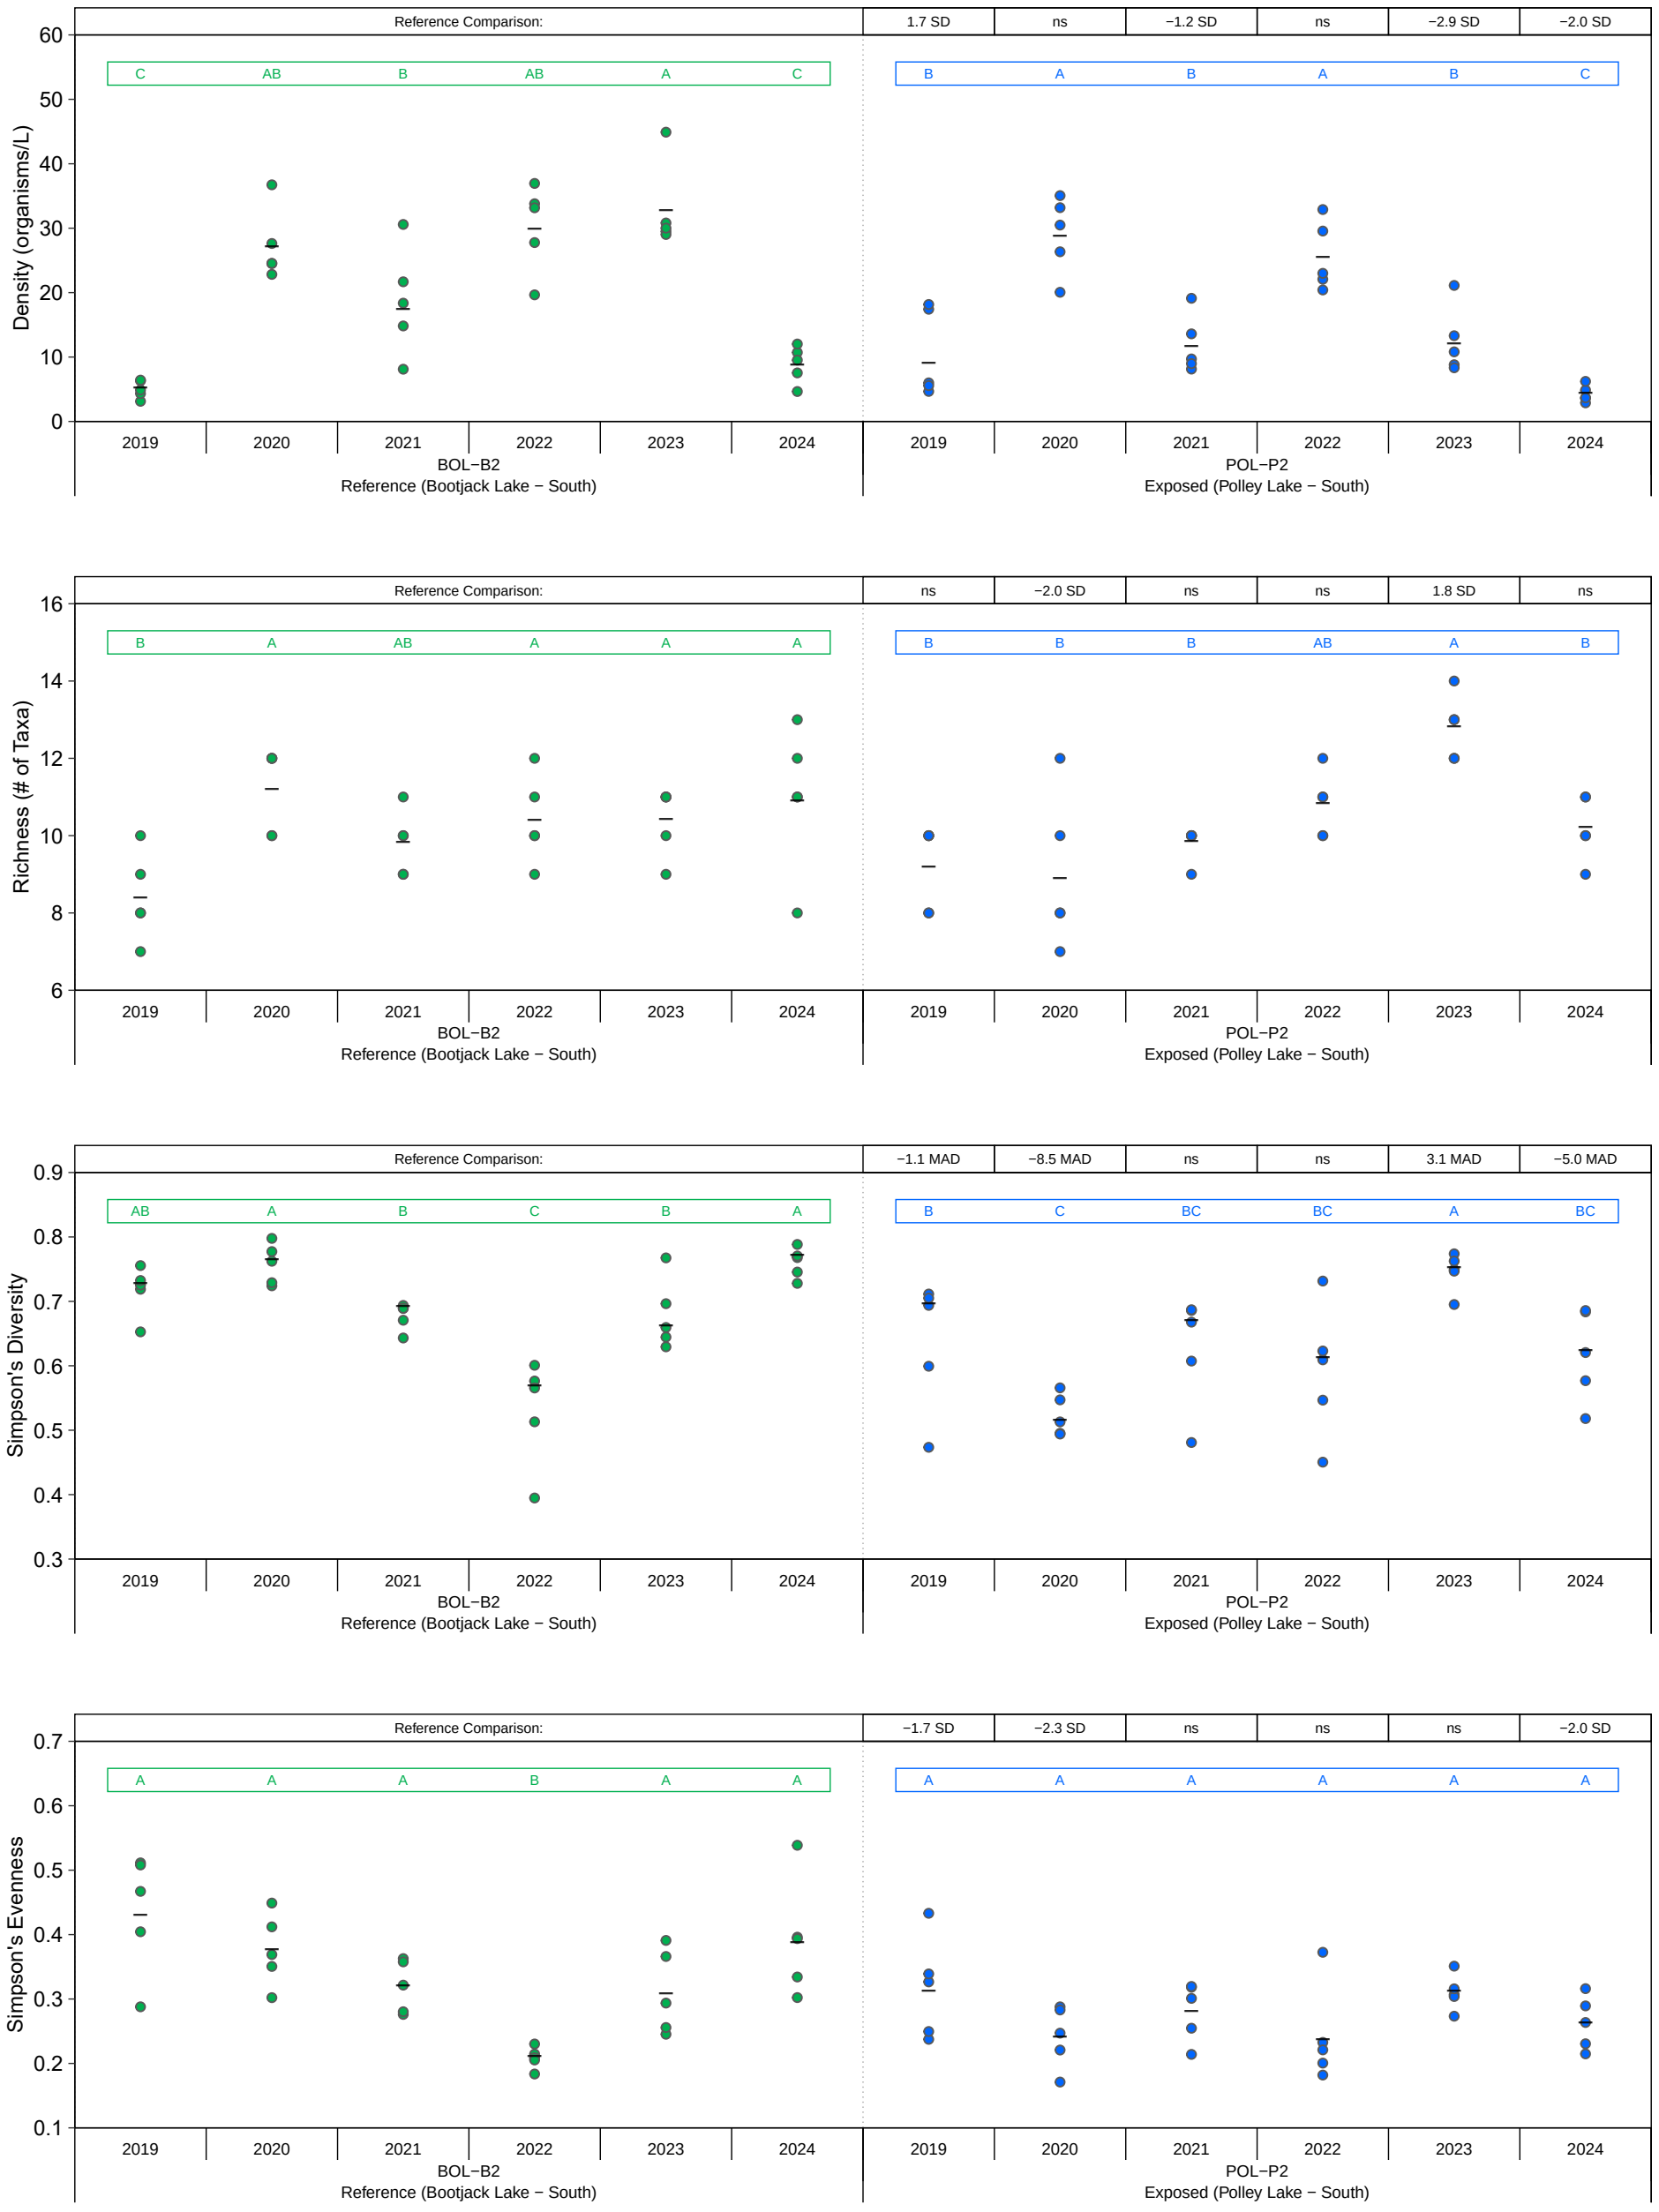

Figure 5.6: Zooplankton Community Metrics for the Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Monitoring Areas in July, 2019 to 2024

Notes: Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'ns' indicates a non−significant contrast. For plots of zooplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single zooplankton samples collected in June and August 2024, see Appendix Table C.3.3.

Table 5.4: Statistical Comparisons of Zooplankton Community Metrics for Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas in July, 2019 to 2024

Magnitude of Difference (MOD) < -2.

Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available, ns = non significant, mg/L = milligrams per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, $\log_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

in 2021 to 2023. Simpson's Evenness has not varied significantly among years at POL-P2 and was either similar to or significantly lower than at BOL-B2 over time (Figure 5.6, Table 5.4).

Qualitative evaluation of seasonal data from 2024 indicated that the zooplankton community at POL-P2 was dominated by Rotifera taxa in June (mean = 72.6%), whereas Cyclopoida and Copepod Nauplii taxa were the dominant taxa in July and August. At BOL-B2 in 2024, the zooplankton community was dominated by Rotifera and Copepod Nauplii in June and July, and by Rotifera and Cladocera in August (Figure 5.7; Appendix Table C.3.3). Statistical analyses of replicated data (from July sampling events) indicated that the community composition at POL-P2 in 2024 differed from that at BOL-B2 in terms of significantly higher relative densities (%) of Calanoida and Cyclopoida and significantly lower Rotifera, but no other differences in the relative densities of taxa (Appendix Figure E.2.5, Appendix Tables C.3.4 and E.2.2).

Temporal analyses indicated that the zooplankton community at POL-P2 has consistently had significantly higher and lower relative densities (%) of Cyclopoida and of Rotifera, respectively, compared to BOL-B2 from 2019 to 2024 (except for Cyclopoida [%] in 2022 which was similar between the areas). The relative densities (%) of Copepod Nauplii at POL-P2 were similar to BOL-B2 in 2023 and 2024, which differed from 2019 to 2022 when they were consistently significantly higher at POL-P2 compared to BOL-B2 (Figure 5.7; Appendix Figure E.2.5, Appendix Table E.2.2). The least dominant taxa (Calanoida and Cladocera) at POL-P2 have shown greater temporal variability relative to the reference area, although for Calanoida (%) this has been due to changes at BOL-B2 since Calanoida (%) at POL-P2 has been temporally stable from 2019 to 2024 in the community in POL-P2 (Appendix Figure E.2.5, Appendix Table E.2.2).

Overall, the zooplankton community in Polley Lake in 2024 was characterized by total density, Simpson's Diversity, and Simpson's Evenness that were significantly lower than at the reference area (Bootjack Lake), and taxon richness that was similar to the reference area. These four zooplankton community endpoints have varied temporally, both within Polley Lake (excluding Simpson's Evenness which has been temporally stable), and relative to the reference area. The zooplankton community in Polley Lake has consistently had a higher dominance of Cyclopoida (%) and lower dominance of Rotifera (%) than Bootjack Lake from 2019 to 2024 (excluding 2022 for Cyclopoida), while Copepod Nauplii (%) in Polley Lake were significantly higher than Bootjack Lake from 2019 to 2022 but similar to the reference area in 2023 and 2024. Collectively, the observed temporally variability in most endpoints at both the exposed and reference areas, and the lack of a directional consistency in the differences of the Polley Lake community endpoints, relative to reference (i.e., no consistent increasing or decreasing patterns), suggested that the observed differences between the exposed and reference zooplankton

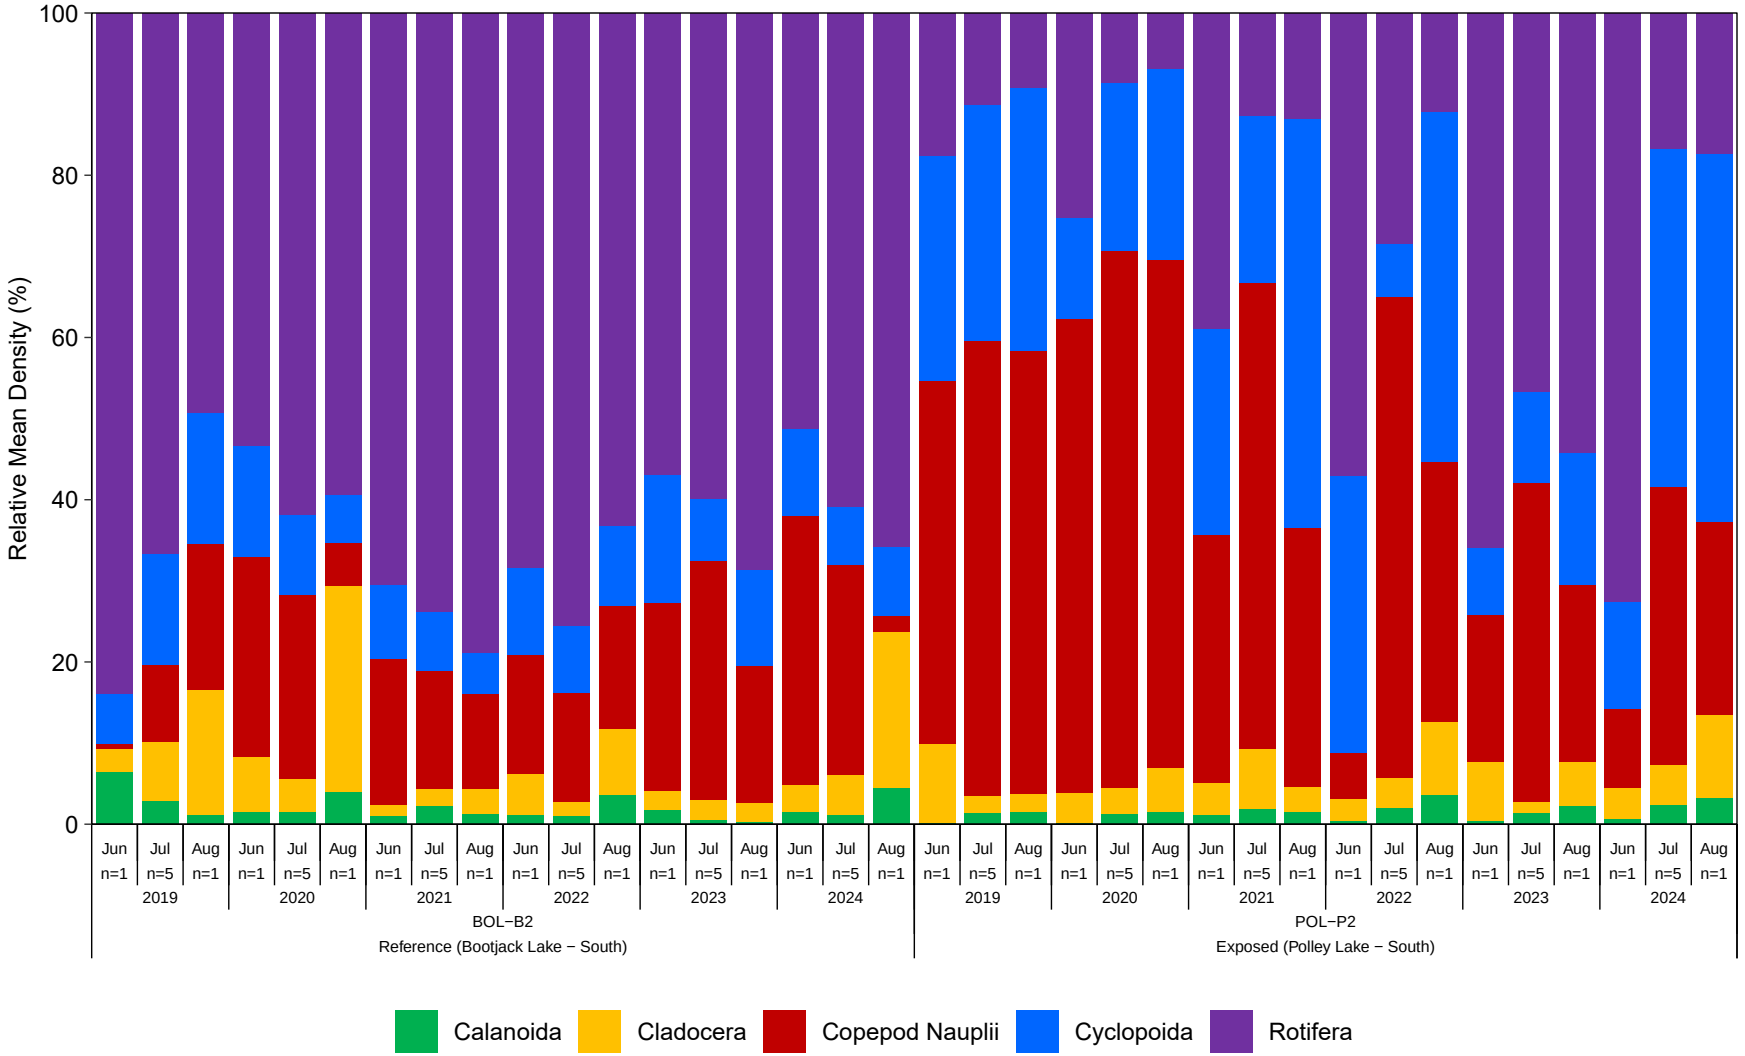

Figure 5.7: Relative Mean Densities of Major Zooplankton Taxa for the Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Monitoring Areas, 2019 to 2024

Notes: Results displayed for POL-P2 (August 2019; above) for the same sampling area and date, differ from those presented in previous reports (Minnow 2020a, 2021a, 2022a) due to revised calculations.

communities were likely related to environmental factors (e.g., water temperature, nutrient availability, phytoplankton community, predation).

5.1.3.2.2 Productivity

Qualitative evaluation of seasonal data from 2024 indicated that zooplankton biomass (dw) at the exposed area (POL-P2) in June and August 2024 were within the range of values observed in July, whereas zooplankton biomass at the reference area (BOL-B2) decreased from June to August (Appendix Figure E.2.4, Appendix Table C.3.3).

Statistical analyses of replicated data (from July sampling events) indicated that mean zooplankton biomass (dw) at Polley Lake (POL-P2) was significantly higher than at the reference area (BOL-B2) in July 2024, similar to the results in 2019 (Figure 5.8, Table 5.4; Appendix Table C.3.4). Zooplankton biomass (dw) at POL-P2 was similar to BOL-B2 between 2020 and 2022 and was significantly lower than at BOL-B2 in 2023 (Figure 5.8, Table 5.4). Within both lakes, there has been variability in zooplankton biomass (dw) over time, and patterns were similar to those for total zooplankton density over time (Figures 5.6 and 5.8, Table 5.4). The general similarity in temporal changes of zooplankton biomass (dw) at POL-P2 compared to BOL-B2 indicated these changes were likely related to natural environmental factors (e.g., water temperature, length of growing season; Shuter and Ing 1997) that have similarly affected zooplankton productivity in both lakes. Despite the significantly lower zooplankton biomass (dw) at POL-P2 in 2023 and 2024 compared to 2022, zooplankton biomass (dw) at POL-P2 has remained similar to or significantly higher than at the reference area (BOL-B2) in all years except 2023 (Figure 5.8, Table 5.4).

5.1.4 Zooplankton Tissue Quality

Zooplankton tissue quality monitoring was completed annually between 2022 to 2024 with three sampling events per year (June, July, and August) in Polley Lake (POL-P2) and at a corresponding reference area in Bootjack Lake (BOL-B2; Figure 3.3, Table 3.6). Replicated results from July (n=5) were used for statistical comparisons (see Section 3.4.3).

A review of the 2024 zooplankton tissue quality results (Appendix B) indicated that the data largely met the established DQOs. Specifically, the data were characterized by appropriate detectability, negligible analyte concentrations in method blank samples, excellent laboratory accuracy; however, laboratory duplicate samples failed the DQO in 5.26% of results. Zooplankton tissue field duplicate samples generally had low agreement, and the recommended DQO for variation within field duplicate samples was exceeded for nickel and tin (both secondary analytes) in duplicate pairs from July and August, while the field duplicate sample in June met the DQO for all analyte comparisons except antimony (Appendix B). Differences in

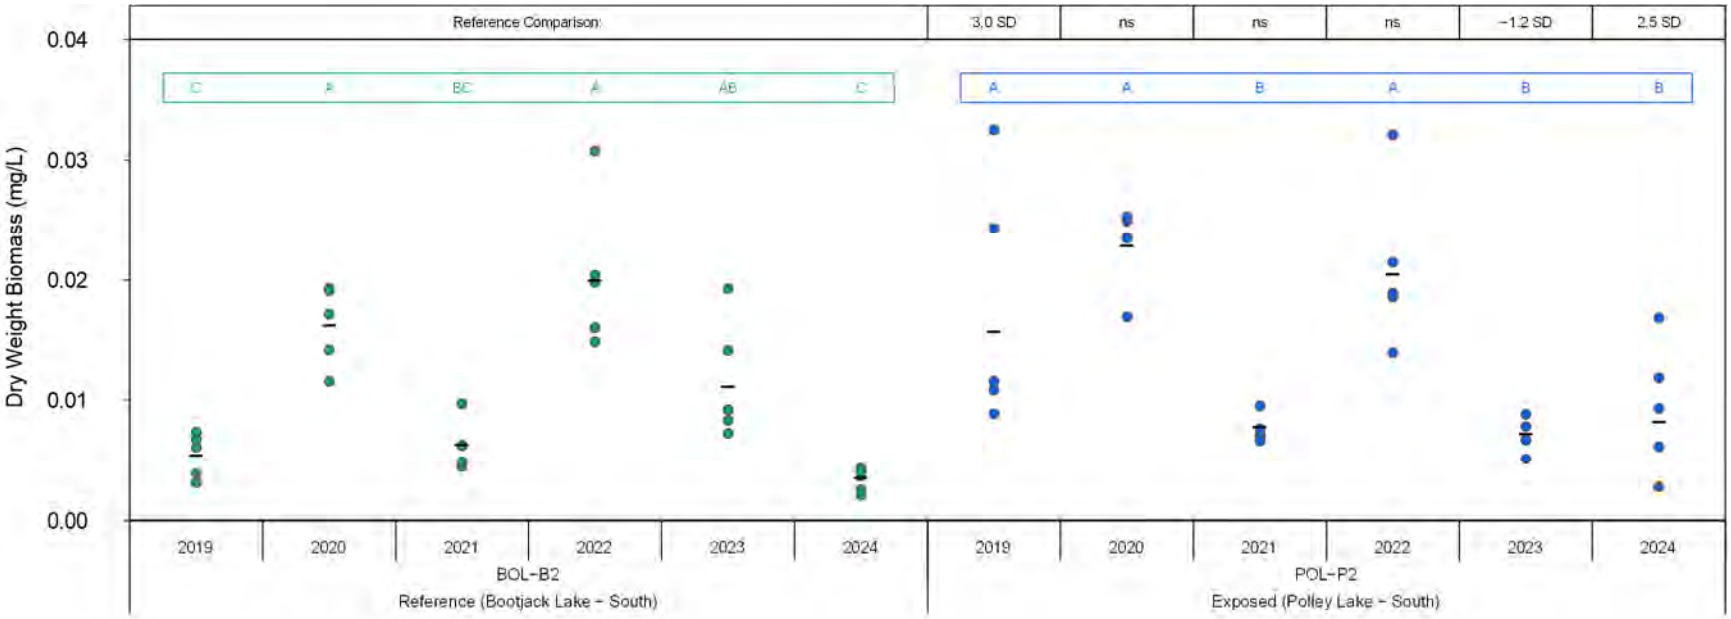

Figure 5.8: Zooplankton Biomass (Total Dry Weight) for the Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Monitoring Areas in July, 2019 to 2024

Notes: mg/L = milligrams per litre. Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD). 'ns' indicates a non− significant contrast. For plots of zooplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single zooplankton samples collected in June and August 2024, see Appendix Table C.3.3.

the agreement of field duplicate pairs are likely the result of natural variability in community composition, which may vary among seasons, and variability associated with multi-element scans. One sample from Polley Lake in June had several analyte concentrations that were elevated relative to historic values, with results confirmed by laboratory reanalysis. Overall, the 2024 zooplankton tissue quality data can be used with an appropriate level of confidence for interpretation, although the occurrence of some natural heterogeneity in analyte results were considered during data interpretation. A review of 2024 supporting water data quality indicated that these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

Data interpretation was focused on primary and secondary analytes (Table 2.4) with a significantly positive relative (exposed-reference) difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant[50]).

Zooplankton tissue from Polley Lake had concentrations of primary or secondary analytes that were either similar to or significantly lower than reference in 2024 (if the *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant; Appendix Table E.3.1). This result contrasts with prior years (i.e., 2019 to 2021, and 2023) when one or both of two primary analytes (copper and selenium) and one or more of several secondary analytes (cadmium, calcium, molybdenum, phosphorus, strontium, tin, and zinc) were significantly higher at the exposed area than reference (Appendix Table E.3.1). Despite temporal variability over the post-breach monitoring period (i.e., 2019 and 2024), the relative (exposed-reference) differences of all primary and secondary analyte concentrations in 2024 were similar to or significantly lower than the first year of monitoring with replication (i.e., 2019; Appendix Table E.3.1), indicating there is no sustained increase in primary or secondary analyte concentrations in zooplankton tissues from Polley Lake. Rather, the concentrations of copper and several secondary analytes (manganese, mercury, molybdenum, nickel, and tin) in zooplankton tissues from Polley Lake in 2024 were significantly lower than the first year of monitoring with replication (i.e., 2019; Appendix Figure E.3.1, Appendix Table E.3.1).

Mean zooplankton selenium concentrations in 2024 from Polley Lake (4.57 mg/kg dw) exceeded the BC interim guideline for aquatic life (4 mg/kg dw; BCMOE 2014) but were below the guideline at the reference area (Bootjack Lake; Appendix Figure C.4.1, Appendix Table C.4.1). Tissue selenium concentrations in 2024 were within the range of results observed in previous post-breach years (i.e., between 2014 and 2019; Appendix Figure C.4.1, Appendix Table C.4.1).

[50] If no significant change was detected in the relative (exposed-reference) difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from 2019 to 2024 were combined for the analyses.

Despite exceeding the guideline, selenium concentrations in zooplankton tissue from Polley Lake in 2024 did not differ significantly from reference and have not increased significantly since the first year of monitoring with replication (i.e., 2019, as described above).

Temporal evaluation of post-breach (2015 to 2024) surface water quality trends in Polley Lake indicated that, except for dissolved copper and total and dissolved vanadium, the surface aqueous concentrations (total and dissolved) of primary and secondary analytes in Polley Lake either decreased significantly or did not change significantly over time (Appendix Figures C.1.2 to C.1.4, Appendix Table E.3.2). Concentrations of aqueous dissolved copper and total and dissolved vanadium concentrations increased significantly in the surface waters of both the Northwest and Southeast basins of Polley Lake (POL-P1 and POL-P2) between 2015 and 2024 (Appendix Figures C.1.2 to C.1.4, Appendix Table E.3.2). A comparison of dissolved copper to the BCWQG is discussed below. A BCWQG for vanadium does not exist; therefore, aqueous concentrations of this analyte could not be compared to guideline values (Appendix Table C.1.1; BCMOWLRS 2024, 2025). However, concentrations of vanadium in zooplankton tissues in Polley Lake did not differ significantly from reference from 2019 to 2024 (Appendix Table E.3.1), indicating no influence of the increased aqueous concentrations of vanadium on zooplankton tissue quality. The absence of a significant increasing trend in aqueous concentrations of the remaining primary and secondary analytes (including selenium) is consistent with the lack of sustained increase in concentrations of these analytes in zooplankton tissue from Polley Lake, relative to reference (Appendix Tables E.3.1 and E.3.2).

Copper has been identified in sediment quality monitoring as the most elevated analyte relative to pre-breach/reference conditions and BCWSQG in both deep and shallow monitoring areas (Minnow 2022a, 2023a) and exhibited an increasing trend in dissolved aqueous concentrations from 2015 to 2024 in Polley Lake (Appendix Table E.3.2). Therefore, to evaluate the potential impact of copper concentrations on aquatic life in Polley Lake, dissolved concentrations were compared to the relevant BLM-based BCWQG to calculate GEFs for dissolved copper (refer to Section 3.8.3.3 for details). The copper GEFs in surface water did not change significantly from 2015 to 2024 at both the Northwest and Southeast basins of Polley Lake, with observed GEFs for Polley Lake typically within the range of previous years and within the range of copper GEFs reported for Bootjack Lake (reference) which suggests there is little risk to aquatic life in the near term (Appendix Figure C.1.3, Appendix Table E.3.2). Copper concentrations in zooplankton tissue from Polley Lake in 2024 were lower than those in 2019 (when replicated sampling was initiated), relative to reference (Appendix Table E.3.1). This indicates that despite the significant increase in dissolved aqueous copper concentrations, copper concentrations in zooplankton tissue from Polley Lake have not increased.

5.1.5 Benthic Invertebrate Community

Benthic invertebrate community monitoring in 2024 was completed at the Northwest basin (POL-P1) and Southeast basin (POL-P2) of Polley Lake with the Southeast basin of Bootjack Lake (BOL-B2) serving as reference (Figure 3.1, Table 3.7). Previous benthic invertebrate community monitoring in Polley Lake was completed most recently in 2021 (Table 3.7).

A review of the 2024 benthic invertebrate community results (Appendix B) indicated that subsampling precision and accuracy, and taxonomic identification accuracy for most samples achieved all laboratory DQO indicating that the data were of acceptable quality, with one exception. The one exception was a benthic community sample from Quesnel Lake (MP_QUL-PFF1_PON-2_2024-08) that did not meet the laboratory DQO for sorting efficiency which may have been attributed to the low number of organisms recovered in the initial sort. However, the average sorting efficiency for all samples (91.5%) was above the DQO (90%) thus the data is considered acceptable and can be used with a high degree of confidence (Appendix B).

The benthic invertebrate community at POL-P1 in 2024 did not differ significantly from the reference area (BOL-B2) in terms of density, taxonomic richness, and Simpson's Evenness. At POL-P2 in 2024, richness did not differ significantly from the reference area, while density and Simpson's Evenness were significantly lower than reference (Figure 5.9, Table 5.5; Appendix Tables C.5.1 and C.5.2). Simpson's Diversity at both deep basins (POL-P1 and POL-P2) in 2024 was significantly lower than at the reference area (BOL-B2), although the magnitude of difference was smaller (-0.48 SD) at POL-P1 than at POL-P2 (-2.7 SD; Figure 5.9, Table 5.5). The benthic invertebrate community at the two deep basins in 2024 had similar taxonomic richness, but the Southeast basin (POL-P2; closer to the location of the breach) had significantly lower density (-1.4 SD), Simpson's Evenness (-1.4 SD), and Simpson's Diversity (-2.2 SD) compared to the Northwest basin (POL-P1; Table 5.5; Appendix Tables C.5.1, C.5.2).

Benthic invertebrate densities at both basins of Polley Lake (POL-P1 and POL-P2) have decreased consistently since 2018 resulting in densities in 2024 that were significantly lower than in 2018 and 2021 (Figure 5.9, Table 5.5). Despite these significant decreases, density at POL-P1 in 2024 remained significantly higher than all prior year (including pre-breach; 1999). Density at POL-P2 in 2024 was similar to 2016, significantly higher than in 2015 and 2016 (shortly after the breach) and remained similar to pre-breach (1999), indicating a return to pre-breach conditions (Figure 5.9, Table 5.5). At POL-P1, the significant decrease in total density in 2024 (relative to 2018 and 2021) was driven by a significant decrease in Chironomidae density over the same period, while at POL-P2 the decrease was due to a combination of significant

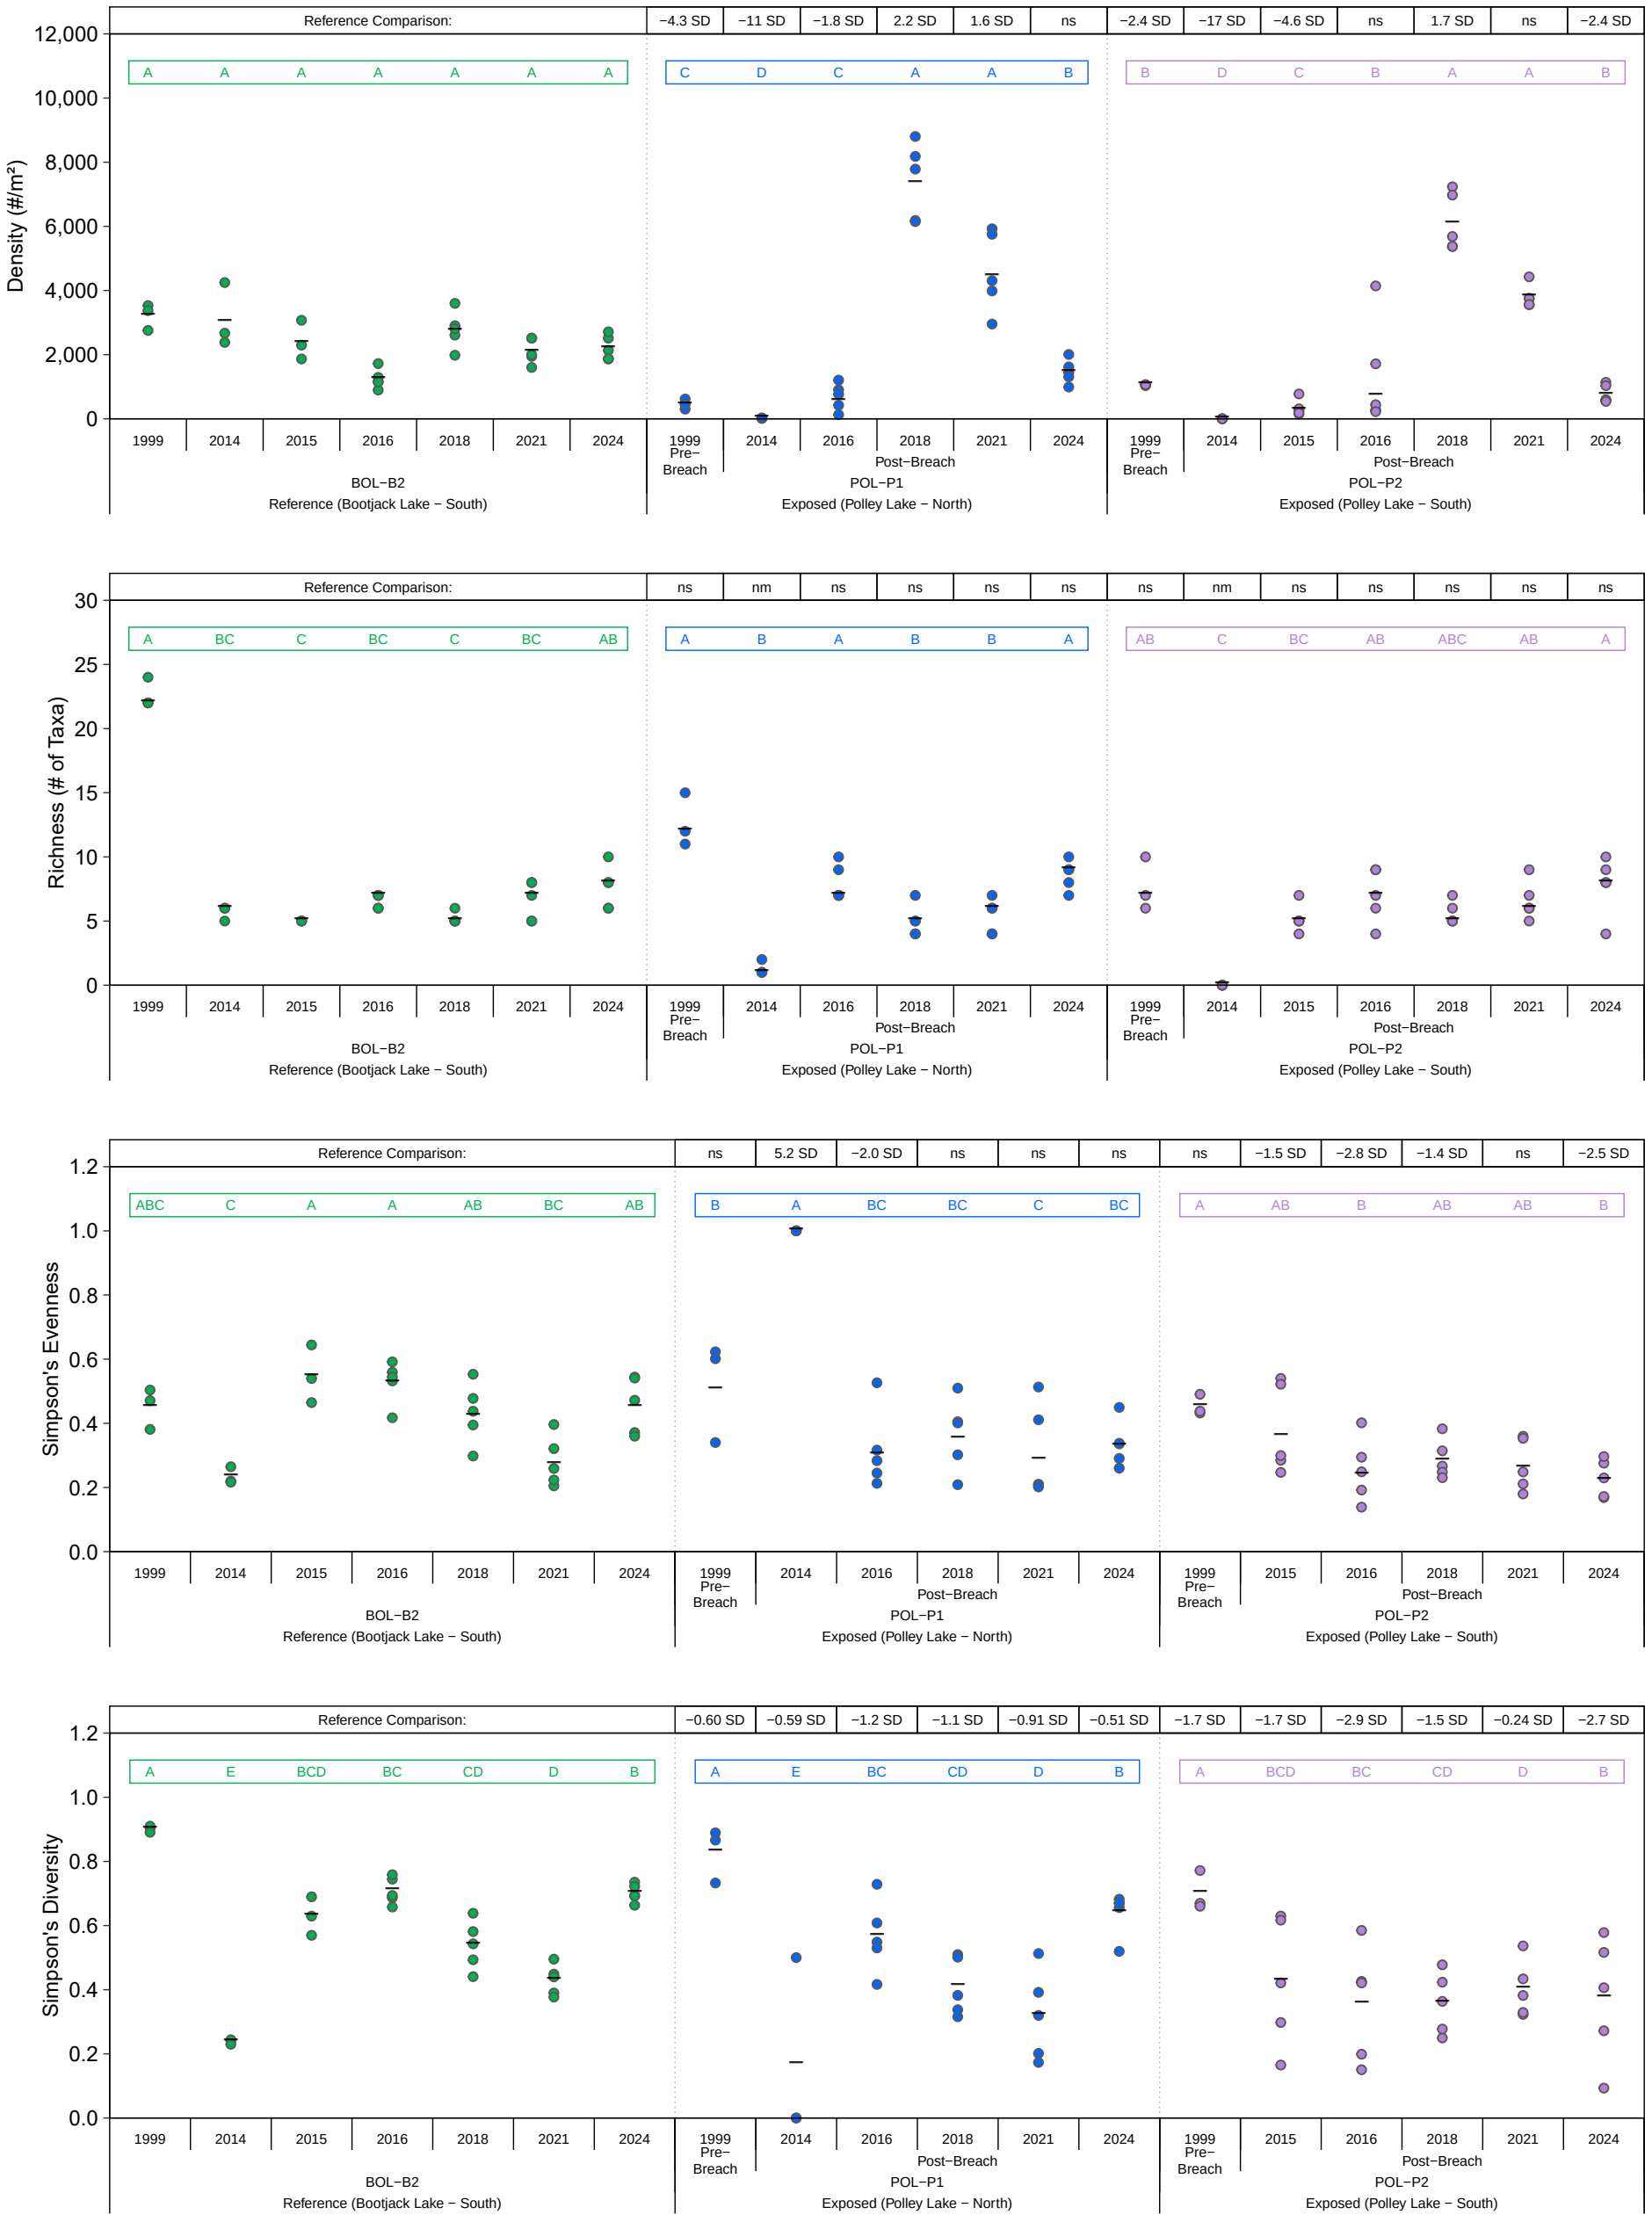

Figure 5.9: Benthic Invertebrate Community Metrics for the Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Deep Monitoring Areas, 1999 to 2024

Notes: Green represents reference data and blue or purple represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area.
A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons is expressed in units of standard deviation (SD) relative to reference. 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. Results displayed for post−breach richness, Simpson's Evenness, and Simpson's Diversity differ from those presented in Minnow (2022a) due to revised calculations.

Magnitude of Difference (MOD) < -2.

Magnitude of Difference (MOD) > 2.

Note: "-" = no data available. "nc" = no comparison. "ns" = no significance. ANOVA = analysis of variance. SD = standard deviation.

[a] Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log_{10}-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Remediated Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

decreases in Arachnida, Chironomidae, and Oligochaeta densities (Appendix Figure E.4.3, Appendix Table E.4.1). Density at both basins has been similar to or significantly higher than at the reference area since 2018, except for density at POL-P2 in 2024 which was significantly lower than reference but was similar to pre-breach (1999; Figure 5.9, Table 5.5).

Taxonomic richness at both basins (POL-P1 and POL-P2) in 2024 was similar to pre-breach conditions (1999), and richness at both basins has not differed from the reference area since 2016. At POL-P1, richness increased significantly between 2021 and 2024, to a richness in 2024 that was similar to both pre-breach (1999) and 2016, and that was significantly higher than all remaining prior years. At POL-P2, richness has been temporally stable (i.e., has not changed significantly) since 2016. (Figure 5.9, Table 5.5; Appendix Tables C.5.1, C.5.2). Simpson's Evenness at POL-P1 has been stable since 2016, similar to the reference area since 2018, and did not differ significantly from pre-breach (1999) conditions in 2024. At POL-P2, Simpson's Evenness has been stable since 2015 but was significantly lower than reference in most of those years (including 2024). Simpson's Evenness at POL-P2 in 2016 and 2024 was also significantly lower than pre-breach conditions (1999; Figure 5.9, Table 5.5).

Simpson's Diversity at the Polley Lake basins has consistently been significantly lower than both reference and pre-breach (1999) conditions since the initiation of post-breach monitoring. However, the magnitude of the difference compared to reference has been relatively small in most years (range = -0.51 to -1.2 SD at POL-P1 and -0.24 to -2.9 SD at POL-P2; Figure 5.9, Table 5.5). In addition, Simpson's Diversity at the reference area (BOL-B2) has been significantly lower than pre-breach conditions throughout the post-breach period (i.e., 2014 to 2024), suggesting that the consistently lower Simpson's Diversity in Polley Lake in the post-breach period compared to the pre-breach conditions is likely of low ecological relevance. Simpson's Diversity at both POL-P1 and POL-P2 increased significantly from 2021 to 2024. While the significant difference at POL-P1 in 2024 compared to reference was slight (-0.51 SD), the difference at POL-P2 was bigger (-2.7 SD) indicating Simpson's Diversity at this area has not yet recovered to a condition similar to reference (Figure 5.9, Table 5.5).

The benthic invertebrate community at both Polley Lake basins (POL-P1 and POL-P2) in 2024 was dominated by Chironomidae (non-biting midges; 51.4% and 84.2% mean relative density, respectively) and to a lesser extent by Oligochaeta (aquatic worms; Figure 5.10; Appendix Figure E.4.3, Appendix Table C.5.2). In most cases, the benthic invertebrate community composition did not differ significantly between the Polley Lake basins and the reference area in 2024. At POL-P1 in 2024, community composition only differed significantly from the reference area (BOL-B2) in terms of a lower Chaoboridae density (phantom midges); a known and pre-existing difference between the exposed and reference areas. At POL-P2 in

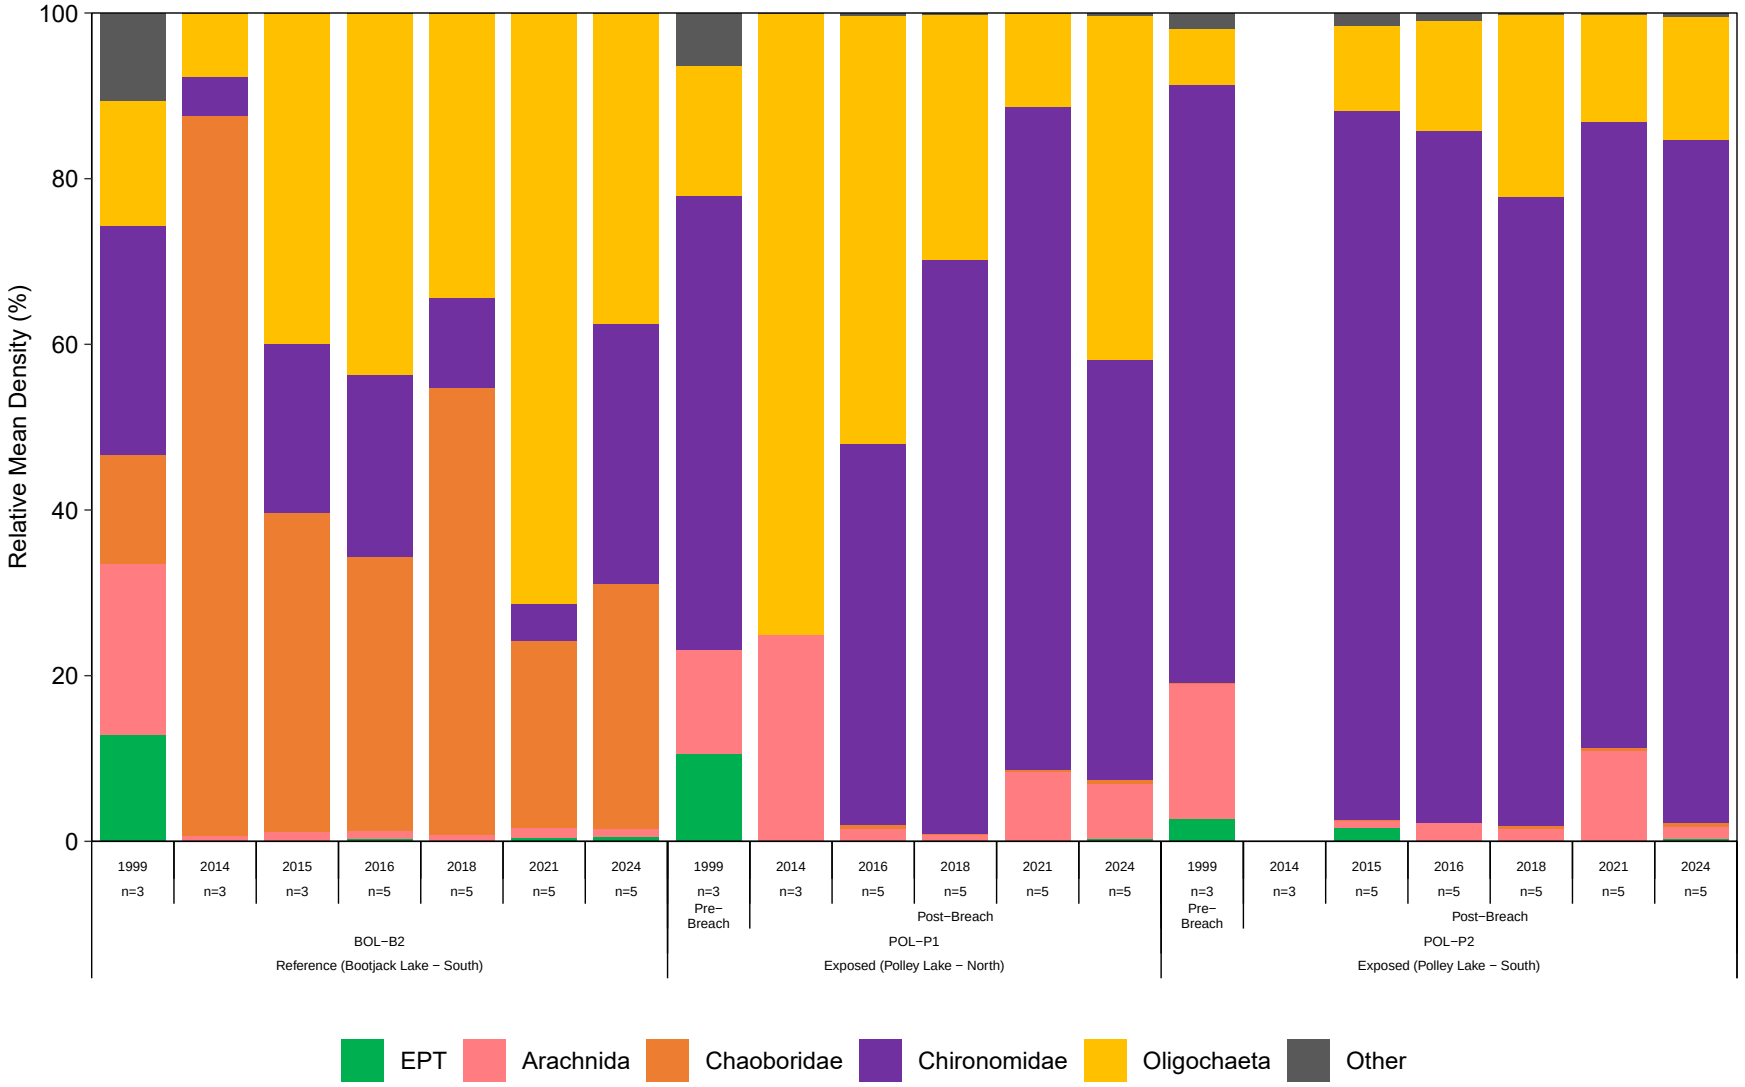

Figure 5.10: Relative Mean Densities of Major Benthic Invertebrate Taxa for the Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Deep Monitoring Areas, 1999 to 2024

Notes: EPT = Ephemeroptera, Plecoptera, Trichoptera. Total organism density at POL−P2 was zero in all replicates collected in 2014.

2024, the community composition differed significantly from the reference area in terms of lower density of Chaoboridae, lower density and relative density (%) of Oligochaeta, and higher relative density (%) of Chironomidae (Figure 5.10; Appendix Figures E.4.2 and E.4.3, Appendix Table E.4.1). The community composition of the two Polley Lake basins in 2024 was similar for most taxa apart from significantly lower Arachnida density, lower Oligochaeta (density and %), and higher Chironomidae density at POL-P2 compared to POL-P1 (Appendix Figure E.4.2, Appendix Table E.4.1).

Among the dominant taxa, specifically Chaoboridae, Chironomidae, and Oligochaeta, relative densities in 2024 did not differ from pre-breach conditions (1999) at either basin of Polley Lake or at the reference lake. The relative densities (%) of Arachnida at both Polley Lake basins significantly lower in 2024 than the pre-breach conditions (1999) but did not differ significantly from reference. However, at all monitoring locations, including the reference lake, the relative density (%) of Arachnida has been significantly lower than pre-breach in all years apart from 2021 (Appendix Figure E.4.2, Appendix Table E.4.1). This pattern likely reflects the influence of abiotic factors in the environment, indicating that the community structure at Polley Lake in 2024 was similar to pre-breach composition. The remaining taxa (i.e., EPT taxa [known to be sensitive to habitat disturbances and water pollution]; Lenat 1988, Herman and Nejadhashemi 2015) represented approximately < 5% of the community in both Polley and Bootjack lakes throughout the post-breach period, therefore were not considered further. Overall, the relative density (%) and density of all major taxa groups (EPT, Arachnida, Chaoboridae, Chironomidae, and Oligochaeta) in the basins of Polley Lake in 2024 were similar to reference and/or pre-breach (1999) conditions (Appendix Figure E.4.2, Appendix Table E.4.1).

Multivariate analysis (CA) was used to further evaluate the benthic invertebrate community composition from 1999 to 2024 at the two Polley Lake basins (POL-P1 and POL-P2) and the reference area (BOL-B2). The first two axes of the CA explained a total of 42.5% of the community variation (25.7% and 16.8% for CA Axes 1 and 2, respectively; Appendix Figures E.4.2 and E.4.4, Appendix Tables C.5.1, C.5.2, E.4.1, E.4.3). Benthic invertebrate community composition between the two Polley Lake basins did not differ significantly in 2024 or most prior years, as evidenced by no significant differences in scores along CA Axes 1, 2, or 3 (Appendix Figure E.4.2, Appendix Table E.4.1). Benthic invertebrate community composition, as represented by scores along CA Axes 1 and 3 (explaining 25.7% and 13.0% of the community variation, respectively), did not differ significantly between the exposed areas (POL-P1 and POL-P2) and reference in 2024, but was significantly different at all areas (exposed and reference) in 2024 compared to pre-breach (1999) conditions. In contrast, the community composition represented by CA Axis 2 (explaining 16.8% of community variation) was significantly lower at the Polley Lake basins in 2024 than at the reference area (in 2024)

but did not differ significantly from pre-breach (1999) conditions (Appendix Figures E.4.2 and E.4.4, Appendix Tables E.4.1 and E.4.3).

The benthic invertebrate community showed considerable and significant separation along CA Axis 1, with both exposed (POL-P1 and POL-P2) and reference (BOL-B2) results from 2024 having significantly higher scores than pre-breach (1999) conditions; a difference that indicated higher relative densities (%) of Oligochaetes of the genera *Rhyacodrilus* and *Limnodrilus*, and Chironomids of the genus *Protanypus* in the 2024 results (Appendix Figures E.4.2 and E.4.4, Appendix Tables E.4.1 and E.4.3). The occurrence of this significant difference in CA Axis 1 scores at both the exposed and reference areas in 2024, relative to pre-breach, suggests it is likely related to natural variability in community composition in both waterbodies. Chaoboridae were a key contributor to positive weightings along CA Axis 2 (Appendix Figure E.6.2, Appendix Table E.6.3). Therefore, the consistent difference in the relative density (%) and density of Chaoboridae between Polley Lake and the reference lake likely accounted for at least some of the significant differences between the exposed and reference results observed along on CA Axis 2. This hypothesis that is supported by the absence of a significant difference between 2024 and pre-breach (1999) CA Axis 2 results for the Polley Lake basins. Although the two Polley Lake basins in 2024 differed from pre-breach (1999) results along CA Axis 3 (a difference characterized by Oligochaetes of the genus *Tubifex*), they did not differ significantly from reference along this axis from 2018 to 2024 (Appendix Figures E.4.2 and E.4.4, Appendix Tables E.4.1 and E.4.3). Overall, the CA results indicate that benthic invertebrate community composition at the Polley Lake basins in 2024 was similar to either reference or pre-breach conditions, but not both.

Evaluation of correlation results indicated there were several significant relationships between station water quality characteristics and benthic invertebrate community endpoints (Appendix Figure E.4.5; Appendix Table E.4.2). Specifically, Simpson's Evenness, Simpson's Diversity, and Oligochaeta (%) were negatively correlated with the bottom water dissolved oxygen (DO; % and mg/L) and positively correlated with temperature (excluding a correlation for Oligochaeta [%] and temperature). In contrast the opposite relationships were observed with Arachnida (density and %), Chironomidae (density and %), and CA Axis 1, which were positively correlated with DO and negatively correlated with temperature (excluding a correlation for CA Axis 1 and temperature). The significant correlations between DO and various endpoints (negative relationships with Simpson's Diversity and Evenness and Oligochaeta [%], and positive relationships with Arachnida and Chironomidae) are consistent with a well-documented deficit in DO concentrations near the bottom of the water column at the deep basins of Bootjack Lake which have consistently been lower than those at Polley Lake, including pre-breach (1999; Beak 2000). This indicates a natural phenomenon unrelated to a mine influence (Figure A.1.1, Appendix

Table C.5.3). The occurrence of lower Chaoboridae and Oligochaeta (density and %) at Polley Lake compared to the reference area (Figure 5.10; Appendix Figure E.4.2) likely reflected the established greater tolerance of these taxa to, and their proliferation under, low dissolved oxygen concentrations (Borkent 1981, Chapman 1982a,b) such as those shown at the Bootjack Lake reference area (Appendix Tables A.1.2, C.5.3, Appendix Figures A.1.1, E.4.5). Chaoboridae (density and %) were negatively correlated with bottom water specific conductance and pH, while Oligochaeta (density) and CA Axis 2 were negatively correlated with specific conductance only. Conversely, Chironomidae (% and density) were positively correlated with both specific conductance and pH (excluding a correlation between density and specific conductance; Appendix Figure E.4.5, Appendix Table E.4.2). Sampling station depth was negatively correlated with several endpoints (Simpson's Evenness, Chaoboridae [density and %], Oligochaeta [density], and CA Axis 2) and positively correlated with Chironomidae (%). The significant correlations observed between station depth or bottom water specific conductance and benthic invertebrate community endpoints were strongly leveraged between the lakes, and therefore of limited interpretive value. For both temperature and pH, the narrow range of these variables (mean range = ~0.5 pH units, ~3°C; Appendix Table C.5.3), and the absence of pH values outside the BCWQG, indicated that it was unlikely that differences in benthic invertebrate community endpoints were related to variation in temperature and pH.

In addition to the significant correlations with water quality and station depths described above, Chaoboridae and Oligochaeta (density and %) and CA Axis 2 (which represented the Polley Lake benthic invertebrate community in the negative direction) were positively correlated to sediment TOC and negatively correlated with sediment arsenic and copper concentrations and sediment PCA Axis 1 and 2 (excluding a correlation between Oligochaeta density and PCA Axis 2). The opposite significant relationships were observed with Chironomidae (%); negative correlations with sediment TOC and positive correlations with sediment characteristics (arsenic and copper concentrations and sediment PCA Axis 1 and 2 [representing higher sediment analyte concentrations]). Notably, Chironomidae density was not significantly correlated with any sediment characteristics. Taxa within the Chironomidae and Oligochaeta groups exhibit a relatively high tolerance to elevated metal concentrations in sediment (Gerritsen et al. 1998), and most taxa in both groups occupy a feeding guild specialized in the consumption of organic carbon food sources (i.e., the collector-gatherer Functional Feeding Group; Mandaville 2002). Therefore, the significant correlations observed between Oligochaeta (density) and sediment TOC and analyte concentrations, but notable absence of similar correlations with Chironomidae (density) suggested a factor (or factors) other than concentrations of metals and TOC in sediment which likely contributed to the occurrence of significantly lower densities of Oligochaeta in Polley Lake compared to

Bootjack Lake. The correlations between Chaoboridae and sediment characteristics were a factor of the known and pre-existing difference in the occurrence of this taxa between the reference and exposed areas.

Overall, based on weight-of-evidence, the differences in benthic invertebrate communities between Polley Lake and the reference area in 2024 appeared to be driven largely by differing dissolved oxygen concentrations at the bottom of the water column. The occurrence of higher dissolved oxygen concentrations near the bottom at deep basins of Polley Lake compared to Bootjack Lake has reflected a natural phenomenon unrelated to past or present mine-influence. The benthic invertebrate community at deep basins of Polley Lake in 2024 were largely comparable to either the communities documented in Polley Lake in 1999 (pre-breach) or the reference area (Bootjack Lake) in 2024 (excluding Simpson's Evenness at POL-P2, and Simpson's Diversity at both exposed areas), indicating that the benthic invertebrate community structure of Polley Lake in 2024 has mostly recovered to pre-breach and/or reference conditions since the breach in 2014.

5.1.6 Fish Usage and Population Health

Fish usage and population health were evaluated for rainbow trout, longnose sucker, and redside shiner at Polley Lake annually between 2022 and 2024, with Bootjack Lake serving as a reference (Figures 3.4 and 3.5). Monitoring was completed in spring and in fall of each year (Appendix Tables C.6.1 to C.6.11), consistent with previous years (see Section 3.6 for details).

5.1.6.1 Community and Catch

Spring fishing in 2024 in Polley and Bootjack lakes was undertaken shortly after ice-out (i.e., April 23 to May 2, 2024). From 2016 to 2022, rainbow trout and longnose sucker were caught in both Polley and Bootjack lakes whereas redside shiner were caught in Polley Lake only (Table 5.6; Appendix Table C.6.1). All three species were caught in both Polley and Bootjack lakes in 2023 and 2024 (Table 5.6; Appendix Table C.6.1). A single largescale sucker (*Catostomus macrocheilus*) was also captured in Bootjack Lake during the spring 2024 sampling event, a species which has been observed in most previous monitoring years at low relative abundance (2019, 2021, 2022, and 2023; Minnow 2020, 2022a, 2023a, 2024a).

The CPUE for rainbow trout from Polley Lake in the spring of 2024 was the second highest (after 2023) recorded since 2016 and was almost unchanged from 2023, following consecutive increases in CPUE in 2022 and 2023 (Table 5.6). Rainbow trout CPUE in Bootjack Lake has been higher than in Polley Lake in most years (excluding 2023), including in 2024 (Table 5.6). However, the magnitude of the difference between the lakes in 2024 should be highlighted; whereas the rainbow trout CPUE observed in Polley Lake in 2024 was stable relative to 2023, the

[a] CPUE - Catch-per-unit-effort (# fish / trap / day).

CPUE in Bootjack Lake increased approximately 10-fold. This anomalous observation was more likely the result of a sampling effect (e.g., temperature effects on activity) than a true 10-fold increase in the density of fish in Bootjack Lake.

Spring fish collections each year target rainbow trout spawners aggregating near the mouth of Hazeltine Creek (in Polley Lake) and Bootjack Creek (in Bootjack Lake; Figure 3.4). From 2019 to 2021, temporal changes in CPUE indicated progressively fewer rainbow trout aggregated for spawning in Polley Lake (Table 5.6) which is consistent with the observation that most spawners present in 2018 would have reached the end of their life expectancy by 2021, with low replacement by recruits from 2014 to 2017 when Hazeltine Creek was inaccessible to spawning rainbow trout (see Section 3.6 for details). Natural mortality of older age classes and decreasing number of spawners observed in Hazeltine Creek during spawning surveys since 2018 resulted in fewer recruits being added to the population in each year (Minnow 2023b). However, because rainbow trout generally begin spawning between age three and five (Scott and Crossman 1998), it was anticipated that a portion of the 2018 cohort would have reached sexual maturity by 2021 and that most would have been sexually mature by 2022, which was consistent with the observed increase in rainbow trout CPUE in 2022 relative to all prior years since 2017. The increase in CPUE in 2023 and maintenance of a similar CPUE in 2024, can likely be attributed to the 2019 and 2020 cohorts reaching sexual maturity (Table 5.6).

The spring CPUE for longnose sucker in Polley Lake has declined over the past four years (2020 to 2024), and in 2024 was the lowest observed since monitoring began in 2016 (Table 5.6). As described above, spring sampling focuses on specific locations where fish are known to aggregate prior to spawning, therefore differences in CPUE over time may be due in part to the non-random sampling design implemented during this period (Appendix Table C.6.1). It is also possible that the decline observed from 2020 to 2024 are partially dependent on the increasing abundance of rainbow trout over the same period (except for rainbow trout in 2024; Table 5.6). A similar decline in longnose sucker CPUE was observed in Bootjack Lake, with CPUE in 2024 the lowest observed since monitoring began. Variable temperatures throughout the monitoring period (i.e., 2020 to 2024) were observed, such that low CPUE observations may have also been influenced by temperature driven effects on activity (e.g., variability in the timing of spring fish collections relative to ice-out and the initiation of fish aggregation for spawning).

The CPUE for redside shiner in Polley Lake increased in 2024, following consecutive annual declines in 2022 and 2023. The CPUE increase was modest, however, and in 2024 remains at its second lowest recorded value since 2017 (Table 5.6). As with longnose sucker, it is possible that redside shiner CPUE may be partially dependent on population dynamics of co-occurring species and/or temperature driven effects on activity (Table 5.6; Appendix Table C.6.1). As in

2023, a single redside shiner was observed in Bootjack Lake in 2024; the species has now been observed in Bootjack Lake for two consecutive years after being absent/undetected since monitoring began post-breach.

In fall, when a randomized sampling design with a standardized level of effort is used, rainbow trout CPUE in 2024 was the lowest value since monitoring began in 2016 (Table 5.6). From 2016 to 2018, fall rainbow trout CPUE decreased, likely reflecting lower recruitment of YOY throughout this period due to the inaccessibility of Hazeltine Creek as spawning habitat. In 2019, rainbow trout CPUE increased substantially from 2018 (CPUE in 2018 was 2-fold greater than 2016) and was driven primarily by the capture of a relatively higher abundance of age-2 or younger fish (age-1 fish from 2018; Minnow 2020a). Rainbow trout CPUE remained relatively consistent from 2019 to 2021, signaling successful recruitment after restoration of access to Hazeltine Creek spawning habitat in 2018 and survival in Polley Lake, but CPUE then decreased in 2022 and 2023 (Table 5.6; Appendix Table C.6.2). This is consistent with a period of higher population density in 2019 to 2021 (driven by the higher proportion of younger fish) and a lower density in 2022 and 2023 as older age classes had greater representation in catches. Although the fall CPUE of rainbow trout in 2024 was the lowest since monitoring began (2.18 fish/trap/day), it was still comparable to CPUE in 2018 (2.84 fish/trap/day; Table 5.6). The higher CPUE between 2019 and 2023 compared to 2016 could be partly explained by a higher representation of smaller fish (i.e., younger age classes) in catches in these years as the population recovered (Minnow 2023a, 2024a). This was supported by length-frequency distributions which showed a progressive shift over the same period (i.e., 2019 to 2023) from catches dominated by smaller fish to catches dominated by larger fish, to distributions in 2022 and 2023 that more closely resembled the length-frequency distribution in 2016 (Table 5.6; Figure 5.11). This pattern continued in 2024, with larger fish (i.e., ages 3+) being as well represented in the catches in 2024 as they were in 2016 (Figure 5.11). As such, considering the similarity in the representation of older fish (i.e., ages 3+) in 2014 compared to 2016, the CPUE recorded in the fall of 2024 was low but not unexpected, especially considering that declines in CPUE were also observed in the spring, in both Polley and Bootjack lakes. Annual monitoring in Polley Lake is planned to continue and will support the evaluation of longer-term trends in rainbow trout CPUE.

Fall CPUE of longnose sucker in Polley Lake declined in 2024 and was the second lowest recorded value since monitoring began in 2016. Although CPUE has declined overall from 2016, CPUE over the past four years has been quite variable (Table 5.6), which might be attributable to temperature driven activity effects and/or gear efficacy. The fall CPUE of redside shiner increased in 2024 for the third consecutive year but overall has been variable since monitoring began in 2016 (Table 5.6).

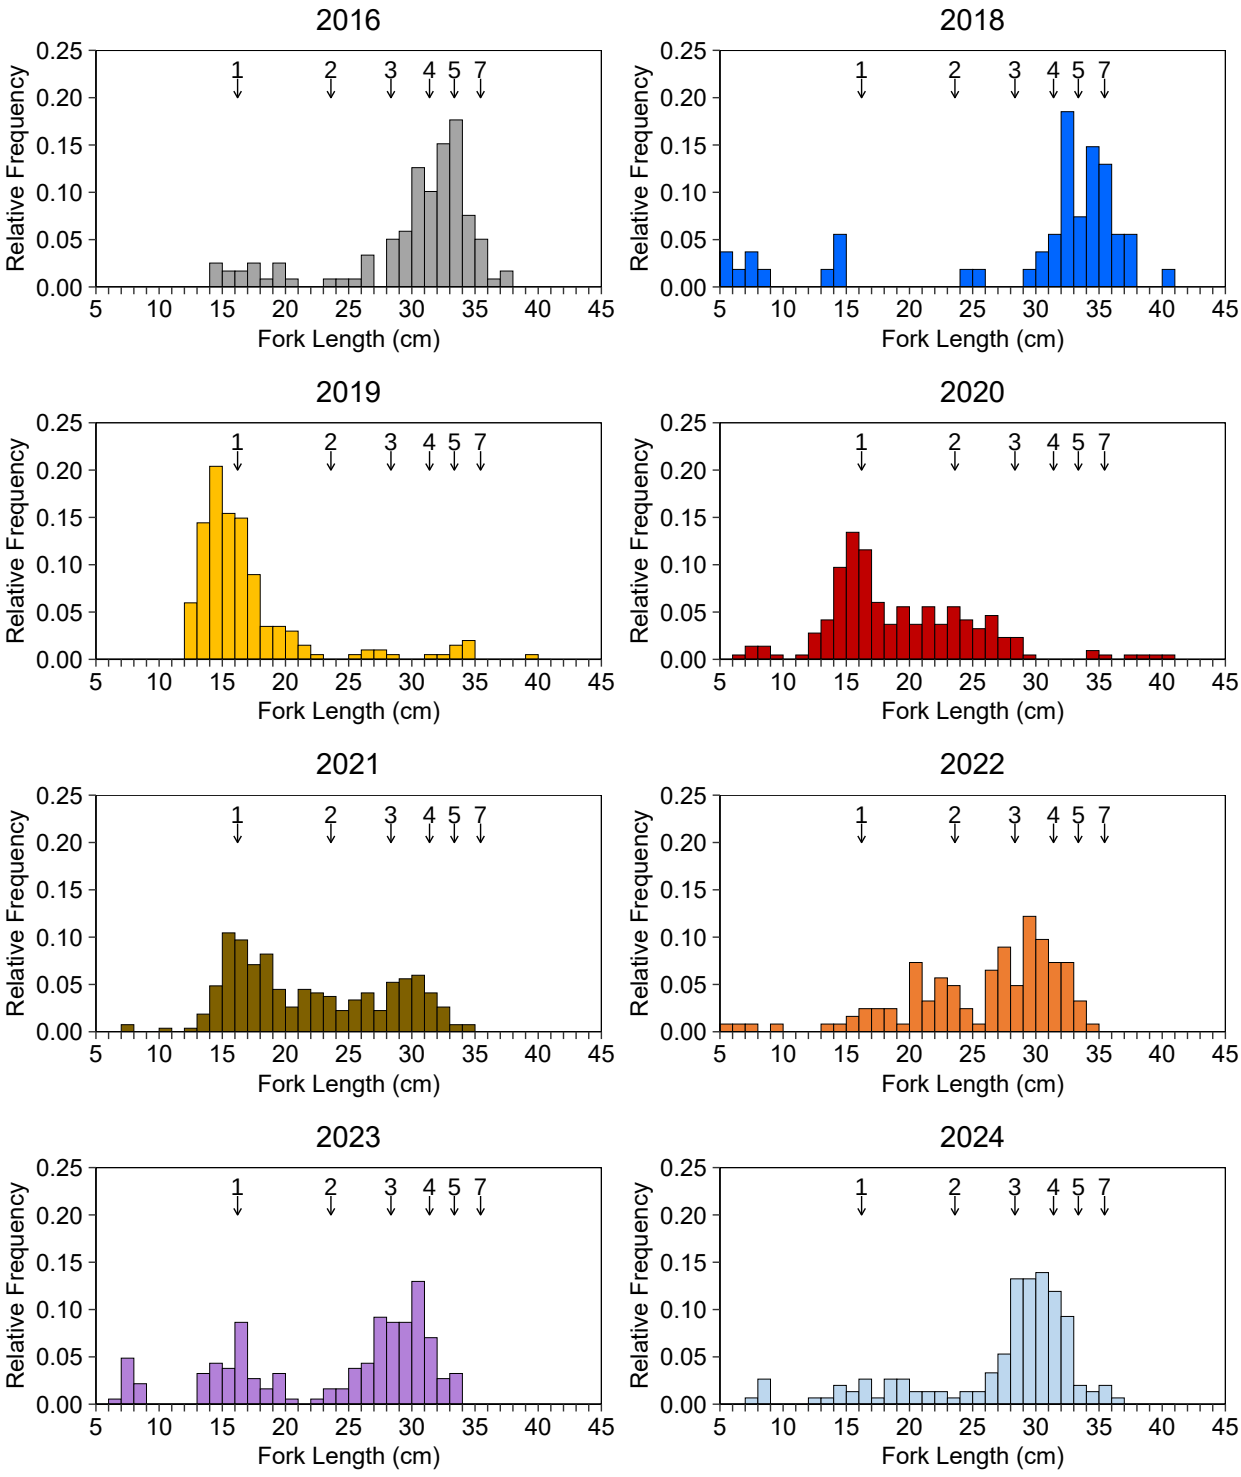

Figure 5.11: Rainbow Trout Length Frequency Distributions for Randomized Fall Hoopnetting in Polley Lake, 2016 to 2024

Notes: Numbers and arrows along the tops of figures represent predicted fork lengths at various ages from a von Bertalanffy growth model with parameters k=0.4415, t0=−0.3103, Linf=36.9021, where k is the growth coefficient, t0 is the theoretical age when size is zero, and Linf is asymptotic size. The von Bertalanffy Growth Model used predicted fork lengths at various ages using fish data collected in spring and fall, but the fork length frequency data plotted for each year includes data from fall only.

5.1.6.2 Fish Population Health

5.1.6.2.1 Spring

Spring condition (weight-at-length) across all rainbow trout captured in Polley Lake in 2024 was greater than in 2022 and 2023, and statistically similar to all other previous years (Table 5.7; Appendix Figure E.5.1, Appendix Tables C.6.3, C.6.11, E.5.1 and E.5.2). When considering either females or males, condition in 2024 was significantly greater than in 2023 but not significantly different from the first year of post-breach monitoring (i.e., 2016; Table 5.7; Appendix Figure E.5.1). Weight-at-age of lethally sampled female rainbow trout in 2024 (n=8; the only group with available age data) was statistically similar to most prior years, including 2016, but significantly lower than in 2020 and 2021 (Table 5.7; Appendix Figure E.5.2).

Spring condition for all longnose sucker caught in Polley Lake in spring of 2024 was significantly lower than all previous years, including the first year of monitoring (17% difference relative to 2016; Table 5.7; Appendix Figure E.5.3, Appendix Tables C.6.4, C.6.10 and E.5.1). The result was the same when the analysis was constrained to a subset of fish greater than 19 cm fork length (i.e., greatest overlap among years; Table 5.7; Appendix Figure E.5.3). For female longnose sucker (n=13), whether constrained to females greater than 25 cm fork length (n = 10) or unconstrained, condition was not statistically different from the previous three years (2021 to 2023) but was significantly lower than all other prior years including 2016 (MOD 12% and 15%, respectively). Weight-at-age of lethally sampled longnose sucker females in 2024 (n=8) was statistically similar to most other years, including 2016, but significantly lower than in 2018 and 2019 (Table 5.7; Appendix Figure E.5.2). For males (n=22), condition in 2024 was statistically similar to 2022 and 2023 but significantly lower than other years including 2016 (19%; Table 5.7).

5.1.6.2.2 Fall

Fall condition of Polley Lake rainbow trout in 2024, whether including or excluding YOY fish (i.e., less than 12 cm FL), was statistically similar to 2022 and 2023, but significantly lower than all other monitoring years including a 15% difference from the first year of post-breach monitoring in 2014 (Table 5.7; Appendix Figure E.5.4, Appendix Tables C.6.7, E.5.1 and E.5.2). Growth dynamics and weight-length relationships of fish species can be quite variable in the life stages that precede maturity (Gregory and Wood 1998, Monnet et al. 2023). Given that the average size of rainbow trout in Polley Lake captured over the duration of post-breach monitoring efforts (for which condition is being reported) is representative of sub-mature fish, the observed differences may simply be the result of natural variance.

Table 5.7: Summary of Statistical Comparisons of Condition and Weight-at-Age of Rainbow Trout and Longnose Sucker for Polley Lake in Spring and Fall, 2014 to 2024

Season	Endpoint	Group	Rainbow Trout										Longnose Sucker									
			2014	2016	2017	2018	2019	2020	2021	2022	2023	2024	2014	2016	2017	2018	2019	2020	2021	2022	2023	2024

Notes: Different letters signify that an endpoint is significantly different among years while the value in brackets indicates the magnitude of difference between the given year and the baseline year (baseline year is 2016 for spring and 2014 for fall data). FL = fork length. "na" = not applicable or no sampling was conducted in the given year. "-" = insufficient data available to conduct comparisons.

[a] Analysis conducted only on individuals with fork length greater than 19 cm for longnose sucker.

[b] Analysis conducted only on individuals with fork length greater than 25 cm for longnose sucker.

[c] Analysis conducted only on individuals with fork length greater than 22 cm for rainbow trout.

[d] Analysis conducted only on individuals with fork length greater than 12 cm for rainbow trout and 11 cm for longnose sucker.

Aging data for rainbow trout has not been available since the discontinuation of gill netting after 2018 (i.e., prior to this, aging was completed for incidental mortalities from gill netting; see Minnow 2022a for details). In the absence of recent age data, length frequency distributions and predicted length-at-age provide an indication of recruitment and survival over time. Comparison of CRFDs for rainbow trout from 2016 to 2024 showed a trend of continued recruitment to the Polley Lake population, with greater representation of YOY in 2024 than in 2016 and a greater representation of larger fish (age 3+) than the previous five years (2019 to 2023; Appendix Figure E.5.5, Appendix Table E.5.3).

In 2016, the rainbow trout catch in Polley Lake was dominated by age 3+ individuals (Figure 5.11), an artifact of low recruitment from 2014 to 2017 when spawning habitat in Hazeltine Creek was inaccessible. In 2018, the first year after access to Hazeltine Creek was restored, the population continued to be dominated by older fish (age-4+), however YOY recruits from the 2018 cohort were also present. These recruits became the dominant year class in 2019 combined with the likely higher mortality of older fish, most of which had likely reached the end of their life expectancy (Figure 5.11). In 2020 and 2021, the population continued to shift towards a more balanced distribution of size classes with the survival of the 2018 and 2019 cohorts and further successful recruitment of individuals from 2020 and 2021. In 2022, the length frequency distribution more closely resembled 2016 than in previous years (Figure 5.11), albeit with a lower frequency of age 3+ fish in lieu of greater strength of the younger age classes. In 2023 and 2024, there was a further strengthening of the mature age classes complemented by continued recruitment from younger age classes (Figure 5.11) such that the length frequency distrbution of rainbow trout in the fall of 2024 more closely resembled 2016 than any of the previous five years (2019 to 2023; Appendix Table E.5.3).

Condition of longnose sucker in the fall of 2024, whether including or excluding YOY, was statistically similar to the previous three years (2021 to 2023), but significantly lower than all other years, including 2014, although the difference relative to 2014 (8.7%) was relatively slight (Table 5.7; Appendix Figure E.5.4, Appendix Tables C.6.8 and E.5.1). Length frequency distributions of longnose sucker showed fewer age-1 fish and more age-3 fish in 2024 relative to 2023 with both years more closely resembling the size structure in 2016 than in 2020 to 2022 (Figure 5.12). Comparison of CRFDs supported this observation, with fewer smaller longnose sucker caught in 2024 than most prior years (except 2019), and more larger fish caught in 2024 than in 2016, 2018, and 2019 (Appendix Figure E.5.5, Appendix Table E.5.3).

For redside shiner, more smaller fish were caught in 2024 relative to 2016, though the CRFD for 2024 resembled the 2016 size structure more closely than all other years except 2018 (Appendix Figure E.5.5, Appendix Tables C.6.9 and E.5.3). The absence or near absence of

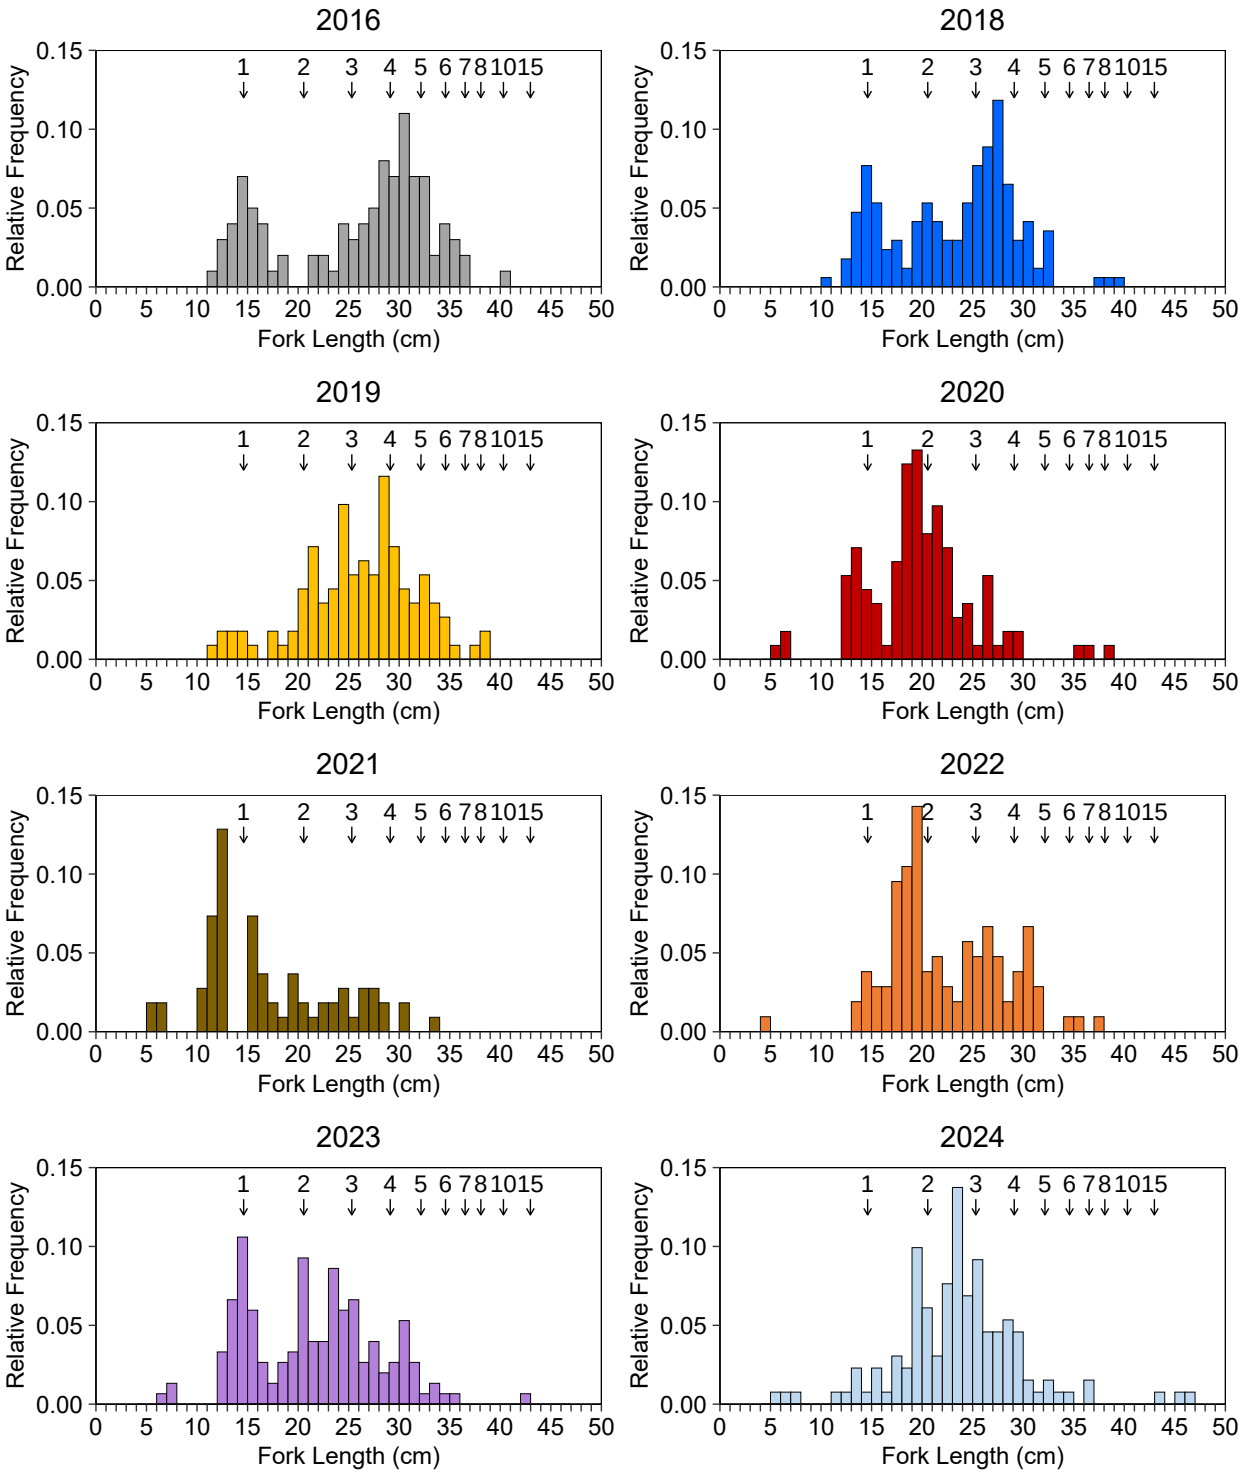

Figure 5.12: Longnose Sucker Length Frequency Distributions from Randomized Fall Hoop Netting in Polley Lake, 2016 to 2024

Notes: Numbers and arrows along the tops of figures represent predicted fork lengths at various ages from a von Bertalanffy growth model with parameters k=0.2237, t0=−0.7904, Linf=44.2718, where k is the growth coefficient, t0 is the theoretical age when size is zero, and Linf is asymptotic size. The von Bertalanffy Growth Model used predicted fork lengths at various ages using fish data collected in spring and fall, but the fork length frequency data plotted for each year includes data from fall only.

smaller redside shiner (e.g., less than 8 cm) in 2016 and 2018 and subsequent lower numbers of larger individuals in 2019 and 2020 is likely indicative of low recruitment in the years immediately following the breach (Appendix Figure E.5.6). The population age structure suggests that a strong age cohort showed good survival from 2019 to 2021, and produced a strong YOY class that dominated catches in fall of 2022 (Appendix Figure E.5.6). In contrast to 2016 and 2018 when younger cohorts were almost entirely absent from Polley Lake, over 50% of the catch in 2022 was comprised of younger fish (e.g., smaller than 7 cm) indicating successful recruitment into the population (Appendix Figures E.5.5 and E.5.6). Recruits from the 2022 and 2023 cohorts continued to be well represented through 2023 and 2024 (8 to 10 cm), and the overall length frequency distribution of the population in 2024 had a more evenly distributed size structure than in prior years, indicating ongoing successful recruitment (Appendix Figures E.5.5 and E.5.6).

5.1.7 Fish Tissue Quality

Fish tissue quality was completed annually between 2022 and 2024 targeting rainbow trout and longnose sucker from Polley (exposed) and Bootjack (reference) lakes (Figure 3.4, Table 3.8).

A review of the 2024 fish tissue results (Appendix B) indicated the data had appropriate detectability, negligible analyte concentrations in method blank samples, and excellent laboratory accuracy. Laboratory duplicate samples failed the DQO in 1.79% of results. Fish tissue field duplicate samples generally had low agreement, and the recommended DQO for field precision was exceeded in 55% of field duplicate pairs (Appendix B). Reanalysis was requested for several duplicate pairs and the results of reanalysis confirmed poor agreement between the parent and duplicate samples. Muscle samples had the greatest number of DQO exceedances while ovary samples had the fewest, except for the Quesnel River rainbow trout ovary field duplicate samples (84.6% of RPDs > DQO). This suggests natural heterogeneity within the tissue samples; however, the level of replication (n=8 per tissue type, species, and area) serves to help capture this variability. One rainbow trout ovary sample from Quesnel River had several analyte concentrations that were elevated relative to historic values, including selenium, iron, manganese, nickel, and vanadium. Laboratory reanalysis did not find any obvious errors in the data nor justification to report the reanalysis results instead than the original data, therefore the original data were reported. Overall, the 2024 fish tissue quality data can be used with an acceptable level of confidence for interpretation, although the occurrence of some natural heterogeneity in analyte results were considered during data interpretation. A review of the 2024 fish aging results (Appendix B) indicated that laboratory accuracy for aging data was excellent, and aging estimates were largely consistent between the primary and secondary analyst.

5.1.7.1 Comparisons to Guidelines and Thresholds

The muscle of rainbow trout and longnose sucker from Polley and Bootjack lakes in 2024 had mercury and selenium concentrations that were below their respective guidelines for human health (0.5 mg/kg ww for mercury, 14.5 mg/kg dw for selenium based on moderate fish consumption; Table 5.8; Appendix Tables C.7.1 to C.7.4). This was consistent with results from 2015 to 2023 for both analytes, except for a single rainbow trout from Polley Lake that had a mercury concentration above the human health guideline in 2021 (Table 5.8). Selenium concentrations in the muscle of rainbow trout and longnose sucker from Polley and Bootjack lakes in 2024 also remained below the human health guideline for high consumption (7.3 mg/kg dw; Table 5.8, Appendix Tables C.7.1 to C.7.4). This represents a change from previous years for longnose sucker muscle samples from Polley Lake, which had selenium concentrations that consistently exceeded the high consumption guideline from 2016 to 2023 (13 to 100% of samples; Table 5.8). However, the likelihood that longnose sucker would be consumed at a high rate (i.e., subsistence consumers) is low.

The mean selenium concentrations in 2024 for rainbow trout muscle (4.22 mg/kg dw) and longnose sucker muscle (6.14 mg/kg dw) from Polley Lake were above the guideline for the protection of aquatic life (4 mg/kg dw; Table 5.9; Appendix Tables C.7.1 to C.7.4). This was consistent with results from previous years (i.e., 2015 to 2023) that reported mean selenium concentrations above the aquatic life guideline in the muscle of rainbow trout and longnose sucker from Polley Lake, except for rainbow trout in 2023 (Table 5.9). Selenium concentrations remained below the aquatic life guideline in all fish muscle samples from Bootjack Lake in 2015 to 2024 (Table 5.9; Appendix Tables C.7.2 and C.7.4). The mercury guideline for fish muscle is specific to human health and a mercury guideline for the protection of aquatic life does not exist.

Egg laying vertebrates are the most selenium-sensitive organisms, with embryo toxicity being the primary mechanism of selenium-associated effects; therefore, the analysis of ovary tissue is recommended for assessing the effects of selenium on fish (e.g., Luoma and Presser 2009, Janz et al. 2010, DeForest et al. 2012, Janz 2012). The mean concentration of selenium in ovary tissue of rainbow trout from Polley Lake in 2024 (9.40 mg/kg dw) was lower than the 11 mg/kg dw guideline for the protection of aquatic life[51], and was also lower than those reported from 2016 to 2021 (excluding 2020; BCMOE 2014; Table 5.10; Appendix Table C.7.1). Of the ovaries collected from Polley Lake in 2024, one rainbow trout sample had a concentration above the guideline for the protection of aquatic life (14.4 mg/kg dw; Appendix Table C.7.1). Furthermore, the mean and individual ovary selenium concentrations of rainbow trout from Polley

[51] This guideline includes a two-fold uncertainty factor (BCMOE 2014).

Table 5.8: Fish Muscle Mercury and Selenium Concentrations from Polley Lake (Exposed) and Bootjack Lake (Reference) Relative to Human Health Consumption Guidelines, 2015 to 2024

Indicates mean selenium concentration greater than the BC Aquatic Life guideline for ovary tissue in fish (11 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than DeForest et al (2012) threshold for ovary tissue in fish (20 mg/kg dw) and the BC Aquatic Life guideline (BCMOE 2014).

Notes: mg/kg dw = milligrams per kilogram dry weight. ">" = greater than. BCMOE = British Columbia Ministry of Environment. "%" = percent.

[a] Data are considered suspect and are likely influenced by laboratory error or contamination (Golder 2016b; Minnow 2017e).

[b] Ovary selenium threshold as described in DeForest et al. (2012).

Lake in 2024 (mean = 9.40 mg/kg dw) and in previous years were well below the 20 mg/kg dw effect threshold developed by DeForest et al. (2012; Table 5.10). Selenium concentrations in ovaries of rainbow trout from Bootjack Lake (2015 to 2024) were consistently below the tissue-specific selenium guideline for the protection of aquatic life and the threshold for reproductive effects (DeForest et al. 2012; Table 5.10; Appendix Table C.7.2). The mean concentrations of selenium in ovary tissue of longnose sucker collected from Polley Lake (7.99 mg/kg dw) and Bootjack Lake (3.98 mg/kg dw) in 2024 were lower than tissue-specific guideline for the protection of aquatic life, as well as the 20 mg/kg dw threshold for reproductive effects (DeForest et al. 2012, BCMOE 2014; Appendix Tables C.7.3, C.7.4), which was consistent with results from 2016 to 2023 (Table 5.10).

5.1.7.2 Spatial and Temporal Comparisons

Age and morphological measures (fork length and body weight) of rainbow trout and longnose sucker captured from Polley and Bootjack lakes between 2015 and 2024 are summarized in Table 5.11 (see Appendix Tables C.6.10 and C.6.11 for detailed 2024 data). Statistical comparisons of these physical measures and age did not exhibit a significant *Area×Year* interaction for rainbow trout (based on data from 1995 to 2024; Table 5.12; Appendix Table E.6.1).[52] Rainbow trout sampled from Polley Lake were similar in size (fork length and body weight) and age to those sampled those from Bootjack Lake in 2024, which was consistent with previous years (i.e., 1995 to 2023; Table 5.12; Appendix Table E.6.1). Conversely, longnose sucker collected from Polley Lake were significantly younger (38% in 2024), significantly shorter (19% in all years), and lighter (69% in 2024) than those from Bootjack Lake (Table 5.12; Appendix Table E.6.2). In previous monitoring years, longnose sucker from Polley Lake were younger, and either smaller (shorter and/or lighter) or similar in size compared to those from Bootjack Lake, consistent with trends observed during baseline data collection for fork length (i.e., 1995; Table 5.12; Appendix Table E.6.2).

Data interpretation was focused on primary and secondary analytes (Table 2.4) with a significant positive relative (exposed-reference) difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2024 (if the analysis *Area×Year* interaction was significant) or in all monitoring years (if the

[52] Results of the two-way ANOVA for age, fork length, and body size may differ among tissue types for the same species in the same area due to differences in data availability across years for the different tissue types (e.g., rainbow trout kidney data were collected from 2018 to 2024 compared to 1995 to 2024 for rainbow trout muscle tissue). For all species sampled for tissue in 2024, discussion of age and body size is focused on results of two-way ANOVA for muscle tissues (which includes the full sample set [n=8] for each area and year).

Table 5.11: Age and Body Size Data of Fish Collected for Tissue Quality Monitoring from Polley Lake (Exposed) and Bootjack Lake (Reference), 2015 to 2024

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: **Bold** = Data for either exposed or reference in the indicated year were entirely below the laboratory reporting limit (LRL), leading to a less accurate estimate of the mean for the <LRL result and greater uncertainty for the calculated MOD. No MOD is displayed if the comparison was not significant. "-" = no data available for analysis (i.e., either data was not collected for the given analyte and time period or data were omitted from analysis because > 50% of data for a given analyte were <LRL in all time periods); "<LRL" = greater than 50% LRL data for both stations so the time period was omitted from the analysis, "ns" = not significant. Data were analysed in units of mg/kg dry weight except mercury which was analysed in units of mg/kg wet weight. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Age, fork length, and body weight results are those that are associated with muscle tissue analyses.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Table E.6.1 to E.6.8). This table only presents results for primary and secondary analytes with a significant positive exposed-reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant). If no significant change was detected in the exposed-reference difference among years (i.e., the Area x Year interaction was not significant), data from 2019 to 2024 were combined for the analyses.

[b] Organ in which the specific metal is known to accumulate (references in Appendix Table E.6.22).

[c] Magnitude of difference (MOD) calculated on back transformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted})\times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[d] Magnitude of difference (MOD) calculated on back transformed least-squares means as (Exp-Ref)/Ref x 100%.

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: **Bold** = Data for either exposed or reference in the indicated year were entirely below the laboratory reporting limit (LRL), leading to a less accurate estimate of the mean for the <LRL result and greater uncertainty for the calculated MOD. No MOD is displayed if the comparison was not significant. "-" = no data available for analysis (i.e., either data was not collected for the given analyte and time period or data were omitted from analysis because > 50% of data for a given analyte were <LRL in all time periods); "<LRL" = greater than 50% LRL data for both stations so the time period was omitted from the analysis, "ns" = not significant. Data were analysed in units of mg/kg dry weight except mercury which was analysed in units of mg/kg wet weight. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Age, fork length, and body weight results are those that are associated with muscle tissue analyses.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Table E.6.1 to E.6.8). This table only presents results for primary and secondary analytes with a significant positive exposed-reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant). If no significant change was detected in the exposed-reference difference among years (i.e., the Area x Year interaction was not significant), data from 2019 to 2024 were combined for the analyses.

[b] Organ in which the specific metal is known to accumulate (references in Appendix Table E.6.22).

[c] Magnitude of difference (MOD) calculated on back transformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted})\times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[d] Magnitude of difference (MOD) calculated on back transformed least-squares means as (Exp-Ref)/Ref x 100%.

Area×*Year* interaction was not significant[53]). Increasing analyte concentrations at the exposed area relative to reference area over time, or consistently elevated analyte concentrations at the exposed area relative to reference, were not detected for most analytes (Appendix Figures E.6.1 to E.6.7, Appendix Tables E.6.1 to E.6.8). The primary analytes arsenic, copper, iron, and selenium, and secondary analytes barium, cadmium, calcium, cobalt, manganese, mercury (ww), molybdenum, nickel, phosphorous, sodium, strontium, titanium, uranium, vanadium, and zinc met the criteria for inclusion in data interpretation outlined above (Figures 5.13 and 5.14, Table 5.12). The following discussion is focused on these four primary analytes and 15 secondary analytes.

Of the primary analytes identified, selenium had concentrations in exposed fish tissues that were the most elevated relative to reference and relative to baseline conditions. Significant *Area*×*Year* interactions were detected for selenium concentrations in most exposed tissues, except for rainbow trout kidney tissue. The significant *Area*×*Year* interaction indicates that the relative (exposed-reference) difference in selenium concentrations changed significantly among years (i.e., the geometric mean concentrations at the exposed area were not trending the same as the geometric mean concentrations at the reference area). The timing of the interactions indicated that selenium accumulation began between 1995 and 2009 in Polley Lake (i.e., may be associated with the 2006 to 2009 uncontrolled surface runoff to Polley Lake; Figure 5.13, Table 5.12; Appendix Tables E.6.1 to E.6.8). In general, selenium concentrations in exposed fish tissues did not continue to increase after the post-release period (2012), except for tissue selenium concentrations in rainbow trout ovary that were significantly higher, relative to reference, in 2015 compared to 2012 (Figure 5.13, Table 5.12; Appendix Table E.6.3)[54]. It is possible that the 2015 peak in exposed rainbow trout ovary selenium concentrations may reflect a short-term impact associated with the breach or possible laboratory error that cannot be separated from potential mine influence between 1995 and 2015.

Post-breach selenium concentrations in exposed rainbow trout muscle, ovary, liver, and kidney have been consistently higher than reference (46% to 564% across tissue types), except in liver tissue in 2017 and 2024. However, there is evidence of decreased selenium concentrations in exposed rainbow trout tissues over time. For instance, selenium concentrations in exposed rainbow trout liver tissue in 2024 were similar to reference and similar to baseline (i.e., 1995), representing a significant decrease compared to prior post-breach years (2015 to 2023) when selenium concentrations were significantly higher than reference (Figure 5.13, Table 5.12;

[53] If no significant change was detected in the relative (exposed-reference) difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

[54] It is considered likely that a subset of the selenium concentrations measured in exposed rainbow trout ovaries from 2015 were subject to laboratory error or contamination, resulting in reporting of increased selenium concentrations (Minnow 2017e).

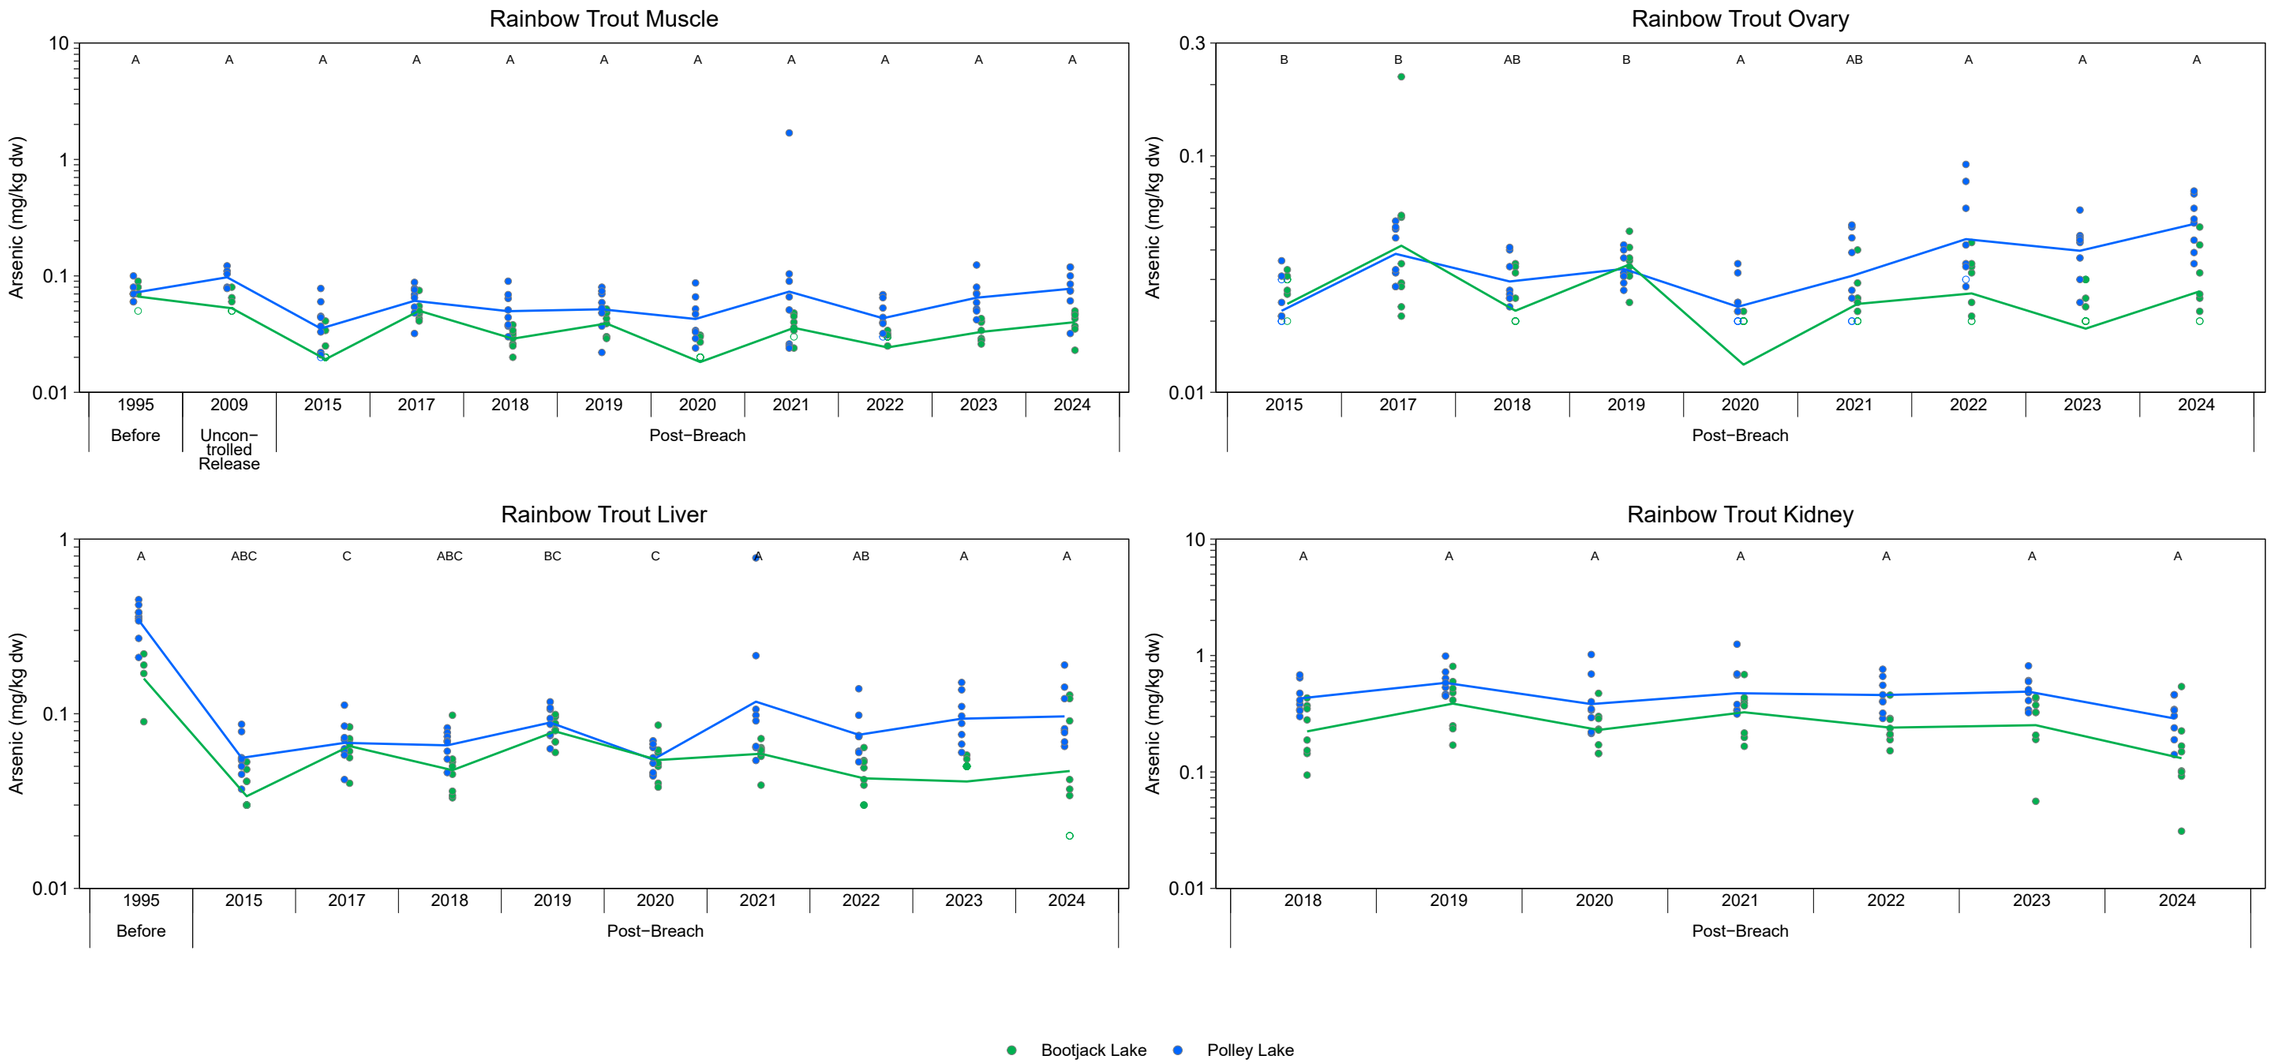

Figure 5.13: Fish Tissue Primary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for Polley Lake (POL; Exposed) and Bootjack Lake (BOL; Reference), 1995 to 2024

Notes: BCMOE = British Columbia Ministry of the Environment, GL = Guideline; dw = dry weight. Green represents reference areas and blue represents exposed areas.. Plots are only included for primary analytes with a significant positive exposed−reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant). Data are not available for all years within the date range identified; only years with available data are displayed and these are analyte−dependent. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two −way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Polley Lake:Bootjack Lake) that do not differ significantly (p−value <0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Polley Lake:Bootjack Lake). Only years with samples from both reference and exposed areas are plotted.

Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors *Area* and *Year* . The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Polley Lake:Bootjack Lake) that do not differ significantly (p−value <0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Polley Lake:Bootjack Lake). Only years with samples from both reference and exposed areas are plotted.

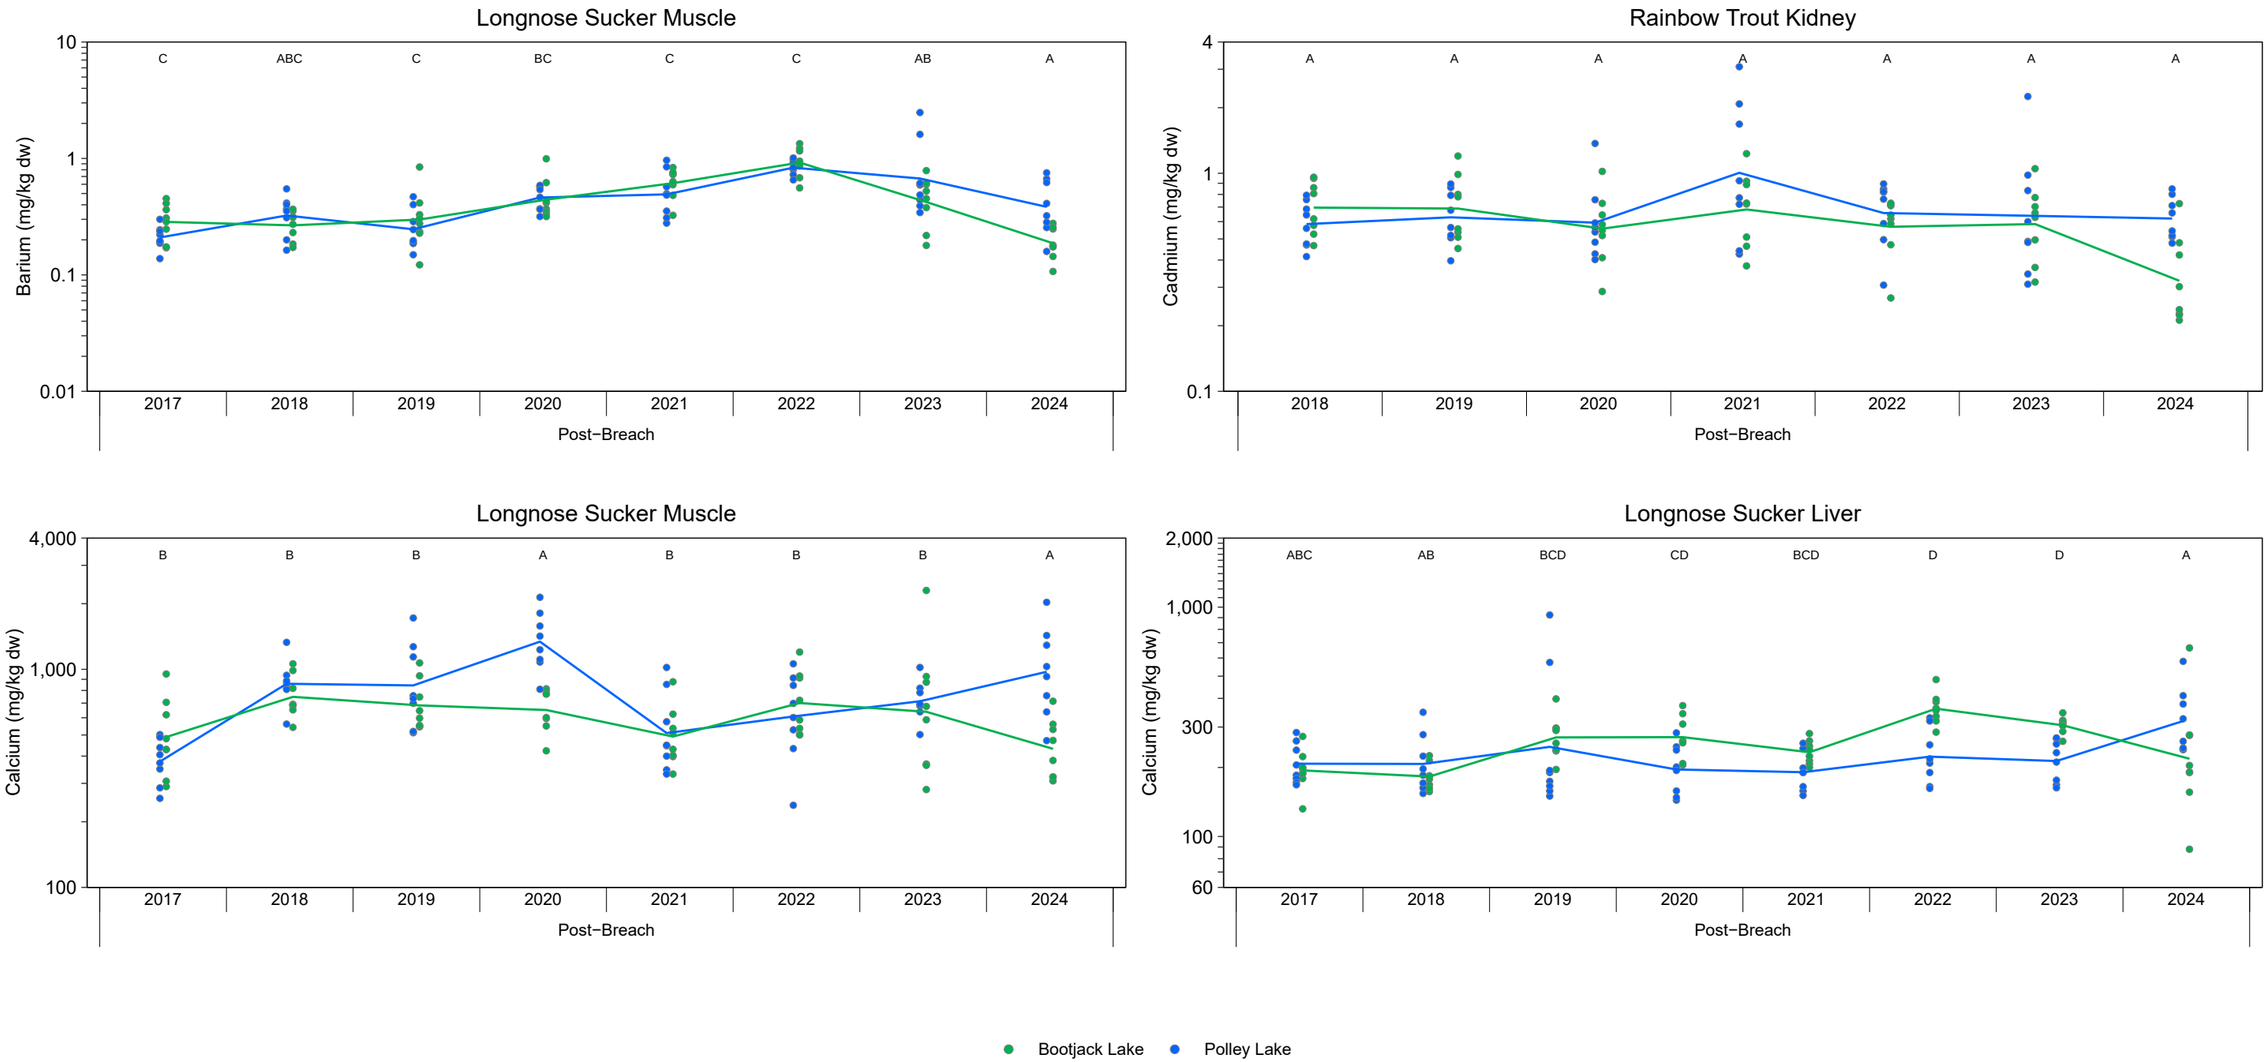

Figure 5.14: Fish Tissue Secondary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for Polley Lake (POL; Exposed) and Bootjack Lake (BOL; Reference), 1995 to 2024

Notes: GL = guideline, mg/kg = milligrams per kilogram, ww = weight weight, dw = dry weight, CFIA = Canadian Food Inspection Agency. Green represents reference areas and blue represents exposed areas. Plots are only included for secondary analytes with a significant positive exposed−reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the *Area×Year* interaction was not significant). Data are not available for all years within the date range identified; only years with available data are displayed and these are analyte−dependent. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors *Area* and *Year* . The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Polley Lake:Bootjack Lake) that do not differ significantly (p−value <0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Polley Lake:Bootjack Lake). Only years with samples from both reference and exposed areas are plotted.

Appendix Table E.6.4). For muscle and ovary tissues, the relative differences of selenium concentrations in 2024 were significantly lower than several consecutive prior years (2017 to 2021 for muscle, 2015 to 2019 for ovary) and were similar to the remaining post-breach years. Selenium concentrations in 2024 were similar to pre-breach (2012) results in the case of ovary tissue, and significantly lower than pre-breach (2012) results in the case of muscle tissue, relative to reference (Figure 5.13, Table 5.12; Appendix Tables E.6.1, E.6.3). The relative differences in selenium concentrations have remained unchanged (i.e., temporally stable) for rainbow trout kidney since 2018 (Figure 5.13, Table 5.12; Appendix Table E.6.8). Tissue selenium concentrations in exposed longnose sucker have been consistently higher than reference in each year since the breach (26% to 389% across tissue types), except for kidney tissue in 2024 (Table 5.12). Similar to the results for rainbow trout tissues, there is evidence of decreases in the relative differences of selenium concentrations in longnose sucker tissues over time. For instance, selenium concentrations in exposed longnose sucker kidney tissue in 2024 were similar to reference for the first time since monitoring began and were significantly lower than the majority of prior post-breach years (2018 to 2020 and 2022), relative to reference (Table 5.12; Appendix Table E.6.7). The relative difference of selenium concentrations in muscle, ovary, and liver tissues in 2024 were similar to or lower than in prior post-breach years, and significantly lower than the post-release period (2012, where data exist; Table 5.12, Appendix Tables E.6.2, E.6.5 to E.6.6). In the case of longnose sucker muscle tissue, the relative difference of selenium concentrations in 2024 was significantly higher than baseline (1995) only, and has been temporally stable for at least the last four years (2021 to 2024; Figure 5.13, Table 5.12; Appendix Table E.6.2).

Concentrations of the primary analytes arsenic, copper, and iron were significantly higher in most rainbow trout tissues (muscle, ovary, liver, and kidney) from Polley Lake compared to Bootjack Lake in 2024 (or in all monitoring years if the *Area×Year* interaction was not significant), with the exception of copper in muscle and liver, and iron in muscle and ovary tissues (Figure 5.13, Table 5.12; Appendix Tables E.6.1, E.6.3, E.6.4, E.6.8). These exceptions were excluded from further discussion. Of the exposed rainbow trout tissues with significantly higher arsenic, copper, and iron concentrations compared to reference, the relative differences for these have been unchanged since the initiation of monitoring (i.e., temporally stable) in most cases, with two exceptions: arsenic in ovary and liver tissues (Figure 5.13, Table 5.12; Appendix Tables E.6.1, E.6.3, E.6.4, E.6.8). Specifically, the relative difference of arsenic in ovary has been temporally stable from 2020 to 2024, and in liver has been temporally stable and similar to baseline (i.e., 1995) from 2021 to 2024 (Figure 5.13). As such, arsenic, copper, and iron concentrations in rainbow trout tissues from Polley Lake have not increased relative to reference since 2021 (i.e., over the last four years) at minimum.

In longnose sucker tissues, concentrations of arsenic in muscle, liver, and kidney, and concentrations of copper and iron in liver were the only analytes that were significantly higher in Polley Lake relative to Bootjack Lake in 2024 (or in all monitoring years if the *Area×Year* interaction was not significant; Figure 5.13, Table 5.12). Therefore, the discussion below is focused on the results for these five tissue-analyte combinations. The relative differences for arsenic concentrations in kidney tissue have been unchanged since initiation of monitoring in 2018 (i.e., temporally stable), and in liver and muscle tissue have been similar to baseline (i.e., 1995) throughout post-breach monitoring (2017 to 2024; Figure 5.13, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7). Similarly, the relative differences for copper concentrations in liver tissue have been similar to baseline (i.e., 1995) in most years, except 2022 which was significantly higher than baseline (Figure 5.13, Table 5.12; Appendix Table E.6.6). The relative differences for iron concentrations in longnose sucker liver were significantly higher in 2024 than all previous years, which may be attributable in part to a decrease at the reference area (Bootjack Lake) in 2024 (Figure 5.13, Table 5.12; Appendix Table E.6.6). Similar increases in iron concentrations in 2024 were not observed in other exposed longnose sucker tissues (muscle, ovary, kidney) nor in exposed rainbow trout tissues, relative to reference, and the increase is isolated to a single year (i.e., 2024 only; Figure 5.13, Table 5.12; Appendix Tables E.6.1 to E.6.8). As such, arsenic, and copper concentrations in exposed longnose sucker tissues, compared to reference, have not increased relative to the first year of monitoring, but there is limited evidence of a potential increase in iron concentrations in exposed liver tissues in 2024.

The concentrations of 15 secondary analytes (i.e., barium, cadmium, calcium, cobalt, manganese, mercury (ww), molybdenum, nickel, phosphorous, sodium, strontium, titanium, uranium, vanadium, and zinc) had significant *Area×Year* interaction terms for at least one tissue type in rainbow trout and/or longnose sucker and had analyte concentrations in Polley Lake fish that were significantly higher than in Bootjack Lake fish in 2024 (i.e., positive relative [exposed-reference] difference) or in all monitoring years (if the *Area×Year* interaction was not significant; Figure 5.14, Table 5.12; Appendix Tables E.6.1 to E.6.8). For most of the analyte-tissue combinations identified for these 15 secondary analytes, the relative differences were either temporally stable (i.e., the *Area×Year* interaction was not significant) or the exposed tissue analyte concentrations in 2024 were higher than reference in only one tissue type in within each species (i.e., barium, cadmium, mercury [ww], and uranium), indicating no sustained increase in secondary analyte concentrations in the exposed fish tissues over time. For simplicity, only those secondary analyte-tissue combinations with a significant positive relative difference in 2024 or in all years (if the *Area×Year* interaction was not significant) in more than one tissue type

within a species are discussed further (i.e., barium, cadmium, mercury [ww], and uranium were not discussed further).

Tissues of longnose sucker had secondary analyte concentrations that met the criteria for further discussion (i.e., having a significant positive relative difference in 2024 or in all years) most often (calcium, cobalt, manganese, molybdenum, phosphorus, sodium, strontium, titanium, vanadium, and zinc). Tissues of rainbow trout had concentrations of secondary analytes that met the criteria for further discussion less often (cobalt, nickel, titanium, vanadium, and zinc). Of these, concentrations of four secondary analytes (cobalt, titanium, vanadium, and zinc) met the criteria for further discussion in tissues of both longnose sucker and rainbow trout (Table 5.12). The discussion below is structured to focus on those secondary analytes in: 1) longnose sucker tissues only, 2) rainbow trout tissues only, and 3) both rainbow trout and longnose sucker tissues, that met the criteria for further discussion.

In longnose sucker tissues only, concentrations of six secondary analytes (calcium, manganese, molybdenum, phosphorus, sodium, and strontium) were significantly higher than reference in two or more tissues in 2024 (or all years; Table 5.12). For most of these secondary analyte-tissue combinations, the relative difference in analyte concentrations has either been stable since the initiation of monitoring or was similar in 2024 to the first year of monitoring (i.e., no consistent temporal increase) with few exceptions (Figure 5.14, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7). Those secondary analyte-tissue combinations that were exceptions are evaluated here in more detail. Specifically, calcium, manganese, sodium, and strontium concentrations in exposed longnose sucker muscle were significantly higher than reference in 2024, but the relative difference was the same as in 2018 (for manganese and sodium) or the same as in 2020 (for calcium and strontium). Similarly, manganese concentrations in exposed ovary tissue from longnose sucker were significantly higher than reference in 2024, but the difference was the same as in 2019 (Figure 5.14, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7). Combined, these results indicate concentrations of these six secondary analytes evaluated in longnose sucker tissues (calcium, manganese, molybdenum, phosphorus, sodium, and strontium) have been either temporally stable or have not increased consistently over at least the last five years (i.e., since at least 2020).

In rainbow trout tissues only, nickel was the only secondary analyte with concentrations in exposed tissues (liver and kidney) that were significantly higher than reference in 2024 (for liver) or in all years (for kidney). The relative difference of nickel concentrations in these two rainbow trout tissues has been stable since the initiation of monitoring (where detectable; Figure 5.14, Table 5.12; Appendix Tables E.6.6 and E.6.7).

In both rainbow trout and longnose sucker tissues, concentrations of four secondary analytes (cobalt, titanium, vanadium, and zinc) were significantly higher than reference in two or more tissues in 2024 (or all years; Table 5.12). For most of these secondary analyte-tissue combinations, the relative difference in analyte concentrations has been stable since the initiation of monitoring except for six analyte-tissue combinations, as detailed below (Figure 5.14, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7). In exposed longnose sucker, cobalt concentrations in ovary and zinc concentrations in muscle and liver were significantly higher than reference, but the relative difference was the same as in the first year of monitoring (Figure 5.14, Table 5.12). The relative difference of titanium concentrations in longnose sucker muscle was significantly higher in 2023 and 2024 compared to prior years, but this was related (at least in part) to a decrease in titanium concentrations in reference tissues (Figure 5.14, Table 5.12). Finally, cobalt concentrations in exposed longnose sucker liver and kidney tissues in 2024 were significantly higher than in all prior years, relative to reference, increasing from similar to or significantly lower than reference in most prior years to significantly higher than reference in 2024 (Figure 5.14, Table 5.12). Combined, these results indicate that of the four secondary analytes evaluated in both rainbow trout and longnose sucker tissues (cobalt, titanium, vanadium, and zinc), only cobalt in longnose sucker liver and kidney was significantly higher in 2024 relative to all prior years.

5.2 Quesnel Lake

5.2.1 Sediment Quality

Sediment quality monitoring in 2024 was completed at two deep exposed areas (QUL-PNF and QUL-PFF1) and one shallow exposed area (QUL-LNF1) exposed area of Quesnel Lake. An unimpacted deep area (QUL-PREF1) served as a reference for the deep exposed areas while an unimpacted shallow area (QUL-LREF1) served as reference for the corresponding shallow exposed area (Figure 3.2, Table 3.2). Prior sediment quality monitoring within the 2022 to 2024 period included annual monitoring of the deep near-field (QUL-PNF) and shallow near-field (QUL-LNF1) and reference (QUL-LREF1) areas (Figure 3.2, Table 3.2).

Sediments were also collected at three deep monitoring areas in Quesnel Lake in 2024 as part of EEM (Phase 4) under the MDMER of the federal *Fisheries Act*. The EEM program included one exposed (QUL-EEMEXP) and two reference areas (QUL-EEMREF1 [non-breach-influenced], and QUL-EEMREF2 [breach-influenced]), with five monitoring stations per area (Figure 3.2; Table 3.2). Results for the Phase 4 EEM are due in a separate report in October 2025 and are therefore not included in the present report. Sediment quality monitoring in support of the Phase 3 of EEM monitoring was previously completed in 2021 (Table 3.2).

A review of the 2024 sediment quality results (Appendix B) indicated that the data met the established DQOs and can be used with a high level of confidence for interpretation (see Section 5.1.1 for details). A review of 2024 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

5.2.1.1 Deep Areas

Sediments collected in 2024 from the exposed deep near-field area (QUL-PNF) of Quesnel Lake were composed primarily of silt and clay particles (mean = 48.6% and 46.5%, respectively; Table 5.13; Appendix Table C.2.8). This texture was similar to the predominantly fine-grained texture of sediments from this area in previous years (2014 to 2023), except for 2022 when sediments had the highest sand content (mean = 10.2%) among years (Table 5.13). The sediment collected from the deep far-field area of Quesnel Lake (QUL-PFF1) was also composed primarily of silt and clay in 2024 (mean = 50.0% and 49.7%, respectively), although the clay content in 2024 was higher than most previous years and only lower than 2021 (62.6%; Table 5.13; Appendix Table C.2.8). As observed in previous monitoring years, sediments from the deep reference station (QUL-PREF1) in 2024 were composed primarily of silt and sand (mean of 69.4% and 19.1%, respectively) and had considerably higher sand content than the exposed QUL-PNF and QUL-PFF1 sediments (mean = 4.90% and <1.0%, respectively; Table 5.13; Appendix Tables C.2.7 and C.2.8).

Despite a steady increase in the TOC content of QUL-PNF and QUL-PFF1 sediments (mean = 0.635% and 0.425%, respectively), the TOC content in 2024 of these sediments remained significantly lower than reference in 2024 (mean = 1.75%; Table 5.13; Appendix Tables C.2.7 and C.2.8, Appendix Table E.1.7). Temporally, the relative (exposed-reference) difference of TOC in 2024 was significantly higher than most prior years but was similar to 2019 at QUL-PFF1 and similar to 2014 at QUL-PNF (Figure 5.15; Appendix Table E.1.6). When considered separately from reference results, the TOC content of sediments from QUL-PFF1 has not changed significantly since 2014 (i.e., temporally stable from 2014 to 2024), and the TOC content of QUL-PNF sediments was significantly higher in 2024 than 2014 (and similar to other prior years; Appendix Table E.1.7). This indicates variability in the TOC content of reference sediments is partly driving the observed temporal relative differences in sediment TOC content. Combined, the TOC results indicate a steady increase in the TOC content of exposed sediments, that is statistically significant at QUL-PNF, but not significant at QUL-PFF1, relative to immediate post-breach conditions (i.e., 2014). Total nitrogen content of sediments from QUL-PNF and QUL-PFF1 in 2024 (mean = 0.0850% and 0.0646%, respectively) were higher than most previous years, except for 2023 at QUL-PNF, but remained lower than those reported

Table 5.13: **Summary of Sediment Quality Data for Quesnel Lake (QUL-PNF and QUL-PFF1; Exposed and QUL-PREF1; Reference) Deep Monitoring Areas, 2014 to 2024**

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics*** indicates exposed value is > reference 95th percentile value (<5th percentile value for pH). Reference 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" = no current BC Working Sediment Quality Guidelines/ no data.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] The 5th percentile is reported and screened for the pH reference data. For calculation of reference 95th and 5th percentile values see Appendix Table C.2.6.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

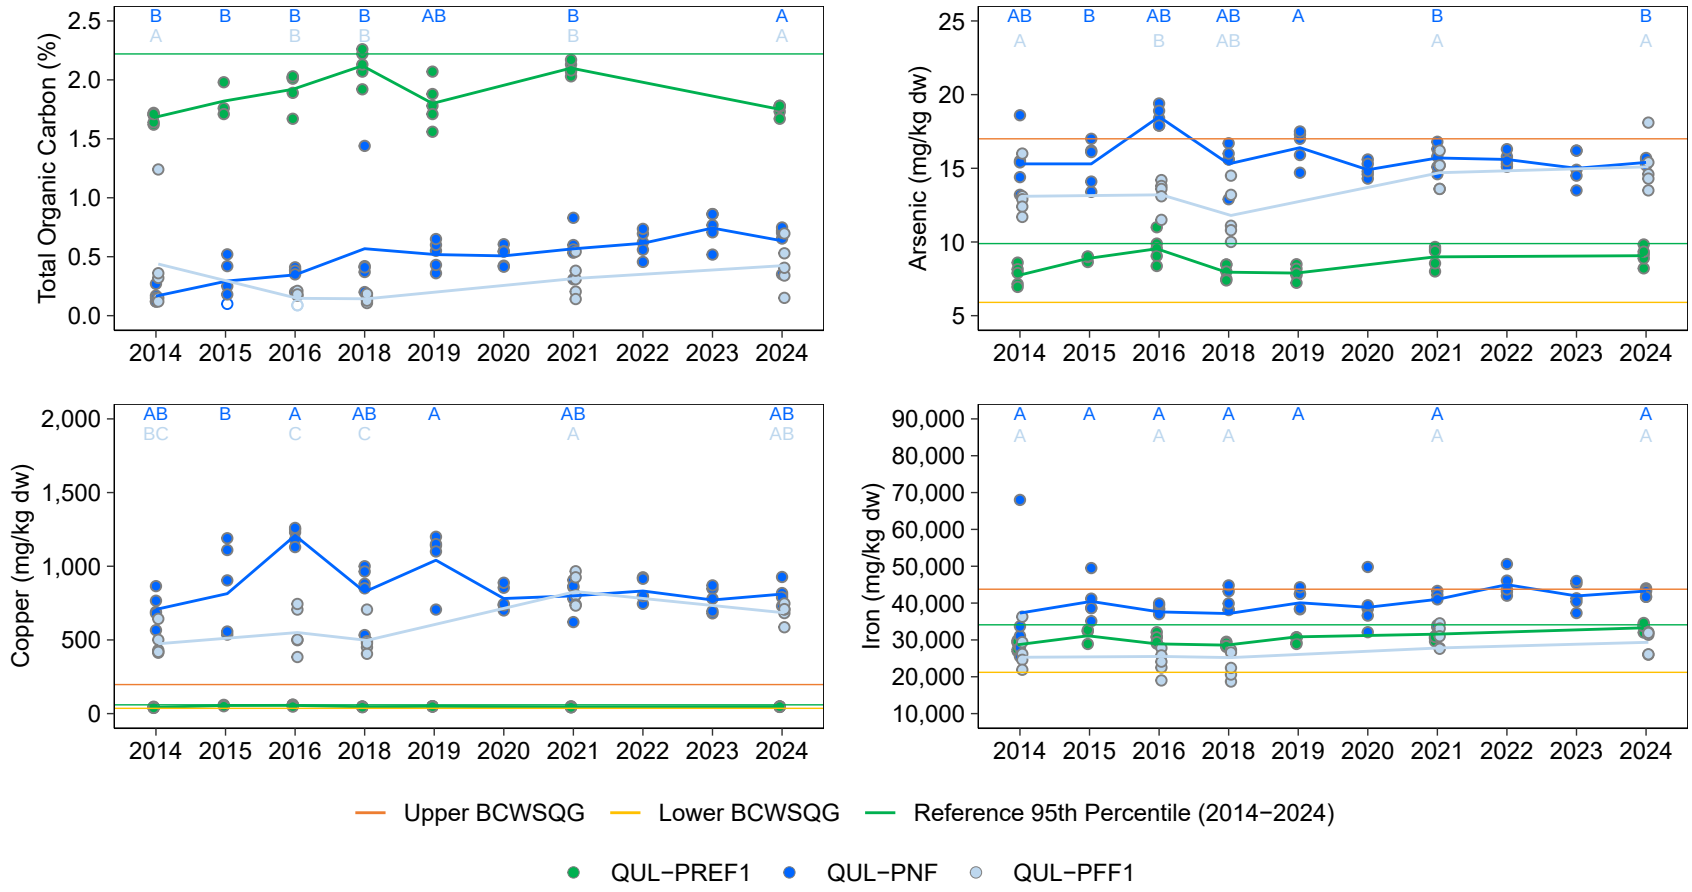

Figure 5.15: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for the Quesnel Lake (QUL−PNF and QUL−PFF1; Exposed and QUL−PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 20245). Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences − TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

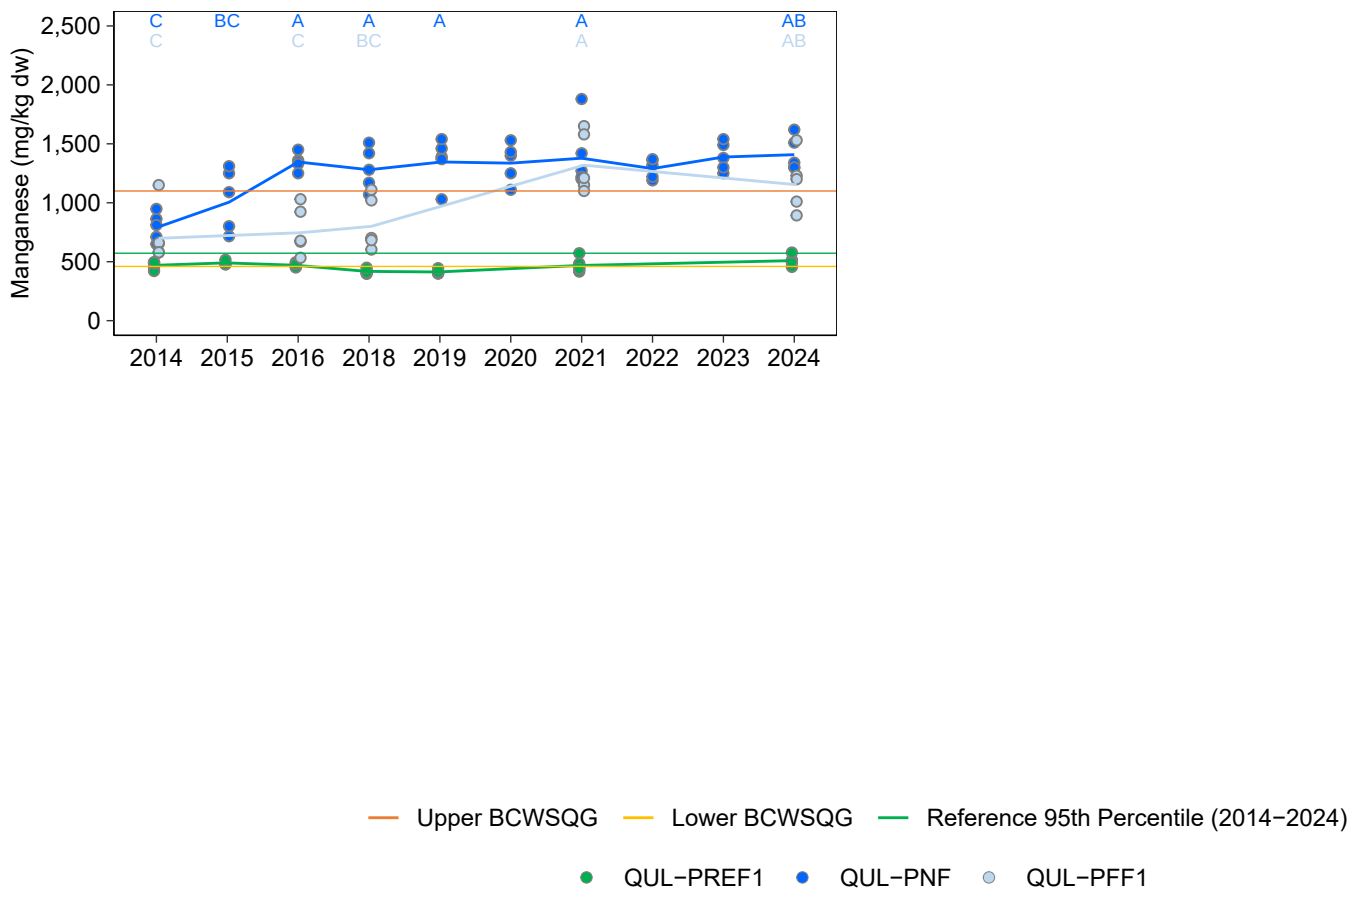

Figure 5.15: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for the Quesnel Lake (QUL−PNF and QUL−PFF1; Exposed and QUL−PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

for the corresponding reference area in 2024 (0.170%; Table 5.13; Appendix Tables C.2.7 and C.2.8).

Mean analyte concentrations in the sediments (<63 µm fraction) collected from QUL-PNF and QUL-PFF1 in 2024 exceeded the reference 95th percentile values for 26 and 22 analytes, respectively (Table 5.13; Appendix Tables C.2.7 and C.2.8). Among these analytes, four (arsenic, copper, iron, and manganese) at QUL-PNF, and three (arsenic, copper, and manganese) at QUL-PFF1 had mean concentrations in 2024 which also exceeded BCWSQG (Table 5.13; Appendix Table C.2.8). Specifically, mean arsenic concentrations in QUL-PNF and QUL-PFF1 sediments in 2024 were both approximately 2.6-times the lower BCWSQG, and the mean iron concentration at QUL-PNF in 2024 was approximately 2.0-times the lower BCWSQG (Figure 5.15, Table 5.13; Appendix Table C.2.8). The mean copper concentrations of QUL-PNF and QUL-PFF1 sediments in 2024 were approximately 4.1- and 3.5-times the upper BCWSQG, respectively, and mean manganese concentrations were 1.3- and 1.1-times the upper BCWSQG, respectively (Figure 5.15, Table 5.13). Mean arsenic, copper, iron, and manganese concentrations at the deep reference area (QUL-PREF1) were naturally elevated above the lower BCWSQG in all monitoring years (Figure 5.15, Table 5.13; Appendix Table C.2.7), demonstrating that these analytes are somewhat naturally elevated in parts of Quesnel Lake.

The relative (exposed-reference) differences of mean arsenic, copper, iron, and manganese concentrations for QUL-PNF sediments in 2024 were similar to those in prior years (2014 to 2023) with two exceptions (Figure 5.15; Appendix Table E.1.6). The two exceptions are that the relative differences in 2024 were significantly lower than in 2019 for arsenic, and significantly higher than in 2014 for manganese (Figure 5.15; Appendix Table E.1.6). When considered separately from reference results (which were not available for all years), mean concentrations of arsenic, copper, iron, and manganese concentrations in sediments from QUL-PNF have not changed significantly since at least 2018 (Appendix Table E.1.7). Combined, these results indicate that sediment concentrations of these four analytes have been stable since at least 2019 (when considered relative to or independent from reference), and that concentrations observed in 2024 were similar to or lower than those from all most prior years (at least 2015 to 2023).

In QUL-PFF1 sediments, the relative differences in Analyte of Interest concentrations have been temporally stable (i.e., have not changed significantly) since 2018 for arsenic, and since 2021 for copper and manganese. The relative difference for arsenic concentrations in 2024 was the same as the first year of monitoring (i.e., 2014). However, for copper and manganese the relative difference in concentrations increased significantly between 2018 and 2021, to a result higher than all prior years, and has not changed since then (Figure 5.15; Appendix Table E.1.6). This increase in copper and manganese concentrations in 2021 and 2024 corresponds with, and

was likely driven by, changes in the physical characteristics of the QUL-PFF1 sediments. There were no significant temporal changes in manganese and copper concentrations of reference sediments over this period (Appendix Table E.1.7). The mean clay composition of the QUL-PFF1 sediments in 2021 and 2024 was 2.0- and 1.6-times higher than in 2018, respectively (Table 5.13). Arsenic, copper, and manganese concentrations were positively correlated with clay content of fine exposed sediments (see below), therefore the concurrent increase in the clay content and copper and manganese concentrations of QUL-PFF1 sediments in 2021 and 2024 may be indicative of the mobilization of breach-related fines from QUL-PNF towards QUL-PFF1 in deep areas of Quesnel Lake.

When considering the fine exposed sediments from deep Quesnel Lake (QUL-PNF and QUL-PFF1), arsenic and copper were positively correlated with TOC, % clay, total nitrogen, and total sulphur content. Iron was positively correlated with TOC, total nitrogen, and total sulphur content and manganese was positively correlated with TOC, % clay, and total nitrogen (Appendix Figure E.1.3, Appendix Table E.1.8). The positive correlation of analytes measured in fine exposed sediments with higher clay content (% clay) is consistent with the input of fine tailings-influenced sediments with elevated analyte concentrations to the deep area of Quesnel Lake. Correlations of sediment characteristics that considered both exposed (QUL-PNF and QUL-PFF1) and reference (QUL-PREF1) areas were highly leveraged results, therefore were excluded from detailed interpretation (Appendix Figure E.1.3).

The results of a PCA of sediment quality data from QUL-PNF, QUL-PFF1, and QUL-PREF1 between 2014 and 2024 (Appendix Figure E.1.4, Appendix Tables E.1.9 and E.1.10) were included in correlations with benthic invertebrate community endpoints from these areas and sampling years (see Section 5.2.5).

Overall, the 2024 monitoring results indicate that physical and chemical characteristics of the deep exposed near-field sediments appear stable, with no difference in analyte (arsenic, copper, iron, or manganese) concentrations compared to within one year following the breach (2015), and no temporal changes since at least 2019. This is consistent with the low sediment deposition rate observed at this deep exposed area, with approximately 1 cm of fresh sediment deposition after 7 to 10 years (Minnow 2019a). In contrast, copper and manganese concentrations in the far-field sediments were significantly higher in 2021 and 2024, relative to reference. This increase was likely driven by the higher clay content of the sampled sediments and may be indicative of the mobilization of breach-related fines from QUL-PNF towards QUL-PFF1 in deep areas of Quesnel Lake.

5.2.1.2 Shallow Areas

Sediments collected from the shallow near-field exposed area of Quesnel Lake (QUL-LNF1) in 2024 were predominantly sand with some silt (mean = 96.8% and 3.20%, respectively), which was consistent with the sediments collected from this area in most previous post-breach years (2015 to 2023; Table 5.14; Appendix Table C.2.11). The high sand content of sediments from QUL-LNF1 was visually evident during sample collection and was likely a result of continued washing of fine particles from these shallow sampling locations towards deeper areas of the lake. Sediments from QUL-LNF1 in 2024 were higher in sand content and lower in silt content than the corresponding reference sediments (QUL-LREF1; mean = 70.9% sand, 22.1% silt), which also exhibited the highest sand content observed relative to prior years (range = 52.8 to 68.6% sand in 2014 to 2023; Table 5.14; Appendix Tables C.2.11 and C.2.12). Mean TOC and total nitrogen content at the exposed area in 2024 (mean TOC = 0.421%, mean total nitrogen = 0.0222%) were lower than at the corresponding reference area (mean TOC = 1.15% TOC, mean total nitrogen = 0.0622%), significantly so for TOC, which was consistent with previous post-breach years (Table 5.14; Appendix Table E.1.11). The relative (exposed-reference) difference in mean TOC of QUL-LNF1 sediments has been temporally stable (i.e., has not changed significantly) since the initiation of sampling in 2014 (Figure 5.16; Appendix Tables E.1.11 and E.1.12).

Mean analyte concentrations in the sediments (<63 µm fraction) collected from QUL-LNF1 in 2024 exceeded both reference and pre-breach 95th percentile values for 26 analytes (Table 5.14; Appendix Tables C.2.10 to C.2.12). Among these, five analytes (arsenic, copper, iron, manganese, and silver) also had mean concentrations that exceeded BCWSQG. Specifically, mean manganese and silver concentrations were approximately 2.2- and 1.6-times the lower BCWSQG, respectively, and mean arsenic, copper, and iron concentrations were approximately 1.1-, 8.7-, and 2.8-times the upper BCWSQG, respectively (Figure 5.16, Table 5.14; Appendix Table C.2.12). Of these analytes, iron concentrations exceeded the lower BCWSQG guidelines in the corresponding shallow reference sediments in each year (2014 to 2024; Figure 5.16, Table 5.14; Appendix Tables C.2.10 and C.2.11), demonstrating that iron is naturally elevated in parts of Quesnel Lake.

The mean concentrations of arsenic, copper, iron, manganese, and silver in QUL-LNF1 sediments have been significantly higher than reference concentrations since monitoring began in 2014 (Figure 5.16, Table 5.14; Appendix Table E.1.11). The relative (exposed-reference) difference in arsenic and iron concentrations observed in 2024 were not significantly different than those observed in previous years (2014 to 2023; Figure 5.16; Appendix Table E.1.12). Similarly, the relative difference in manganese concentrations in 2024 was not significantly different from most

Table 5.14: Summary of Sediment Quality Data for Quesnel Lake (QUL-LNF1; Exposed and QUL-LREF1; Reference) Shallow Monitoring Areas, 2007 to 2024

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics:*** Exposed value is > both reference and pre-breach 95th percentile values (<5th percentile for pH); reference value is > reference 95th percentile value (<5th percentile value for pH). Reference or pre-breach 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. "SD" = standard deviation. All summary statistics were calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Table C.2.9).

[b] The 5th percentile is reported and screened for the pH reference data. For calculation of reference 95th percentile values see Appendix Table C.2.10 and for calculation of pre-breach 95th percentile values see Appendix Table C.2.9.

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Table 5.14: Summary of Sediment Quality Data for Quesnel Lake (QUL-LNF1; Exposed and QUL-LREF1; Reference) Shallow Monitoring Areas, 2007 to 2024

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics:*** Exposed value is > both reference and pre-breach 95th percentile values (<5th percentile for pH); reference value is > reference 95th percentile value (<5th percentile value for pH). Reference or pre-breach 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. "SD" = standard deviation. All summary statistics were calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Table C.2.9).

[b] The 5th percentile is reported and screened for the pH reference data. For calculation of reference 95th percentile values see Appendix Table C.2.10 and for calculation of pre-breach 95th percentile values see Appendix Table C.2.9.

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

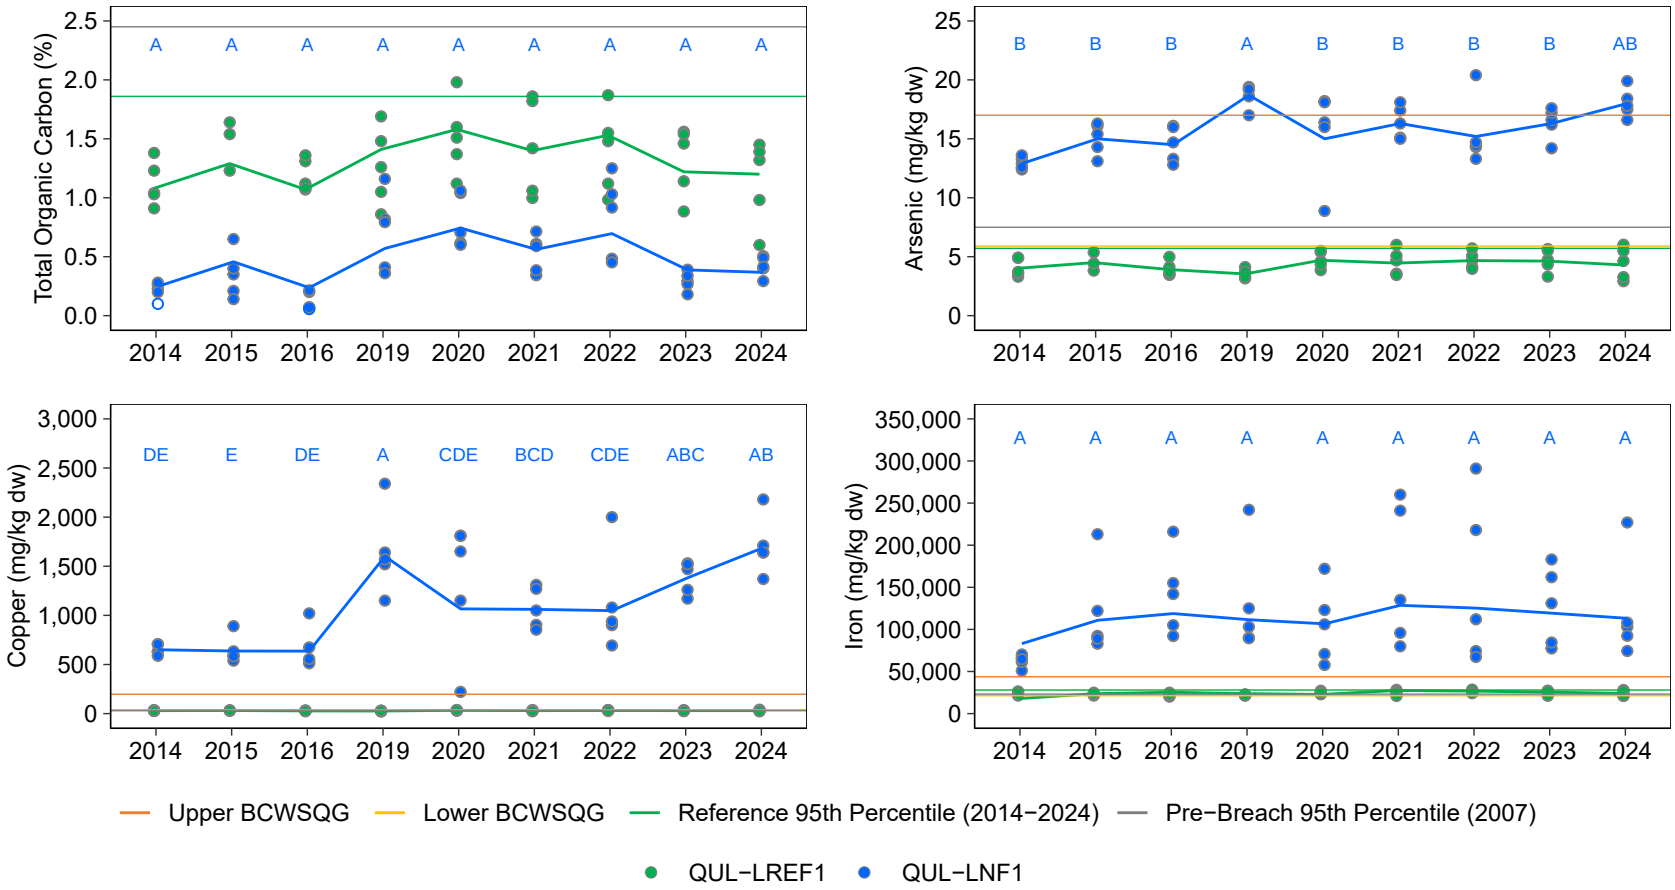

Figure 5.16: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for the Quesnel Lake (QUL−LNF1; Exposed and QUL−LREF1; Reference) Shallow Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025). Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences − TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

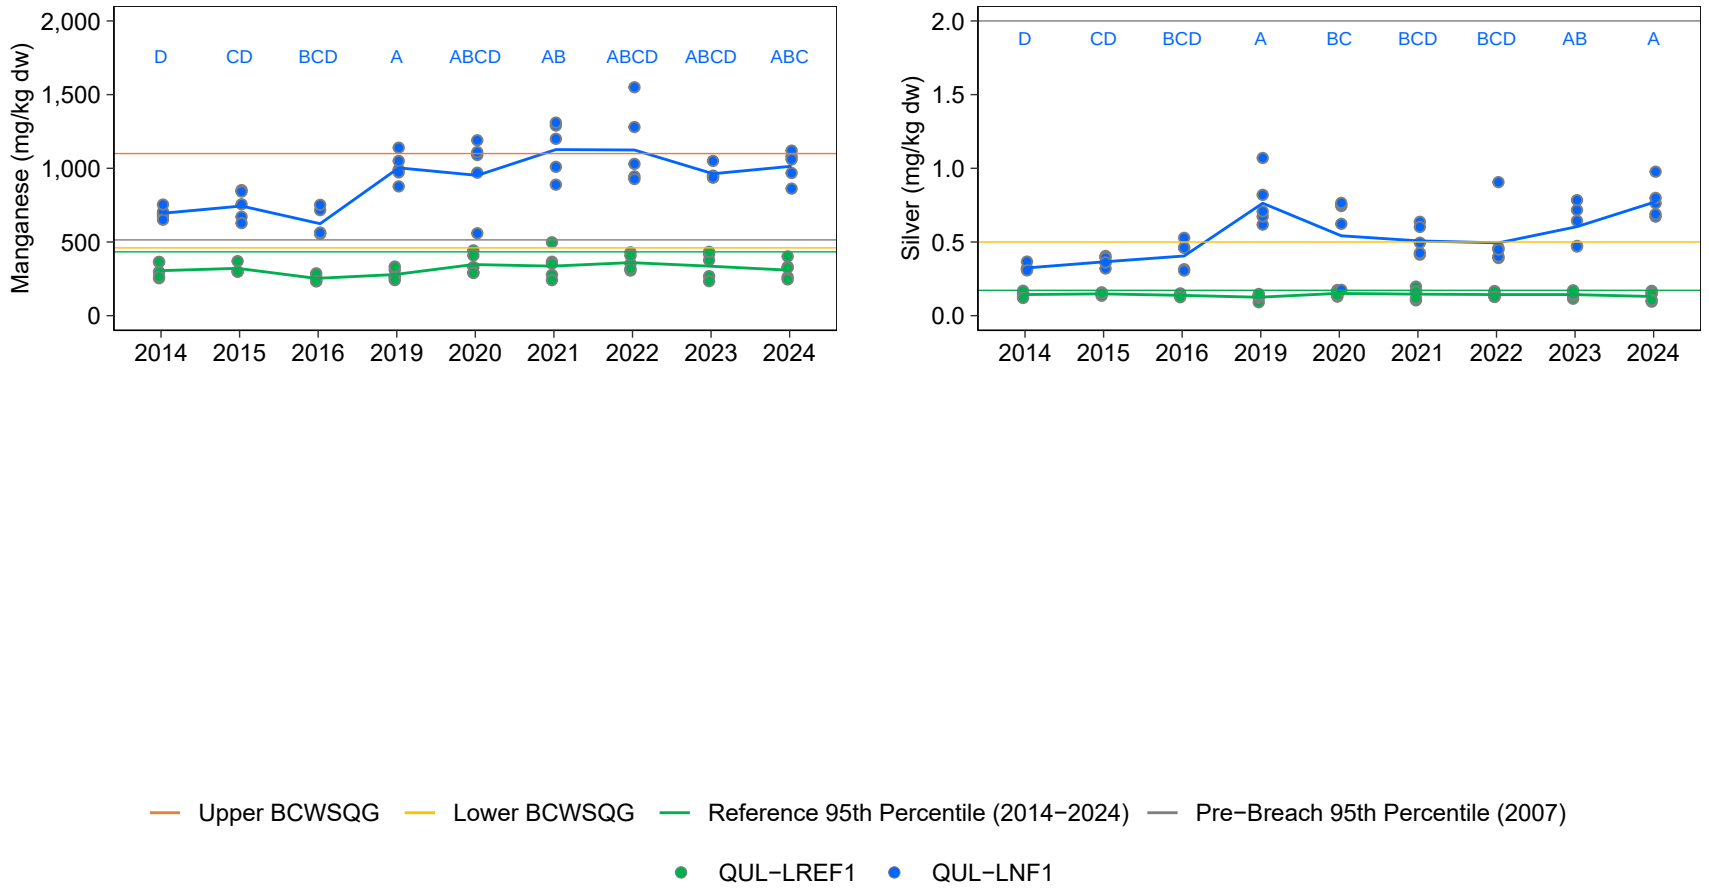

Figure 5.16: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for the Quesnel Lake (QUL−LNF1; Exposed and QUL−LREF1; Reference) Shallow Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025). Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). prior years (2015 to 2023), and has been temporally stable (i.e., has not changed significantly) from 2019 to 2024 (Figure 5.16; Appendix Table E.1.12). For both copper and silver concentrations, the relative difference in 2024 was similar to 2023, and to 2019, but was significantly higher than most (for copper) or all (for silver) remaining prior years. In 2019, most Analyte of Interest concentrations (except iron) were significantly higher than in prior years, which was likely associated with the relocation of QUL-LNF1 in 2019 (Figure 5.16; Appendix Table E.1.12).[55] Temporal changes in the relative differences of copper and silver concentrations were consistent with those shown by the temporal evaluation of exposed sediments only (i.e., not compared to reference; Appendix Table E.1.11). Overall, these results indicate that the relative difference in arsenic, manganese, and iron concentrations at the shallow exposed area in 2024 were similar to those shortly following the breach (i.e., 2014 or 2015) and have been stable since at least 2019. Copper and silver concentrations in 2024 were similar to 2023 and 2019, relative to reference, but were significantly higher than most (copper) or all (silver) remaining prior years, indicating that sediment concentrations copper and silver have not increased to concentrations significantly greater than those observed in 2019 when sampling station relocation occurred.

In the exposed sediments from QUL-LNF1, arsenic, copper, manganese, and silver concentrations were positively associated with % clay content, and copper, manganese, and silver were also positively associated with TOC (Appendix Figure E.1.5, Appendix Table E.1.13). The significant correlations in exposed sediments infer that the tailings-influenced sediments at the shallow sampling areas of Quesnel Lake with higher clay and TOC content tend to have higher concentrations of Analytes of Interest (e.g., arsenic, copper, manganese, and silver). Correlations of sediment characteristics that considered both exposed (QUL-LNF1) and reference (QUL-LREF1) areas were highly leveraged results, therefore were excluded from detailed interpretation (Appendix Figure E.1.5).

5.2.2 Sediment Toxicity

Sediment toxicity testing in Quesnel Lake was completed in 2024 using *C. dilutus* (10-day standard test using static methods) to test deep near-field (QUL-PNF) and reference (QUL-PREF1) sediments, and was completed using *H. azteca* (14-day standard test using static methods) to test shallow near-field (QUL-LNF1) and reference (QUL-LREF1) sediments (Figure 3.2, Table 3.3). Prior sediment toxicity monitoring within the 2022 to 2024

[55] The shallow near-field area of Quesnel Lake (QUL-LNF1) was moved in 2019 from its previous location due to variable water levels in the lake. Specifically, QUL-LNF1 stations that were originally sampled in 2015 to 2016 were either dry in 2019 or only very shallow (<0.5 m depth). As such, the QUL-LNF1 monitoring locations were moved in 2019 to adjacent locations that were deeper and continually submerged (see Minnow 2020a for details). These sediment stations established in 2019 were resampled in 2020 to 2024.

period included annual testing of *H. azteca* using sediments from the shallow near-field (QUL-LNF1) and reference (QUL-LREF1) areas (Figure 3.2, Table 3.3).

A review of the 2024 sediment toxicity results (Appendix B) indicated that the data met the established DQOs and can be used with a high level of confidence for interpretation (see Section 5.1.2 for details). A review of 2024 supporting water data quality associated with toxicity testing indicated that DOC was detected in one of three method blanks at a concentration of 0.51 mg/L, which surpassed the limit of reporting (LOR) of 0.5 mg/L (see Appendix B for more details). However, the DOC content of samples collected in 2024 was at least an order of magnitude greater than the LOR and, therefore, data are considered acceptable for interpretation. The exceedance for DOC does not affect the interpretation of sediment toxicity data but could influence the BCWQG calculated for dissolved copper since DOC is used in this guideline calculation.

5.2.2.1 Deep Areas

Survival of *C. dilutus* exposed to QUL-PNF sediments in 2024 showed a moderate response relative to the lab control and a low response relative to the reference sediments (23 to 46% mortality; Table 5.15). Although the control-normalized survival of *C. dilutus* in 2024 was lower than all prior years (Figure 5.17; i.e., greater mortality), the response classification relative to the lab control was similar to 2018 results (moderate response; Minnow 2019a). When compared to reference sediments, the survival of *C. dilutus* in 2024 had a lower response (i.e., lower mortality) than in 2018 (i.e., moderate response), but a higher response (i.e., greater mortality) than remaining prior years (Figure 5.17). The growth of *C. dilutus* exposed to QUL-PNF sediments showed no unacceptable response relative to laboratory control, but growth showed a low response relative to reference (QUL-PREF1; 25% reduction; Table 5.15). In contrast to the survival rate of *C. dilutus* in 2024, which was the lowest control-normalized survival rate observed across all studied years, control-normalized growth of *C. dilutus* in 2024 was the highest growth (lowest response) observed to date (Figure 5.17).

Evaluation of regression relationships indicated that control-normalized *C. dilutus* survival were positively related to TOC and negatively related to copper concentrations, however, correlation coefficients of these significant relationships were both weak after removal of outliers (r^2 values of 0.152 and 0.0724, respectively; Figure 5.18, Table 5.16). The regression relationships of control-normalized growth with TOC and copper concentrations after removal of outliers were significant and had stronger r^2 values of 0.400 and 0.548, respectively, which are consistent with moderate descriptive power (Milton and Arnold 2002).

The observed impact on growth and survival of *C. dilutus* exposed to deep near-field sediments is consistent with a breach-related effect that occurs due to a combination of low TOC and high

Table 5.15: Summary of *Chironomus dilutus* 10-day Survival and Growth Responses for Sediment Toxicity Testing of Quesnel Lake (QUL-PNF; Exposed and QUL-PREF1; Reference) Deep Monitoring Areas, 2024

Results and Classification	Profundal Near Field (QUL-PNF)	
	Survival	Growth[a]
	%	mg
Raw Area Result	54 ± 30.5	2.44 ± 1.11
Raw Laboratory Control Result	100 ± 0	1.66 ± 0.12
Raw Reference Result (QUL-PREF1)	70 ± 18.7	3.25 ± 0.29
Control Normalized Response[c]	54%	147%
Reference Normalized Response[c]	77%	75%
Statistical Difference from Control	Y	N
Statistical Difference from Reference	N	N
CLASSIFICATION[b]	**MR / LR**	**NR / LR**

No unacceptable response (<20% reduction) - **NR**.
Low response (20-50% reduction) and not significantly different than control and reference - **LR**.
Moderate response (20-50% reduction) and significantly different than control and reference - **MR**.
High response (>50% reduction) - **HR**.

Notes: Y = Yes. N = No.

[a] Growth = dry weight per surviving organism (mg).

[b] Where comparisons to mean laboratory control result and the mean field reference result did not fall into the same response classification, the result was discussed relative to both the control and the field reference.

[c] Response for survival differed significantly from the laboratory control but not the reference. The result was classified as moderate/low response. Since comparisons of survival to mean laboratory control result and the mean field reference result did not fall into the same response classification, the result was discussed relative to both the control and the field reference.

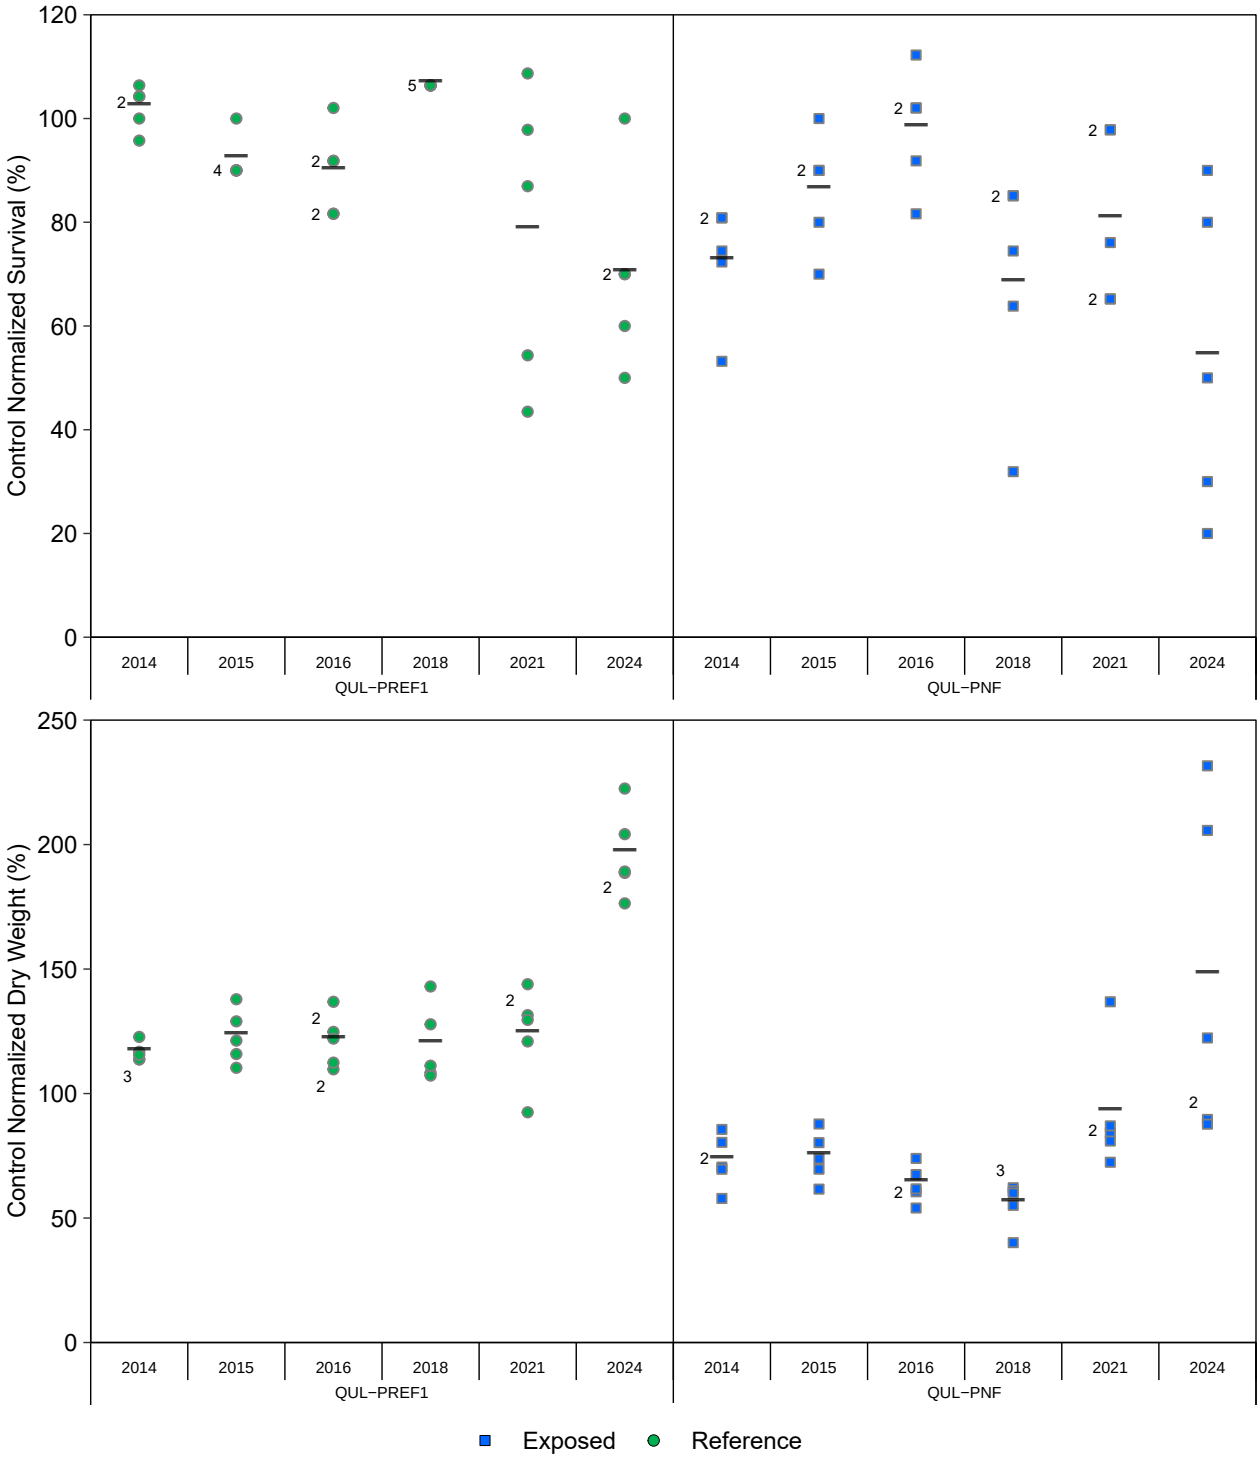

Figure 5.17: *Chironomus dilutus* Survival and Growth Responses (10−day) for Sediment Toxicity Testing at the Quesnel Lake (QUL−PNF; Exposed and QUL−PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: Green represents reference areas and blue represents exposed areas. Survival and growth data were normalized as a percentage of control performance for the same test batch. Numbers beside points on the plot indicate the number of overlapping results plotted.

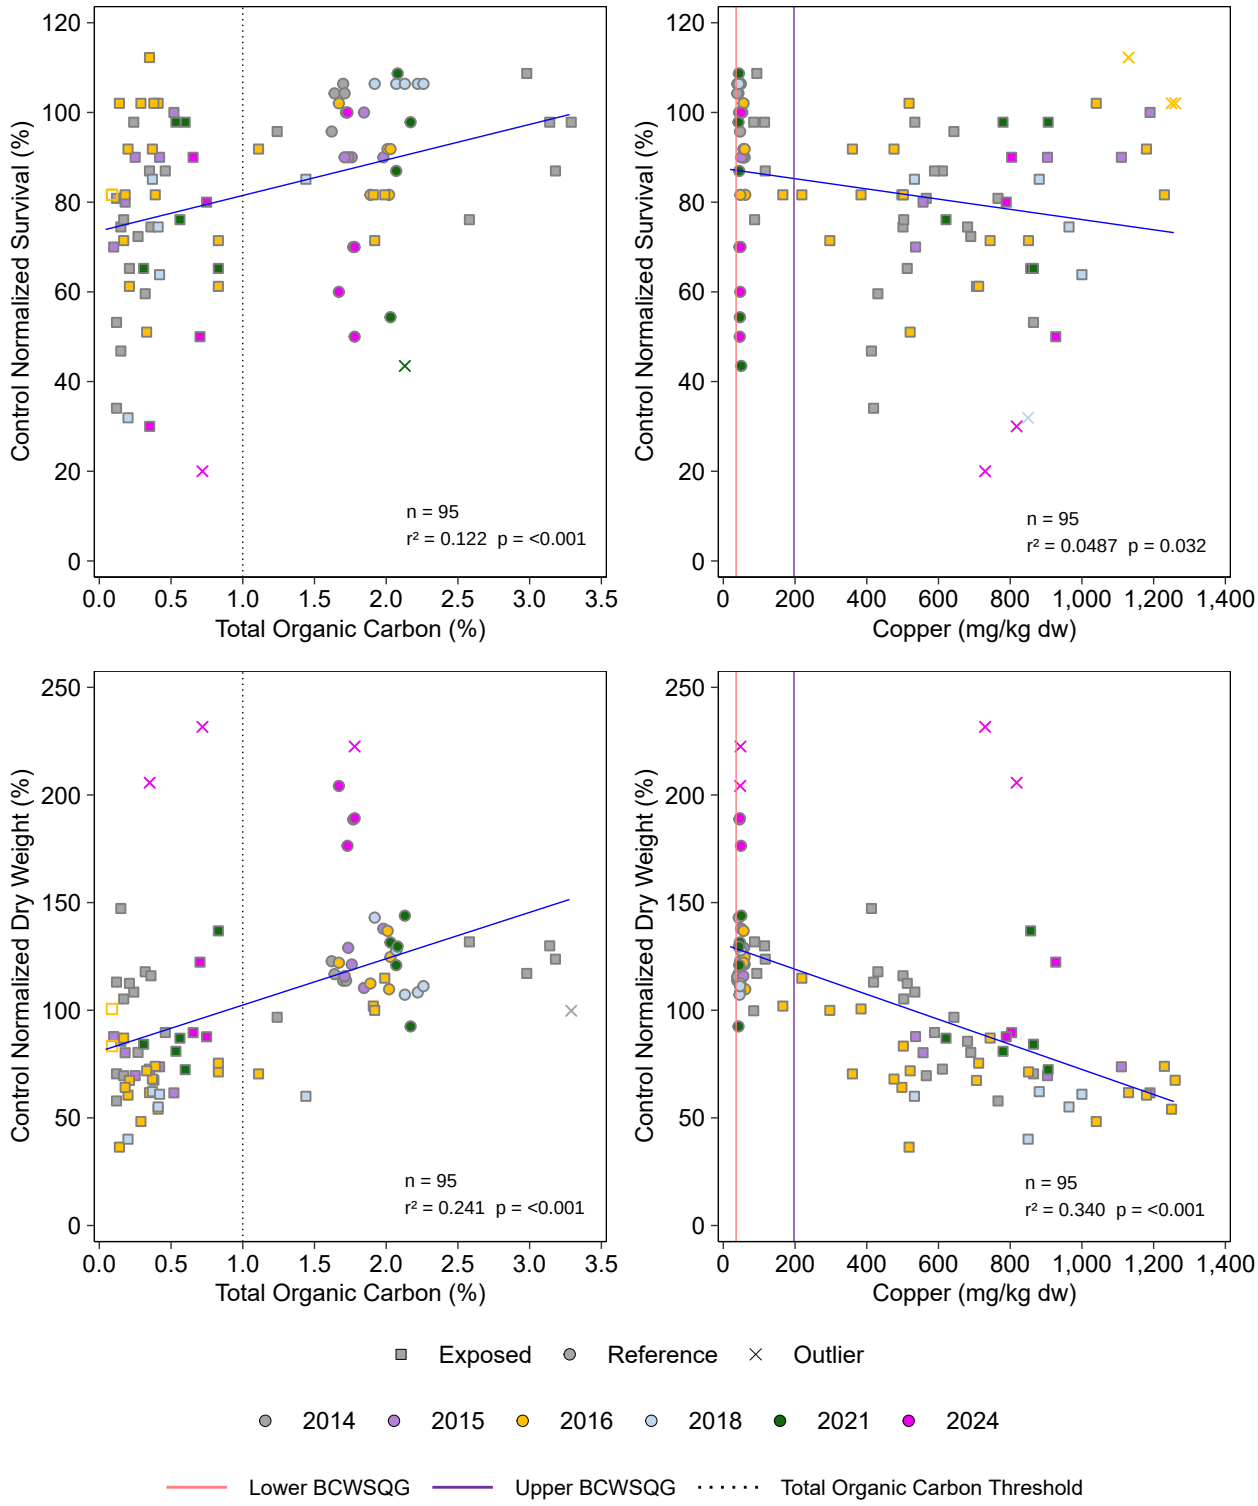

Figure 5.18: Simple Linear Regression Models of Control Normalized *Chironomus dilutus* Survival and Growth (10-day) Responses Relative to Sediment Characteristics at the Quesnel Lake (QUL−PNF; Exposed and QUL−PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024). Total Organic Carbon Threshold = the Total Organic Carbon concentration below which *C. dilutus* have been shown to be intolerant (Suedel et al. 1993). Control normalized survival and growth data were normalized as a percentage of control performance for the same test batch. Censored values are shown as open symbols. Statistical comparison shown (n, p, r^2) are based on linear regression before the removal of outliers. Outliers are noted with a ×. Regression model includes data from the following deep areas of Quesnel Lake (2014 to 2024): QUl-PNF, QUL-PFF1, QUL-PFF2, QUL-PFFF, QUL-I, QUL-PREF1, and QUL-PREF2.

Table 5.16: Simple Linear Regression Models of Control Normalized *Chironomus dilutus* 10-day Survival and Growth Responses Relative to Sediment Characteristics of Quesnel Lake Deep Monitoring Areas, 2014 to 2024

Response	Predictor	Data Set	n	Slope	Intercept	P-value	r^2

P-value < 0.05

Notes: mg/kg dw = milligrams per kilogram dry weight, TOC = total organic carbon. Total organic carbon and copper concentrations measured in the <63 µm sediment fraction. Regression model includes data from the following deep areas of Quesnel Lake (2014 to 2024): QUL-PNF, QUL-PFF1, QUL-PFF2, QUL-PFFF, QUL-I, QUL-PREF1, and QUL-PREF2.

[a] Outliers were removed from the regression based a Cook's Distance > 6/n.

concentrations of copper and the suite of breach-related analytes that correlate positively with copper (see Section 5.2.1). It is notable that Suedel et al. (1993) reported the intolerance of *Chironomus tentans* (the commonly used former name of *C. dilutus*) to sediments with organic content less than 1% and Suedel and Rodgers (1994) reported poor survival of *C. tentans* at organic content of 0.5% or lower. More specifically, Suedel and Rodgers (1994) documented a minimum organic matter requirement between 0.76% and 0.91% even when *C. tentans* were fed daily during 10-day exposures. For comparison, the mean TOC content in sediments collected from the Quesnel Lake deep near-field area (QUL-PNF) in 2024 was 0.635 ± 0.162% and ranged from 0.351% to 0.748% (Appendix Table C.2.8), which is similar to TOC content in previous years for this area (Table 5.13). The upper BCWSQG for copper is 197 mg/kg and is considered to represent a concentration that, if exceeded, will likely cause severe effects on aquatic life (BCMOWLRS 2024). Despite substantial evidence that bioavailability of copper in breach-influenced sediments may be limited (SRK 2015a,b; Minnow 2015a, 2018f, 2019a, 2020a; Golder 2017c), it is plausible that mean concentrations 3.5-times the upper BCWSQG, which were observed in 2024, would also have an influence on the growth of *C. dilutus*.

Overall, the survival of *C. dilutus* exposed to deep near-field sediments in 2024 showed a low to moderate response, and growth showed either no response or a low response. The survival response in 2024 was similar to 2018, but showed lower survival than other prior years, while growth in 2024 was higher than in prior years. It is apparent that low TOC and high sediment copper concentrations in deep near-field sediments of Quesnel Lake continue to be effective descriptors of growth responses in sediment toxicity tests of *C. dilutus*. This does not indicate that elevated copper and/or low TOC (both of which are indicative of the influence of the breach) are the sole causes of the observed responses, only that they predict the responses at concentrations that make mechanistic sense and are indicative of an influence of both physical and chemical conditions on the observed organism responses.

5.2.2.2 Shallow Areas

Survival of *H. azteca* exposed to QUL-LNF1 sediments in 2024 showed a moderate response (31 to 38% mortality; Table 5.17), which was consistent with most prior years (i.e., 2016, 2020, 2021, 2022) but represented lower mortality than in 2019 and 2023 when survival responses were high (Figure 5.19). Growth of *H. azteca* exposed to QUL-LNF1 sediments showed a moderate to high response (48 to 63% reduction in growth; Table 5.17), which was consistent with the growth response in 2020, and a lower response (i.e., higher growth) than most prior years (i.e., 2016, 201, 2021, 2022, 2023) which had high growth responses (for similar 14-day standard static tests Figure 5.19).

Table 5.17: Summary of *Hyalella azteca* 14-day Survival and Growth Responses for Sediment Toxicity Testing of Quesnel Lake (QUL-LNF1; Exposed and QUL-LREF1; Reference) Shallow Monitoring Areas, 2024

Results and Classification	Littoral Near Field (QUL-LNF)	
	Survival	Growth[a]
	%	mg
Raw Area Result	62.0 ± 20.5	0.12 ± 0.02
Raw Laboratory Control Result	100.0 ± 0.00	0.23 ± 0.05
Raw Reference Result (QUL-LREF1)	90.0 ± 12.30	0.32 ± 0.04
Control Normalized Response	62%	52%
Reference Normalized Response	69%	38%
Statistically Significant Reduction from Control	Y	Y
Statistically Significant Reduction from Reference	Y	Y
CLASSIFICATION [b]	**MR**	**MR** / **HR**

No unacceptable response (<20% reduction) - **NR**.
Low response (20-50% reduction) and not significantly different than control and reference - **LR**.
Moderate response (20-50% reduction) and significantly different than control and reference - **MR**.
High response (>50% reduction) - **HR**.

Notes: Y = Yes. N = No.

[a] Growth = dry weight per surviving organism (mg).

[b] Where comparisons to mean laboratory control result and the mean field reference result did not fall into the same response classification, the result was discussed relative to both the control and the field reference.

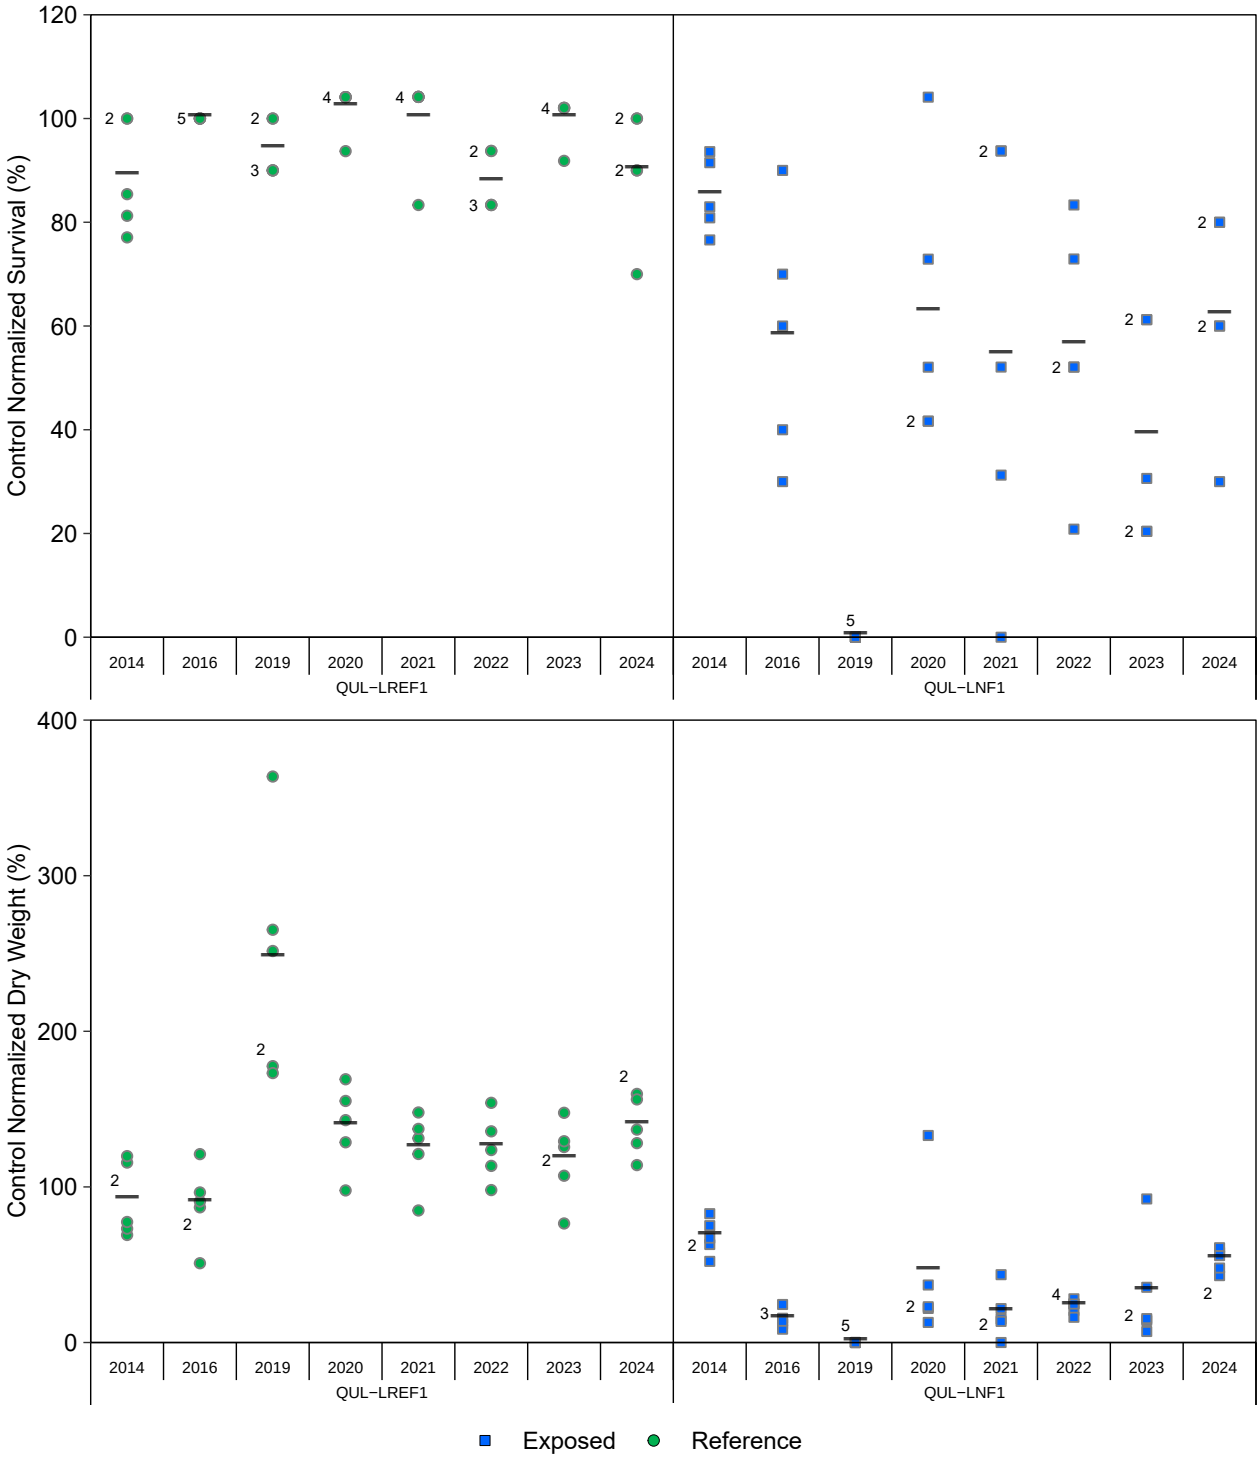

Figure 5.19: *Hyalella azteca* Survival and Growth Responses (14−day) for Sediment Toxicity Testing at the Quesnel Lake (QUL−LNF1; Exposed and QUL−LREF1; Reference) Shallow Monitoring Areas, 2014 to 2024

Notes: Green represents reference areas and blue represents exposed areas. Survival and growth data were normalized as a percentage of control performance for the same test batch. Numbers beside points on the plot indicate the number of overlapping results plotted.

Mean sediment copper concentrations at QUL-LNF1 in 2024 were 1,708 ± 294 mg/kg (Appendix Table C.2.12), which was greater than a laboratory determined copper 10-day LC_{50} (lethal concentration to 50% of test organisms) of 1,078 mg/kg for *H. azteca* (Cairns et al. 1984). The corresponding dissolved aqueous copper LC_{50} concentration from the Cairns et al. (1984) study was 39 µg/L. The mean dissolved copper concentrations observed in overlying water of QUL-LNF1 toxicity testing vessels on day 14 of the test in 2024 (84.2 ± 10 µg/L; Appendix G) was approximately 2.2-times higher than the LC_{50} reported by Cairns et al. (1984) and approximately 3.4-times higher than the BLM-based acute BCWQG (24.9 µg/L; Figure 5.20). Dissolved copper concentrations in the overlying water of toxicity test vessels were notably higher for exposed (QUL-LNF1; mean of 84.2 µg/L ± 10 µg/L) than for reference sediments (QUL-LREF1; mean of 3.27 ± 0.84 µg/L; Figure 5.20; Appendix G). The mean dissolved copper concentrations of laboratory-collected overlying water for both exposed and reference treatments were also notably higher than field-collected (*in situ*) overlying water samples (QUL-LNF1 mean = 0.502 µg/L; QUL-LREF1 mean = 0.580 µg/L; Appendix Table C.1.3), which remained below the BLM-based chronic BCWQG (1.0 µg/L; Figure 5.20). Specifically, the ratio of mean dissolved copper concentrations in toxicity testing overlying waters compared to *in situ* field-collected waters was 168-times for QUL-LNF1 sediments in 2024 (Appendix G; Appendix Table C.1.3). This ratio was similar to the ratio observed in 2019 (175-times), and higher than the ratio observed in 2020 (74-times), 2021 (114-times), 2022 (97-times), and 2023 (78-times; Figure 5.20; Minnow 2020a, 2021a, 2022a, 2023a, 2024a). Combined, these results suggest copper mobilization occurred in the test setup that has either not occurred in the field or has attenuated over time.

In 2021, the 14-day *H. azteca* testing was conducted using static and static-renewal methods (i.e., renewing the testing waters during the test) to better understand the evolution of dissolved copper to overlying test waters and associated implications to toxicity test results (Minnow 2022a). While the dissolved copper concentrations in overlying water of bioassay vessels were decreased by using static-renewal methods, the test methods were not representative of *in situ* conditions, with dissolved copper concentrations in overlying water remaining 56-times higher than *in situ* (Minnow 2022a). Except for the use of both static and static-renewal methods in 2021, 14-day *H. azteca* toxicity testing has been completed solely using static test methods in other monitoring years.

Evaluation of regression relationships indicated that control-normalized survival and growth of *H. azteca* were significantly positively related to sediment TOC and significantly negatively related to sediment copper concentrations and to aqueous dissolved copper concentrations in the overlying water of bioassay vessels. No significant relationships existed between control-normalized survival and growth and dissolved aqueous copper in water overlying

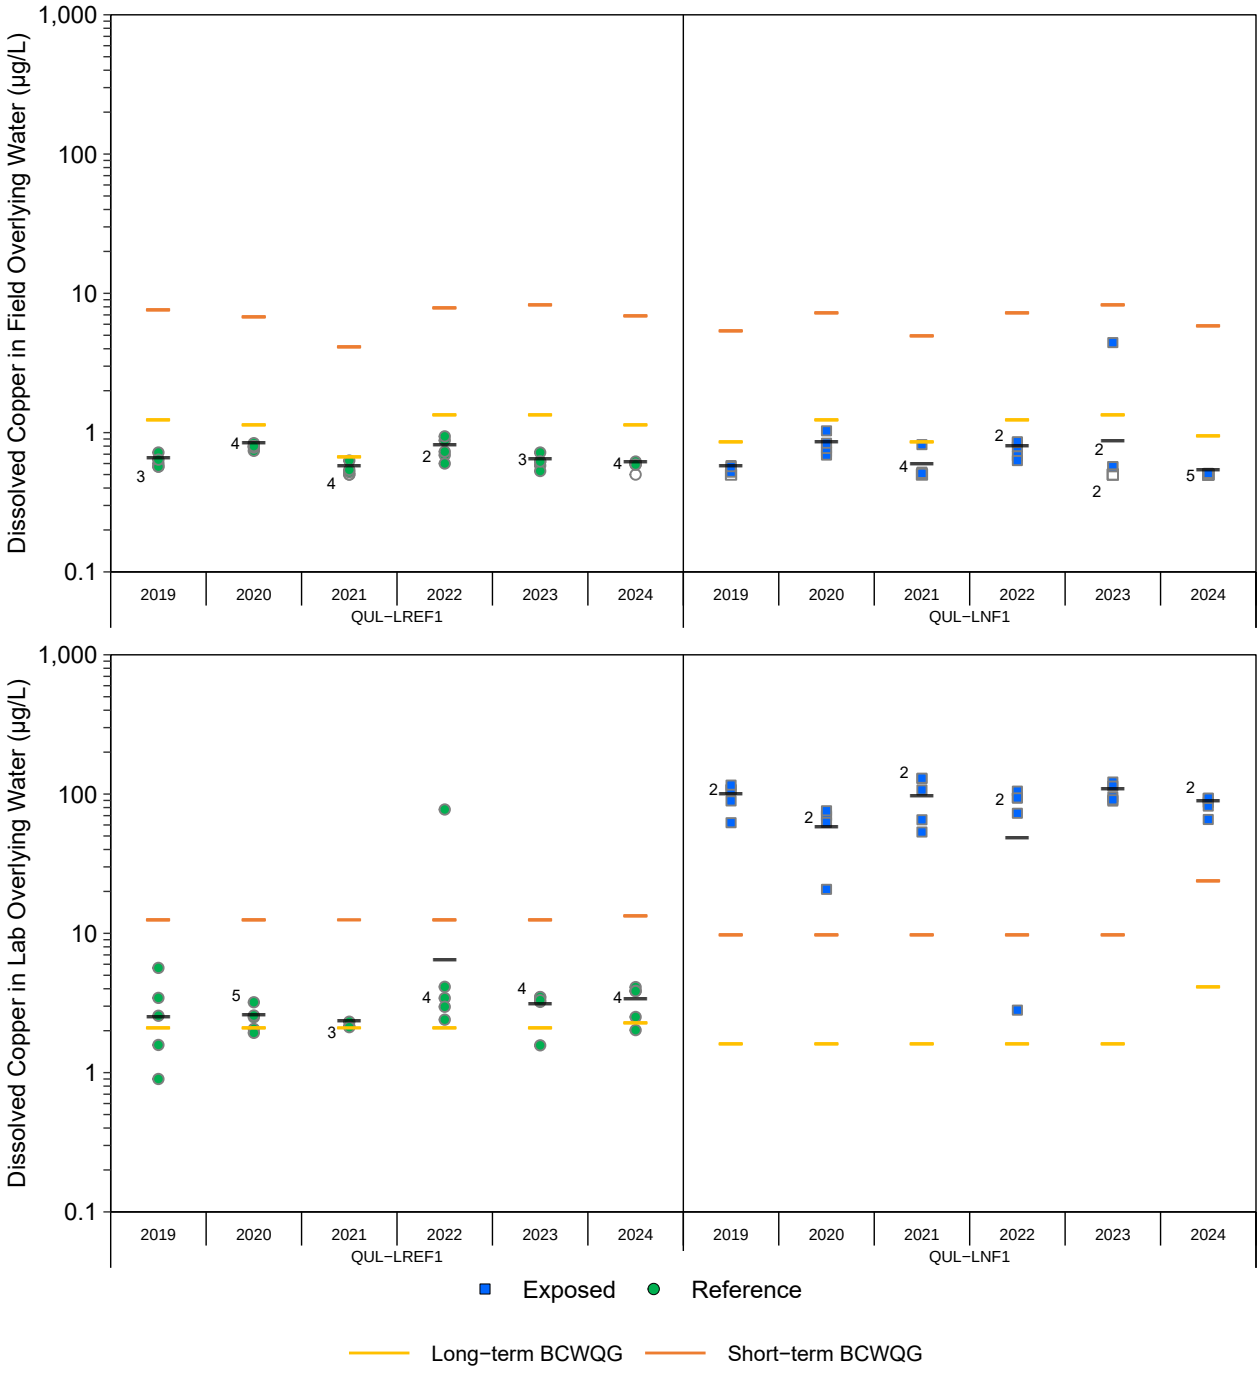

Figure 5.20: Dissolved Copper Concentrations in Laboratory and Field Overlying Water Associated with *Hyalella azteca* Survival and Growth (14−day) Sediment Toxicity Testing at the Quesnel Lake (QUL−LNF1; Exposed and QUL−LREF1; Reference) Shallow Monitoring Areas, 2019 to 2024

Notes: BCWQG = British Columbia Water Quality Guidelines (BCMOWLRS 2024, 2025). Green represents reference areas and blue represents exposed areas. Numbers beside dots on the plot indicate the number of overlapping points. Copper guidelines were calculated based on the Biotic Ligand Model (BLM) Look−up Table using temperature, pH, dissolved organic carbon, and hardness (BCMOWLRS 2025). Copper WQG shown on plots are the most conservative (lowest) guidelines for replicate sets at for a given area and year. Data for estimating the copper guideline using the BLM were not available for before 2023 for overlying lab water; therefore, the 2023 guideline is shown for all years up to and including 2023.

sediment *in situ* (Figure 5.21, Table 5.18). The relationships with copper concentrations in sediment and test overlying waters (dissolved copper) had strong r^2 values ranging from 0.612 to 0.709 after removal of outliers, which are r^2 values consistent with strong descriptive power (Milton and Arnold 2002). These relationships infer lower *H. azteca* growth and survival at higher dissolved copper concentrations in the overlying water, which is consistent with the fact that *H. azteca* have been documented to derive little nutrition from sediment and to respond primarily to contaminants in overlying water (Wang et al. 2004). As indicated above, dissolved copper concentrations in overlying water of the exposed (QUL-LNF1) test vessels were approximately 3.4-times higher than the BLM-based acute BCWQG, which is consistent with the moderate to high mortality rate observed in this test in 2024. Mean dissolved copper concentrations in the overlying test waters for reference sediments (QUL-LREF1; mean = 3.27 µg/L) were lower than the acute BLM-based acute BCWQG (11.4 µg/L) but higher than the chronic BCWQG (1.9 µg/L; Figure 5.20).

Overall, temporal trends of *H. azteca* toxicity test results suggest a residual breach-related influence on *H. azteca* toxicity for both growth and survival within the small shallow near-field area near the mouth of Hazeltine Creek. However, the substantial difference in overlying water quality between laboratory and field conditions (as noted earlier) indicates the toxicity test results from this area cannot be reliably extrapolated to field (*in situ*) exposure but suggests potential for copper mobilization in this area with disturbance.

5.2.3 Plankton Community and Productivity

Plankton community and productivity monitoring was completed annually between 2022 and 2024 with three sampling events per year (June, July, and August) in exposed (QUL-ZOO-1) and reference (QUL-ZOO-7) areas of Quesnel Lake (Figure 3.3, Tables 3.4 and 3.5). Single phytoplankton and zooplankton samples were collected in June and August, whereas replicate samples were collected in July of each year (n = 5 per area; see Section 3.3.1 for details).

A review of the 2024 plankton community and productivity results and supporting water quality results (Appendix B) indicated that these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

5.2.3.1 Phytoplankton

5.2.3.1.1 Community

Qualitative evaluation of seasonal data from 2024 indicated that phytoplankton total densities at QUL-ZOO-1 (exposed) and QUL-ZOO-7 (reference) were highest in June and July and decreased in August, while taxon richness at both QUL-ZOO-1 and QUL-ZOO-7 was lower in June and July relative to August 2024 (Appendix Figure E.2.7, Appendix Table C.3.5).

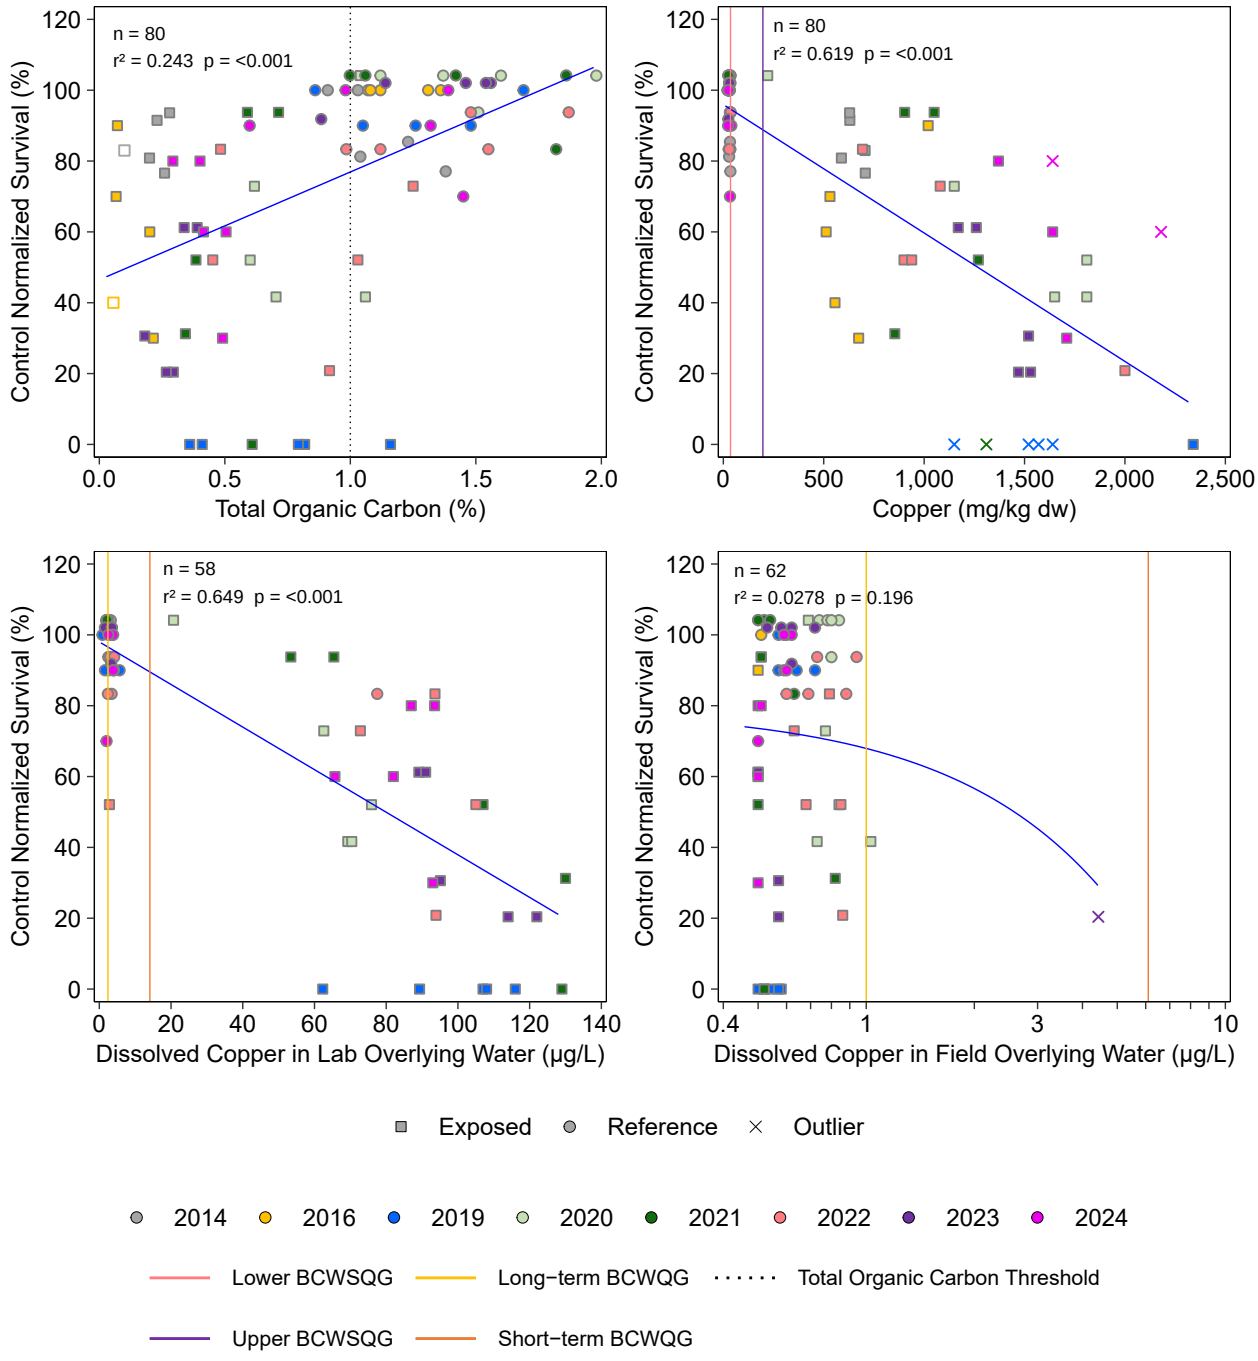

Figure 5.21: Simple Linear Regression Models of Control−Normalized *Hyalella azteca* Survival and Growth (14−day) Responses Relative to Sediment and Overlying Water Characteristics at the Quesnel Lake (QUL−LNF1; Exposed and QUL−LREF1; Reference) Shallow Monitoring Areas, 2014 to 2024

Notes: BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024). BCWQG = British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025). Total Organic Carbon Threshold = the Total Organic Carbon concentration below which *C. dilutus* have been shown to be intolerant (Suedel et al. 1993). Displayed BCWQG for dissolved copper are the most conservative values for QUL−LNF for 2024 calculated using the Biotic Ligand Model Look−up Table (BCMOWLRS 2025). Field and lab overlying water dissolved copper data are only available from 2019 to 2024. Censored values are shown as open symbols. Outliers are noted with a ×. Statistical comparison shown (n, p, r²) are based on linear regression before the removal of outliers. For plots showing dissolved copper concentrations in water measured in the field, the x−axis has been log10 −transformed to better display the data.

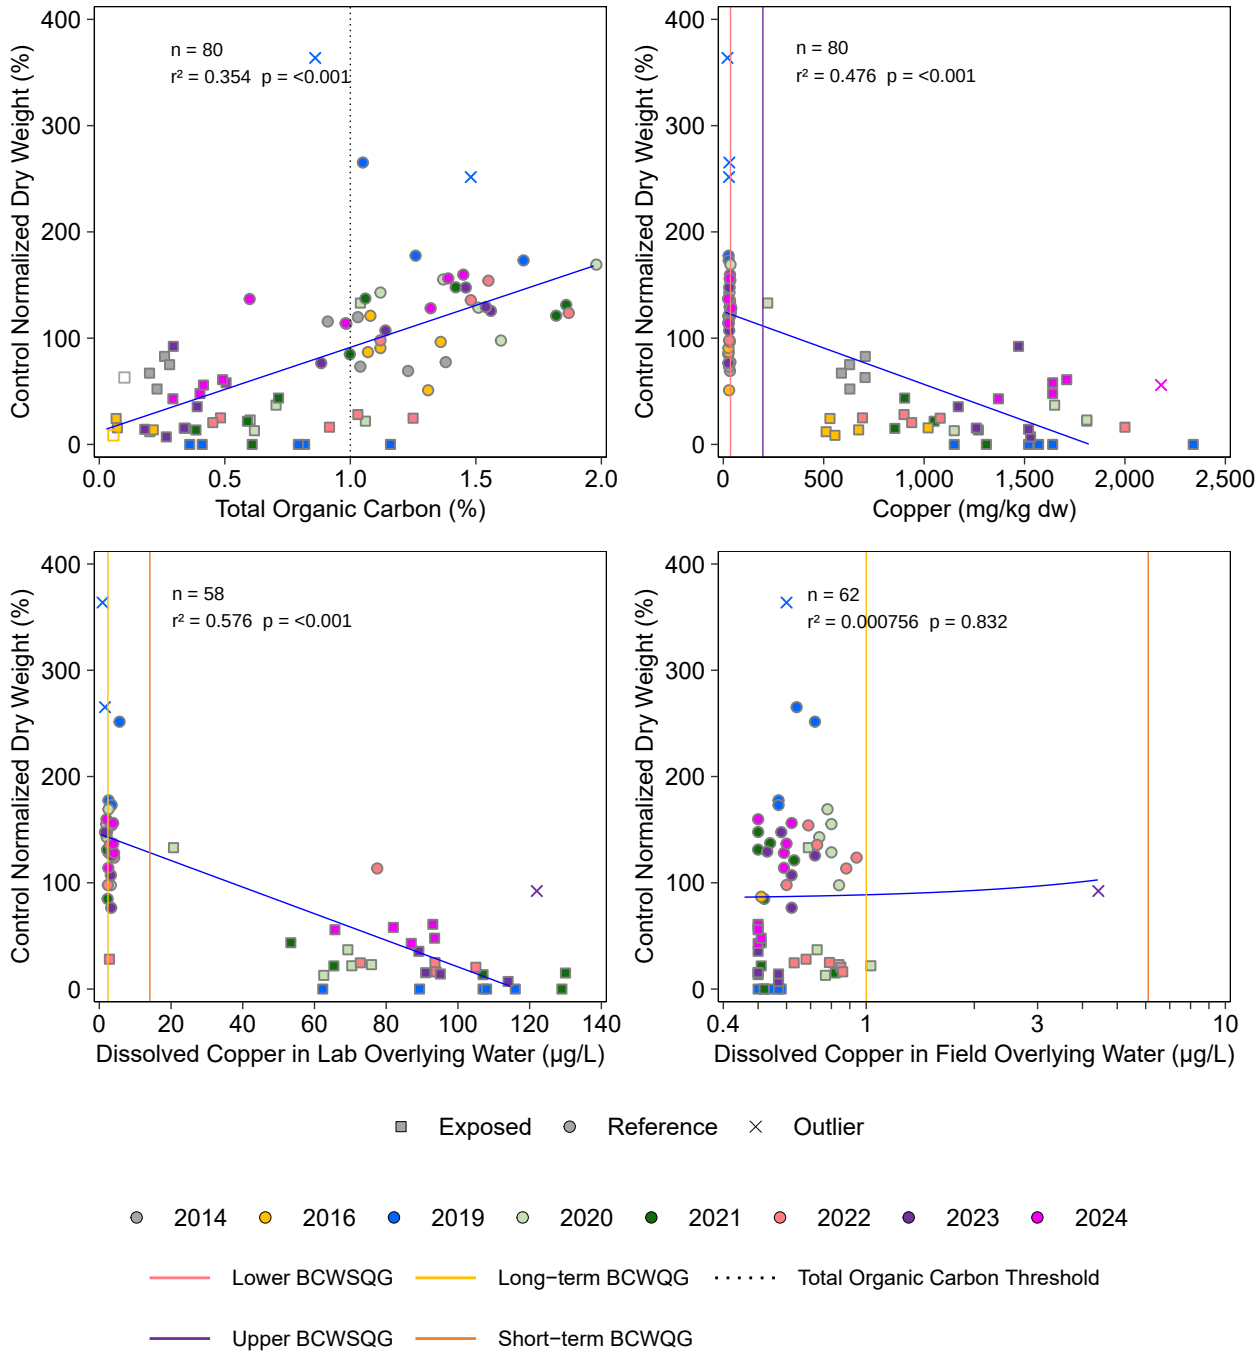

Figure 5.21: Simple Linear Regression Models of Control−Normalized *Hyalella azteca* Survival and Growth (14−day) Responses Relative to Sediment and Overlying Water Characteristics at the Quesnel Lake (QUL−LNF1; Exposed and QUL−LREF1; Reference) Shallow Monitoring Areas, 2014 to 2024

Notes: BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024). BCWQG = British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025). Total Organic Carbon Threshold = the Total Organic Carbon concentration below which *C. dilutus* have been shown to be intolerant (Suedel et al. 1993). Displayed BCWQG for dissolved copper are the most conservative values for QUL−LNF for 2024 calculated using the Biotic Ligand Model Look−up Table (BCMOWLRS 2025). Field and lab overlying water dissolved copper data are only available from 2019 to 2024. Censored values are shown as open symbols. Outliers are noted with a ×. Statistical comparison shown (n, p, r^2) are based on linear regression before the removal of outliers. For plots showing dissolved copper concentrations in water measured in the field, the x−axis has been log10 −transformed to better display the data.

P-value < 0.05.

Notes: mg/kg dw = milligrams per kilogram dry weight, TOC = total organic carbon, µg/L = micrograms per liter. TOC content and copper concentrations measured in the <63 µm sediment fraction.

[a] Outliers were removed from the regression based a Cook's Distance > 6/n.

Statistical analyses of replicated data (from July sampling events) indicated that mean phytoplankton density, taxon richness, Simpson's Diversity, and Simpson's Evenness were all similar between the exposed (QUL-ZOO-1) and reference (QUL-ZOO-7) areas of Quesnel Lake in 2024 (Figure 5.22, Table 5.19; Appendix Tables C.3.5 and C.3.6).

Temporal analyses showed similar patterns of phytoplankton density, richness, and Simpson's Evenness and Diversity between the exposed and reference areas of Quesnel Lake from 2019 to 2024. At both QUL-ZOO-1 and QUL-ZOO-7, mean phytoplankton densities increased significantly year-over-year from 2021 to 2023, then decreased significantly in 2024 but remained significantly higher than in 2019 to 2022 (Figure 5.22, Table 5.19). The similarity in temporal changes in total density between the areas over time suggests that these temporal patterns were related to variability in local environmental factors (e.g., light exposure and water temperature). The higher total densities of phytoplankton observed in 2023 and 2024 relative to previous years were driven by significantly higher Diatom densities at both the exposed and reference areas (Appendix Figures E.2.8 and E.2.9, Appendix Tables C.3.5 and E.2.3). Diatom densities at QUL-ZOO-1 have been similar to the reference area over time, except in 2020 when Diatom density was higher at the exposed area (Appendix Figure E.2.8, Appendix Table E.2.3).

At both QUL-ZOO-1 and QUL-ZOO-7, mean taxon richness was significantly higher in 2024 relative to 2023, but was significantly lower than prior post-breach years (i.e., 2019 to 2021 for QUL-ZOO-1; 2020 to 2022 for QUL-ZOO-7; Figure 5.22, Table 5.19). The significantly lower taxon richness in 2023 and 2024 at both the exposed and reference areas compared to prior years coincided with significantly higher total densities and dominance of Diatoms (Figures 5.22 and 5.23; Appendix Figure E.2.8, Appendix Table E.2.3). Taxon richness at QUL-ZOO-1 has been similar to the QUL-ZOO-7 reference area in most years, except for being significantly lower than reference in 2022 and 2023 (Figure 5.22, Table 5.19). Mean Simpson's Diversity and Evenness followed a similar temporal pattern as taxon richness with significantly lower Simpson's Diversity and Evenness at both QUL-ZOO-1 and QUL-ZOO-7 in 2022 to 2024 compared to all prior years (except for Simpson's Diversity at QUL-ZOO-7 in 2020; Figure 5.22, Table 5.19). Simpson's Diversity at QUL-ZOO-1 has consistently been similar to or significantly higher than at the reference area (QUL-ZOO-7), except for in 2022, which was likely associated with a significant increase in the relative density (%) of Chrysophytes. Simpson's Evenness at QUL-ZOO-1 has consistently been similar to QUL-ZOO-7 since 2021 (Figure 5.22, Table 5.19).

Qualitative evaluation of seasonal data from 2024 indicated that Diatoms and Chrysophytes were dominant at both the exposed and reference areas in June and July Figure 5.23, Appendix Table C.3.,). In August, the density and dominance of Diatoms decreased substantially in both areas and the relative densities (%) of Cryptomonads and Cyanobacteria increased

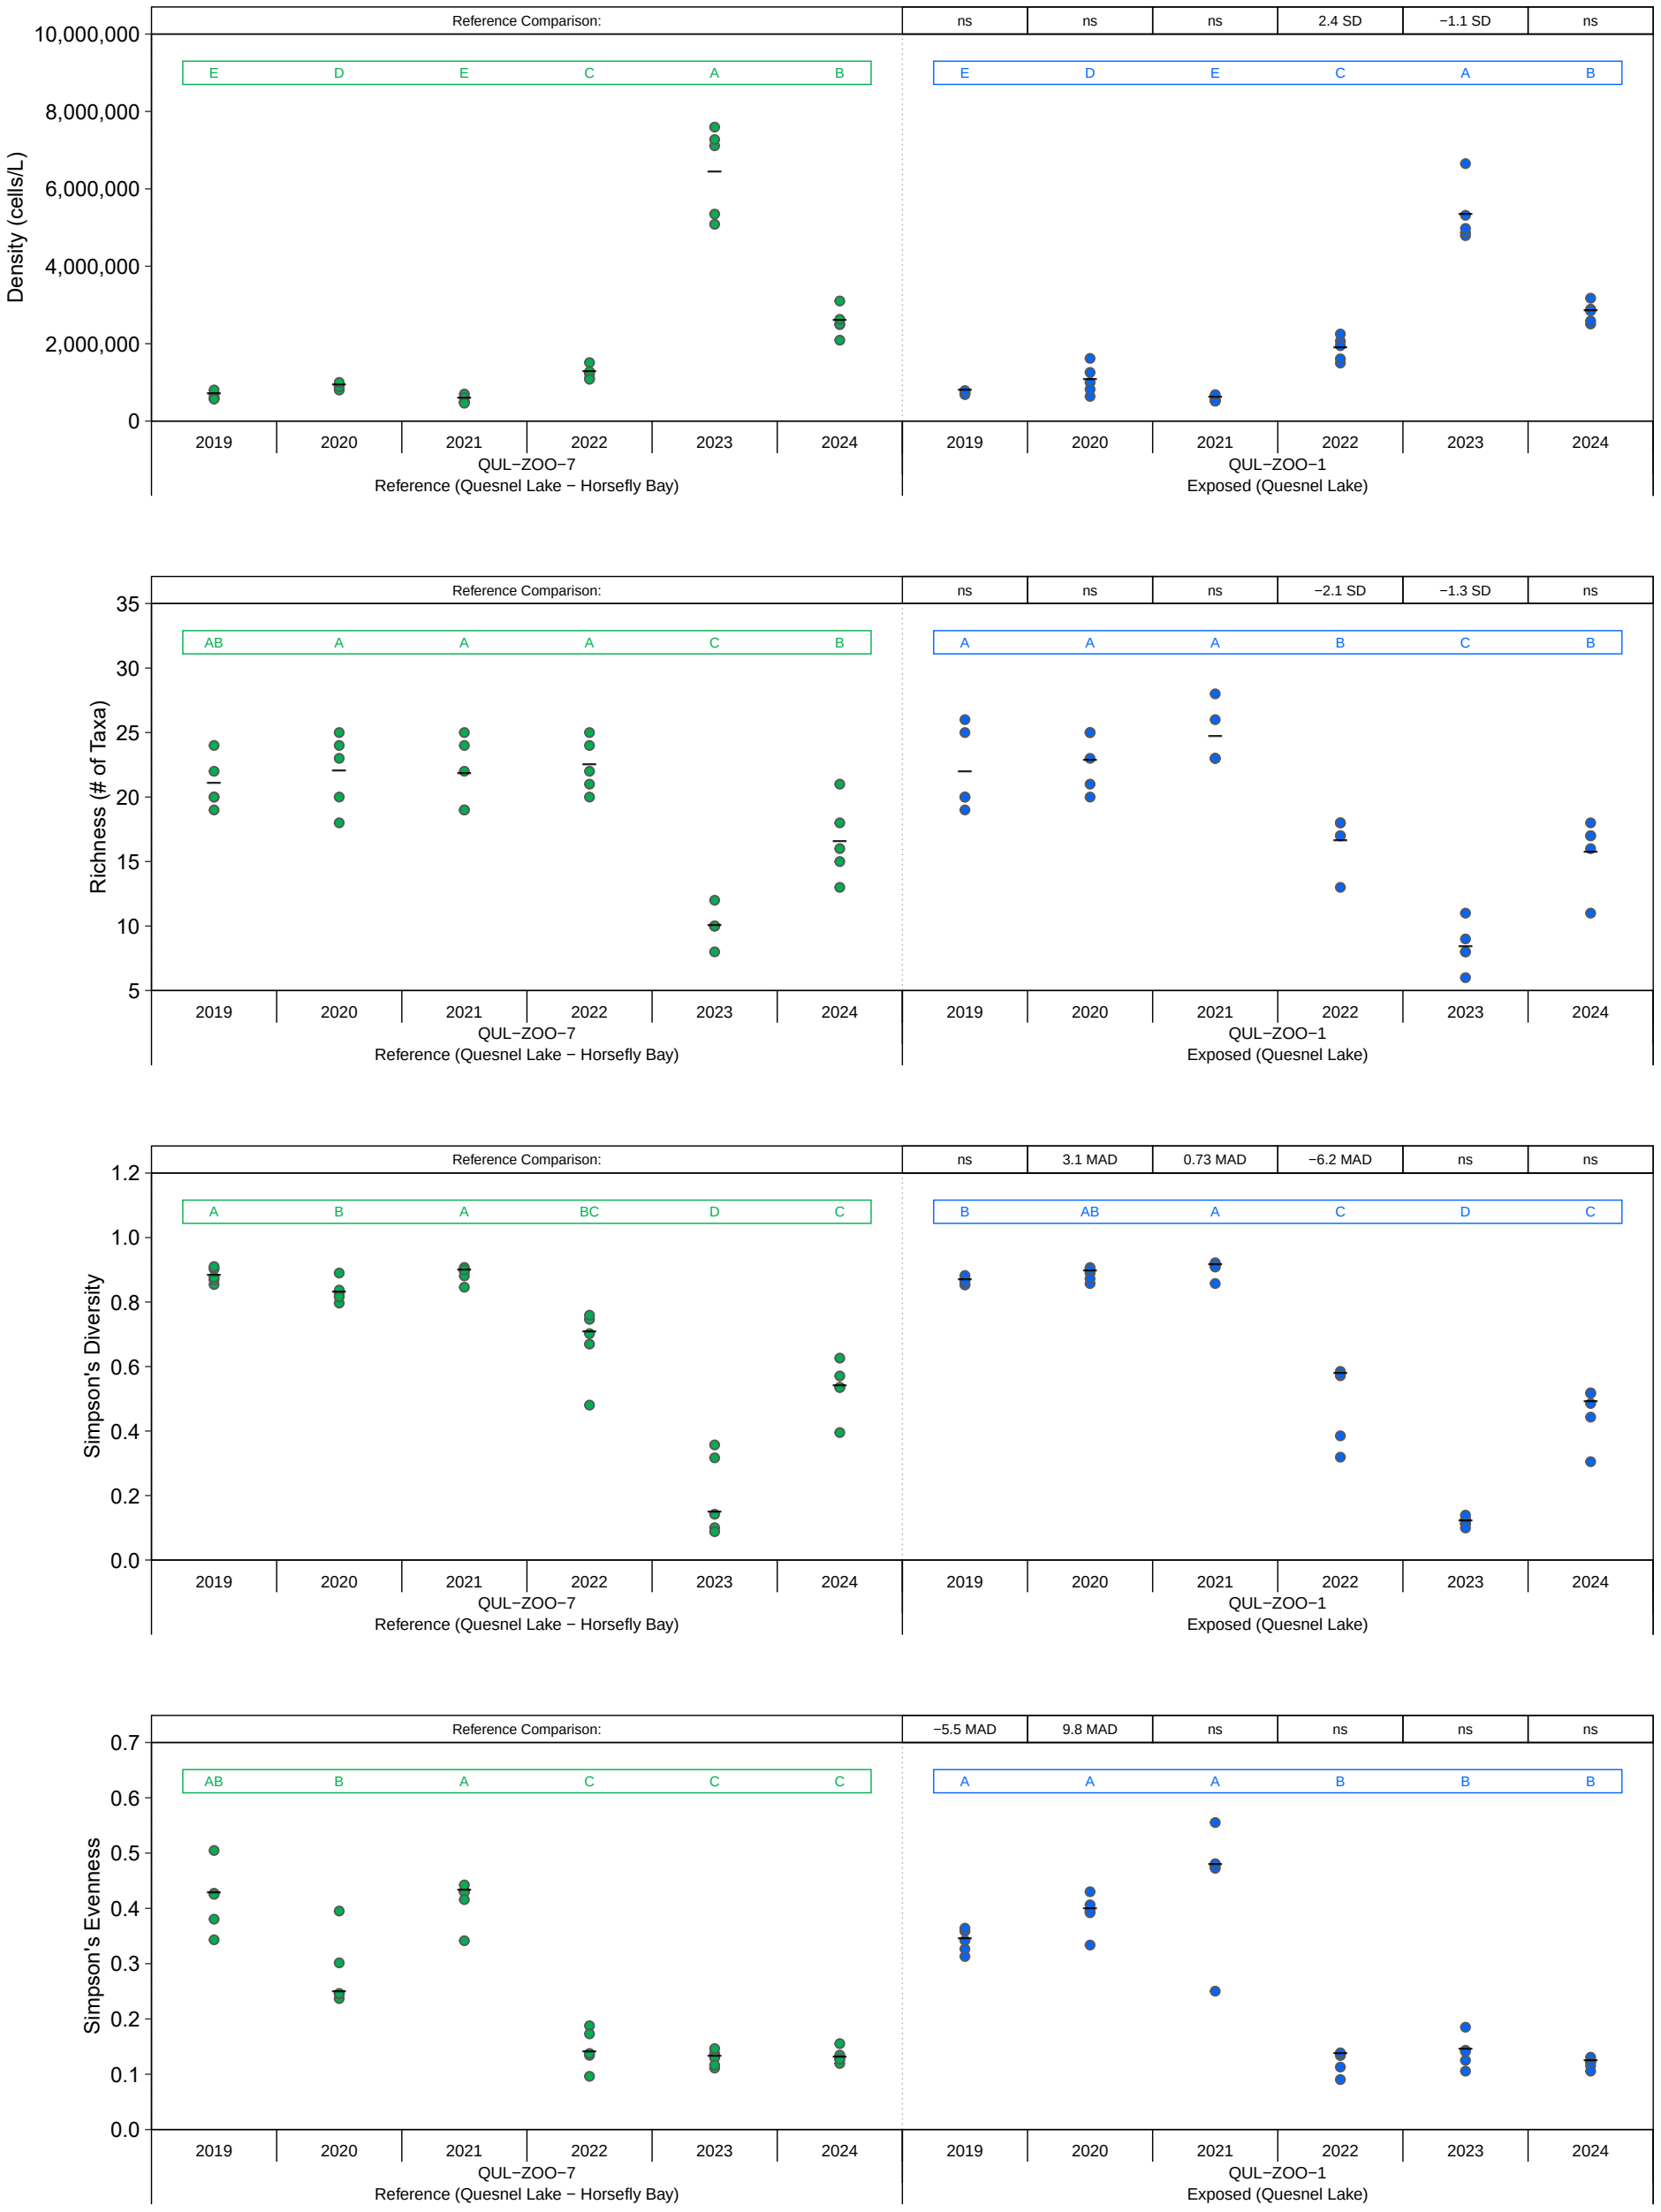

Figure 5.22: Phytoplankton Community Metrics for the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas in July, 2019 to 2024

Notes: Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value<0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'ns' indicates a non-significant contrast. For plots of phytoplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single phytoplankton samples collected in June and August 2024, see Appendix Table C.3.5.

Magnitude of Difference (MOD) < -2.

Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available. "ns" = non significant. µg/L = micrograms per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log $_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

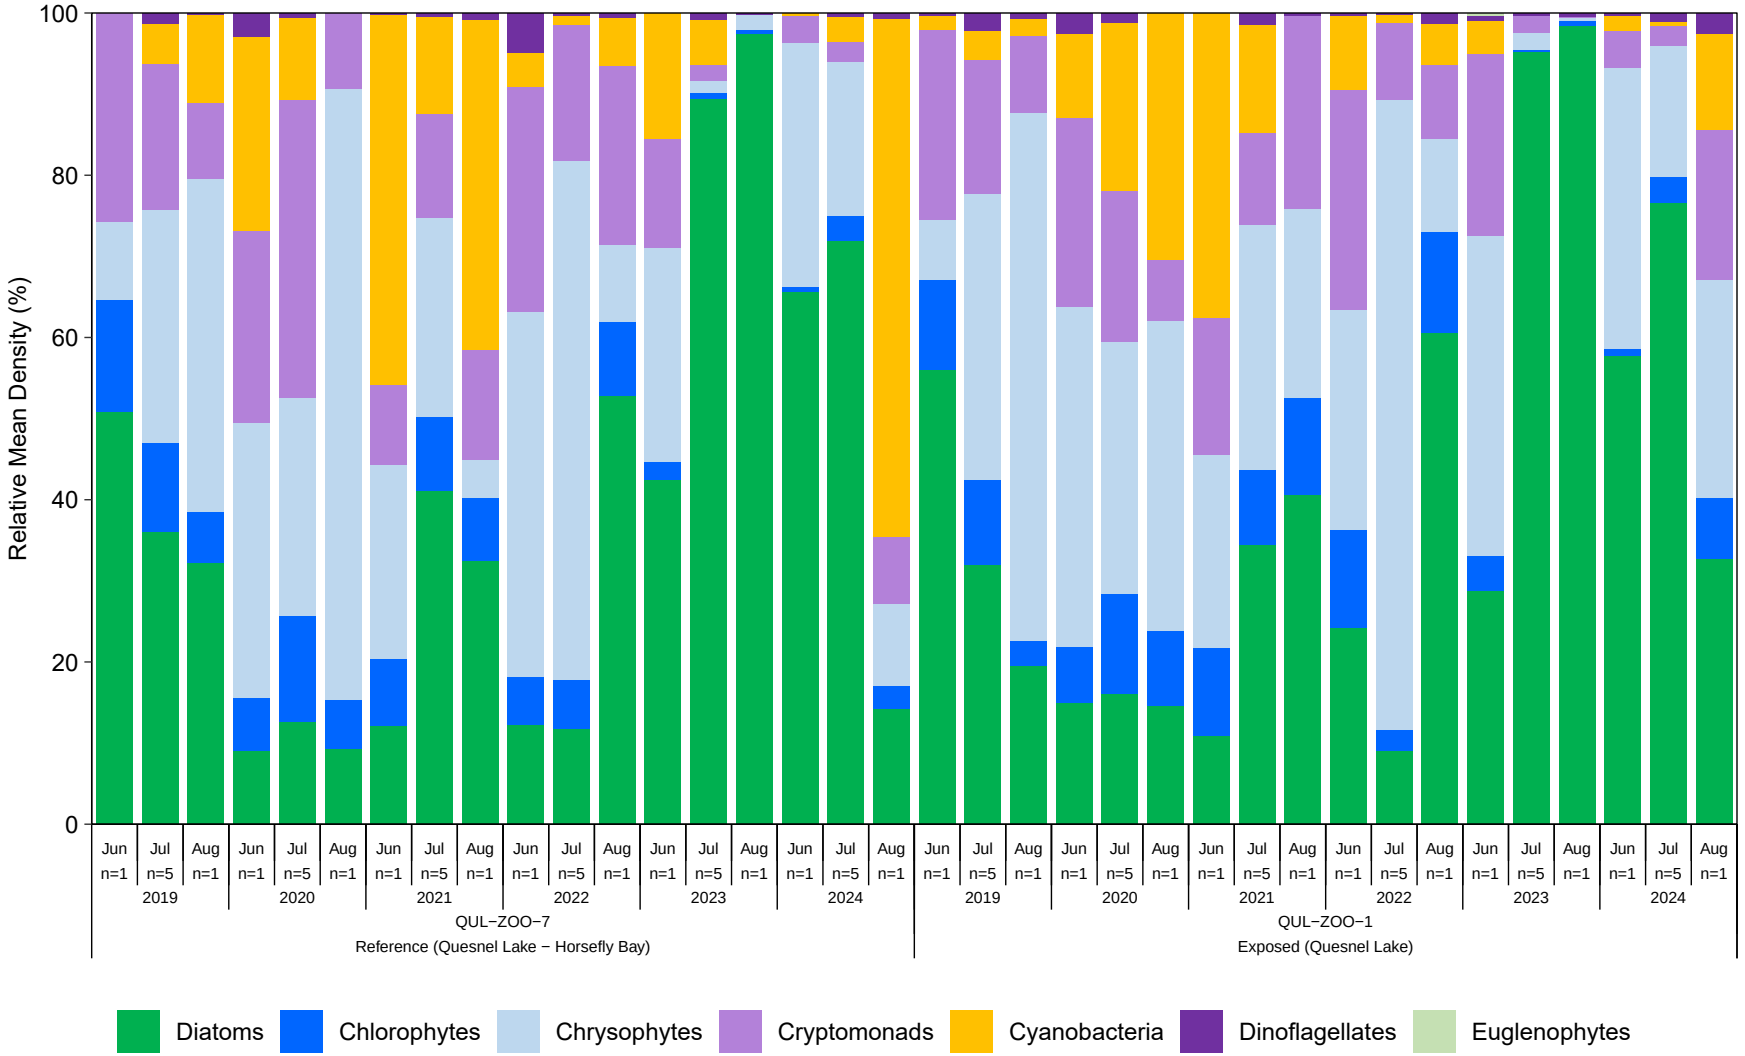

Figure 5.23: Relative Mean Densities of Major Phytoplankton Taxa for the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas, 2019 to 2024

(especially Cyanobacteria at QUL-ZOO-7; Figure 5.23; Appendix Figure E.2.9; Appendix Table C.3.5). Statistical analyses of replicated data (from July sampling events) indicated that the densities and relative densities (%) of taxa at QUL-ZOO-1 did not differ significantly from QUL-ZOO-7 in 2024, except for slightly fewer Chrysophytes at QUL-ZOO-1 relative to QUL-ZOO-7 (MODs -0.73 to -0.32 SD; Appendix Figure E.2.8, Appendix Table E.2.3).

Temporal analysis of community composition indicated there have consistently been no significant differences in the densities and relative densities (%) of Diatoms, Chlorophytes, and Cyanobacteria between the exposed and reference areas from 2019 to 2024, except for a significantly higher mean Diatom density at QUL-ZOO-1 in 2020 (Appendix Figure E.2.8, Appendix Table E.2.3). The density and relative density (%) of Chrysophytes at QUL-ZOO-1 compared to QUL-ZOO-7 were significantly higher than from 2019 to 2023, but significantly lower in 2024, although the difference was slight as outlined above. The temporal patterns in the density and relative density (%) of Chrysophytes have been similar between the exposed and reference areas (Appendix Figures E.2.8, Appendix Table E.2.3). The relative densities (%) of Cryptomonads at QUL-ZOO-1 were similar to those at QUL-ZOO-7 in most years, but significantly lower in 2022 and 2020 compared to QUL-ZOO-7 (Appendix Figure E.2.8, Appendix Tables C.3.5 and E.2.3). The remaining taxa (i.e., Dinoflagellates) represented approximately < 5% of the community at both the exposed and reference areas, therefore were not considered further. The relative similarities between the phytoplankton communities at the exposed and reference areas of Quesnel Lake from 2019 to 2024 can likely be attributed to similar water temperatures and nutrient concentrations at the surface and throughout the photic zones (Appendix Figures A.1.6 and C.1.5, Appendix Table C.1.4), given these factors are known to affect phytoplankton communities (Schnurr and Allen 2015).

Overall, the phytoplankton community at the exposed area (QUL-ZOO-1) from 2019 to 2024 was characterized by total density, taxon richness, and Simpson's Diversity that were similar to or significantly higher than at the reference area (QUL-ZOO-7), with few exceptions (density in 2023, richness in 2022 and 2023, and Simpson's Diversity in 2022). These exceptions were primarily related to significantly increased densities and dominance of Chrysophytes in 2022 and Diatoms in 2023, at both the exposed and reference areas. Simpson's Evenness of the phytoplankton community at the exposed area has consistently been similar to the reference area since 2021. The composition of the phytoplankton community at the exposed area has been consistently similar to the reference area from 2019 to 2024 in terms of the relative densities (%) of most taxa (i.e., Diatoms, Chlorophytes, and Cyanobacteria), and statistically significant differences between the areas for other taxa (i.e., Chrysophytes) have been small. The similarities between the phytoplankton communities at exposed and reference areas over time suggest an influence of local environmental factors on the phytoplankton community of Quesnel Lake.

5.2.3.1.2 Productivity

Qualitative evaluation of seasonal chlorophyll-a concentrations in 2024 indicated that productivity was highest in July and lower in June and August at both QUL-ZOO-1 and QUL-ZOO-7 (Appendix Figure E.2.7, Appendix Table C.3.5). Statistical analyses of replicated data (from July sampling events) indicated that mean chlorophyll-a concentrations at the exposed area (QUL-ZOO-1) in 2024 were significantly higher than those at the reference area (QUL-ZOO-7) but the difference was slight (0.45 MAD), suggesting that the difference was not ecologically meaningful.

Chlorophyll-a concentrations at QUL-ZOO-1 have been significantly different from QUL-ZOO-7 in each year from 2019 to 2024, but the difference has been slight (-0.37 to 0.82 MAD) in most years, except for 2022 (-2.9 MAD) and 2023 (2.6 MAD; Figure 5.24, Table 5.19). The temporal changes in mean chlorophyll-a concentrations have been the same at the exposed area compared to the reference area; concentrations were significantly higher in 2022 relative to previous years and then decreased significantly in 2023, such that concentrations in 2023 and 2024 were similar to 2021 (Figure 5.24, Table 5.19; Appendix Tables C.3.5 and C.3.6). The similar temporal changes of chlorophyll-a concentrations at both the exposed and reference areas is likely directly related to the similar nutrient concentrations, surface water temperatures, and water temperatures throughout the photic zones of both areas (Appendix Figures A.1.6 and C.1.5, Appendix Table C.1.4).

A lake's trophic status classification corresponds to its overall productivity in terms of phytoplankton biomass (chlorophyll-a) and nutrient concentration (Wetzel 2001). Based on the mean concentrations of chlorophyll-a at QUL-ZOO-1 (1.07 µg/L) and QUL-ZOO-7 (0.987 µg/L) in 2024, Quesnel Lake was classified as ultraoligotrophic (<1 µg/L; Vollenweider and Kerekes 1982; Figure 5.24; Appendix Figure E.2.7, Appendix Table C.3.6). The trophic status of Quesnel Lake in 2024 has therefore become similar to the ultraoligotrophic system that was observed in earlier years post-breach years (i.e., 2016 to 2018) compared to between 2019 and 2023, when chlorophyll-a concentrations resulted in the lake being classified as oligotrophic (<2.5 µg/L) or mesotrophic (2022; Vollenweider and Kerekes 1982; Table 5.19; Appendix Figure E.2.7, Appendix Table C.3.5).

5.2.3.2 Zooplankton

5.2.3.2.1 Community

Qualitative evaluation of seasonal data from 2024 indicated that zooplankton total density remained similar over the season at the exposed area (QUL-ZOO-1), whereas density in June was lower than July and August at the reference area (QUL-ZOO-7; Appendix Figure E.2.10,

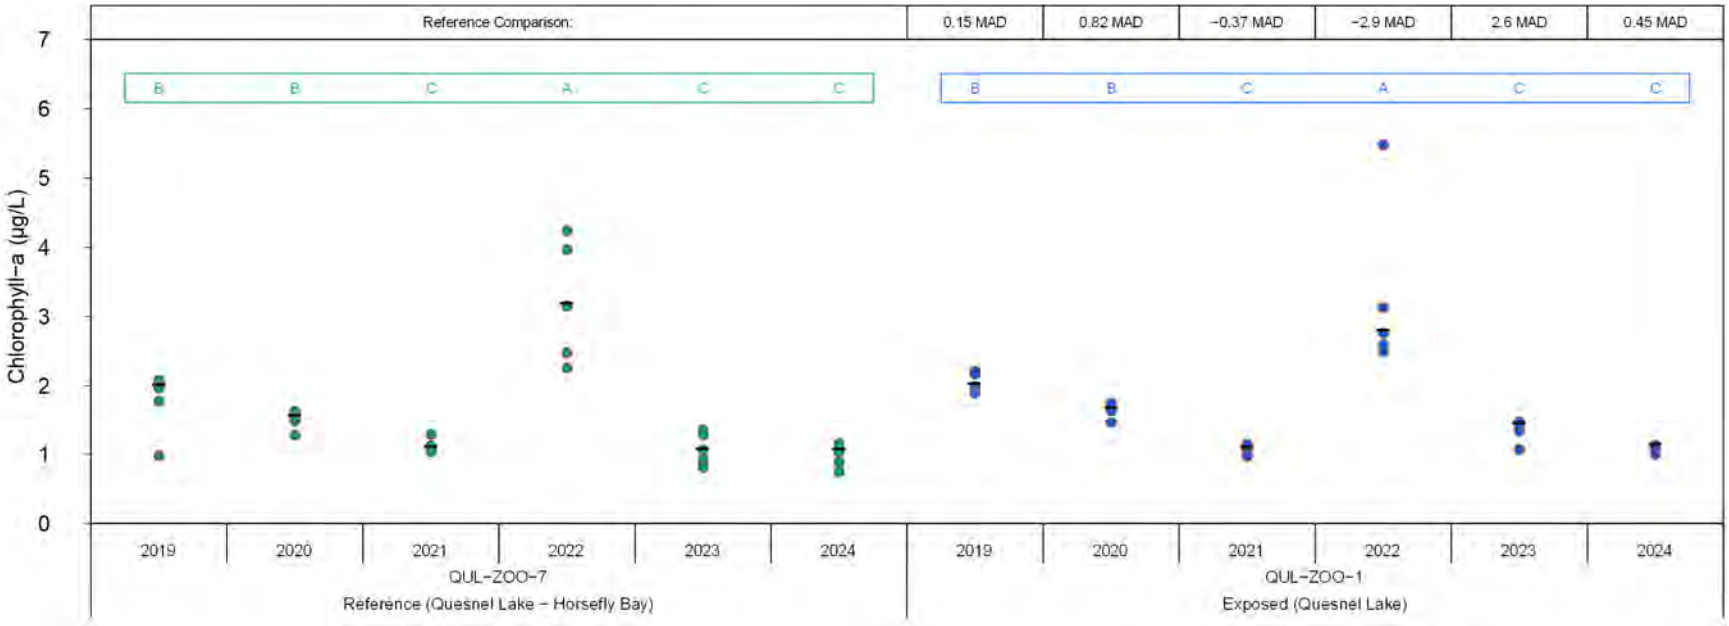

Figure 5.24: Phytoplankton Chlorophyll−a Concentrations for the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas in July, 2019 to 2024

Notes: µg/L = micrograms per litre. Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of median absolute deviations (MAD; if the data were rank −transformed prior to analysis) relative to reference. 'ns' indicates a non−significant contrast. For plots of phytoplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single phytoplankton samples collected in June and August 2024, see Appendix Table C.3.5.

Appendix Table C.3.7). Qualitative comparisons indicate that zooplankton taxon richness was highest in August for both areas of Quesnel Lake compared to in June and July (Appendix Figure E.2.10, Appendix Table C.3.7). Statistical analyses of replicated data (from July sampling events) indicated that zooplankton mean density, taxon richness, and Simpson's Diversity were all similar between QUL-ZOO-1 and QUL-ZOO-7 in July 2024 (Figure 5.25, Table 5.20; Appendix Tables C.3.7 and C.3.8). Simpson's Evenness in July 2024 was significantly higher at QUL-ZOO-1 compared to QUL-ZOO-7; however, the MOD was small (0.43 SD), suggesting that the difference was not ecologically meaningful (Figure 5.25, Table 5.20).

Temporal analyses indicated that total density and taxon richness have not differed significantly between the exposed and reference areas in all years (2019 to 2024; Figure 5.25, Table 5.20). Total density decreased significantly from 2023 to 2024 at both the exposed and reference areas (Figure 5.25, Table 5.20), which was driven by a significant decrease in densities of all taxonomic groups between 2023 and 2024 at both areas (Appendix Figure E.2.11, Appendix Table E.2.4). Simpson's Diversity at QUL-ZOO-1 was similar to or significantly higher than at QUL-ZOO-7 in all years, whereas Simpson's Evenness was consistently slightly (i.e., MOD = 0.33 to 1.3 SD) higher at QUL-ZOO-1 compared to QUL-ZOO-7 from 2020 to 2024 (Figure 5.25, Table 5.20).

Qualitative evaluation of seasonal data from 2024 indicated that the zooplankton community from June to August was dominated by Rotifera, and the composition remained relatively similar from June to August at both areas, with slight shifts in relative densities (%) of the main taxonomic groups (Figure 5.26; Appendix Table C.3.7). Statistical analyses of replicated data (from July sampling events) indicated that the exposed and reference zooplankton communities in 2024 differed only in terms of the density and relative density (%) of Copepod Nauplii and the relative density (%) of Rotifera, although the differences were small (-0.60 to 1.2 SD; Figure 5.26; Appendix Figures E.2.11 and E.2.12, Appendix Table E.2.4).

Temporal analyses indicated that the zooplankton community at both the exposed and reference areas have been largely similar from 2019 to 2024, and have been consistently dominated by Rotifera over the monitoring period (Figure 5.26; Appendix Figure E.2.11, Appendix Table E.2.4). Specifically, the relative densities (%) of Calanoida, Cladocera, and Cyclopoida have been similar between the exposed and reference areas from 2020 to 2024. The relative densities (%) of Copepod Nauplii were consistently higher, and Rotifera were consistently lower, at QUL-ZOO-1 compared to QUL-ZOO-7 from 2019 to 2024, however the differences were small (-0.67 to 1.6 SD from 2020 to 2024; Appendix Figure E.2.11, Appendix Table E.2.4). This similarity in temporal trends in community composition at the exposed and reference areas indicates these changes were likely driven by natural variability in environmental parameters that affected the two

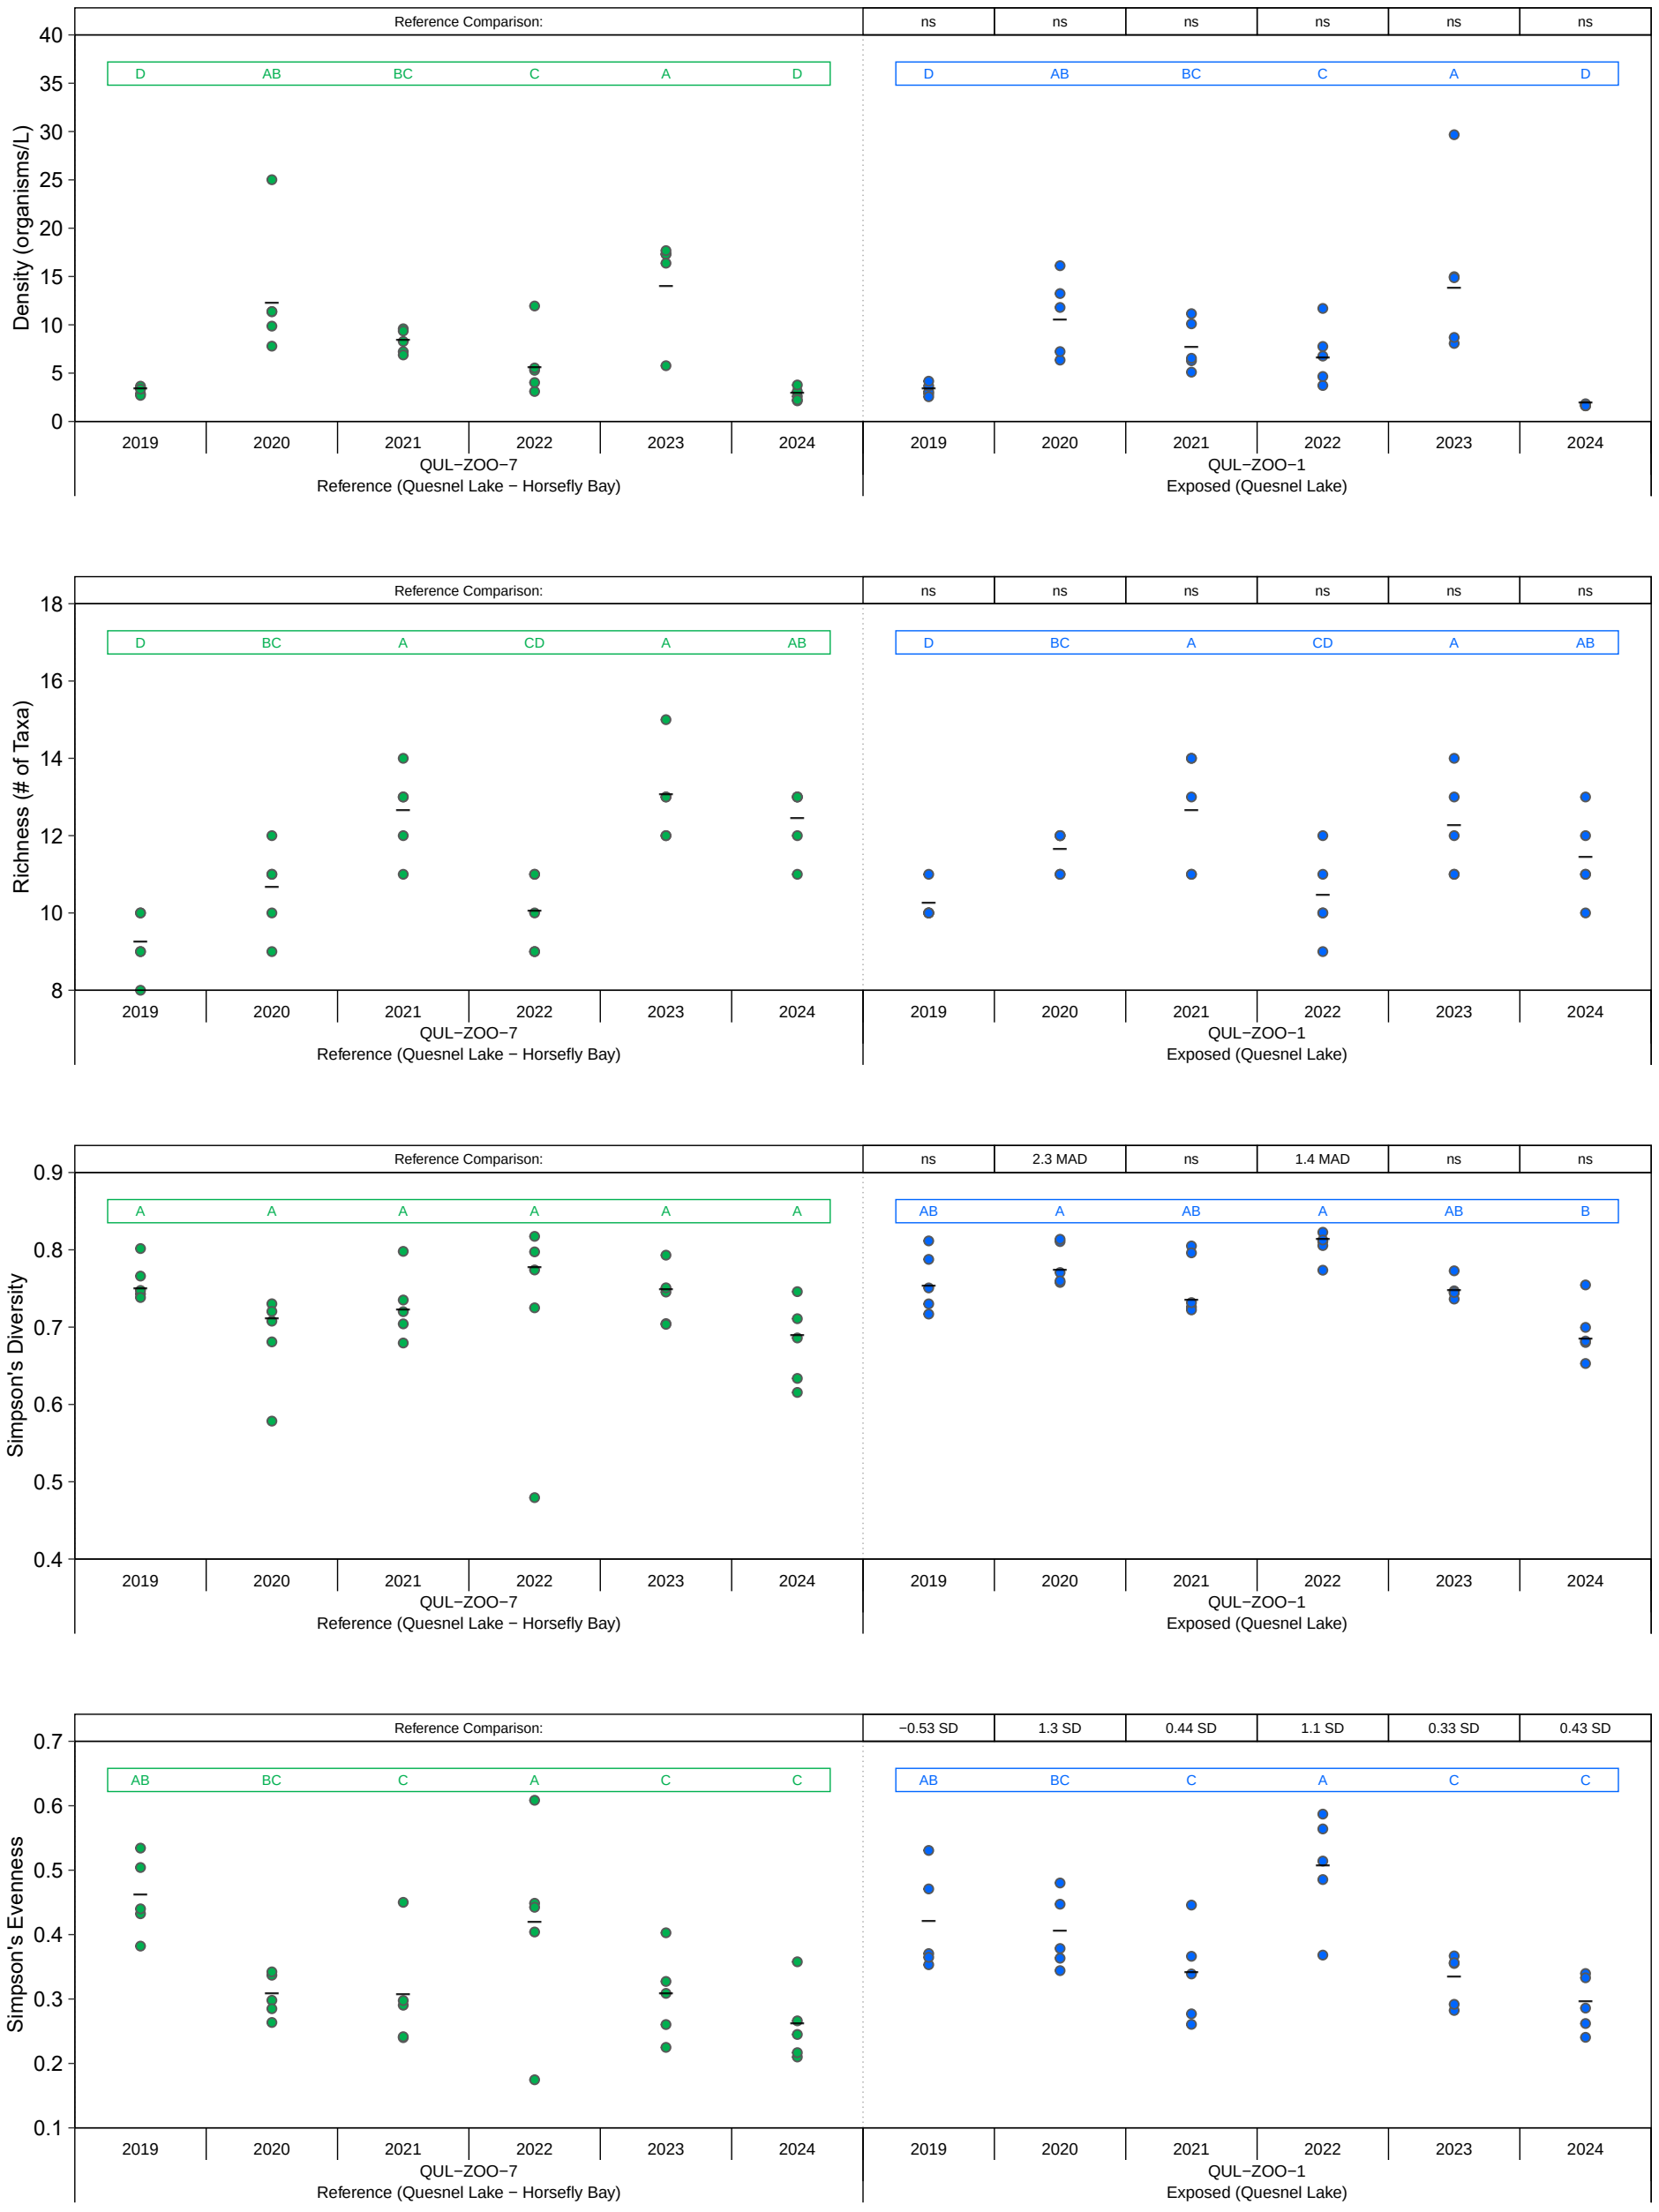

Figure 5.25: Zooplankton Community Metrics for the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas in July, 2019 to 2024

Notes: Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value<0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'ns' indicates a non-significant contrast. For plots of zooplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single zooplankton samples collected in June and August 2024, see Appendix Table C.3.7.

Magnitude of Difference (MOD) < -2.

Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available. "ns" = non significant. mg/L = milligrams per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log $_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Remediated Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

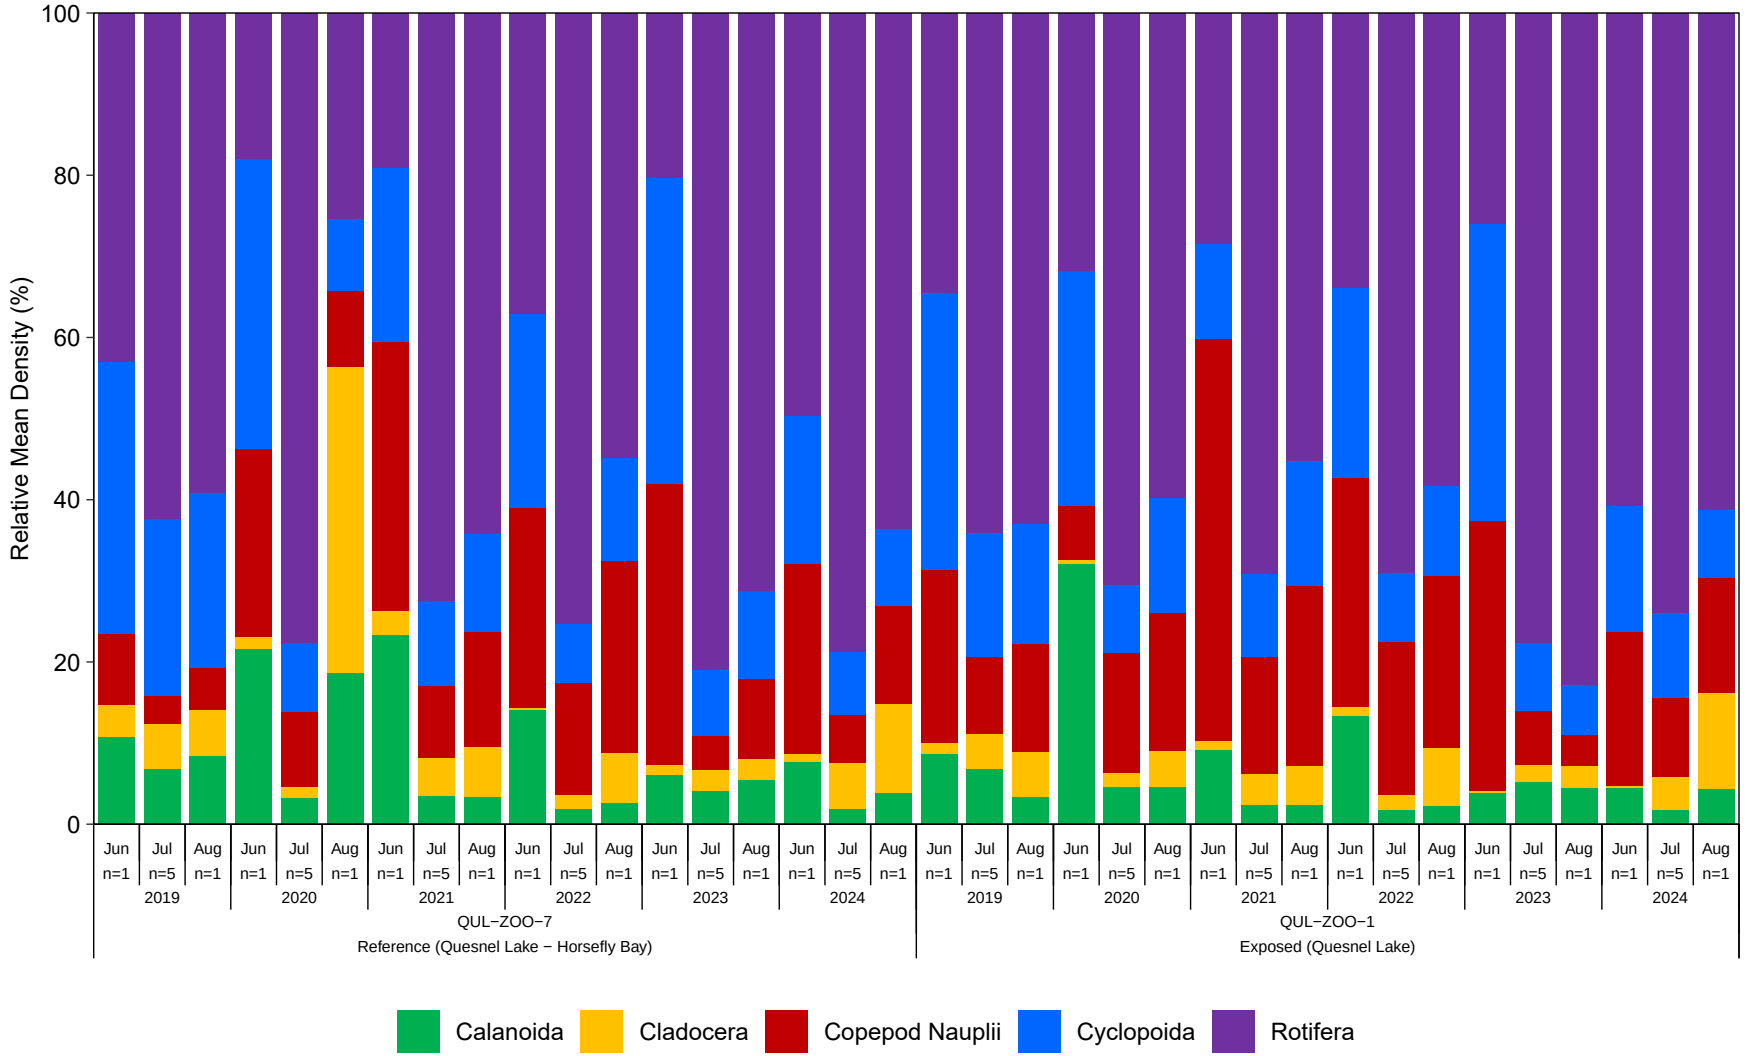

Figure 5.26: Relative Mean Densities of Major Zooplankton Taxa for the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas, 2019 to 2024

areas similarly (e.g., water temperature, nutrient availability, and phytoplankton community; Appendix Figures A.1.6 and C.1.5, Appendix Table C.1.4).

Overall, the zooplankton community at the exposed area of Quesnel Lake from 2019 to 2024 has been characterized by density and taxon richness that were similar to the reference area, and Simpson's Diversity that was similar to or significantly higher than at the reference area. Simpson's Evenness of the exposed zooplankton community has been consistently higher than at the reference area since 2021, but the difference has been slight. Community composition at the exposed area has largely been similar to the reference area from 2020 to 2024, except for consistent but small differences in the relative densities of Copepod Nauplii and Rotifera (higher and lower than at the reference area, respectively). Although there was some temporal variability in zooplankton community metrics, the changes (i.e., direction and relative magnitude) were generally similar between the exposed and reference areas. The similarity between the exposed and reference areas for most endpoints over the monitoring period suggests that changes in the zooplankton community were largely driven by environmental conditions common to both areas (e.g., water temperatures and nutrient concentrations) over time.

5.2.3.2.2 Productivity

Qualitative evaluation of seasonal data from 2024 indicated that zooplankton biomass (dw) at both QUL-ZOO-1 and QUL-ZOO-7 was comparable among June, July, and August (Appendix Figure E.2.10, Appendix Table C.3.7).

Statistical analyses of replicated data (from July sampling events) indicated that mean zooplankton biomass (dw) was consistently similar between QUL-ZOO-1 and QUL-ZOO-7 from July 2019 to 2024 (Figure 5.27, Table 5.20; Appendix Tables C.3.7 and C.3.8). The temporal changes in zooplankton biomass (dw) were similar at both areas throughout the monitoring period (i.e., significantly higher in 2020 and 2023 relative to 2019, but significantly lower in 2024 relative to all prior years) indicating these temporal changes were likely driven by natural variability in environmental parameters that similarly affected the two areas (e.g., water temperature, nutrient availability, and phytoplankton community; Appendix Figures A.1.6 and C.1.5, Appendix Table C.1.4). The consistent similarity in zooplankton productivity between exposed and reference areas throughout the monitoring period suggests a lack of mine-related influence on zooplankton productivity in Quesnel Lake

5.2.4 Zooplankton Tissue Quality

Zooplankton tissue quality monitoring was completed annually between 2022 and 2024 with three sampling events per year (June, July, and August) in exposed (QUL-ZOO-1) and reference

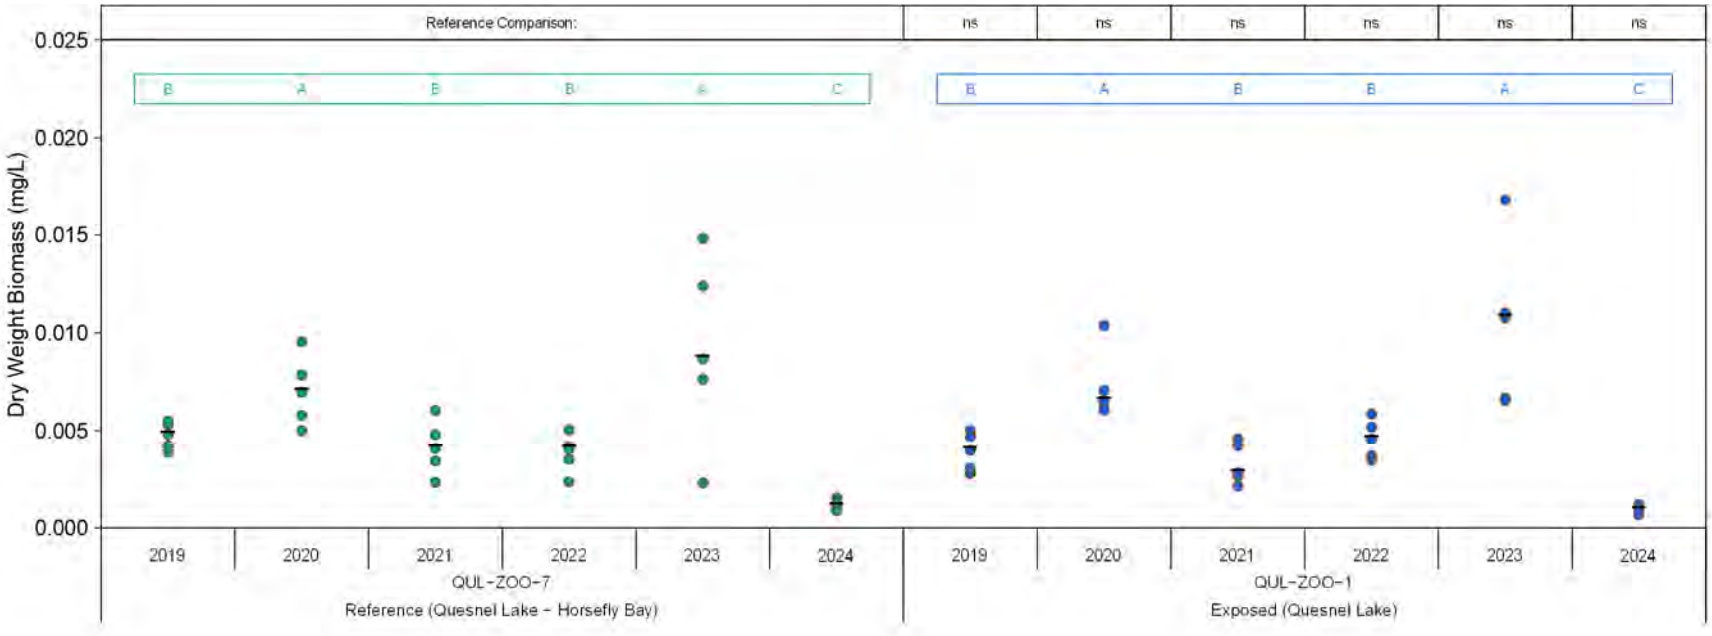

Figure 5.27: Zooplankton Biomass (Total Dry Weight) for the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas in July, 2019 to 2024

Notes: mg/L = milligrams per litre. Green represents reference data and blue represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value<0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of median absolute deviations (MAD; if the data were rank −transformed prior to analysis) relative to reference. 'ns' indicates a non−significant contrast. For plots of zooplankton results prior to 2019, see Minnow (2019a, 2020a, 2021a). For results of single zooplankton samples collected in June and August 2024, see Appendix Table C.3.7.

(QUL-ZOO-7) areas of Quesnel Lake (Figure 3.3, Table 3.6). Replicated results from July (n=5) were statistically contrasted (see Section 3.4.3).

A review of the 2024 zooplankton tissue quality results (Appendix B) indicated that these data can be used with an appropriate level of confidence for interpretation, although some natural heterogeneity in analyte results were considered during data interpretation (see Section 5.1.4 for details). A review of 2024 supporting water data quality indicated that these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

Data interpretation was focused on primary and secondary analytes (Table 2.4) with a significantly positive relative (exposed-reference) difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis *Area×Year* interaction was significant) or in all monitoring years (if the *Area×Year* interaction was not significant[56]).

Of the primary and secondary analytes, copper, molybdenum, tin, and titanium exhibited a significant *Area×Year* interaction with exposed concentrations that were significantly higher than reference in 2024 (MOD = 280%, 267%, 495%, and 283%, respectively); a difference that has not been previously observed (i.e., 2019 to 2023; Appendix Table E.3.3). The significant *Area×Year* interaction indicated that the relative (exposed-reference) differences in concentrations of these four analytes has differed significantly among years (Figure 5.28, Table 5.21; Appendix Table E.3.3). Specifically, the relative differences of copper, tin, and titanium concentrations were significantly higher in 2024 than in all prior years (i.e., 2019 to 2023), and for molybdenum in 2024 were similar to 2022 but significantly higher than all remaining prior years (Figure 5.28, Table 5.21; Appendix Table E.3.3). Despite the significant temporal increase in 2024, relative to reference, concentrations of copper, molybdenum, tin, and titanium in exposed zooplankton tissues in 2024 remained within the range of previous post-breach years (i.e., 2014 and 2023) although the variability among samples was often greater in 2024 than in prior years (Appendix Figure C.4.2). The temporal increase in the relative differences of concentrations of these four analytes in 2024 was driven, at least in part, by a decrease in concentrations in reference tissues (Figure 5.28). Continued monitoring will help to determine whether the observed increase in copper, molybdenum, tin, and titanium concentrations of exposed zooplankton tissues in 2024, relative to reference, is part of a long-term trend or a single anomalous year.

The remaining primary and secondary analytes had concentrations in exposed zooplankton tissues that were similar to reference in all monitoring years (i.e., the Area×Year interaction was not significant; Appendix Table E.3.3).

[56] If no significant change was detected in the relative (exposed-reference) difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from 2019 to 2024 were combined for the analyses.

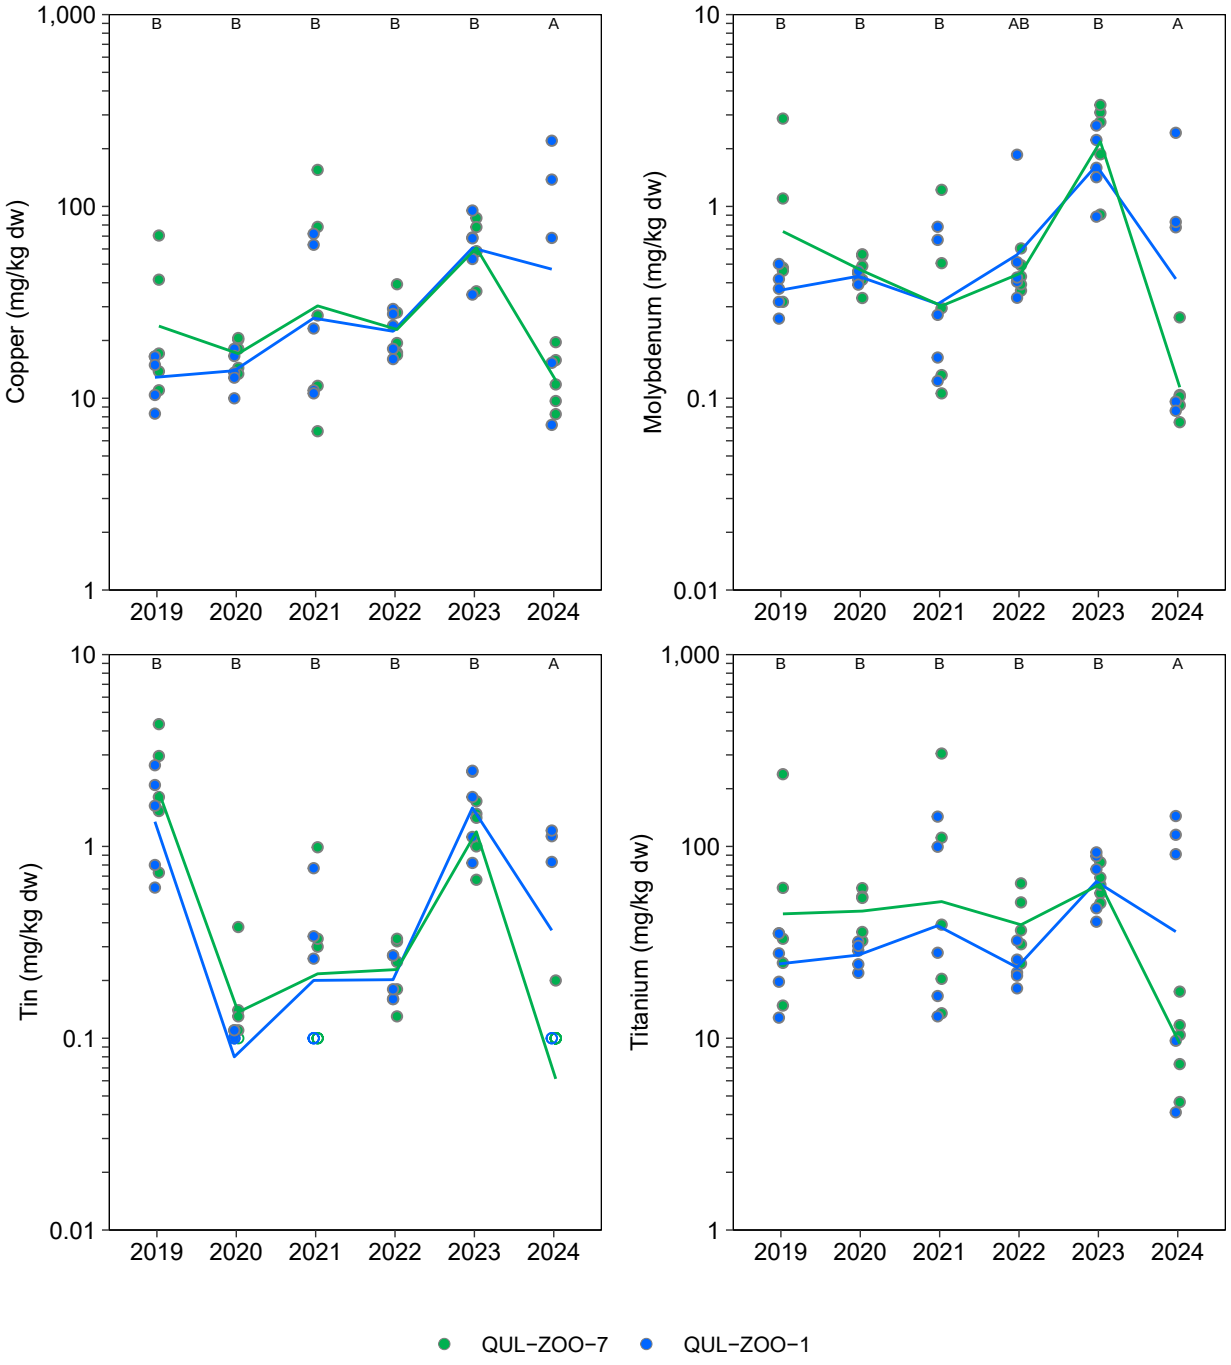

Figure 5.28: Zooplankton Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas in July, 2019 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. Green represents reference areas and blue represents exposed areas. Plots are only included for primary or secondary analytes with a significant and positive exposed − reference difference in 2024 or in all monitoring years. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed : Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed : Reference). Only years with samples from both reference and exposed areas are plotted.

Table 5.21: Summary of Statistical Contrasts for Zooplankton Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Relative Difference for Quesnel Lake (QUL-ZOO-1; Exposed and QUL-ZOO-7; Reference) Monitoring Areas in July, 2019 to 2024

Analyte		Magnitude of Difference in (Exposed – Reference) Relative to Baseline Period (%)[a]						Magnitude of Difference for Exposed Mean Relative to Reference (%)[b]					
		Post-Breach Period						Post-Breach Period					
		2019	2020	2021	2022	2023	2024	2019	2020	2021	2022	2023	2024
Primary Analytes	Copper	baseline	ns	ns	ns	ns	603	ns	ns	ns	ns	ns	280
Secondary Analytes	Molybdenum	baseline	ns	ns	ns	ns	646	ns	ns	ns	ns	ns	267
	Tin	baseline	ns	ns	ns	ns	748	ns	ns	ns	ns	ns	495
	Titanium	baseline	ns	ns	ns	ns	599	ns	ns	ns	ns	ns	283

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: ns = not significant. Baseline = first year of data included in analysis. Data were analysed in units of mg/kg dry weight. Only years with samples from both reference and exposed were included in the analysis.

[a] Magnitude of difference (MOD) calculated on backtransformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted})\times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[b] Magnitude of difference (MOD) calculated on backtransformed least-squares means as (Exp-Ref)/Ref x 100%.

The increased relative differences of copper, tin, and titanium concentrations in zooplankton tissues in 2024 were not mirrored in surface water quality results for Quesnel Lake, with molybdenum being an exception. Post-breach (2015 to 2024) surface water quality in exposed areas of Quesnel Lake has showed temporal stability for most analytes. The exceptions are total and dissolved molybdenum, dissolved sodium, and total and dissolved selenium, which were the only primary or secondary analytes that showed significant increasing trends from 2015 to 2024 in surface water from QUL-18 (near QUL-ZOO-1) and/or QUL-2a exposed water quality monitoring stations (Figure 3.3; Appendix Table E.3.4). Significant increasing trends in total and dissolved selenium, as well as dissolved molybdenum were identified at both exposed stations (QUL-18 and QUL-2a), whereas an increasing trend was identified at only one of the two stations for the remaining analytes (QUL-18 [total molybdenum] or QUL-2a [dissolved sodium]; Appendix Figures C.1.6 to C.1.8, Appendix Table E.3.4). In 2024, the GEF for acute dissolved copper showed a significant decreasing trend at the exposed station QUL-2a (Appendix Table E.3.4).

There is no existing BCWQG for dissolved aqueous selenium (BCMOWLRS 2025). However, total selenium concentrations in routine water quality samples from QUL-18 and QUL-2a remained approximately 10-times lower than the BCWQG for total selenium (2 µg/L; BCMOWLRS 2025) from 2015 to 2024 (Appendix Figure C.1.8) as did total selenium concentrations in spot water quality samples from QUL-ZOO-1 (exposed) and QUL-ZOO-7 (reference) in 2024 (Appendix Table C.1.4). In addition, zooplankton selenium concentrations did not differ significantly between the exposed and reference areas from 2019 to 2024 (Appendix Table E.3.3). Zooplankton selenium concentrations at both QUL-ZOO-1 (exposed) and QUL-ZOO-7 (reference) in 2024 were below the BC interim guideline for aquatic life (4 mg/kg dw; BCMOE 2014), except for one sample at QUL-ZOO-1 (4.35 mg/kg dw; Appendix Table C.4.2). Mean zooplankton tissue selenium concentrations at the exposed area were also below the guideline in 2018 to 2023, while results from 2015 to 2017 exceeded the guidelines (Appendix Figure C.4.2). Concentrations of selenium in zooplankton tissue at the reference area exceeded the BC interim tissue guideline in 2015 to 2017, 2019, 2021, and 2023 indicating that selenium concentrations in zooplankton tissue were naturally higher than the guideline in some areas of Quesnel Lake (Appendix Figure C.4.2, Appendix Table C.4.2).

Of the remaining water quality analytes identified as increasing since 2015 at the exposed area(s), BCWQGs exist only for total molybdenum, and not for dissolved molybdenum or sodium (BCMOWLRS 2024, 2025; Appendix Figure C.1.6). Concentrations of total molybdenum from 2015 to 2024 remained approximately 20,000-times lower than the BCWQG (Appendix Figure C.1.8, Appendix Table C.1.4), indicating no risk aquatic life. Although a significant temporal increase in the molybdenum concentrations of exposed zooplankton tissues

was observed in 2024, relative to reference, this was driven (at least in part) by a decrease in reference results (Figure 5.28). Combined, these results indicate little to no evidence that the increase in molybdenum concentrations in water and zooplankton tissue might present a risk to aquatic life. A measurable increase of sodium concentrations in zooplankton tissues was not observed from 2019 to 2024, indicating no influence of the increased aqueous sodium concentrations on zooplankton tissue quality (Appendix Table E.3.3).

Given the observed significant temporal increase in the copper concentrations of exposed zooplankton tissue in 2024, relative to reference, the potential impacts of copper concentrations on aquatic life were evaluated by comparing dissolved copper concentrations to the relevant BLM-based BCWQG to calculate GEFs (refer to Section 3.8.3.3 for details). The dissolved copper GEFs in surface water did not change significantly from 2015 to 2024 at QUL-120a (reference) or QUL-18 (exposed) and decreased significantly at QUL-2a (exposed; Appendix Figure C.1.7, Appendix Table E.3.4). The GEFs observed in 2024 for Quesnel Lake exposed areas (QUL-18 and QUL-2a) were typically within the range of previous years and results remained within the range of copper GEFs reported for the reference (QUL-120a), which suggests little risk to aquatic life in the near term (Appendix Figure C.1.7).

5.2.5 Benthic Invertebrate Community

Benthic invertebrate community monitoring in 2024 was completed at two deep exposed areas (QUL-PNF and QUL-PFF1) with an unimpacted deep area (QUL-PREF1) serving as a reference (Figure 3.2, Table 3.7). Prior benthic invertebrate community monitoring within the 2022 to 2024 period included annual monitoring of the deep near-field (QUL-PNF) area (Figure 3.2, Table 3.7). Comparisons to reference were only possible in years when the deep reference area (QUL-PREF1) was sampled (Table 3.7).

A review of the 2024 benthic invertebrate community results indicated these data were of acceptable quality and can be used with a high degree of confidence in data interpretation (see Section 5.1.5 for details).

The mean benthic invertebrate densities at the near-field (QUL-PNF) and far-field (QUL-PFF1) areas in 2024 were significantly lower than reference (QUL-PREF1) but did not differ significantly from one another. Taxonomic richness, Simpson's Evenness, and Simpson's Diversity at QUL-PNF and QUL-PFF1 in 2024 did not differ significantly from the reference area (QUL-PREF1), nor from one another (Figure 5.29, Table 5.22; Appendix Tables C.5.4 and C.5.5).

Densities at both QUL-PNF and QUL-PFF1 have remained significantly lower than the densities at the reference area (QUL-PREF1) since 2014 (in years when comparison to reference was possible), though the magnitude of difference has decreased at both exposed areas

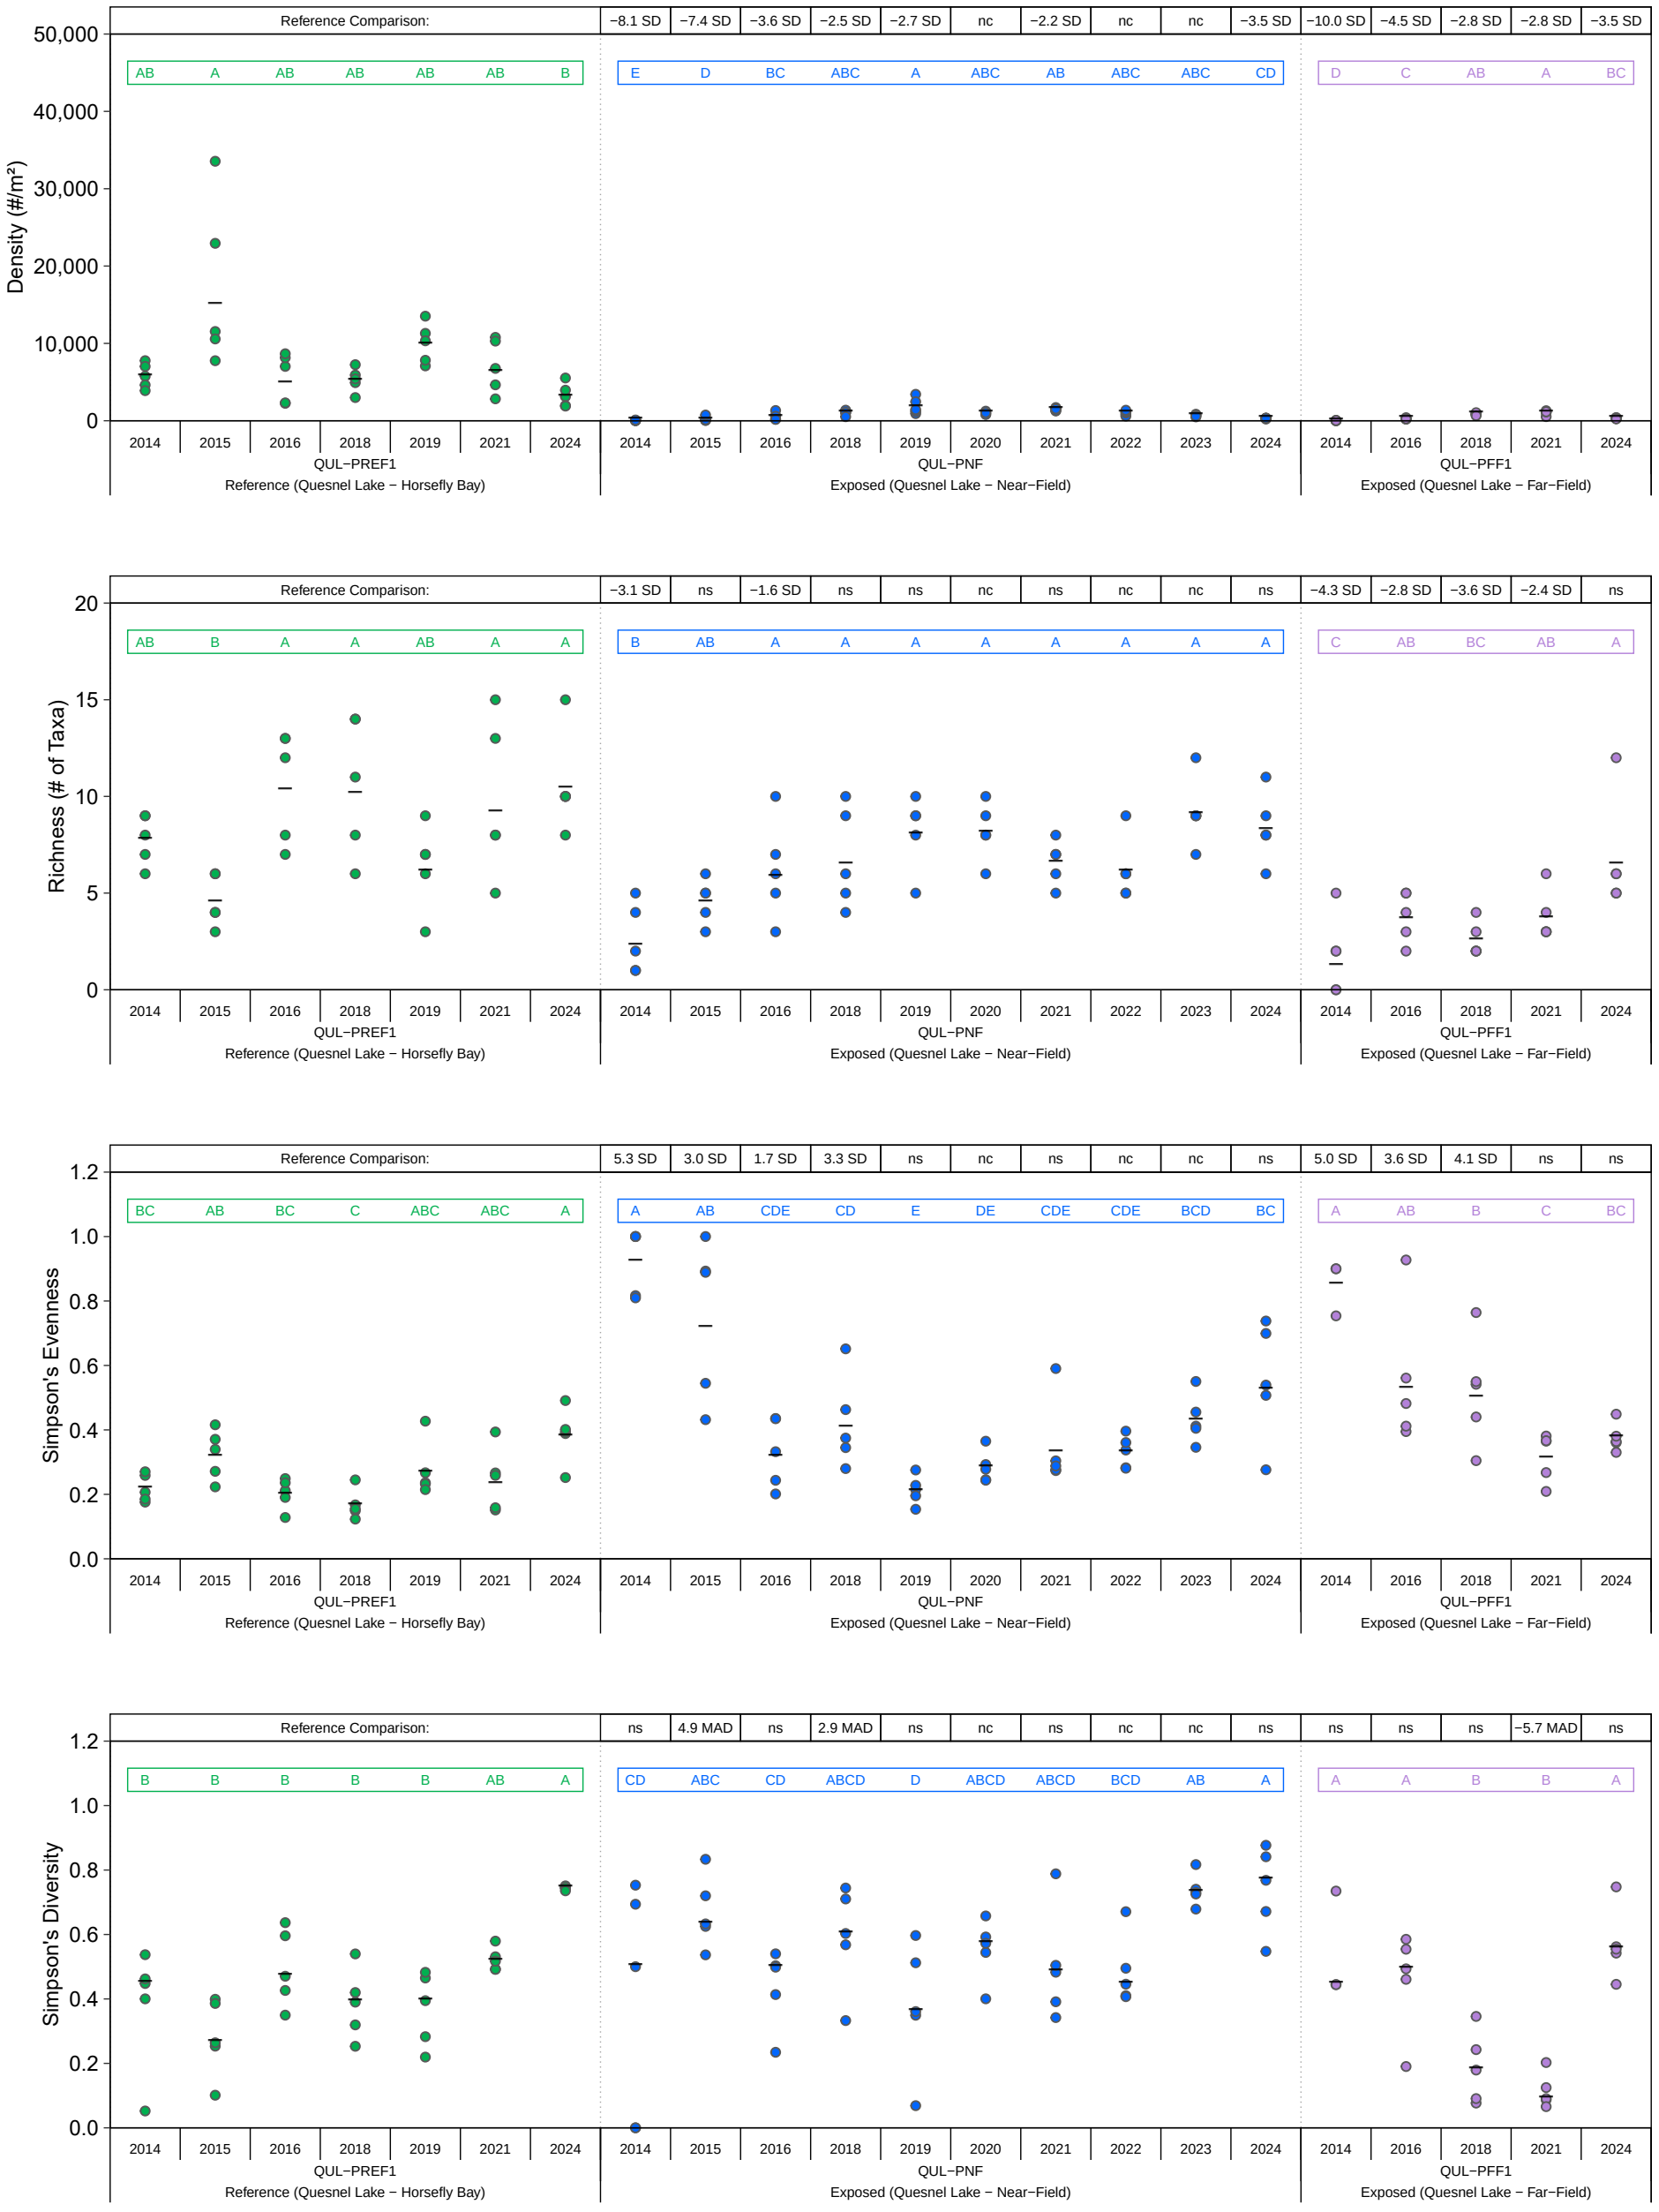

Figure 5.29: Benthic Invertebrate Community Metrics for the Quesnel Lake (QUL−PNF and QUL−PFF1; Exposed and QUL−PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: Green represents reference data and blue or purple represents exposed data. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area.
A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast.

Area x Year or Area P-value < 0.1.
Magnitude of Difference (MOD) < -2
Magnitude of Difference (MOD) > 2

Notes: "-" = no data available. "nc" = no comparison. "ns" = no significance. ANOVA = analysis of variance. SD = standard deviation.

[a] MCT = Measure of Central Tendency, which is the mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way Analysis of Variance (ANOVA) as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled Median Absolute Deviation.

over time (Figure 5.29, Table 5.22). Additionally, mean densities at both exposed areas have been significantly higher in all years compared to 2014 (immediately post-breach) and have been temporally stable (i.e., have not changed significantly) since 2022 at QUL-PNF. The density at QUL-PNF in 2024 was similar to most prior years since 2015 but was significantly lower than in 2019 and 2021 (Figure 5.29, Table 5.22). A significant decrease in density was observed at QUL-PFF1 between 2021 and 2024, to a mean density that was similar to 2016 and 2018. This is consistent with slight declines in density at both at the near-field area (QUL-PNF) and the reference area (QUL-PREF1) since 2021, though this decline was only significant at QUL-PNF.

Taxonomic richness at the near-field area (QUL-PNF) has been stable since 2015 and has not differed significantly from reference since 2018, suggesting stabilization of richness at this area. At the far-field area (QUL-PFF1), richness increased significantly between 2014 and 2016, and again between 2018 and 2024 to a richness that was similar to reference conditions in 2024 (Figure 5.29, Table 5.22; Appendix Tables C.5.4 and C.5.5). Simpson's Evenness at the near field area (QUL-PNF) has been stable since 2021 and similar to the reference area since 2019 (in years where comparison was possible). At the far-field area, Simpson's Evenness has been stable since 2016, and similar to the reference area since 2021 (Figure 5.29, Table 5.22). Simpson's Diversity at the near-field area (QUL-PNF) has been similar to or significantly higher than the reference (QUL-PREF1) in all years (i.e., since 2014) while at the far-field area Diversity was significantly different (lower) than reference only in 2021 due to particularly low Simpson's Diversity that year. A significant increase in Simpson's Diversity was observed at QUL-PFF1 between 2021 and 2024, which returned Simpson's Diversity to values that were similar to those in 2014 and 2016 (Figure 5.29, Table 5.22). At the near-field area, Simpson's Diversity has been temporally stable from 2021 to 2024, with Diversity observed in 2024 similar to most prior years except 2014, 2016, 2019, and 2022 (Figure 5.29, Table 5.22).

The benthic invertebrate community at both the near-field (QUL-PNF) and far-field (QUL-PFF1) areas in 2024 was dominated by Chironomidae (88.6% and 88.7% mean relative density, respectively), which has been observed at both these area since 2014 (Figure 5.30; Appendix Figures E.4.6 and E.4.7, Appendix Tables C.5.4 and E.4.4). The relative density (%) of Chironomidae at both QUL-PNF and QUL-PFF1 in 2024 was significantly higher than at the reference area (QUL-PREF1), which is consistent with 2015 and 2016 results at QUL-PNF, and with the results in most prior years at QUL-PFF1 (i.e., 2016 to 2021; Appendix Figure E.4.6, Appendix Table E.4.4). The benthic invertebrate community at QUL-PNF and QUL-PFF1 in 2024 also differed from the reference area in terms of significantly lower Oligochaeta (%), which is consistent with all prior years, but did not differ from reference in the relative densities of any other taxa (i.e., EPT and Arachnida; Appendix Figure E.4.6, Appendix Table E.4.4).

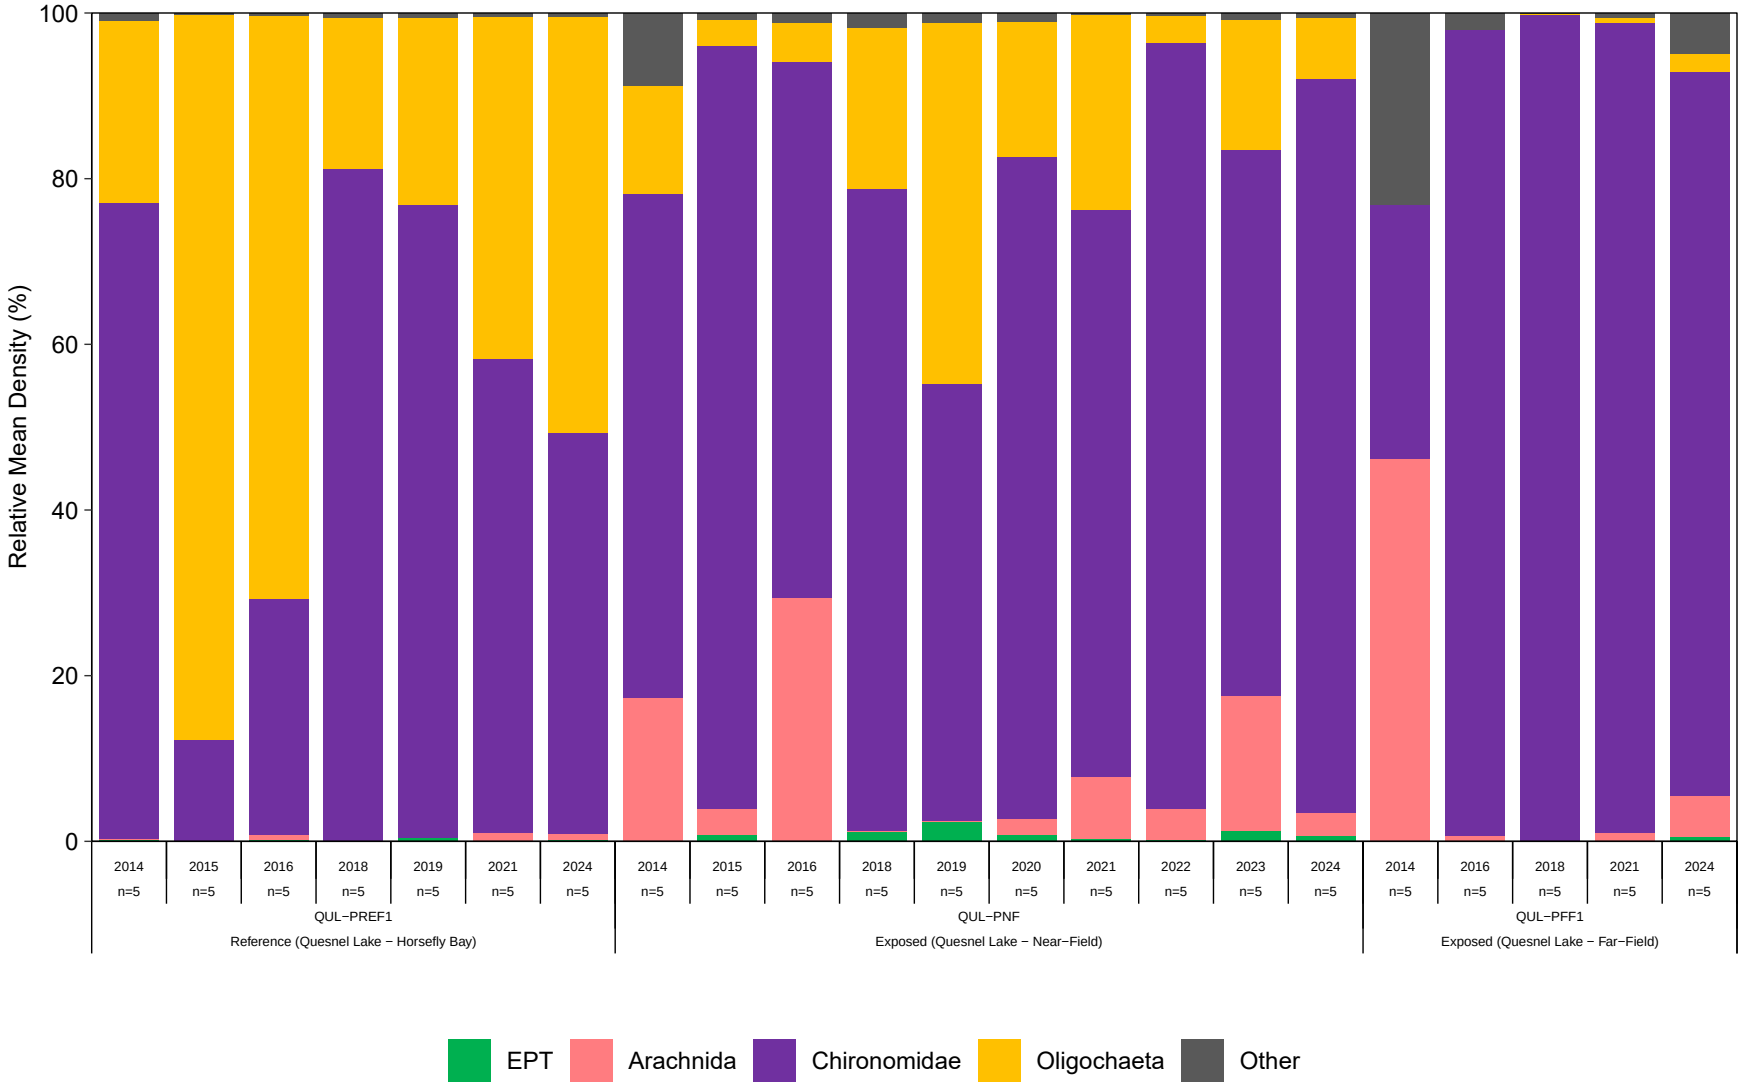

Figure 5.30: Relative Mean Densities of Major Benthic Invertebrate Taxa for the Quesnel Lake (QUL−PNF and QUL−PFF1; Exposed and QUL−PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: EPT = Ephemeroptera, Plecoptera, Trichoptera. QUL−PREF1 was not sampled in 2020, 2022, or 2023; QUL−PFF1 was not sampled in 2015, 2019, 2020, 2022, or 2023.

The benthic invertebrate community in Quesnel Lake in 2024 was very similar to all prior monitoring years. This was evidenced by mean relative densities (%) of major benthic invertebrate taxa at all areas in 2024 that did not differ significantly compared to all previous years, except for EPT taxa (known to be sensitive to habitat disturbances and water pollution; Lenat 1988, Herman and Nejadhashemi 2015) and Chironomidae. The relative density (%) of EPT at the near-field and reference areas in 2024 was significantly lower than in 2019, and Chironomidae (%) at the far-field area in 2024 was significantly higher than in 2014 (Appendix Figure E.4.6, Appendix Table E.4). Overall, the relative densities (%) of taxa at the exposed areas have not changed significantly since at least 2020. Densities of the two most dominant taxa (Chironomidae and Oligochaeta) at the two exposed areas have been significantly lower than reference in all years (2014 to 2024), consistent with total density results (Table 5.22; Appendix Figure E.4.6, Appendix Table E.4.4). At the QUL-PNF near-field area, the densities of both Chironomidae and Oligochaeta have remained stable since at least 2016. At the QUL-PFF1 far-field area, the density of Oligochaeta has been stable since 2014, while the density of Chironomidae decreased significantly between 2021 and 2024 but remained significantly higher than in 2014 (Table 5.22; Appendix Figure E.4.6, Appendix Table E.4.4). Densities of Arachnida and EPT at both exposed areas have been similar to reference in all years (i.e., 2014 to 2024), except for EPT at QUL-PFF1 which has remained significantly lower than reference from 2014 to 2024 (Appendix Figure E.4.6, Appendix Table E.4.4).

Multivariate analysis (CA) was used to further evaluate temporal changes in community composition from 2014 to 2024 at the near-field (QUL-PNF), far-field (QUL-PFF1), and reference (QUL-PREF1) for years with available data. The first two axes of the CA explained a total of 47.4% of the community variation (30.9% and 16.5% for CA Axes 1 and 2, respectively; Appendix Figures E.4.6 and E.4.8, Appendix Tables C.5.4, C.5.5, E.4.4 and E.4.6). Significantly lower CA Axis 1 scores were observed at both the near-field and far-field areas in 2024 compared to reference, consistent with most prior years (except 2016 at the near-field area). In addition, CA Axis 1 scores for QUL-PNF were significantly higher compared to QUL-PFF1 in most years where comparison was possible, except 2014 and 2024. The benthic invertebrate community at the near-field and far-field areas in 2024 did not differ from reference along CA Axis 2 or 3 (Appendix Figure E.4.6, Appendix Table E.4.4), therefore these axes were not discussed further. Temporal evaluation indicated CA Axis 1 scores have not changed significantly since 2018 and 2016 at the near-field and far-field areas, respectively (Appendix Figure E.4.6, Appendix Table E.4.4). This lack of temporal change and the significant difference in CA Axis 1 scores compared to reference in all years was consistent with the continued differences in community composition at QUL-PNF and QUL-PFF1 relative to reference: primarily the significantly higher Chironomidae and lower Oligochaeta relative densities (%). These CA results

suggest no substantial or consistent change has occurred in Quesnel Lake community composition since at least 2018, which is consistent with the temporal stability in the relative densities of the taxa since at least 2020 at the exposed areas.

Evaluation of statistically significant correlation results indicated that benthic invertebrate total density, Oligochaeta (density and relative density [%]), Chironomidae (density), and CA Axis 1 were positively correlated with sediment TOC and sediment PCA Axis 1 (representing lower concentrations of several analytes in sediment). These same five benthic community endpoints were also negatively correlated with bottom water temperature and specific conductance, sediment percent fines, sediment concentrations of arsenic, copper, and manganese, and sediment PCA Axis 2 (representing higher sediment analyte concentrations; Appendix Figures E.1.4 and E.4.9, Appendix Tables E.1.9, E.1.0 and E.4.5). Similarly, taxonomic richness was positively correlated with sediment TOC and negatively correlated with bottom water temperature and specific conductance, and sediment PCA Axis 2 (Appendix Table E.4.5, Appendix Figure E.4.9). Tailings impacted sediments from the breach were characterized by higher proportions of fines and lower TOC content compared to reference sediments, and concentrations of analytes of interest (arsenic, copper, iron, and manganese) elevated above reference and BCWSQG (see Section 5.2.1.1). Therefore, these significant correlation results suggested that physical and chemical characteristics of the deep exposed sediments (i.e., finer particle size, lower TOC content, and elevated concentrations of copper, arsenic, and manganese compared to reference) were related to lower total density, taxon richness, Chironomidae (density), and Oligochaeta (density and %). The positive correlation between Chironomidae (density), total density (which is dominated by Chironomidae) and sediment TOC content is consistent with the documented intolerance of chironomids (*Chironomus tentans*) to sediments with TOC below 1% (Suedel et al. 1993), and poor survival in sediments with TOC below 0.5% (Suedel and Rodgers 1994). Mean TOC concentrations in deep exposed sediments from Quesnel Lake in 2024 were 0.635 ± 0.162% at QUL-PNF and 0.425 ± 0.205 % at QUL-PFF1 (see Section 5.2.1.1).

Simpson's Evenness and Chironomidae (%) were negatively correlated with sediment TOC and PCA Axis 1, and positively correlated with temperature, sediment percent fines, and sediment concentrations of copper. Simpson's Evenness was also positively correlated with sediment arsenic concentrations, while Chironomidae (%) was positively correlated with sediment PCA Axis 2 and sediment manganese concentrations (Appendix Figure E.4.9, Appendix Table E.4.5). The direction of these correlations was opposite to those discussed above (for total density and Chironomidae density) because Chironomidae (%) were more dominant at the exposed areas (QUL-PNF and QUL-PFF1) compared to the reference area (QUL-PREF1), despite lower densities of this taxa at the exposed areas relative to reference (Figure 5.30; Appendix Figure

E.4.6, Appendix Table E.4.4). The correlations with Simpson's Evenness were driven primarily by, and in some cases leveraged by, results from the early post-breach years in which Simpson's Evenness at the exposed areas was higher than at the reference area (i.e., 2014 to 2018 at both QUL-PNF and QUL-PFF1; Figure 5.29; Appendix Figures E.4.6 and E.4.9, Appendix Tables E.4.4 and E.4.6). Therefore, higher Chironomidae (%) and Simpson's Evenness at the exposed areas were related with the characteristics associated with breach-impacted sediments.

In addition to the correlations between benthic invertebrate community endpoints and bottom water quality discussed above (i.e., temperature and specific conductance), DO (% or mg/L) was positively correlated with total density, Chironomidae (density and %), and negatively correlated with Simpson's Evenness. The relationships with bottom water quality variables (temperature, specific conductance, and DO) were often highly leveraged by immediate post-breach results (i.e., 2014) and the ranges of the water quality variables for majority of results were small and therefore likely not a driving factor in the observed differences in the benthic invertebrate community endpoints (Figure E.4.5, Appendix Table E.4.5). Station depth was also positively correlated with Oligochaeta (density and %) and CA Axis 1, and negatively correlated with Chironomidae (%; Appendix Figure E.4.9, Appendix Table E.4.5). However, these relationships were largely driven by the differences in station depths between the QUL-PFF1 far-field area compared to the QUL-PNF near-field and reference areas, therefore because station depth and sediment characteristics covary, the potential influence of each of these variables on the benthic invertebrate community endpoints cannot be distinguished from one another.

Overall, the benthic invertebrate communities at the deep near-field and far-field areas in 2024 were similar to each other in terms of total density, taxon richness, and Simpson's Evenness and Diversity. Although the benthic invertebrate communities at the near- and far-field areas have shown recovery since 2014, they remained similar to 2015 conditions. Despite this, some recovery towards reference conditions has occurred at both the exposed areas for taxon richness, Simpson's Evenness, and Simpson's Diversity, with these endpoints being similar to reference conditions since 2019 or earlier at the near-field area and since 2021 or 2024 at the far-field area. Total density at both exposed areas was significantly lower in 2024 compared to 2021 (at the far-field area this was due to a significant decrease in Chironomidae density) but remained similar to all other years since 2015, and density has remained significantly lower than reference in all post-breach years. Benthic invertebrate community composition at the deep exposed areas have shown very few temporal changes since 2014, and continued to differ from reference in terms of significantly lower relative densities of Oligochaeta, consistent with all prior years. The differences in benthic invertebrate community composition between the exposed and reference areas appeared related to a greater proportion of fines, lower proportion of TOC, and higher metal concentrations in sediment at the exposed areas compared to the reference area;

sediment properties which were consistent with the presence of breach-impacted sediments at this deep exposed near-field area.

5.2.6 Fish Community, Catchability, and Population

Fishing efforts in Quesnel Lake and Quesnel River were completed annually between 2022 and 2024 to collect the fish species required for fish tissue quality monitoring in these areas (see Section 5.2.7): peamouth chub, northern pikeminnow, and lake trout from Quesnel Lake, and rainbow trout from Quesnel River. Total fish catches and CPUE associated with these fishing efforts in 2024 are summarized in Appendix Tables C.6.12 to C.6.16. The supporting *in situ* water quality measurements and habitat data recorded during fish efforts are summarized in Appendix Figure A.1.7 and Appendix Table A.1.5.

Comparisons of CPUE for hoop netting efforts in exposed and reference areas of Quesnel Lake in 2024 indicated that the catchability of the target species northern pikeminnow was higher in the exposed area relative to the reference area in 2024, consistent with results from 2019, 2021, 2022, 2023 (Minnow 2020a, 2022a, 2023a, 2024a). The catchability of the target species peamouth chub was also higher in the exposed fishing area relative to the reference fishing area in 2024, consistent with results from 2021 and 2022 (Minnow 2022a, 2023a). For non-target species, catchability of longnose sucker, burbot (*Lota lota*), and sockeye salmon (*Oncorhynchus nerka*) were 11.3-, 2.2-, and 1.9-times higher, respectively, at the exposed area (near Hazeltine Creek) than at the reference area (near Grain Creek) in 2024 (Appendix Table C.6.12). Conversely, the catchability of mountain whitefish (*Prosopium williamsoni*), largescale sucker, and redside shiner were 13.8-, 4.2-, and 1.8-times lower at the exposed area (near Hazeltine Creek) than at the reference area (near Grain Creek) in 2024. Kokanee (*Oncorhynchus nerka*), bull trout (*Salvelinus confluentus*), and rainbow trout were not at the exposed area (near Hazeltine Creek) but were caught at the reference area (near Grain Creek) but in 2024 (Appendix Table C.6.12).

Comparisons of CPUE for gill net sets in Quesnel Lake in 2024 indicated that the catchability of most non-target species except for mountain whitefish, longnose sucker, and rainbow trout was greater at the exposed area (near Cedar Point) than at the reference area (East Arm; Appendix Table C.6.13). Catchability of the target species lake trout by gill netting in 2024 was lower at the exposed area than at the reference area (by 15-times; Appendix Table C.6.13), but for both areas was within the range of prior years (2019 to 2022; Appendix Table C.6.13; Minnow 2020a, 2021a, 2022a, 2023a).

The CPUE of angling efforts for rainbow trout in 2024 in the Quesnel River was 2.4-times higher than 2023, the same as 2022, 1.6-times lower than 2021, 1.1-times higher than 2020, and

2.5-times higher than 2019 (Appendix Table C.6.14; Minnow 2020a, 2021a, 2022a, 2023a, 2024a).

Temporal comparisons could not be made for the minnow trapping methods used at the exposed (near Hazeltine Creek) and reference (near Grain Creek) areas (Appendix Table C.6.14) or the angling methods used at the reference area (near Grain Creek; Appendix Table C.6.15) since these techniques were used for the first time in 2024 at these areas.

5.2.7 Fish Tissue Quality

Fish tissue quality was completed annually between 2022 and 2024 at exposed and unimpacted (reference) areas of Quesnel Lake, and in Quesnel River (exposed; Figure 3.6, Table 3.8). In Quesnel Lake, annual fish tissue quality monitoring has evaluated peamouth chub and northern pikeminnow collected near Hazeltine Creek and lake trout collected near Cedar Point, with an area near Grain Creek serving as reference for peamouth chub and northern pikeminnow and an area in the East Arm serving as a reference for lake trout.[57] In Quesnel River, annual fish tissue quality monitoring has evaluated rainbow trout (Figure 3.6, Table 3.8).

A review of the 2024 fish tissue quality results (Appendix B) indicated that these data can be used with an acceptable level of confidence for interpretation, although some natural heterogeneity in analyte results were considered during data interpretation (see Section 5.1.7 for details). A review of the 2024 fish aging results (Appendix B) indicated that laboratory accuracy for aging data can be used with a high level of confidence for interpretation (see Section 5.1.7 for details).

5.2.7.1 Comparisons to Guidelines and Thresholds

Muscle and whole-body samples of fish from Quesnel Lake and Quesnel River in 2024 had mean selenium concentrations that were consistently below consumption guidelines for the protection of human health (7.3 mg/kg dw and 14.5 mg/kg dw for moderate and high fish consumption, respectively; BCMOE 2014), which was consistent with all prior years (i.e., 2015 to 2023; Table 5.23; Appendix Tables C.7.5 to C.7.11). Mean mercury concentrations in muscle and whole-body samples of fish from Quesnel Lake and Quesnel River in 2024 were also below the human health guideline (0.5 mg/kg ww; CFIA 2015) but exceeded the human health guideline in muscle tissue of exposed (in 2019 and 2023) and reference lake trout (in 2020 and 2021; Table 5.23; Appendix Tables C.7.5 to C.7.11).

[57] Lake trout have been targeted for annual collection from the East Arm of Quesnel Lake (reference area). In 2023, angling techniques were used to target lake trout in Quesnel Lake (in accordance with conditions of DFO Permit XR 195 2023) and no lake trout were captured from the East Arm (reference area) despite considerable angling effort.

Table 5.23: Fish Muscle and Whole-body Mercury and Selenium Concentrations from Quesnel Lake (Exposed and Reference) and Quesnel River (Exposed) Relative to Human Health Consumption Guidelines, 2015 to 2024 [a]

Waterbody or Area		Species	Year/Season	Sample Size	Mercury		Selenium		
					Human Health (CFIA 2015)		Human Health (BCMOE 2014)		
					Guideline = 0.5 mg/kg ww		Moderate Consumption = 14.5 mg/kg dw		
							High Consumption = 7.3 mg/kg dw		
					Mean	Frequency > Guideline	Mean	Frequency > Moderate	Frequency > High

Mean mercury concentration greater than the Health Canada's Human Health guideline for muscle tissue in fish (0.5 mg/kg dw; CFIA 2015).
Mean selenium concentration greater than the Human Health guideline for moderate fish consumption (14.5 mg/kg dw; BCMOE 2014).
Mean selenium concentration greater than the Human Health guideline for high fish consumption (7.3 mg/kg dw; BCMOE 2014).

Notes: mg/kg ww = milligrams per kilogram wet weight. mg/kg dw = milligrams per kilogram dry weight. > = greater than. % = percent. guidelines for the protection of human health were applied to edible fish tissues only (i.e., muscle) not whole-body tissue results (e.g., northern pikeminnow results for 2016 to 2024).

[a] Muscle tissue concentrations are presented for all species except for northern pikeminnow, for which whole-body tissue concentrations are presented except for data from Fall 2015 and Fall 2017 (muscle tissue concentrations presented for northern pikeminnow).

[b] Gill netting was not approved by Department of Fisheries and Oceans (DFO) in 2023 for the collection of lake trout from Quesnel Lake. As such, lake trout in Quesnel Lake were targeted using angling methods. Four lake trout were captured near Cedar Point (exposed) and no lake trout were captured in the East Arm (reference) in 2023 using angling.

Mercury bioaccumulation in fish is positively related to fish age (Kidd and Batchelar 2012). Therefore, given the longevity of lake trout and their trophic position it is not unexpected for muscle mercury concentrations in larger/older fish to naturally exceed the human health guideline at both the exposed and reference areas.

Mean selenium concentrations in fish muscle or whole-body samples from Quesnel Lake and Quesnel River were below the guideline for the protection of aquatic life in 2024 (4 mg/kg dw; BCMOE 2014). When considering individual sample results, two (25%) of the whole-body northern pikeminnow samples from 2024 had selenium concentrations that exceeded the aquatic life guideline (Appendix Tables C.7.5 to C.7.11), which was within the historic range of guideline exceedances for this species (Table 5.24). In prior years, the guideline for the protection of aquatic life (4 mg/kg dw) was exceeded in exposed muscle samples of peamouth chub (13% to 63% of samples in 2015, 2018, 2021, and 2022), whole-body samples of northern pikeminnow (25% to 38% of samples in 2019, 2020, and 2022), and muscle samples of rainbow trout (13% of samples in 2017 and 2022; Table 5.24).

As indicated previously (Section 5.1.7.1), the analysis of ovary tissue is recommended for assessing the effects of selenium on fish (e.g., Luoma and Presser 2009; Janz et al. 2010; DeForest et al. 2012; Janz 2012). Selenium analysis was completed for ten fish ovary samples from Quesnel Lake (exposed: n=4; reference: n=6) and five samples from Quesnel River in 2024. Selenium concentrations in the exposed ovary tissues from 2024 (peamouth chub: n=2; lake trout: n=2) remained below the guideline for the protection of aquatic life (11 mg/kg dw[58]; BCMOE 2014) and below the threshold for reproductive effects (20 mg/kg dw; DeForest et al. 2012; Table 5.25; Appendix Tables C.7.5 to C.7.11). In contrast, 40% of the reference peamouth chub ovary tissues in 2024 exceeded the guideline for the protection of aquatic life but remained below the threshold for reproductive effects (Table 5.25; Appendix Table C.7.10). This suggests natural elevation of selenium in peamouth chub ovaries, as was previously observed in 2022 and 2023 (Table 5.25). In prior years, selenium concentrations in ovary samples of exposed peamouth chub exceeded the guideline for the protection of aquatic life (25% to 86% of samples from 2018 to 2023) and the threshold for reproductive effects (25% to 43% of samples in 2018 and 2022), while selenium concentrations in lake trout ovary samples (exposed and reference) have remained below the aquatic life guideline (Table 5.25).

The mean selenium concentration of ovary samples from exposed rainbow trout in 2024 (27.9 mg/kg dw) was the highest observed to date (by 1.8-times), exceeded the guideline for the protection of aquatic life by 2.5-times, and exceeded the threshold for reproductive effects

[58] This guideline includes a two-fold uncertainty factor (BCMOE 2014).

Table 5.24: Fish Muscle and Whold-body Selenium Concentrations from Quesnel Lake (Exposed and Reference) and Quesnel River (Exposed) Relative to the British Columbia Guideline for the Protection of Aquatic Life, 2015 to 2024

Mean selenium concentration greater than the BC Aquatic Life guideline for ovary tissue in fish (11 mg/kg dw; BCMOE 2014).

Mean selenium concentration greater than DeForest et al. (2012) threshold for ovary tissue in fish (20 mg/kg dw) and the BC Aquatic Life guideline (BCMOE 2014).

Notes: mg/kg dw = milligrams per kilogram dry weight, > = greater than, % = percent. BC = British Columbia.

[a] Ovary selenium threshold as described in DeForest et al. (2012).

[b] No female lake trout were collected from the Quesnel Lake East Arm (reference) in 2021, therefore results for lake trout from this area are not displayed in 2021.

[c] Gill netting was not approved by Department of Fisheries and Oceans (DFO) in 2023 for the collection of lake trout from Quesnel Lake. As such, lake trout in Quesnel Lake were targeted using angling methods. Four lake trout were captured near Cedar Point (exposed) and no lake trout were captured in the East Arm (reference) in 2023 using angling.

by 1.4-times (Table 5.25; Appendix Table C.7.11). Selenium concentrations in 80% of the exposed rainbow trout ovaries from 2024 exceeded the aquatic life guideline; a result that was within the range guideline exceedances observed in previous years (range = 50 to 100% of samples in 2018, 2019, and 2021 to 2023). In contrast, selenium concentrations in rainbow trout ovaries in 2024 exceeded the threshold for reproductive effects for the second time (the first time being in 2023), but the 2024 results marked the highest rate of exceedance to date (60%; Table 5.20; Appendix Table C.7.11). The increased guideline and threshold exceedance rate for selenium concentrations in rainbow trout ovaries in 2024 could be related to the early development stage of the collected ovary tissues (Table C.6.20) since selenium concentrations have been shown to be inversely related to ovary tissue development (i.e., higher selenium concentrations in ovary tissues at earlier development stages; Brix et al. 2025). In addition, high variability was observed in the reported ovary tissue analyte concentrations (due to sample heterogeneity; see Appendix B.10 for more details). Continued monitoring will help to determine whether the 2024 rainbow trout ovary results are part of a long-term trend. Temporal trends in fish tissue quality from Quesnel Lake and Quesnel River are discussed in the next section (Section 5.2.7.2).

5.2.7.2 Spatial and Temporal Comparisons

Age and morphological measures (fork length and body weight) of lake trout, peamouth chub, and northern pikeminnow from Quesnel Lake, and rainbow trout from Quesnel River between 2015 and 2024 are summarized in Table 5.26 (see Appendix Tables C.6.17 to C.6.20 for detailed 2024 data). Statistical comparisons exhibited a significant *Area×Year* interaction for at least one of the physical measures for two of the species with paired exposed and reference data in 2024 (i.e., peamouth chub and northern pikeminnow)[59]. The physical measures of lake trout did not exhibit a significant *Area×Year* interaction, indicating there has been no significant temporal change in the relative (exposed-reference) difference of their morphological measures (Table 5.27). The size (length or weight) and age of exposed peamouth chub in 2024 were similar to those from the reference area, and were similar to all prior years (i.e., 2016 to 2023) except for being significantly shorter and lighter than peamouth chub caught in 2020 (Table 5.27; Appendix Table E.6.9). The size (length and weight) and age of exposed northern pikeminnow in 2024 were similar to those from the reference area, but were significantly younger than in 2022,

[59] Results of the two-way ANOVA for age, fork length, and body size may differ among tissue types for the same species in the same area due to sub-sampling (i.e., the number of females sampled for ovary tissue may be a subset of the total samples) or differences in data availability across years for the different tissue types (e.g., peamouth chub kidney and ovary data were collected from 2018 to 2024 compared to 2016 to 2024 for peamouth chub muscle and liver tissue). In 2024, discussion of age and body size focused on results of two-way ANOVA for muscle tissues (peamouth chub and lake trout) and whole-body tissues (northern pikeminnow), or one-way ANOVA for muscle tissues (rainbow trout).

Table 5.26: Age and Body Size Data of Fish Collected for Tissue Quality Monitoring from Quesnel Lake (Exposed and Reference) and Quesnel River (Exposed), 2015 to 2024

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: **Bold** = Data for either exposed or reference in the indicated year were entirely below the laboratory reporting limit (LRL), leading to a less accurate estimate of the mean for the <LRL result and greater uncertainty for the calculated MOD. No MOD is displayed if the comparison was not significant. "-" = no data available for analysis (i.e., either data was not collected for the given analyte and time period or data were omitted from analysis because > 50% of data fora given analyte were <LRL in all time periods). "<LRL" = greater than 50% LRL data for both stations so the time period was omitted from the analysis. "ns" = not significant. "ww" = wet weight. "Exp" = exposed. "Ref" = reference. "ANOVA" = Analysis of Variance. "MLE" = Maximum Likelihood Estimation. Data were analysed in units of mg/kg dry weight except mercury which was analysed in units of mg/kg wet weight. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Age, fork length, and body weight results are those that are associated with muscle tissue analyses.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Tables E.6.9 to E.6.16). This table only presents results for primary and secondary analytes with a significant positive exposed-reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant). If no significant change was detected in the exposed-reference difference among years (i.e., the Area x Year interaction was not significant), data from all years were combined for the analyses.

[b] Muscle tissue was analyzed for peamouth chub and lake trout, while whole-body tissue was analyzed for northern pikeminnow. Lake trout ovary tissues could not be analyzed using two-way ANOVA due to insufficient sample sizes at the reference area. See

[c] Magnitude of difference (MOD) calculated on back transformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted})\times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[d] Magnitude of difference (MOD) calculated on back transformed least-squares means as (Exp-Ref)/Ref x 100%.

[e] Organ in which the specific metal is known to accumulate (references in Appendix Table E.6.22).

significantly shorter than in 2020 and 2022, and significantly lighter relative to 2020 (Table 5.27; Appendix Table E.6.10). The size (length and weight) and age of lake trout have been temporally stable over the entire monitoring period (i.e., no significant *Area×Year* interaction), with lake trout size being similar at the exposed and reference areas, but exposed lake trout being significantly younger than those from the reference area (Table 5.27; Appendix Table E.6.11). Temporal comparisons of the physical measures of rainbow trout were made without contrasts between areas because associated reference data were not collected (see Section 3.7.1). Rainbow trout from Quesnel River in 2024 were of similar size (length and weight) and age relative to all prior years (i.e., 2015 to 2023; Table 5.28; Appendix Table E.6.18).

Data interpretation of paired exposed and reference results (i.e., peamouth chub, northern pikeminnow, and lake trout[60]) was focused on primary and secondary analytes (Table 2.4) with a significant positive relative (exposed-reference) difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2024 (if the analysis *Area×Year* interaction was significant) or in all monitoring years (if the *Area×Year* interaction was not significant[61]). Data interpretation of exposed data only (i.e., no associated reference results; lake trout [ovary] and rainbow trout [all tissues]) was focused on primary and secondary analytes with a significant *Year* effect and analyte concentrations that were significantly higher in 2024 than one or more prior years.

Increasing analyte concentrations at exposed areas relative to reference areas over time, or consistently elevated analyte concentrations at the exposed area relative to reference, were not detected for most analytes in tissues of peamouth chub, northern pikeminnow, or lake trout (excluding ovary; Figures 5.31 and 5.32, Table 5.27; Appendix Figures E.6.8 to E.6.11, Appendix Tables E.6.9 to E.6.16) or over time in lake trout (ovary only) and rainbow trout (all tissues; Table 5.28; Appendix Figures E.6.12 to E.6.16, Appendix Tables E.6.17 to E.6.21). The four primary analytes (arsenic, copper, iron, and selenium) and 13 secondary analytes (barium, cadmium, calcium, manganese, mercury [ww], molybdenum, phosphorus, sodium, strontium, titanium, uranium, vanadium, and zinc) met the criteria outlined above for inclusion in data interpretation for peamouth chub, northern pikeminnow, and lake trout (excluding ovary) tissues (Table 5.27). A subset of these analytes met the criteria for inclusion in data interpretation for lake trout (ovary only) and rainbow trout (all tissues; Table 5.28): one primary analyte (selenium) and three secondary analytes (phosphorus, sodium, and zinc).

[60] Paired exposed and reference data was available for lake trout muscle, liver, and kidney tissue only. Lake trout ovary data was analyzed using a one-way ANOVA due to an insufficient (i.e., $n < 2$) sample size for the reference area in 2024.

[61] If no significant change was detected in the relative (exposed-reference) difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

Table 5.28: Summary of Temporal Comparisons of Fish Tissue Primary and Secondary Analyte Concentrations for Quesnel Lake (Exposed) and Quesnel River (Exposed), 2015 to 2024[a]

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: "-" = no data available. "LRL" = Laboratory reporting limit. "nt" = not tested because all data were reported below the method detection limit (LRL) or because there were only data for a single time period. "ns" = not significant. "baseline" = first year of data included in analysis. "<LRL" = greater than 50% of the concentrations were reported as < LRL so the time period was omitted from the analysis. "ANOVA" = one way analysis of variance. ANCOVA = one-way analysis of covariance. "MOD" = Magnitude of Difference. 'MLE" = censored regression using maximum likelihood estimation. Data were analysed in units of mg/kg dry weight (dw) except mercury which was analysed in units of mg/kg wet weight (ww). Age, fork length, and body weight results are those that are associated with muscle tissue analyses. Lake trout ovary tissue was assessed using a one-way ANOVA as the sample size from the Quesnel Lake East Arm reference area in 2024 was insufficient for a two-way ANOVA (n < 2). Statistical comparisons of lake trout muscle, liver, and kidney were conducted using a two-way ANOVA and are presented in Table 5.27.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Tables E.6.17 to E.6.21). This table only presents results for primary and secondary analytes with a significant Year effect, and a mean exposed concentration in 2024 that was significantly higher than baseline (i.e., significant positive MOD in 2024).

[b] Organ in which the specific metal is known to accumulate (references in Appendix Table E.6.22).

[c] Magnitude of difference (MOD) calculated on back transformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/ (Exp_{predicted})\times100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

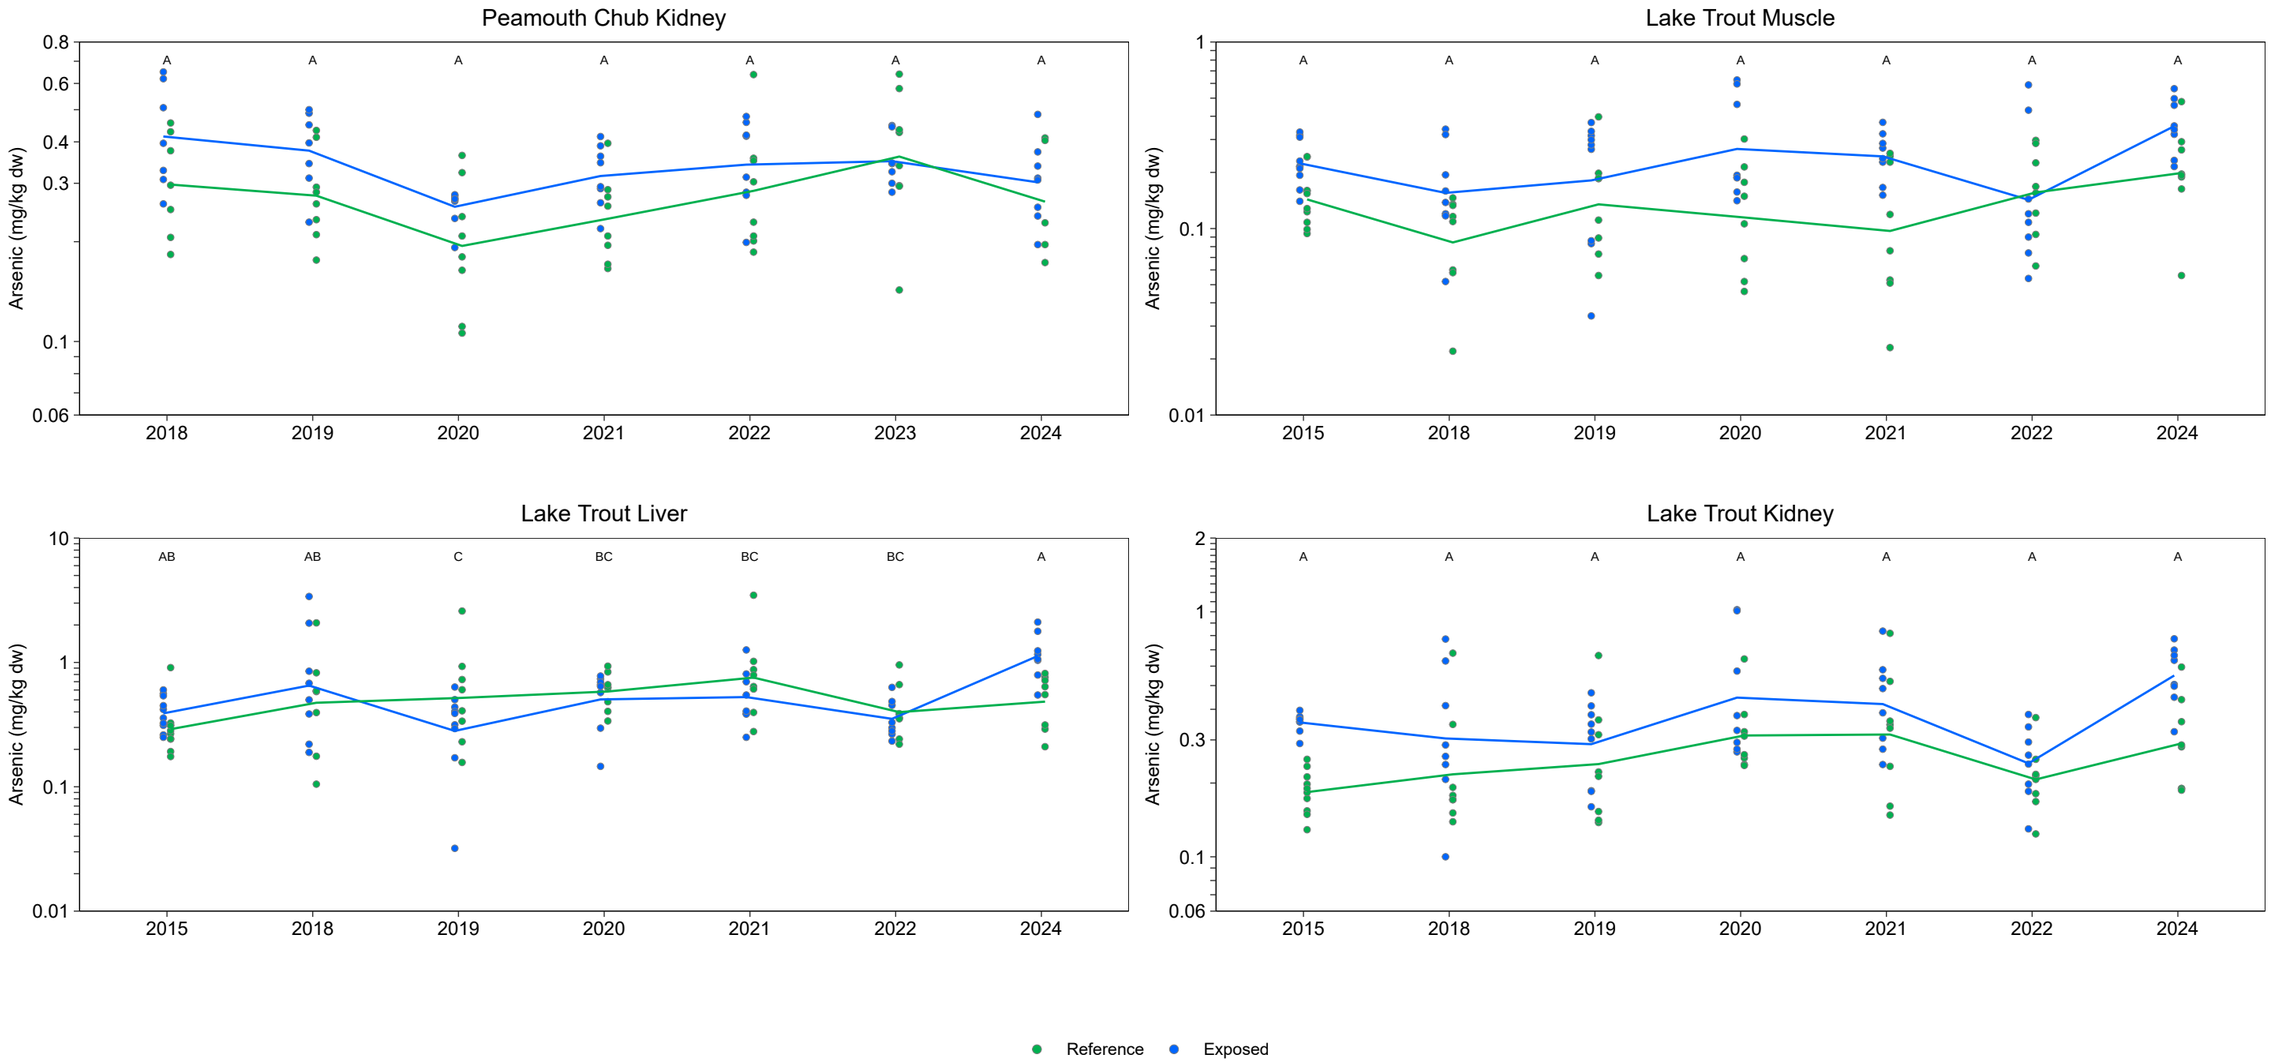

Figure 5.31: Fish Tissue Primary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for Quesnel Lake (Exposed and Reference), 2015 to 2024

Notes: GL = Guideline, dw = dry weight. Green represents reference areas and blue represents exposed areas. Plots are only included for primary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2024 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given species and tissue type. Data are not available for all years within the date range identified, only years with available data are displayed and these are analyte−dependent. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

Concentrations of the primary analytes arsenic, copper, iron, and selenium in most exposed peamouth chub, northern pikeminnow, and lake trout (excluding ovary) tissues were either statistically similar to or significantly lower than reference in 2024, or lacked a significant *Area×Year* interaction in the analyses (Figure 5.31, Table 5.27; Appendix Figures E.6.8 to E.6.11, Appendix Tables E.6.9 to E.6.16). The absence of a significant *Area×Year* interaction indicates that the relative differences in analyte concentrations were temporally stable and did not change significantly among years (i.e., the geometric mean concentrations at the exposed area were trending the same as the geometric mean concentrations at the reference area). Arsenic in lake trout liver tissue was the only occurrence of a primary analyte with a significant *Area×Year* interaction and significantly higher concentrations in exposed tissues compared to reference in 2024 (Figure 5.31, Table 5.27; Appendix Table E.6.15). Although 2024 is the first year that arsenic concentrations in exposed lake trout liver were significantly higher than reference, the relative (exposed-reference) difference of arsenic concentrations in this tissue has not increased significantly compared to the first year of monitoring (i.e., 2015; Figure 5.31; Appendix Table E.6.15). Combined, these results indicate there is no sustained increase in the concentrations of primary analytes in exposed peamouth chub, northern pikeminnow, and lake trout (excluding ovary) tissues, as evidenced by analyte concentrations that were: 1) similar to or significantly lower than at the reference area in 2024 (indicating no mine-related influence), and/or 2) temporally stable over the monitoring period, and/or 3) similar to or significantly lower than in prior years in 2024, relative to reference.

The concentrations of 13 secondary analytes (i.e., barium, cadmium, calcium, manganese, mercury [ww], molybdenum, phosphorus, sodium, strontium, titanium, uranium, vanadium, and zinc) had significant *Area×Year* interaction terms for at least one tissue type from peamouth chub, northern pikeminnow, and/or lake trout (excluding ovary) and had analyte concentrations in exposed tissues that were significantly higher than reference in 2024 (i.e., positive relative [exposed-reference] difference) or in all monitoring years (if the *Area×Year* interaction was not significant; Figure 5.32, Table 5.27; Appendix Figures E.6.8 to E.6.11, Appendix Tables E.6.9 to E.6.14). For most of the analyte-tissue combinations identified for these 13 secondary analytes, the relative differences were either temporally stable (i.e. the *Area×Year* interaction was not significant), or the exposed tissue analyte concentrations in 2024 were higher than reference in only one tissue type within a fish species (i.e., sodium, titanium, and uranium), indicating no sustained increase in secondary analyte concentrations in the exposed fish tissues over time. Therefore, these analyte-tissue combinations were excluded from further discussion. There were seven occurrences of secondary analyte-tissue combinations in 2024 that were exceptions to the above observations; each had a significant *Area×Year* interaction term and secondary analyte concentrations that were significantly higher in at least two exposed fish

tissues in 2024, compared to reference (Table 5.27, Figure 5.32; Appendix Tables E.6.9 to E.6.16). These seven analyte-tissue combinations occurred in peamouth chub tissues only and are discussed in further detail below.

The secondary analyte-tissue combinations in peamouth chub tissues that met the criteria for further discussion were as follows: barium, calcium, manganese, mercury (ww), phosphorus, and strontium concentrations in muscle, and mercury (ww) concentrations in kidney (Figure 5.32, Table 5.27; Appendix Tables E.6.9 and E.6.13). Specifically, mercury (ww) concentrations in the muscle and kidney tissues of exposed peamouth chub and phosphorous concentrations in exposed peamouth chub muscle were significantly higher than reference in 2024, but the relative differences in 2024 were the same as in the first year of monitoring (i.e., 2016 and 2018, respectively; Figure 5.32, Table 5.27; Appendix Tables E.6.9 and E.6.13). Concentrations of barium, calcium, manganese, and strontium in exposed peamouth chub muscle were significantly higher than at the reference area in 2024, with the relative differences for these analytes in 2024 significantly higher compared to one or more prior years (i.e., 2016 to 2023; Figure 5.32, Table 5.27; Appendix Table E.6.9). The 2024 results for exposed peamouth chub muscle represent a temporal change for three of these analytes (calcium, manganese, and strontium), which have had exposed concentrations that were similar to or significantly lower than reference from 2016 to 2023. The relative differences for calcium, manganese, and strontium in peamouth chub muscle in 2024 were significantly higher than most (calcium) or all (manganese and strontium) prior years. From 2016 to 2021, exposed barium concentrations were similar to reference and increased to significantly higher than reference from 2022 to 2024; however, the relative difference of barium concentrations has not changed significantly over the last three years (i.e., 2022 to 2024; Figure 5.32, Table 5.27; Appendix Table E.6.9). The significantly higher relative differences of barium, calcium, manganese, and strontium concentrations in peamouth chub muscle in 2024 were related (at least in part) to observed decreases in reference tissue analyte concentrations (Figure 5.32).

One female lake trout was captured from the reference area in Quesnel Lake in 2024 (Appendix Tables C.6.17), therefore data analysis and interpretation for lake trout ovary tissue focused on temporal changes at the exposed area from 2015 to 2024 (i.e., no comparisons to reference were possible; see Section 3.7.3.2 for details). Three primary analytes (arsenic, copper, and iron) and six secondary analytes (barium, cobalt, manganese, mercury [ww], silver, and zinc) were identified as having a significant *Year* effect; however, concentrations of these analytes in exposed lake trout ovary tissues in 2024 were similar to the first year of monitoring (i.e., 2015 for most analytes, except silver [2020]). This result was consistent with that observed in most prior years, except for 2022, when barium and silver concentrations were significantly lower than the first year of monitoring (i.e., 2018) and silver was significantly higher

than the first year of monitoring (i.e., 2020), respectively (Table 5.28; Appendix Figure E.6.12, Appendix Table E.6.17). As such, there has been no sustained temporal increase in primary or secondary analyte concentrations in exposed lake trout ovary tissues.

Data analysis and interpretation of rainbow trout from Quesnel River focused on temporal changes from 2015 to 2024 since there is no corresponding reference area for Quesnel River (i.e., no comparisons to reference were possible; see Section 3.7.3.2 for details). The primary analytes arsenic, copper, iron, and selenium were identified as having a significant *Year* effect in at least one rainbow trout tissue (muscle, liver, or kidney). However, selenium in rainbow trout kidney tissue was the only analyte that met the criteria for further discussion (i.e., the analyte concentration was significantly higher in 2024 than one or more prior years; Table 5.28; Appendix Figures E.6.13 to E.6.16, Appendix Tables E.6.18 to E.6.21). Mean concentrations of selenium in rainbow trout kidney tissues in 2023 and 2024 were significantly higher compared to the first year of monitoring (i.e., 2015) and 2020 but similar to all remaining prior years (Table 5.28; Appendix Figure E.6.16, Appendix Table E.6.21). Selenium concentrations in rainbow trout kidney tissue over the last four years (i.e., 2021 to 2024) have been temporally stable and were similar to the second year of monitoring (i.e., 2017; Table 5.28; Appendix Figure E.6.16, Appendix Table E.6.21), indicating no sustained increase in the selenium concentrations of exposed rainbow trout kidney tissues. Despite the higher rate of selenium guideline/threshold exceedances identified in rainbow trout ovaries in 2024 compared to prior years (see Section 5.2.7.1), selenium concentrations in rainbow trout ovary tissue did not exhibit a significant *Year* effect (i.e., have not changed significantly over the entire monitoring period; Table 5.28; Appendix Table E.6.19). Since pre-breach data are not available for lake trout ovary tissues, definitive conclusions as to the potential factors influencing the rate of selenium guideline/threshold exceedances in the post-breach period cannot be made (e.g., due to a breach or post-breach mine-related influence or due to inherent temporal variability that may have existed pre-breach).

Three secondary analytes were identified in rainbow trout as having a significant *Year* effect and concentrations that were significantly higher in 2024 than one or more prior years (phosphorous, sodium, and zinc; Appendix Figures E.6.13 to E.6.16, Appendix Tables E.6.18 to E.6.21). For simplicity, only those secondary analytes that were significantly higher in 2024 than in one or more prior years, and in more than one rainbow trout tissue, were discussed further (i.e., phosphorus, and zinc were not discussed further; Table 5.28; Appendix Tables E.6.18 to E.6.21). Sodium concentrations in exposed rainbow trout ovary in 2022 and 2024 were significantly higher than the first year of monitoring with replication (i.e., 2018) while sodium concentrations in exposed rainbow trout kidney have been consistently higher than the first year of monitoring (i.e., 2015; Appendix Figures E.6.14 and E.6.16; Appendix Tables E.6.19

and E.6.21). Despite this, sodium concentrations in rainbow trout ovary in 2024 were similar to those from 2022 and 2023, and have been stable since 2021, in rainbow trout kidney tissues, suggesting no sustained increases in tissue sodium concentrations over time (Table 5.28; Appendix Figures E.6.13 and E.6.15, Appendix Tables E.6.18 and E.6.20). Overall, there have been no sustained increases in secondary analyte concentrations in exposed rainbow trout tissues since at least 2022.

6 RESULTS – CREEK HABITAT

6.1 Hazeltine Creek

6.1.1 Sediment Quality

Sediment quality monitoring was completed annually between 2022 and 2024, with monitoring in each year including one area in upper Hazeltine Creek (HAC-U [HAC-R2]), and one in lower Hazeltine Creek (HAC-D [HAC-R5]), with upper and lower Edney Creek (EDC-U and EDC-D [EDC-REF]) serving as reference areas, respectively (Figure 4.1, Table 4.1) [62].

A review of the 2024 sediment quality results (Appendix B) indicated that the data met the established DQOs and can be used with a high level of confidence for interpretation (see Section 5.1.1 for details).

6.1.1.1 Upper Hazeltine Creek

Sediments collected from upper Hazeltine Creek (HAC-U) in 2024 were composed primarily of silt and clay (mean = 74.2% and 19.3%, respectively) and were higher in silt content than the reference sediments (EDC-U), which were composed predominantly of sand and silt (mean = 47.0% and 42.7%, respectively; Table 6.1; Appendix Tables D.2.6 and D.2.7). The silt and clay content of the sediments from HAC-U in 2024 were within the range of those previously observed from 2018 to 2023 (Table 6.1; silt = 30.5% to 77.7%, clay = 13.4% to 21.0%). The mean sand content of HAC-U sediments in 2024 (6.48%) was higher than 2023 (3.90%), but lower than from 2018 to 2022 (range of 11.2% to 38.5%; Table 6.1; Appendix Tables D.2.3, D.2.6, and D.2.7). The presence of fine sediments (i.e., silt and clay) in these erosional sampling areas has been limited in some years, particularly in Edney Creek, which has necessitated opportunistic sampling in both the exposed and reference areas (as described in Section 4.1.1). Therefore, variability in particle size is likely related, at least in part, to temporal changes in the presence of fine sediments in these erosional habitats. The deposition of fines in pool areas of Hazeltine Creek is thicker than in Edney Creek, which is likely related to the lack of natural flow regime (see Section 4.1.1); therefore, temporal changes in sediment particle size in upper Hazeltine Creek are also likely influenced by sediment accumulation.

The total nitrogen content of HAC-U sediments (mean = 0.782%) was 2.4-times higher than at the reference area (mean = 0.330%) in 2024, which is consistent with results from 2021 and 2023 which were 2.10- to 2.95-times higher than at the reference area, respectively. The total nitrogen

[62] For HRWG reporting, HAC-R2, HAC-R5, and EDC-REF are the alternate names used for the HAC-U, HAC-D, and EDC-D sampling areas. The original area names only (i.e., HAC-U, HAC-D, and EDC-D) are used throughout the remainder of this report section (Section 6.1.1).

Value is > Lower BC Working Sediment Quality Guideline.
Value is > Upper BC Working Sediment Quality Guideline.

Notes: dw = dry weight. ***Bold/ Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (< 5th percentile value for pH). Reference or pre-breach 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. "SD" = standard deviation. HAC-R2 is the alternate name for the HAC-U sampling area for HRWG reporting. All summary statistics were calculated to three significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025)

[b] For calculation of pre-breach 95th percentile values see Appendix Table D.2.2, for calculation of reference 95th percentile values see Appendix Table D.2.3. The 5th percentile is reported for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Table 6.1: Summary of Sediment Quality Results for the Upper Hazeltine Creek (HAC-U [HAC-R2]; Exposed) and Upper Edney Creek (EDC-U; Reference) Monitoring Areas, 2014 to 2024

Value is > Lower BC Working Sediment Quality Guideline.
Value is > Upper BC Working Sediment Quality Guideline.

Notes: dw = dry weight. ***Bold/ Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (< 5th percentile value for pH). Reference or pre-breach 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. "SD" = standard deviation. HAC-R2 is the alternate name for the HAC-U sampling area for HRWG reporting. All summary statistics were calculated to three significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025)

[b] For calculation of pre-breach 95th percentile values see Appendix Table D.2.2, for calculation of reference 95th percentile values see Appendix Table D.2.3. The 5th percentile is reported for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

content of HAC-U sediments prior to 2021 has been more variable (range of 0.0244% to 0.656% in 2018 to 2020; Table 6.1). The mean TOC content of HAC-U sediments has been similar to the reference area (EDC-U) in most years (including 2024) except for 2018 and 2020, when TOC content of HAC-U sediments was significantly lower than reference (Figure 6.1; Appendix Tables D.2.6, D.2.7 and F.1.1). Following a period of temporal variability in 2018 to 2020, the relative (exposed-reference) difference of sediment TOC content has been temporally stable from 2021 to 2024 (Figure 6.1, Table 6.1; Appendix Table F.1.2). This temporal stability in TOC content of HAC-U sediments coincides with the period of temporal stability also observed for total nitrogen content (i.e., 2021 to 2024). Combined, these results indicate that following a period of temporal variability from 2018 to 2020, there is evidence that physical composition of HAC-U sediments (as evidenced by total nitrogen and TOC content) has begun to stabilize as sediment accumulation continues to occur in this remediated system. The temporal variability in both TOC content and total nitrogen observed in HAC-U in 2018 to 2020 was likely associated, at least in part, with differences in sediment texture (see Minnow 2023a, 2024a for details).

Mean analyte concentrations in the sediments (<63 µm fraction) collected from HAC-U in 2024 exceeded both pre-breach[63] and reference 95th percentile values for 19 analytes. Among these, copper, iron, manganese, and selenium were the only Analytes of Interest with mean sediment concentrations at HAC-U in 2024 that also exceeded the BCWSQG (Figure 6.1, Table 6.1; Appendix Table D.2.7).

Mean iron and selenium concentrations in HAC-U sediments in 2024 were 1.7 and 3.9-times the lower BCWSQG, respectively, while copper and manganese concentrations were 2.6-times and 3.4-times the upper BCWSQG, respectively (Figure 6.1, Table 6.1; Appendix Table D.2.7). Sediments from the reference area (EDC-U) in 2024 had mean concentrations of copper and iron that were naturally elevated above the lower BCWSQG, and a mean manganese concentration that was naturally elevated above the upper BCWSQG (Table 6.1; Appendix Tables D.2.3 and D.2.6). Copper, iron, and manganese concentrations were also naturally elevated above BCWSQG in sediments from many of the previous monitoring years at the reference area (Table 6.1; Appendix Tables D.2.3 and D.2.6), indicating that these analytes are naturally elevated in stream habitats in the vicinity of the Mount Polley Mine.

[63] TOC and analyte concentrations reported for pre-breach sediments were based predominantly on bulk sediment, but were reported for the <63 µm fraction of sediments collected post-breach. This difference in the fraction of sediment evaluated (i.e., bulk sediments for pre-breach and <63 µm fraction for post-breach) should be considered when making comparisons of TOC and analyte concentrations between the two time periods. Formal statistical temporal comparisons were conducted using data from between 2018 to 2024 which reported TOC and analyte concentrations in the <63 µm fraction of sediments (see Sections 4.1.2 and 4.1.3.2).

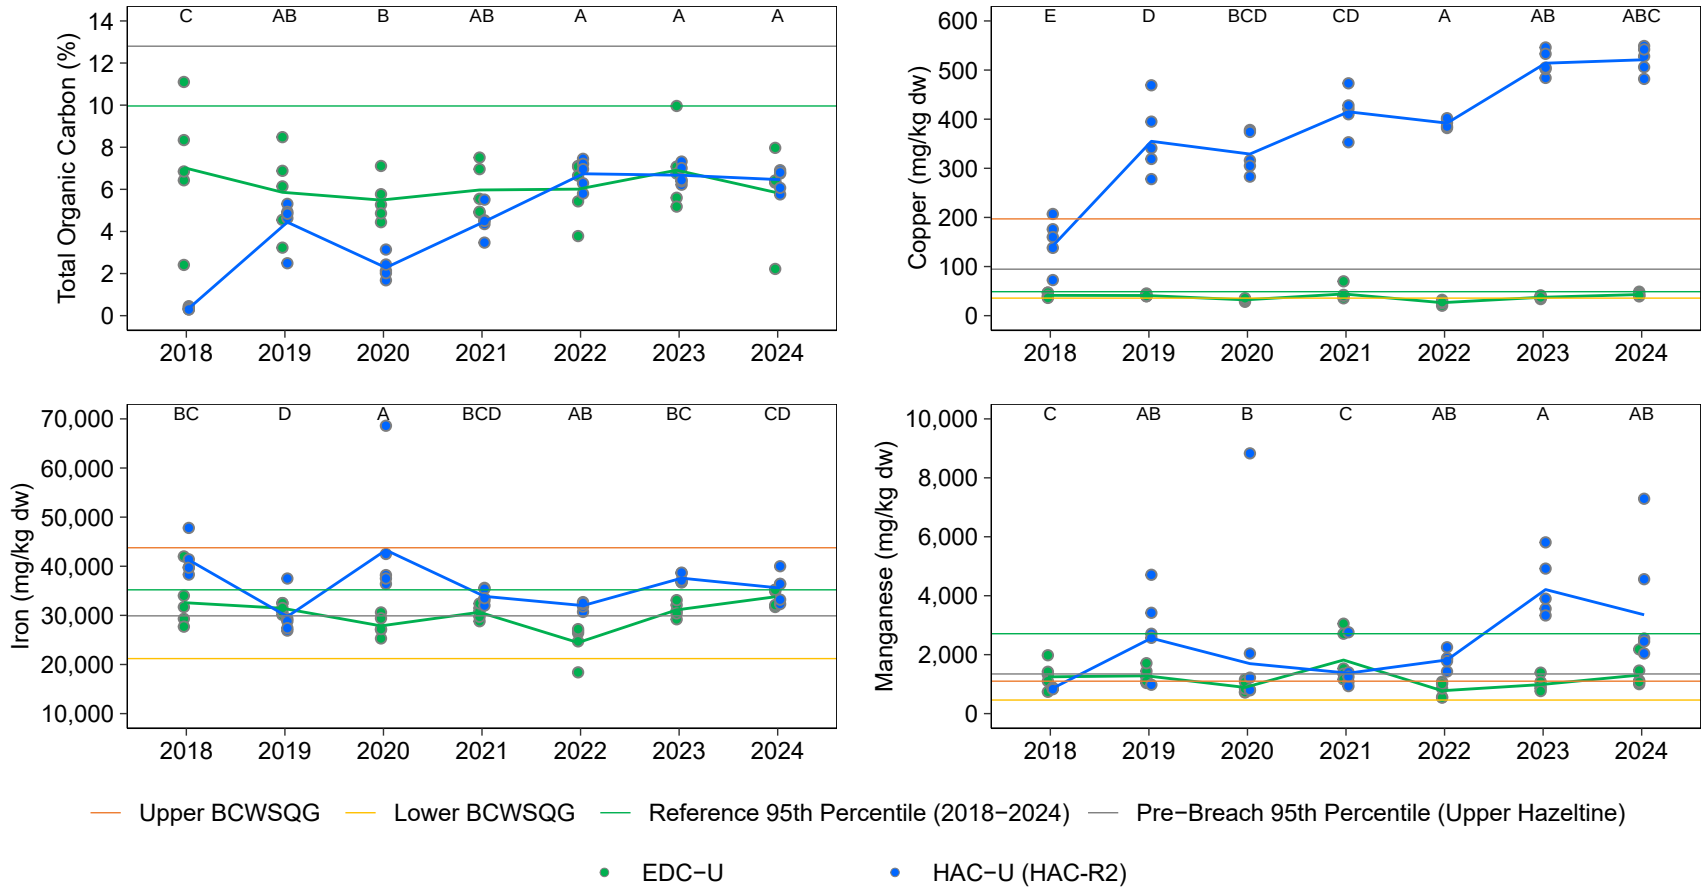

Figure 6.1: Sediment Analyte of Interest Concentrations (<63 µm Fraction) forthe Upper Hazeltine Creek (HAC−U [HAC−R2]; Exposed) and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 2018 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025). HAC-R2 is the alternate name for the HAC-U sampling area for HRWG reporting. Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences − TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference).

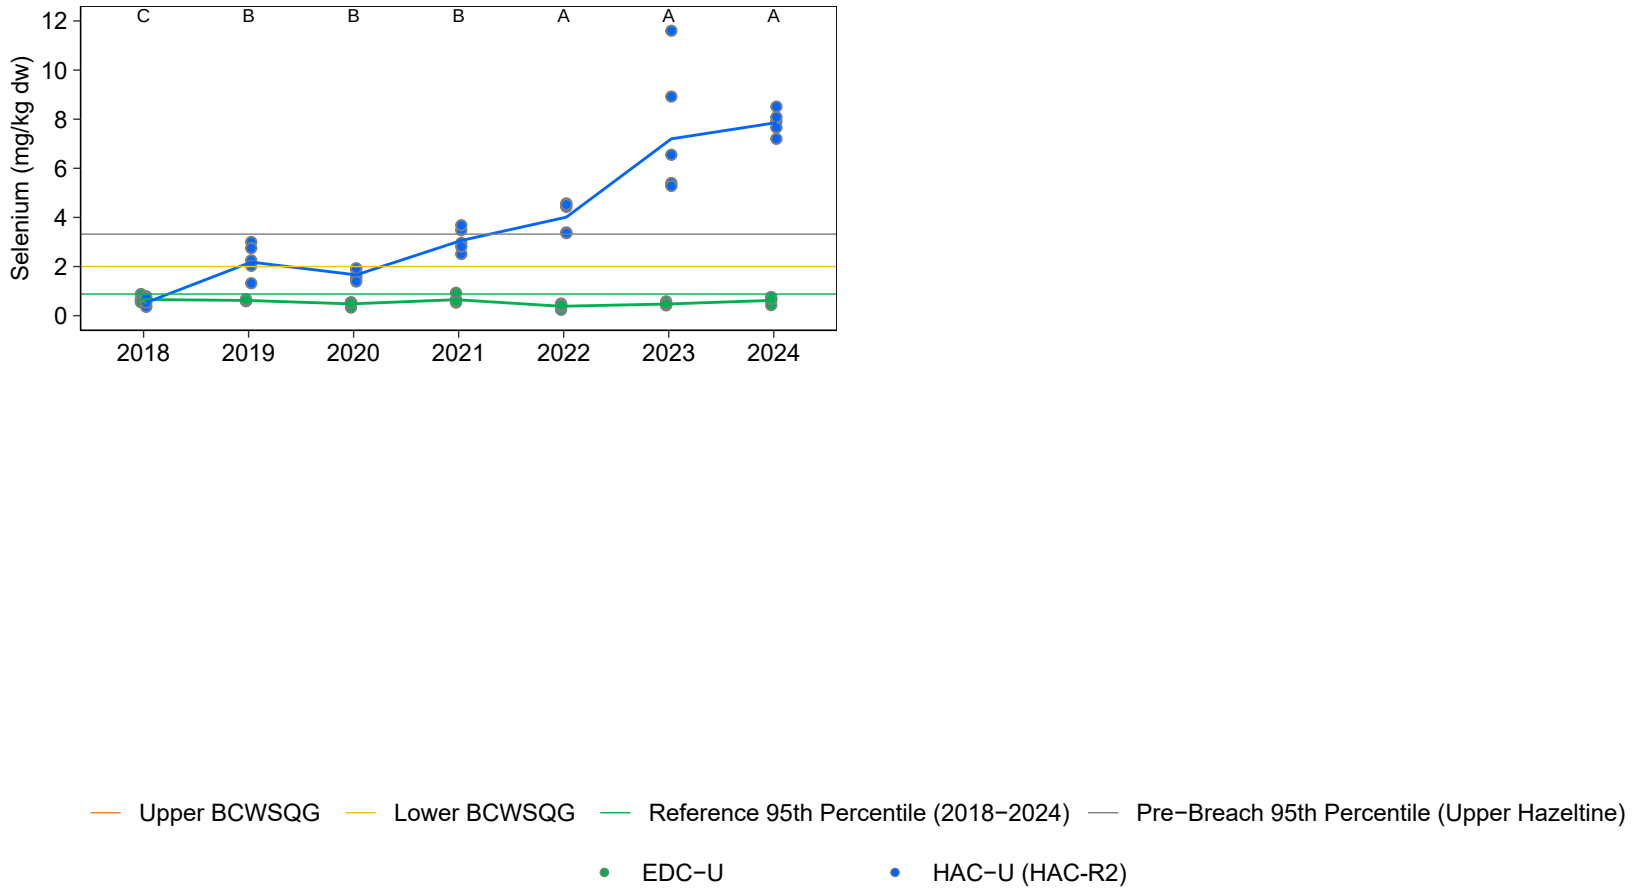

Figure 6.1: Sediment Analyte of Interest Concentrations (<63 µm Fraction) forthe Upper Hazeltine Creek (HAC−U [HAC−R2]; Exposed) and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 2018 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025). HAC-R2 is the alternate name for the HAC-U sampling area for HRWG reporting. Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences − TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference).

Mean iron concentrations in HAC-U sediments were not significantly different than reference (EDC-U) in 2024 (Appendix Table F.1.1), despite exceeding the reference and pre-breach 95th percentiles (Table 6.1). This differs from most prior years (except 2019 and 2021), when the iron concentrations of HAC-U sediments were significantly higher than at the reference area (Appendix Table F.1.1). The relative (exposed-reference) difference of iron concentrations in 2024 was similar to or significantly lower than all prior years (Figure 6.1; Appendix Table F.1.2), indicating there is no sustained increase in iron concentrations in upper Hazeltine Creek sediment.

The relative differences of copper, manganese, and selenium concentrations in 2024 were similar to 2022 and 2023 but significantly higher than many of the prior years (i.e., 2018 and 2019 for copper, 2018 and 2021 for manganese, and all prior years for selenium; Figure 6.1; Appendix Table F.1.2). Although copper, selenium, and manganese concentrations in HAC-U sediments did not increase significantly from 2022 to 2024, relative to reference, these analytes showed an average 1.3-, 1.9-, and 2.1-fold increase over this interval, respectively. In contrast, sediment physical characteristics have remained relatively stable from 2021 to 2024 (i.e., particle size, TOC, and total nitrogen content; Table 6.1, Figure 6.1; Appendix Tables D.2.6 and D.2.7). The non-significant increase in copper, selenium, and manganese concentrations in HAC-U sediment between 2022 and 2024 may be associated with continued sediment accumulation in this area. To better characterize the relationships between variability in sediment physical characteristics and sediment analyte concentrations, these relationships were explored through correlation analysis.

Concentrations of copper, manganese, and selenium in upper and lower Hazeltine Creek sediments (when considered separately from reference sediments) were positively correlated with the total sulphur, TOC, and total nitrogen content of the sediments, while iron concentrations were negatively correlated with these three sediment characteristics (Appendix Figure F.1.1, Appendix Table F.1.3). When Hazeltine Creek and Edney Creek (reference) sediments were considered together (from both upper and lower creek areas), copper, manganese, and selenium concentrations were positively correlated with clay content, total sulphur, and total nitrogen content, and manganese concentrations were positively correlated to TOC content (Appendix Figure F.1.1, Appendix Table F.1.3). Iron was negatively correlated with total nitrogen and TOC content and positively correlated with clay content (Appendix Figure F.1.1, Appendix Table F.1.3). The significant positive correlations of copper concentrations with clay content, total sulphur, total nitrogen, and TOC content were strongly leveraged by the exposed sediment results, with reference sediments showing relatively little variability in copper concentrations (Appendix Figure F.1.1). Correlations between Analyte of Interest concentrations (i.e., copper, iron, manganese, and selenium) and total sulphur were

generally the strongest relationships (Appendix Figure F.1.1, Appendix Table F.1.3). Combined, the correlation results suggest that the analyte concentrations of exposed sediments are related to the physical and chemical characteristics of these sediments, which is likely driven by a combination of opportunistic sampling methods and continued sediment accumulation in upper and lower Hazeltine Creek.

Overall, the temporal increases were observed in the concentrations of copper, selenium, and to a lesser extent manganese, in upper Hazeltine Creek sediments, relative to reference. Benthic invertebrate community and tissue quality monitoring both provide more directly applicable approaches for evaluating the potential effects of increased analyte concentrations to aquatic life in these erosional creek habitats, compared to sediment monitoring (see Section 6.1.4 for tissue quality results for creek habitats).

6.1.1.2 Lower Hazeltine Creek

Sediments collected from lower Hazeltine Creek (HAC-D) in 2024 were composed primarily of silt and clay particles (mean = 70.9% and 15.3%, respectively), and were higher in silt content than the reference sediments (EDC-D) which were composed primarily of sand and silt (mean = 48.9% and 43.0%, respectively; Table 6.2; Appendix Tables D.2.8 and D.2.9). The particle size of sediments collected at HAC-D have shown a high degree of variability from 2018 to 2024, with mean silt concentration ranging from 21.2% to 70.9% and mean sand concentration ranging from 13.8% to 73.9% (Table 6.2). Sediments collected from HAC-D in 2024 had the highest silt content, second highest clay content, and the lowest sand content since 2018 (Table 6.2). The presence of fine sediment in these erosional creek habitats has been limited in some years which has necessitated opportunistic sampling. In addition, sediment deposition in pool areas of Hazeltine Creek is thicker than in Edney Creek, reflecting sediment accumulation (as described in Section 4.1.1). As such, the observed variability in the particle size of sediments is likely related to a combination of the required opportunistic sampling methods and the continued sediment accumulation in lower Hazeltine Creek.

The mean total nitrogen content of HAC-D sediments has been lower than in reference (EDC-D) sediments in all years except 2023, and the total nitrogen content of HAC-D sediments in 2024 (mean = 0.255%) was lower than in 2023, but higher than the range observed from 2018 to 2022 (0.0218 to 0.152%, respectively; Table 6.2; Appendix Tables D.2.8 and D.2.9). The TOC content of HAC-D sediments was significantly lower than at the reference area (EDC-D) in all years except 2023, when it was similar to reference (Appendix Table F.1.4). Temporally, the relative (exposed-reference) difference in sediment TOC content in 2024 was significantly lower than 2021 and 2023 but not significantly different than all other previous years (2018 to 2020, 2022;

Table 6.2: Summary of Sediment Quality Results for the Lower Hazeltine Creek (HAC-D [HAC-R5]; Exposed) and Lower Edney Creek (EDC-D [EDC-REF]; Reference) Monitoring Areas, 2014 to 2024

Value is > Upper BC Working Sediment Quality Guideline.

Notes: dw = dry weight. ***Bold/ Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (< 5th percentile value for pH). Reference or pre-breach 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. "SD" = standard deviation. HAC-R5 and EDC-REF are the alternate names for the HAC-D and EDC-D sampling areas, respectively, for HRWG reporting. All summary statistics were calculated to three significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] For calculation of pre-breach 95th percentile values see Appendix Table D.2.4, for calculation of reference 95th percentile values see Appendix Table D.2.5. The 5th percentile is reported for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Figure 6.2; Appendix Table F.1.5). When considered independently from reference results, the TOC content of HAC-D sediments has been stable since 2022 (Appendix Table F.1.4).

Mean analyte concentrations in the sediments (<63 µm fraction) collected from HAC-D in 2024 exceeded both pre-breach[64] and reference 95th percentile values for 23 analytes (Table 6.2). Among these analytes, arsenic, copper, iron, and selenium were the only Analytes of Interest with mean sediment concentrations that also exceeded the BCWSQG in 2024 (Figure 6.2, Table 6.2; Appendix Table D.2.9). Specifically, mean iron and selenium concentrations were 1.9- and 1.2-times the lower BCWSQG, respectively, and mean arsenic and copper concentrations were 1.6- and 1.5-times the upper BCWSQG, respectively (Figure 6.2, Table 6.2; Appendix Table D.2.9). Sediments from the reference area (EDC-D) had mean arsenic, copper, and iron concentrations that were above the lower BCWSQG in at least two monitoring years (all years for arsenic and iron; Figure 6.2; Appendix Table D.2.5), indicating that these analytes are somewhat naturally elevated in stream habitats in the vicinity of the Mount Polley Mine.

Mean Analyte of Interest concentrations in HAC-D sediments have been significantly higher than at the reference area (EDC-D) in all monitoring years (2018 to 2024) for arsenic and copper, and in most years (except 2019) for iron (Figure 6.2, Table 6.2; Appendix Table F.1.4). The relative (exposed-reference) differences of arsenic, copper, and iron concentrations in 2024 were similar to or significantly lower than all prior years (Figure 6.2; Appendix Table F.1.5). Specifically, the relative differences in sediment concentrations of these analytes have been stable since 2018 (for arsenic), 2023 (for copper), and 2021 (for iron), with iron concentrations in 2021 to 2024 significantly lower than in 2018 (Figure 6.2; Appendix Table F.1.5).

Mean selenium concentrations in HAC-D sediments were significantly higher than at the reference area (EDC-D) from 2022 to 2024. This coincided with significantly higher and temporally stable relative differences of sediment selenium concentrations in 2022 to 2024 compared to most prior years (i.e., 2018 to 2020; Figure 6.2; Appendix Tables F.1.4 and F.1.5). Mean selenium concentrations in HAC-D sediments in 2024 also exceeded the lower BCWSQG (2 mg/kg dw) for the second consecutive year (Figure 6.2; Appendix Table D.2.9). The significantly higher relative differences of sediment selenium concentrations in 2022 to 2024, compared to 2018 to 2020, coincided with higher silt content of HAC-D sediments in 2022 to 2024.

[64] TOC and analyte concentrations reported for pre-breach sediments were based predominantly on bulk sediment, but were reported for the <63 µm fraction of sediments collected post-breach. This difference in the fraction of sediment evaluated (i.e., bulk sediments for pre-breach and <63 µm fraction for post-breach) should be considered when making comparisons of TOC and analyte concentrations between the two time periods. Formal statistical temporal comparisons were conducted using data from between 2018 to 2024 which reported TOC and analyte concentrations in the <63 µm fraction of sediments (see Sections 4.1.2 and 4.1.3.2).

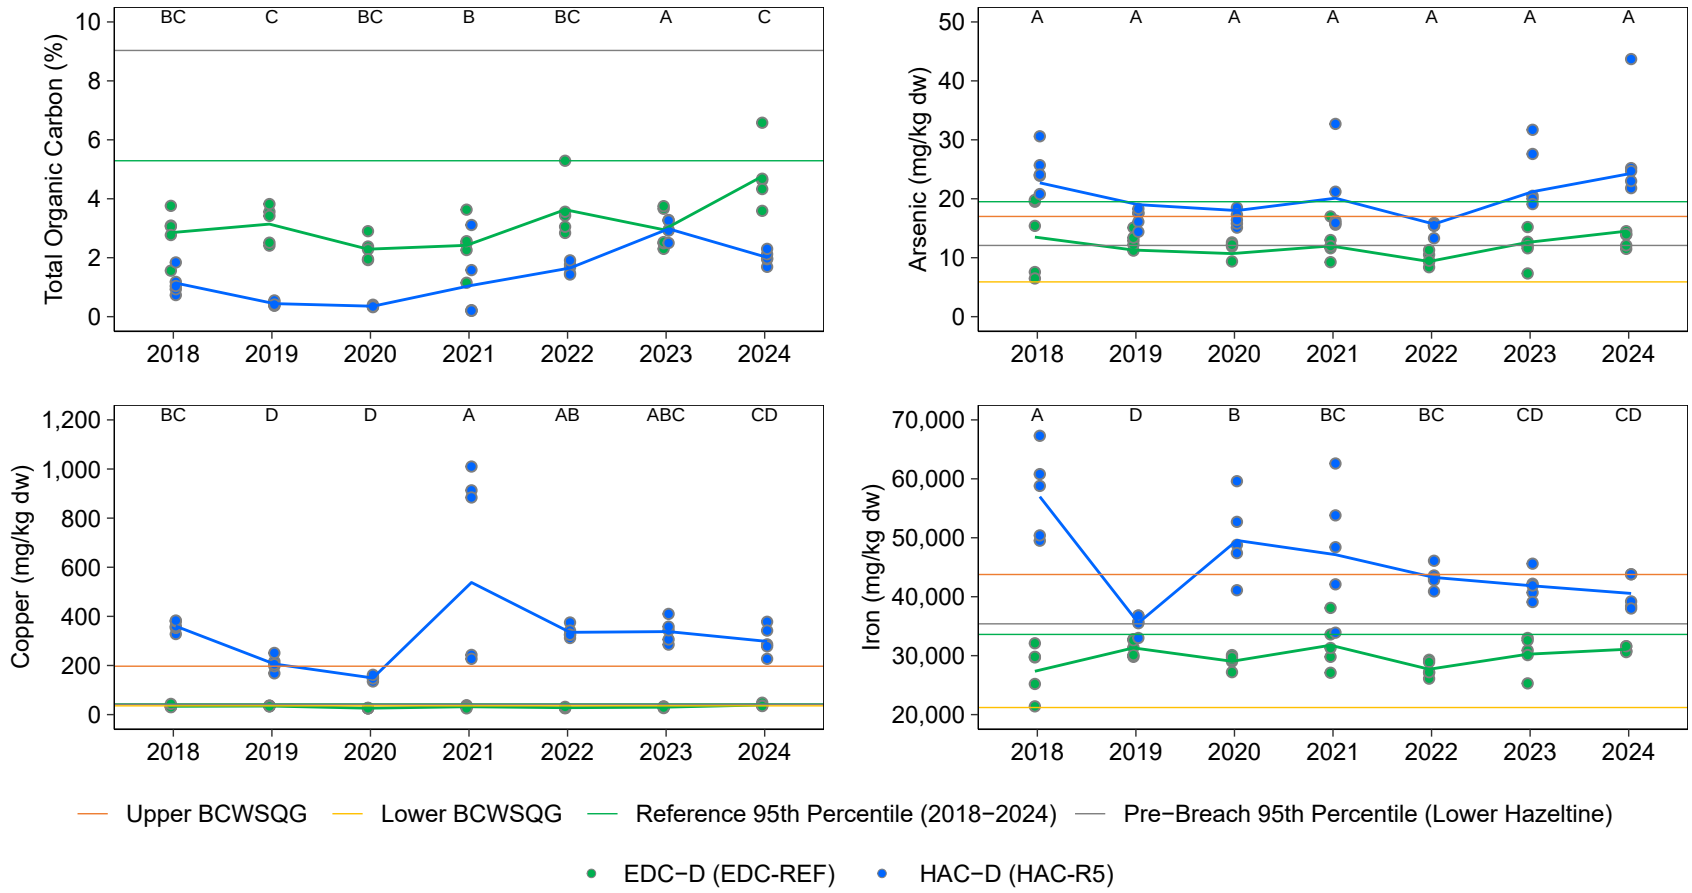

Figure 6.2: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for the Lower Hazeltine Creek (HAC−D [HAC-R5]; Exposed) and Lower Edney Creek (EDC−D [EDC-REF]; Reference) Monitoring Areas, 2018 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025). HAC-R5 and EDC-REF are the alternate names for the HAC-D and EDC-D sampling areas, respectively, for HRWG reporting. Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences − TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference).

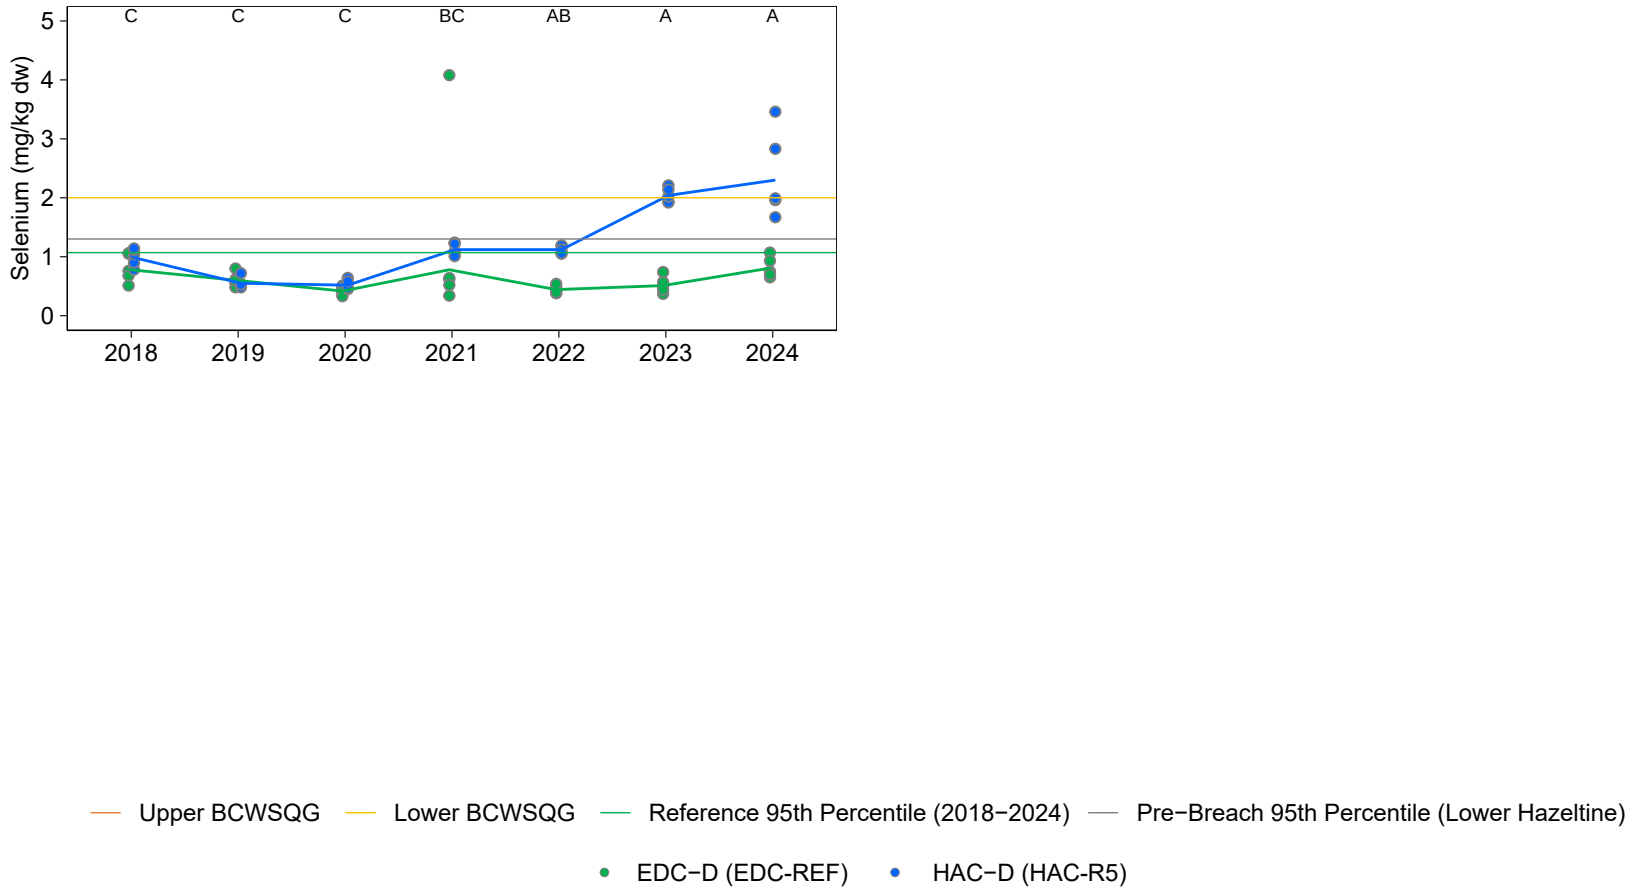

Figure 6.2: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for the Lower Hazeltine Creek (HAC−D [HAC-R5]; Exposed) and Lower Edney Creek (EDC−D [EDC-REF]; Reference) Monitoring Areas, 2018 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. BCWSQG = British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025). HAC-R5 and EDC-REF are the alternate names for the HAC-D and EDC-D sampling areas, respectively, for HRWG reporting. Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences − TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference).

As outlined in Section 6.1.1.1, the relationships between variability in sediment physical characteristics and sediment analyte concentrations were explored through correlation analysis.

Concentrations of copper, iron, manganese, and selenium in upper and lower Hazeltine Creek sediments were significantly correlated with sediment physical and chemical characteristics (Appendix Table F.1.3). In addition, arsenic sediment concentrations were negatively correlated with sediment total sulphur, TOC, and total nitrogen content, when considering Hazeltine Creek sediments only (independent of reference) or a combination of Hazeltine Creek and Edney Creek (reference) sediments. The correlation results suggested that the analyte concentrations of exposed sediments were related to the physical and chemical characteristics of these sediments, which is likely driven by a combination of opportunistic sampling methods and continued sediment accumulation in upper and lower Hazeltine Creek.

Overall, temporal increases were observed in the selenium concentrations of lower Hazeltine Creek sediments, relative to reference. Benthic invertebrate community and tissue quality monitoring both provide more directly applicable approaches for evaluating the potential effects of increased analyte concentrations to aquatic life in these erosional creek habitats, compared to sediment monitoring (see Sections 6.1.3 and 6.1.4 for benthic invertebrate community and tissue quality results for creek habitats, respectively).

6.1.2 Periphyton Community and Productivity

Periphyton community and productivity monitoring was completed annually between 2022 and 2024, with monitoring in each year including three remediated (exposed) areas of upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2] and HAC-R3 [productivity only]) with upper Edney Creek (EDC-U) serving as a reference area for both community and productivity monitoring and Frypan Creek (FPC-R3) serving as a reference area for productivity monitoring only (Figures 4.2 and 4.3, Table 4.2). [65] Prior periphyton community and productivity monitoring within the 2022 to 2024 period included monitoring completed in 2023 at one remediated (exposed) area of lower Hazeltine Creek (HAC-D [HAC-R5]) and one remediated (exposed) area of lower Edney Creek (E1), with an unimpacted area of lower Edney Creek (EDC-D [EDC-REF]) serving as a reference area for both of the exposed lower creek areas (Figure 4.2, Table 4.2). The periphyton community and productivity monitoring frequency at these

[65] For HRWG reporting, HAC-R2, HAC-R5, EDC-REF, and EDC-EXP are the alternate names used for the HAC-U, HAC-D, EDC-D, and E1 sampling areas, respectively. The original area names only (i.e., HAC-U, HAC-D, EDC-D, and E1) are used throughout the remainder of this report section (Section 6.1.2).

lower creek areas (i.e., HAC-D [HAC-R5], E1 [EDC-EXP], and EDC-D [EDC-REF) is biennial (Table 4.2; MPMC 2019).

As detailed in Section 4.2, the sole purpose of the annual periphyton productivity monitoring at areas HAC-R3 and FPC-R3 is to support the evaluation of fish habitat in upper Hazeltine Creek as part of HRWG monitoring objectives (e.g., Minnow 2025). Chlorophyll-a concentrations correspond to periphyton productivity in terms of algal biomass, and benthic algae is a food source for invertebrates (Lamberti and Resh 1983) and fish, including rainbow trout (McKinney and Speas 2001), making it a proxy for algal food availability. Periphyton AFDM represents the available biomass of autotrophic (e.g., algae) and heterotrophic (e.g., fungi, bacteria, etc.) components of periphyton assemblages (Biggs and Close 1989). Previous CEMP Sediment and Aquatic Life reports (e.g., Minnow 2024a) have presented periphyton productivity data from HAC-R3 and FPC-R3 in tabular form only, but periphyton productivity results from these two areas have been incorporated in the present report throughout all data tabulation, analyses, and interpretation with the objective of improving reporting clarity and efficiency with the HRWG report (see Section 4.2).

A review of the 2024 periphyton productivity and community results (Appendix B) indicated that the data met the established DQOs. Specifically, periphyton productivity data were characterized by appropriate detectability, negligible analyte concentrations in method blank samples, and good laboratory accuracy. Laboratory precision could not be evaluated as the productivity analyses required consumption of the entire sample. The recommended hold time (28 days) for periphyton chlorophyll-a was exceeded by one day in three samples due to a delay between sample receipt at the analytical laboratory and sample analysis; however, results were comparable to prior years when hold times were met. Periphyton community data were characterized by good subsampling accuracy and taxonomic consistency. Overall, the 2024 periphyton productivity and community data can be used with a high level of confidence in the derivation of conclusions. A review of 2024 supporting water data quality indicated that these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

6.1.2.1 Area Characteristics

During sampling in upper Hazeltine Creek and the associated reference areas (i.e., Frypan Creek and Edney Creek), an attempt was made to match sampling habitats both between the exposed and reference sampling areas and from year-to-year as closely as possible (as outlined in Section 4.2.1). However, matching habitat characteristics of Hazeltine Creek to the reference areas was difficult since the supplemental pumping of water from Polley Lake to Hazeltine Creek resulted in increased average water depth and velocity in Hazeltine Creek (see Section 4.2.1 for details). This was consistent with challenges encountered in previous monitoring years due

to the supplemental pumping (2018 to 2024) which were exacerbated in some years by extreme climate events in the Cariboo Region (i.e., severe drought from August 2023 to April 2024 and moderate drought or abnormally dry conditions from May to August 2024; Agriculture and Agri-Foods Canada 2025). As such, the variability in water depth and velocity among years and between the exposed and reference areas were considered when interpreting temporal changes, and these physical habitat variables are summarized below.

Among the upper Hazeltine Creek areas (HAC-R1, HAC-U and HAC-R3; exposed), mean water depth and velocity in 2024 (controllable by sample station selection) were largely similar (varied by <34% among areas) but these habitat characteristics were more variable among years (Table 6.3). Water depth and velocity also differed between the upper Hazeltine Creek areas and the reference areas (FPC-R3 and EDC-U) in most years (Table 6.3). In 2024, mean water depth in upper Hazeltine Creek was approximately 1.9- to 4.4-times greater than the mean water depth in the Edney Creek and Frypan Creek reference areas. The mean water velocity at HAC-R1, HAC-U, and HAC-R3 was 0.210 m/s, 0.160 m/s and 0.160 m/s, respectively, whereas there was no flow (0 m/s) at FPC-R3 and EDC-U due to local drought conditions (Table 6.3; Appendix Table A.2.3). The substrate size, which was controlled to some extent during sampling, was similar among areas in 2024 (median substrate size = 4.3 to 5.8 cm in 2024; Appendix Table A.2.5) and among years (Table 6.3).

Remediation work following the breach was completed at HAC-R1 in 2016, at HAC-U in 2017, and at HAC-R3 in 2019 (Table 4.2; see Section 4.2). The regeneration of riparian vegetation at these remediated areas is a long-term process and canopy cover over the creek channel in upper Hazeltine Creek (i.e., HAC-R1, HAC-U, HAC-R3) remained absent in 2024 despite substantial regrowth of the riparian vegetation in these areas. This was consistent with all previous sampling years in upper Hazeltine Creek (2018 to 2023; Tables 6.3) and canopy coverage in 2024 remained a key difference between the remediated areas of upper Hazeltine Creek (0% canopy coverage at all areas) and the reference areas (40% and 35% canopy coverage at FPC-R3 and EDC-U, respectively; Table 6.3; Appendix Table A.2.2).

6.1.2.2 Upper Hazeltine Creek

6.1.2.2.1 Community

In 2024, the periphyton community at both exposed areas (HAC-R1 and HAC-U) had significantly lower mean densities but similar total taxon richness, Simpson's Evenness, Simpson's Diversity and Diatom richness compared to the reference area (EDC-U; Figure 6.3, Table 6.4).

The periphyton communities of the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) in 2024 were similar to each other in terms of density, total taxon richness, Simpson's Evenness,

Table 6.3: Physical and Chemical Characteristics for Periphyton Sampling at the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]; Exposed) and Upper Edney Creek (EDC-U; Reference) Monitoring Areas, 2017 to 2024

[c] For the Frypan Creek (FPC-R3) and Edney Creek (EDC-U) reference areas, water quality results represent a single grab water sample collected within a week of biological sampling as routine water quality data is not collected at these areas. For the Hazeltine Creek (HAC-R1, HAC-U, and HAC-R3) routine water quality monitoring areas, water quality results represent the mean of results collected during the year preceding biological sampling (i.e., from September to August). See Appendix Tables D.1.3 to D.1.5 for complete results (September 2023 to August 2024) and the reports listed in Table 4.2 for results from previous years.

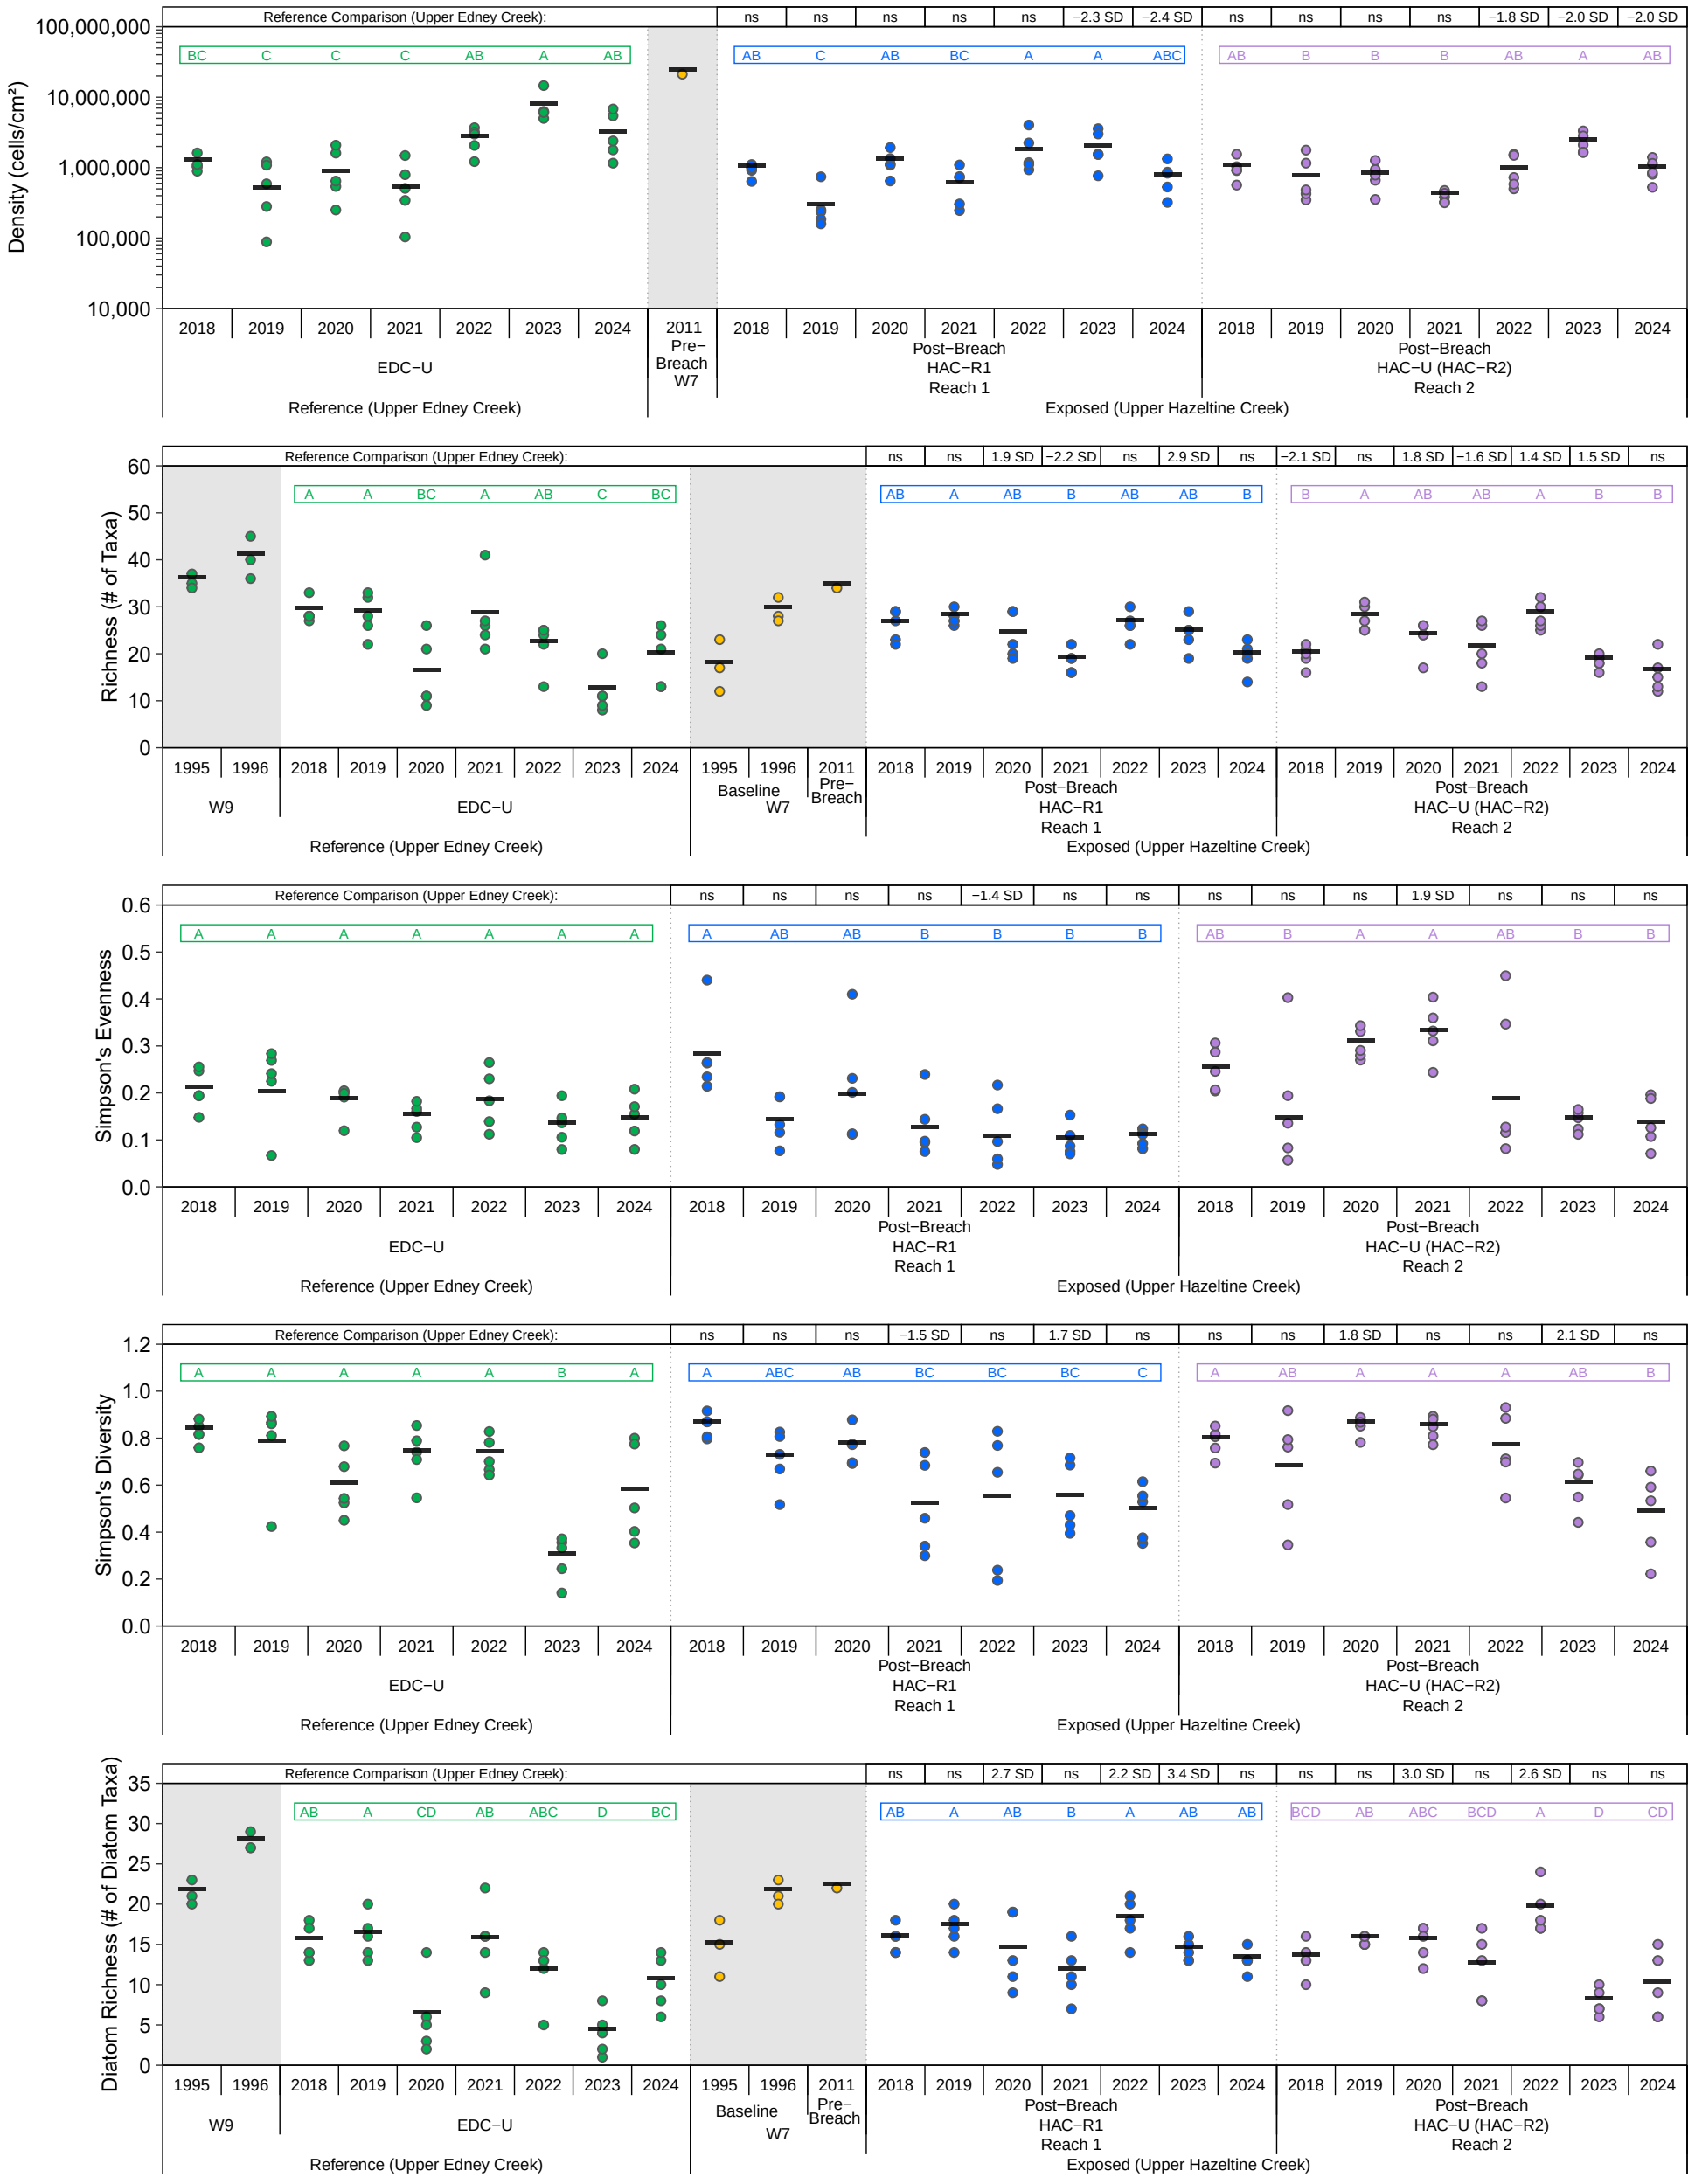

Figure 6.3: Periphyton Community Metrics for the Upper Hazeltine Creek (HAC−R1, HAC−U [HAC−R2]; Exposed) and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 1995 to 2024

Notes: The sampling area W7 is the baseline and pre−breach equivalent of the post−breach sampling areas HAC−R1 and HAC−U (2018 to 2024). HAC−R2 is the alternate name used for the HAC−U sampling area for Habitat Remediation Working Group (HRWG) reporting. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD) relative to reference. A 'ns' indicates a non−significant contrast. Grey shading indicates semi−quantitative data that were not included in statistical comparisons but are shown for visual comparison only.

Table 6.4: Statistical Comparisons of Periphyton Community Metrics for the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]; Exposed) and Upper Edney Creek (EDC-U; Reference) Monitoring Areas, 2018 to 2024

[c] HAC-R2 is the alternate name used for the HAC-U sampling area for Habitat Remediation Working Group (HRWG) reporting.

Simpson's Diversity and Diatom richness (Table 6.4). From 2018 to 2024, the periphyton communities at HAC-R1 and HAC-U have been generally similar to each other in terms of these metrics, except for higher density in 2019, lower total taxon richness in 2018 and 2023, higher Simpson's Evenness and Diversity in 2021 and 2022, and lower Diatom richness in 2023 at HAC-U compared to HAC-R1 (Figure 6.3, Table 6.4). The similarity in periphyton communities at the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) for most metrics in 2024 and in prior years, indicates that recovery of the periphyton community in these two areas has been largely similar in progression.

Periphyton densities in upper Hazeltine Creek have been significantly lower than at the reference area (EDC-U) since 2022 and 2023 at HAC-U and HAC-R1, respectively. Prior to this, densities at HAC-R1 and HAC-U were similar to the reference area (Figure 6.3, Table 6.4; Appendix Tables D.3.1 and D.3.2). The significantly lower periphyton densities at HAC-R1 (in 2023 to 2024) and HAC-U (in 2022 to 2024) compared to the reference area were due to a significant increase in the densities at the reference area (EDC-U) in 2022 to 2024 compared to 2019 to 2021, rather than a decrease in densities at the upper Hazeltine Creek areas (Figure 6.3, Table 6.4). Periphyton densities at both HAC-R1 and HAC-U in 2024 were similar to all prior years within each area. Densities at HAC-R1 have varied temporally, with the highest densities occurring in 2022 and 2023 and the lowest occurring in 2019 and 2021. Densities at HAC-U were largely temporally stable, with the only temporal change over this period being densities in 2023 that were significantly higher than those in 2019 to 2021 (Figure 6.3, Table 6.4).

Total taxon richness at both exposed areas (HAC-R1 and HAC-U) has been similar to or significantly higher than at the reference area (EDC-U) in most years, except for 2021 at HAC-R1 and 2018 and 2021 at HAC-U (Figure 6.3, Table 6.4). However, total taxon richness at each of the exposed areas has shown limited temporal variability, with total taxon richness within HAC-R1 and HAC-U in 2024 similar to all prior years (2018 to 2023) except for being significantly lower than in 2019 (HAC-R1 and HAC-U) and 2022 (HAC-U; Figure 6.3, Table 6.4; Appendix Tables D.3.3 and D.3.4). Diatom richness at both exposed areas was similar to or higher than reference in all years (2018 to 2024; Figure 6.3, Table 6.4). At HAC-R1, Diatom richness was similar in 2024 to all prior years (2018 to 2023), with the only temporal change over this period being significantly lower Diatom richness in 2021 compared to 2019 and 2022. At HAC-U, Diatom richness was stable from 2018 to 2021, increased significantly between 2021 and 2022, then decreased significantly in 2023. Diatom richness at HAC-U in 2024 was similar to most prior years except for being significantly lower than in 2019 and 2022 (Figure 6.3, Table 6.4; Appendix Tables D.3.1 and D.3.2). Despite the observed temporal variability in Diatom richness at HAC-U, Diatom richness at this area remained similar to or significantly higher than at the reference area in all years (as outlined above). Total taxon richness of the periphyton community is generally

used as a relative measure for assessment of stream health in that differences in the number of taxa are interpreted as improvement (increasing taxon richness) or degradation (decreasing taxon richness; Amblard et al. 1990). Similar to taxon richness, Diatom richness is used as a metric for determining relative stream health (Barbour et al. 1999). The similar or significantly higher total taxon richness and Diatom richness at both exposed areas compared to the reference area in most years (2018 to 2024), indicated that the periphyton communities at the exposed areas recovered to reference conditions following channel remediation works in these areas, and that periphyton community health has been sustained since then.

Temporal comparisons indicated that mean Simpson's Diversity and Evenness at both exposed areas was similar to or significantly higher than at the reference area from 2018 to 2024 except for significantly lower Simpson's Diversity and Evenness at HAC-R1 in 2021 and 2022, respectively (Figure 6.3, Table 6.4). At HAC-R1 in 2024, Simpson's Diversity was significantly lower than in 2018 to 2020, and Simpson's Evenness was significantly lower than 2018, but both endpoints were similar to all remaining prior years. At HAC-U Simpson's Diversity and Evenness in 2024 were similar to most prior years but significantly lower than 2020 and 2021 (for Diversity and Evenness) and 2022 (for Diversity only; Figure 6.3, Table 6.4). The consistently similar or higher Simpson's Diversity and Evenness at both exposed areas compared to the reference area from 2018 to 2024 (with one exception each) further indicate recovery of the periphyton communities at the exposed areas to reference conditions following remediation works, and sustained periphyton community health since then.

In 2024, periphyton communities of upper Hazeltine Creek and the reference area were dominated by Cyanobacteria (blue-green algae; Figure 6.4). The remainder of the periphyton community at HAC-R1 and HAC-U in 2024 was primarily composed of Phaeophytes (brown algae), Diatoms, and Chlorophytes (green algae; Figure 6.4). The periphyton communities at HAC-R1 and HAC-U in 2024 had significantly higher relative densities (%) of Phaeophytes than at the reference area (EDC-U; Appendix Figure F.2.1, Appendix Tables D.3.1, D.3.2, and F.2.1). Rhodophytes (red algae) were not observed at either exposed area in 2024 (and all previous monitoring years) despite being present at the reference area (EDC-U). The relative densities (%) of all remaining taxa were similar between the exposed areas and the reference area in 2024. The periphyton communities of HAC-R1 and HAC-U in 2024 were similar to each other in terms of the relative densities of all dominant taxa (Appendix Figure F.2.1, Appendix Table F.2.1).

Temporal evaluation of periphyton community composition has demonstrated that Phaeophytes (%), Diatoms (%), and Chlorophytes (%) at HAC-R1 and HAC-U have been similar to or significantly higher than EDC-U from 2018 to 2024. In contrast, the relative densities of

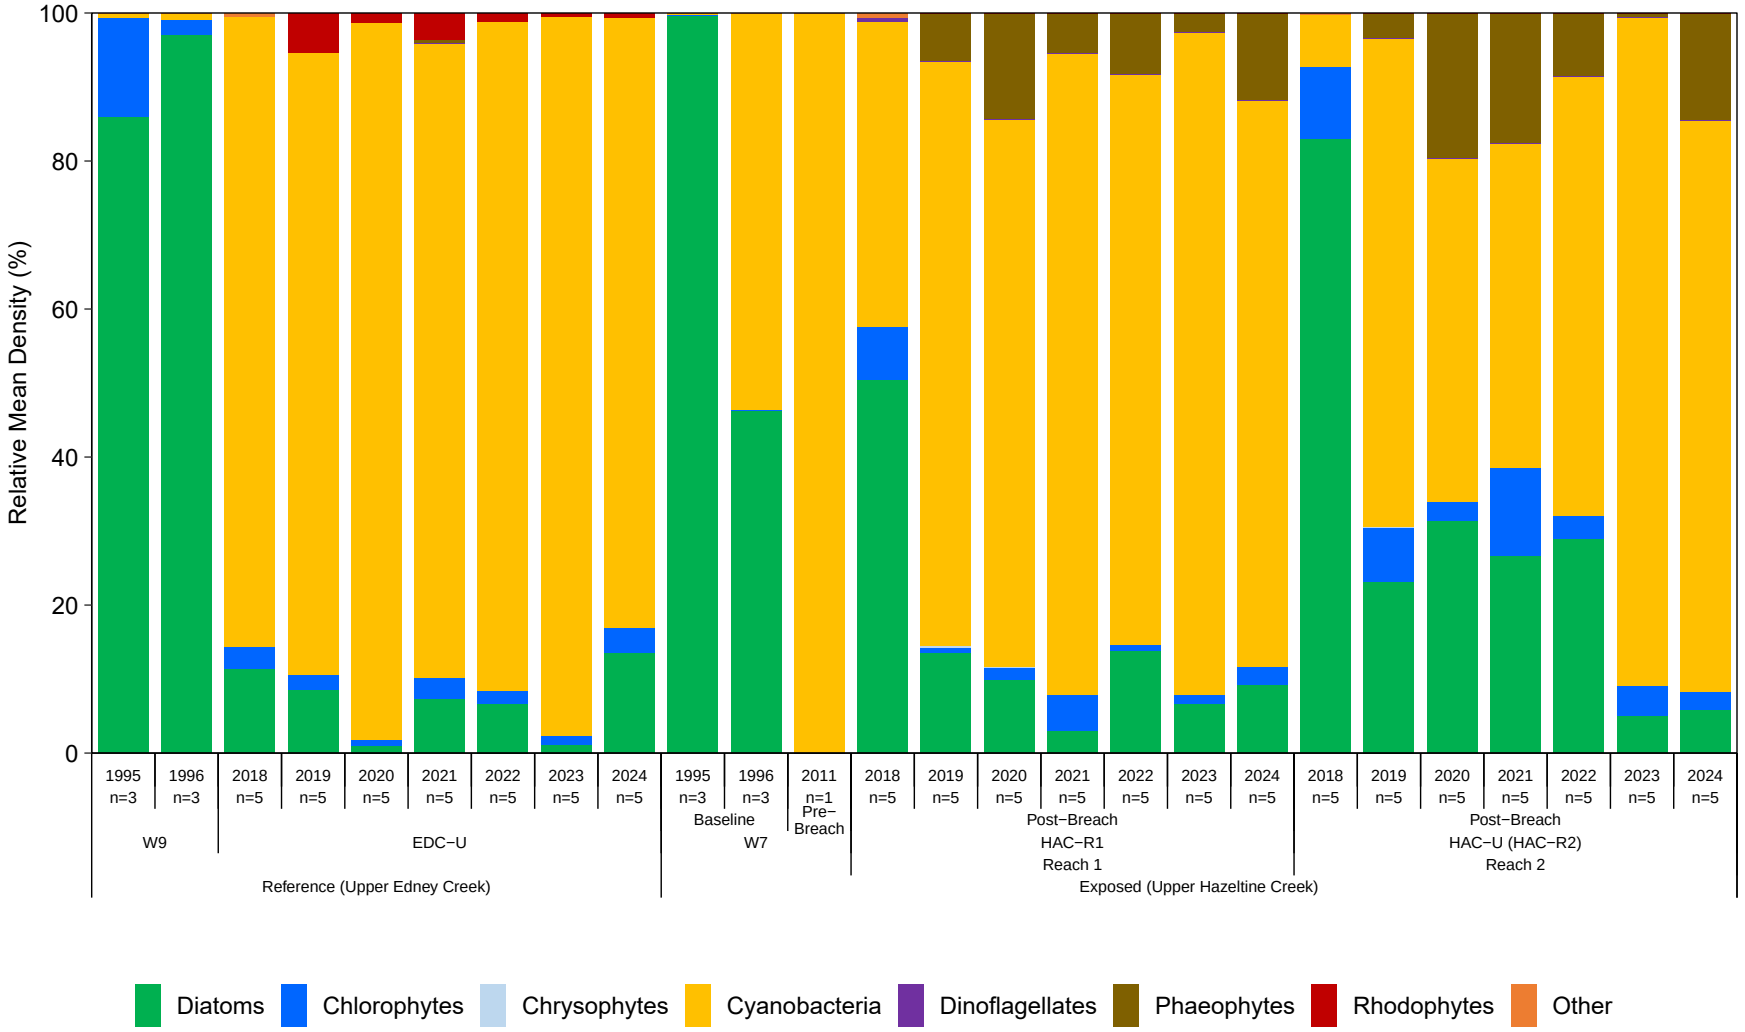

Figure 6.4: Relative Mean Densities of Major Periphyton Taxa for the Upper Hazeltine Creek (HAC−R1, HAC−U [HAC−R2]; Exposed) and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 1995 to 2024

Notes: The sampling area W7 is the baseline and pre−breach equivalent of the post−breach sampling areas HAC−R1 and HAC−U (2018 to 2024). HAC−R2 is the alternate name used for the HAC−U sampling area for Habitat Remediation Working Group (HRWG) reporting. In 2018 and earlier, Chrysophytes, Phaeophytes, and Rhodophytes are grouped into the 'Other' category. Periphyton data were classified as 'Other' taxa in laboratory results issued in 2018 but the taxonomic groups contained in this category were unknown (i.e., unknown taxonomic idenification of these organisms), but suspected to include Phaeophytes, Chrysophytes, and Rhodophytes. See Minnow 2019a for detailed laboratory results for 2018. Periphyton taxonomy results have not been reported in an 'Other' category by the laboratory since 2018. See report Section 4.2.3.1 for details.

Cyanobacteria (%) at HAC-R1 and HAC-U in most (at HAC-R1) or all (at HAC-U) years from 2018 to 2022 were significantly lower than reference, and similar to reference in 2023 to 2024 (Appendix Figure F.2.1, Appendix Table F.2.1). For the two most dominant taxa (Cyanobacteria and Diatoms), the similar or significantly lower Cyanobacteria (%) and similar or significantly higher Diatoms (%) at HAC-R1 and HAC-U for most years, relative to reference, were indicative of healthy periphyton communities (Pandey et al. 2018; Xue et al. 2019).

Within HAC-R1, Cyanobacteria (%) and Diatoms (%) in 2024 were similar to those in 2019 to 2023, and these metrics have been stable since 2022 or earlier (Appendix Figure F.2.1, Appendix Table F.2.1). At HAC-U in 2024, Cyanobacteria (%) were significantly higher than 2018 but similar to all remaining prior years, while Diatoms (%) were similar to 2019 and 2023 but significantly lower than all remaining prior years (Appendix Figure F.2.1, Appendix Table F.2.1). The decrease in the relative densities (%) of Diatoms at HAC-U in 2023 and 2024 relative to most prior years was consistent with the temporal pattern observed for Diatom richness at this area (Figure 6.3, Table 6.4). Evaluation of densities of the dominant taxa indicated that the significantly lower total density at HAC-R1 and HAC-U compared to the reference in 2024 was driven primarily by significantly lower Cyanobacteria density at both exposed areas relative to reference, and to a lesser extent by significantly lower Diatom and Rhodophyte densities compared to reference (Appendix Figures F.2.1 and F.2.2, Appendix Table F.2.1). The consistently similar or lower Cyanobacteria (%), and the similar or higher Diatoms (%) in all years, compared to reference, are indicative of relatively stable and healthy periphyton communities at the upper Hazeltine Creek areas.

Overall, the periphyton community of upper Hazeltine Creek (HAC-R1 and HAC-U) had taxon richness, Diatom richness, and Simpson's Diversity and Evenness that were similar to the reference area in 2024 and were similar to or higher than reference conditions in most years since 2018. Periphyton densities at the exposed areas have been lower than reference since 2022 and 2023 at HAC-U and HAC-R1, respectively, due to a significant increase in density at the reference area. Densities at the exposed areas have remained relatively stable since 2018, and in 2024 were similar to all prior years. In 2024, the periphyton community composition at the exposed areas (HAC-R1 and HAC-U) differed from the reference area based on Phaeophytes (%) and Rhodophytes (%) but was similar to the reference area in terms of the relative densities (%) of all other taxa. In all years, the relative densities (%) of Diatoms at the exposed areas have been similar to or higher than reference, while Cyanobacteria (%) have been similar to or lower than reference; community composition characteristics that were indicative of healthy periphyton communities. Collectively, the results indicated that except for density, the periphyton communities at the exposed areas have recovered to reference conditions following channel remediation works in these areas (or to conditions that are indicative of healthy periphyton

communities) and periphyton community health has been maintained since then. The similarity between the periphyton community between the two exposed areas indicated that recovery of the periphyton community in the two areas of upper Hazeltine Creek has been largely similar in progression.

6.1.2.2.2 Productivity

In 2024, mean periphyton chlorophyll-a concentrations (mg/m²) in upper Hazeltine Creek (HAC-R1, HAC-U and HAC-R3) and in the Frypan Creek (FPC-R3) and Edney Creek (EDC-U) reference areas were below the BCWQG of 100 mg/m² (BCMOWLRS 2025) but above the threshold indicative of moderately enriched streams at HAC-R1 and FPC-R3 (21 mg/m²; Biggs 1996; Figure 6.5; Appendix Tables D.3.1 and D.3.2). Periphyton chlorophyll-a concentrations in upper Hazeltine Creek areas in 2024 were similar to both reference areas with two exceptions: HAC-R1 had significantly higher results than EDC-U, and HAC-R3 had significantly lower results than FPC-R3 (Figure 6.5; Appendix Table F.2.2). The higher chlorophyll-a at HAC-R1 in 2024 compared to the Edney Creek reference area (EDC-U) may be related, at least in part, to elevated water temperatures and increased exposure to sunlight due to the lack of canopy cover in upper Hazeltine Creek (Table 6.3; Schnurr and Allen 2015).

In 2024, HAC-R1 had significantly higher chlorophyll-a concentrations than both downstream areas (HAC-U and HAC-R3). This was consistent with results observed since 2020, except for in 2021 and 2023 when HAC-U had chlorophyll-a concentrations that were similar to HAC-R1. Similarly, HAC-U has also consistently had higher chlorophyll-a concentrations than the downstream area (HAC-R3) since 2020, except for 2024 (Figure 6.5; Appendix Table F.2.2). The decreasing periphyton chlorophyll-a concentrations with increasing distance downstream in upper Hazeltine Creek is likely primarily influenced by the different completion dates for the remediation works in these areas (i.e., 2016, 2017, and 2019 at HAC-R1, HAC-U, and HAC-R3, respectively; Table 4.2), but may also be influenced by proximity to Polley Lake. Additionally, HAC-R3 has a higher proportion of riffle habitat (i.e., a higher proportion of habitat with higher water velocity; Minnow 2022b) than HAC-R1 and HAC-R2; therefore, habitat differences among the areas may also have influenced the chlorophyll-a concentrations (due to differences in water temperature, depth, and velocity).

From 2019 to 2024, chlorophyll-a concentrations at HAC-R1 were significantly higher than EDC-U, except in 2022 when the concentrations similar between the two areas. In contrast chlorophyll-a concentrations at HAC-R1 were similar to FPC-R3 in all years (i.e., 2017 to 2024), except 2020, when the results at HAC-R1 were significantly higher (Figure 6.5; Appendix Table F.2.2). At HAC-U, chlorophyll-a concentrations were similar to both reference areas from 2018 to 2024, except for being significantly higher than EDC-U in 2021

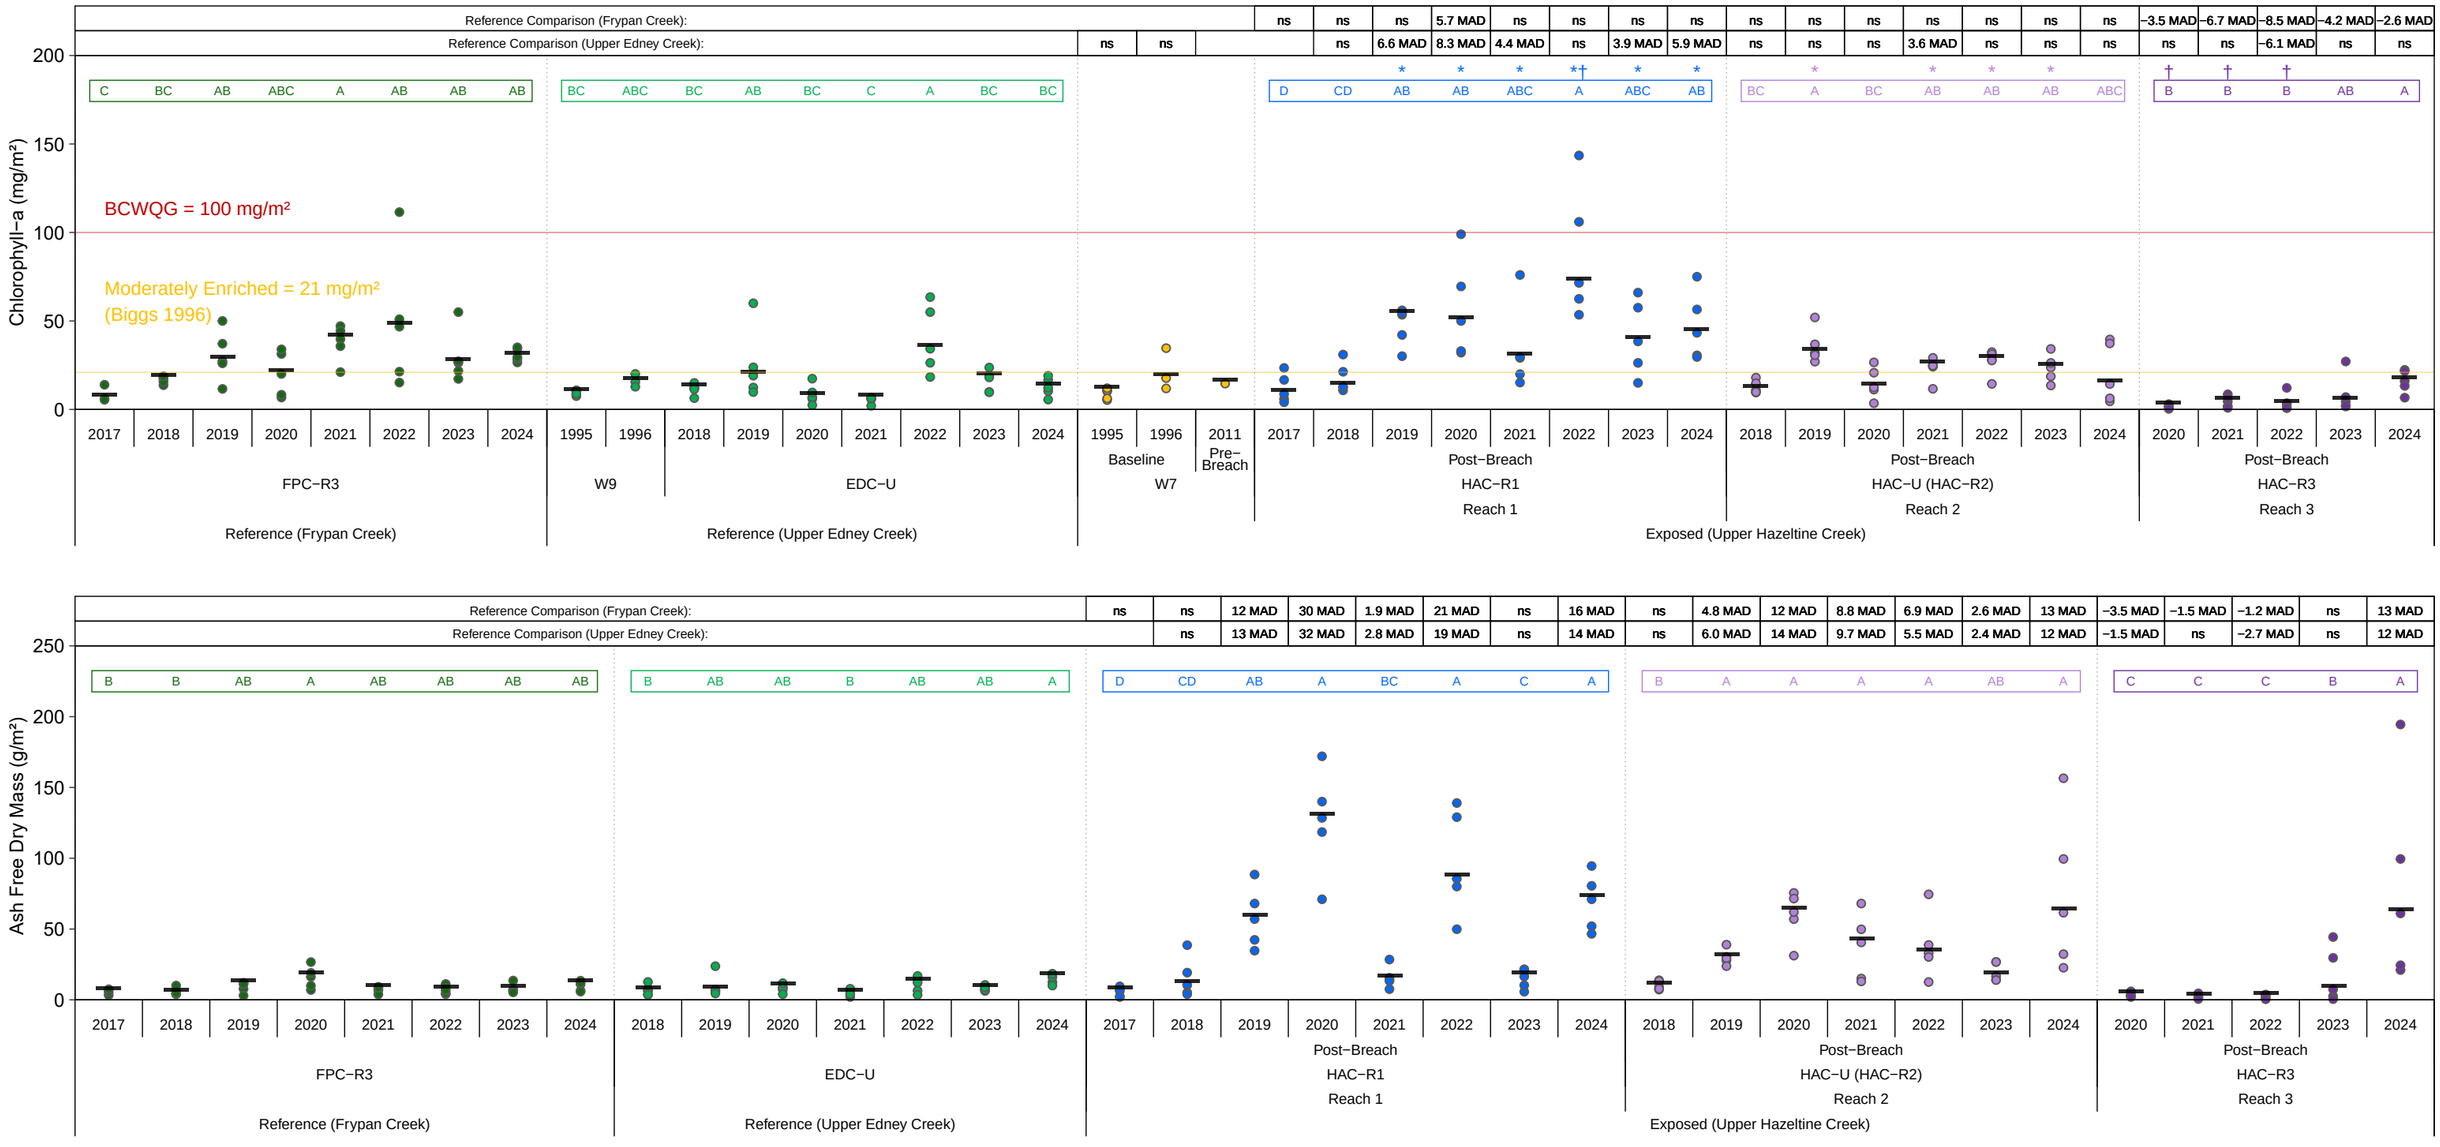

Figure 6.5: Periphyton Productivity Metrics for the Upper Hazeltine Creek (HAC−R1, HAC−U [HAC−R2], HAC−R3; Exposed), Frypan Creek (FPC−R3; Reference), and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 1995 to 2024

Notes: The sampling area W7 is the baseline and pre−breach equivalent of the post−breach sampling areas HAC−R1, HAC−U, and HAC−R3 (2017 to 2024). HAC−R2 is the alternate name used for the HAC−U sampling area for Habitat Remediation Working Group (HRWG) reporting. Coloured letters represent significant (p−value <0.1) post hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. For statistical contrasts of chlorophyll−a in post−breach years compared to baseline and pre−breach years, an * indicates significant differences to W7 in 1995, a † indicates significant differences to W7 in 1996, and a ‡ indicates significant differences to W7 in 2011. A number above the plot indicates significant exposed vs. reference post hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank-transformed prior to analysis) relative to reference. A 'nc' indicates no comparisons were possible, a 'ns' indicates a non−significant contrast.

(when chlorophyll-a concentrations at EDC-U were lowest). Chlorophyll-a concentrations at HAC-R3 were significantly lower than FPC-R3 from 2020 to 2024 and lower than EDC-U in 2022 but were otherwise similar to both reference areas in all other monitoring years (Figure 6.5; Appendix Table F.2.2). Periphyton chlorophyll-a concentrations in upper Hazeltine Creek (particularly at HAC-R1) have generally followed similar relative temporal patterns as the reference areas (Figure 6.5), suggesting that temporal changes may be related to natural variability in physical and chemical factors (e.g., light exposure, water temperature, nutrient availability). Chlorophyll-a concentrations at all three areas in upper Hazeltine Creek (i.e., HAC-R1, HAC-U, and HAC-R3) in 2024 were similar to baseline (1995 and 1996) and pre-breach (2011) results, except for results at HAC-R1 in 2024, which was significantly higher than in 1995 (Figure 6.5; Appendix Table F.2.2). This indicated that periphyton productivity (in terms of chlorophyll-a concentrations) in upper Hazeltine Creek has recovered to conditions similar to, but generally not higher than, pre-breach conditions.

Periphyton productivity measured as AFDM in 2024 in each of the three upper Hazeltine Creek areas was significantly higher than both reference areas (FPC-R3 and EDC-U), which was dissimilar to the chlorophyll-a results (except HAC-R1 compared to EDC-U; Figure 6.5; Appendix Tables D.3.1, D.3.2, and F.2.2). Mean AFDM at HAC-R1 has been similar to or significantly higher than both reference areas in all years (2018 to 2024), while AFDM at HAC-U has been consistently higher than both reference areas since 2018. At HAC-R3, AFDM was similar to or significantly lower than both reference areas until 2024 (when AFDM at HAC-R3 was significantly higher than reference; Figure 6.5; Appendix Table F.2.2).

In 2024, AFDM at HAC-R1 was similar to 2019 to 2020 and 2022 but overall has shown temporal variability since 2017, while AFDM at HAC-U has been temporally stable from 2019 onward. At HAC-R3, AFDM significantly increased year-over-year in 2023 and 2024 after remaining unchanged from 2020 to 2022 (Figure 6.5; Appendix Table F.2.2). The significantly higher periphyton AFDM in upper Hazeltine Creek, compared to reference, in most years may be related to the elevated water temperature and increased exposure to sunlight from lack of canopy cover in these exposed areas (Table 6.3; Schnurr and Allen 2015). In 2024, periphyton AFDM within upper Hazeltine Creek (i.e., HAC-R1, HAC-U and HAC-R3) was similar among areas, which differed from the periphyton chlorophyll-a results for these areas that showed a spatial gradient (i.e., chlorophyll-a concentrations decreased significantly with increasing distance downstream; Appendix Table F.2.2).

In situ measures of dissolved oxygen recorded in upper Hazeltine Creek in 2024 during periphyton sampling were consistently higher than the acute and chronic BCWQG (Appendix Tables D.1.2 to D.1.5) indicating no potential adverse effects to aquatic life from dissolved oxygen depletion

related to periphyton growth at these exposed areas. *In situ* dissolved oxygen concentrations were below the chronic BCWQG at the Edney Creek reference area (EDC-U), which was likely related to the absence of flow at this area (Table 6.3; Appendix Table A.2.3). Metrics of periphyton biomass (i.e., AFDM) in upper Hazeltine Creek were either similar to or higher than at the reference areas (Frypan Creek and Edney Creek), indicating that the availability of nutrition for grazers (benthic invertebrates and fish) was higher in these exposed areas when compared reference conditions. No baseline or pre-breach results exist for AFDM in Hazeltine Creek (Figure 6.5; Appendix Table F.2.2).

Overall, monitoring indicated that periphyton chlorophyll-a concentrations in the remediated (exposed) areas upper Hazeltine Creek in 2024 were similar to reference and baseline/pre-breach conditions with few exceptions and remained well below the BCWQG. Periphyton chlorophyll-a concentrations in upper Hazeltine Creek decreased with increasing distance downstream and this spatial gradient was likely primarily related to the amount of time since completion of remediation in these areas. Periphyton productivity as measured by AFDM in 2024 was higher in upper Hazeltine Creek than reference conditions, which was the first time this occurred at HAC-R3. The greater periphyton productivity in upper Hazeltine Creek (as measured by AFDM and chlorophyll-a at HAC-R1 and AFDM at HAC-U) in most years from 2018 to 2024, relative to one or both references, was likely related in part to greater exposure to sunlight due to the absence of canopy cover at these exposed areas. The lack of cover in the exposed areas also drives higher water temperatures, which although mitigated to some extent by supplemental pumping from below the thermocline in Polley Lake (see Section 6.1.2), could contribute to higher productivity. Overall, periphyton productivity in upper Hazeltine Creek increased following remediation efforts and has largely remained greater than or similar to the reference area and baseline/pre-breach productivity levels. *In situ* measures of dissolved oxygen in upper Hazeltine Creek in 2024 were consistently higher than BCWQG indicating no potential adverse effects to aquatic life from dissolved oxygen depletion related to periphyton growth.

6.1.2.3 Lower Hazeltine Creek

Periphyton community and productivity monitoring was conducted at a remediated (exposed) area of lower Hazeltine Creek (HAC-D) in 2023, with an unimpacted area of lower Edney Creek (EDC-D) serving as reference (Minnow 2024a). The results of this monitoring are summarized briefly herein with detailed methods and results presented in Minnow (2024a).

6.1.2.3.1 Community

In 2023, the periphyton community at the exposed area in lower Hazeltine Creek (HAC-D) had significantly higher density, and similar total taxon richness, Diatom richness, and Simpson's

Diversity and Evenness compared to the reference area in lower Edney Creek (EDC-D). Density was higher than in previous years at both the exposed and reference areas. Total taxon and Diatom richness at the exposed area also increased in 2023 compared to 2021, increasing from significantly lower than reference in 2021 to similar to reference in 2023 for both endpoints. Simpson's Evenness and Diversity remained similar compared to reference over sampling years (2019, 2021, and 2023). Overall, the similarity or improvement over time of the periphyton community metrics, relative to the reference area, indicated recovery of the lower Hazeltine Creek periphyton community following completion of final remediation works in the lower Hazeltine Creek area in 2021.

The community composition (%) of lower Hazeltine Creek was dominated by Cyanobacteria, with smaller contributions of Diatoms, Chlorophytes and Phaeophytes, and had lower relative densities (%) of Diatoms and Chlorophytes but higher relative densities (%) of Cyanobacteria than at the reference area. Chlorophytes have been consistently lower in lower Hazeltine Creek compared to the reference are, but Diatoms and Cyanobacteria have displayed temporal variation likely related to natural variation in physical and chemical factors (e.g., light exposure, water temperature and flow, nutrient availability).

Increased density, total taxon richness, and Diatom richness between 2021 and 2023 in lower Hazeltine Creek, and the similarity in taxon richness, Diatom richness, and Simpson's Diversity and Evenness compared to the reference area in 2023, indicated substantial recovery of the periphyton community following the remediation works in lower Hazeltine Creek in 2021. Remaining differences in community composition at HAC-D compared to reference (i.e., higher Cyanobacteria [%] and lower Diatoms and Chlorophytes [%]) suggested that complete recovery of community composition was ongoing.

6.1.2.3.2 Productivity

Mean periphyton chlorophyll-a concentrations (mg/m²) in lower Hazeltine Creek in 2023 were well below the BCWQG of 100 mg/m² (BCMOWLRS 2025) and below the threshold indicative of moderately enriched streams (21 mg/m²; Biggs 1996). Periphyton productivity (both chlorophyll-a and AFDM) in lower Hazeltine Creek was higher in 2023 relative to 2017. Chlorophyll-a concentrations at HAC-D in 2023 remained lower than reference conditions but were more similar to the reference area than in prior years (although not significantly so). The AFDM at HAC-D increased between 2021 and 2023 and was similar to reference in both years. The greater similarity of lower Hazeltine chlorophyll-a concentrations to reference in 2023 (although not significant), along with AFDM at HAC-D in 2023 that was similar to reference, were evidence of ongoing periphyton productivity recovery in lower Hazeltine Creek (i.e., becoming more similar to reference) following remediation works in 2021.

6.1.3 Benthic Invertebrate Community and Productivity

Benthic invertebrate community and productivity monitoring was completed annually between 2022 and 2024, with monitoring in each year including three remediated (exposed) areas of upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], HAC-R3) with areas of Frypan Creek (FPC-R3) and upper Edney Creek (EDC-U)[66] serving as reference (Figures 4.2 and 4.3, Table 4.3).[67] Prior benthic invertebrate community and productivity monitoring within the 2022 to 2024 period included monitoring completed in 2023 at one remediated (exposed) area of lower Hazeltine Creek (HAC-D [HAC-R5]) and one remediated (exposed) area of lower Edney Creek (E1 [EDC-EXP]), with an unimpacted area of lower Edney Creek (EDC-D [EDC-REF]) serving as a reference area for both of the exposed lower creek areas (Figure 4.2, Table 4.3). The benthic invertebrate community and productivity monitoring frequency at these lower creek areas (i.e., HAC-D [HAC-R5], E1 [EDC-EXP], and EDC-D [EDC-REF) is biennial (Table 4.3; MPMC 2019).

As detailed in Section 4.3, the sole purpose of the annual benthic invertebrate community and productivity monitoring at areas HAC-R3 and FPC-R3 is to support the evaluation of fish habitat in upper Hazeltine Creek as part of HRWG monitoring objectives (e.g., Minnow 2025). Previous CEMP Sediment and Aquatic Life reports (e.g., Minnow 2024a) have presented benthic invertebrate community and productivity data from HAC-R3 and FPC-R3 in tabular form only, but the benthic invertebrate community and productivity results from these two areas have been incorporated in the present report throughout all data tabulation, analyses, and interpretation with the objective of improving reporting clarity and efficiency with the HRWG report (see Section 4.3).

A review of the 2024 benthic invertebrate community results (Appendix B) indicated these data were of acceptable quality and can be used with a high degree of confidence (see Section 5.1.5 for details). A review of 2024 supporting water quality results indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

6.1.3.1 Area Characteristics

During sampling in upper Hazeltine Creek and the associated reference areas (i.e., Frypan Creek and Edney Creek), an attempt was made to match sampling habitats both between the paired exposed and reference sampling areas and year-to-year as closely as possible (as outlined in Section 4.2.1). The similarities and differences in habitat between the paired exposed and

[66] Upper Edney Creek (EDC-U; reference) was not sampled in 2020 due to habitat differences relative to upper Hazeltine Creek (Minnow 2021a). As such, temporal data comparisons to reference results exclude 2020.

[67] For HRWG reporting, HAC-R2, HAC-R5, EDC-EXP, and EDC-REF are the alternate names used for the HAC-U, HAC-D, E1, and EDC-D sampling areas. The original area names only (i.e., HAC-U, HAC-D, E1, and EDC-D) are used throughout the remainder of this report section (Section 6.1.3).

reference areas in 2024 and among years are detailed in Section 6.1.2.1 (Table 6.5; Appendix Tables A.2.2 to A.2.5), with canopy coverage in 2024 remaining a key difference between the remediated areas of Hazeltine Creek (0% canopy coverage at all areas) and the reference areas (40% and 35% canopy coverage at FPC-R3 and EDC-U, respectively; Table 6.5; Appendix Table A.2.2).

Evaluation of water quality collected routinely in upper Hazeltine Creek (at HAC-13, HAC-05a, and HAC-14; Figure 4.2) indicated that analyte concentrations were below the chronic BCWQGs except for dissolved copper and total selenium (Appendix Figures D.1.1 to D.1.3, Appendix Tables D.1.3 and D.1.5) in the year preceding sampling (i.e., September 2023 to August 2024). Dissolved copper concentrations at HAC-13 (near HAC-R1), HAC-05a (near HAC-U), and HAC-14 (near HAC-R3) exceeded the chronic BCWQG in 92%, 75%, and 100% of samples, respectively, with 8.3% of samples at HAC-13 that also exceeded the acute BCWQG. Total selenium concentrations at HAC-13, HAC-05a, and HAC-14 exceeded the chronic BCWQG in 8.3%, 33%, and 15% of samples, respectively (Appendix Figures D.1.1 to D.1.3, Appendix Tables D.1.3 and D.1.5). Temporal analysis of routine water quality data from HAC-13, HAC-05a, and HAC-14 from 2015 to 2024 indicated that concentrations of total vanadium at HAC-13 and dissolved vanadium at all three stations (HAC-13, HAC-05a, and HAC-14) have increased since 2015, and all remaining analyte concentrations were either unchanged or decreased significantly over this period (Appendix Figures D.1.1 to D.1.3, Appendix Table D.1.9). Water quality is not routinely monitored at the Frypan Creek (FPC-R3) nor the upper Edney Creek (EDC-U) reference areas, but the spot (single) water quality samples collected with biological monitoring (in August 2024) demonstrated analyte concentrations that were below the BCWQG (Appendix Table D.1.2). *In situ* dissolved oxygen measured at EDC-U (3.77 mg/L) was below the chronic BCWQG (Appendix Table D.1.2), which was likely related to the absence of water flow at this area (Table 6.5; Appendix A.2.3).

6.1.3.2 Upper Hazeltine Creek

6.1.3.2.1 Community

The benthic invertebrate communities at exposed areas of upper Hazeltine Creek (HAC-R1, HAC-U, HAC-R3) in 2024 were similar to both reference areas (FPC-R3 and EDC-U) in terms of density, taxon richness, and Simpson's Evenness and Diversity, with one exception. The exception was that Simpson's Evenness and Diversity at HAC-R1 were significantly higher than FPC-R3 (but similar to EDC-U; Figure 6.6, Table 6.6; Appendix Tables D.4.1 and D.4.2). Density and taxon richness at the upper Hazeltine Creek areas in 2024 were significantly lower compared to pre-breach conditions except for density at HAC-U in 2024 (similar to pre-breach). Conversely, Simpson's Evenness and Diversity at the upper Hazeltine Creek areas in 2024 were

Table 6.5: Physical and Chemical Characteristics for Benthic Invertebrate Community Sampling at the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], HAC-R3; Exposed), Frypan Creek (FPC-R3; Reference), and Upper Edney Creek (EDC-U; Reference) Monitoring Areas, 2018 to 2024

HAC-R2 is the alternate name for the HAC-U sampling area for HRWG reporting. The EDC-U reference area was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC-R1 and HAC-U (HAC-R2). See Section 4.3 for details.

[a] The displayed median substrate size represents the median (50^{th} percentile) of 100 pebble measures recorded for each sampling area. See Appendix Table A.2.5 for pebble count data.

[b] Canopy cover includes dense and partially open cover.

[c] For the Frypan Creek (FPC-R3) and Edney Creek (EDC-U) reference areas, water quality results represent a single grab water sample collected within a week of biological sampling as routine water quality data is not collected at these areas. For the Hazeltine Creek (HAC-R1, HAC-U, and HAC-R3) routine water quality monitoring areas, water quality results represent the mean of results collected during the year preceding biological sampling (i.e., from September to August). See Appendix Tables D.1.3 to D.1.5 for complete results (September 2023 to August 2024) and the reports listed in Table 4.2 for results from previous years.

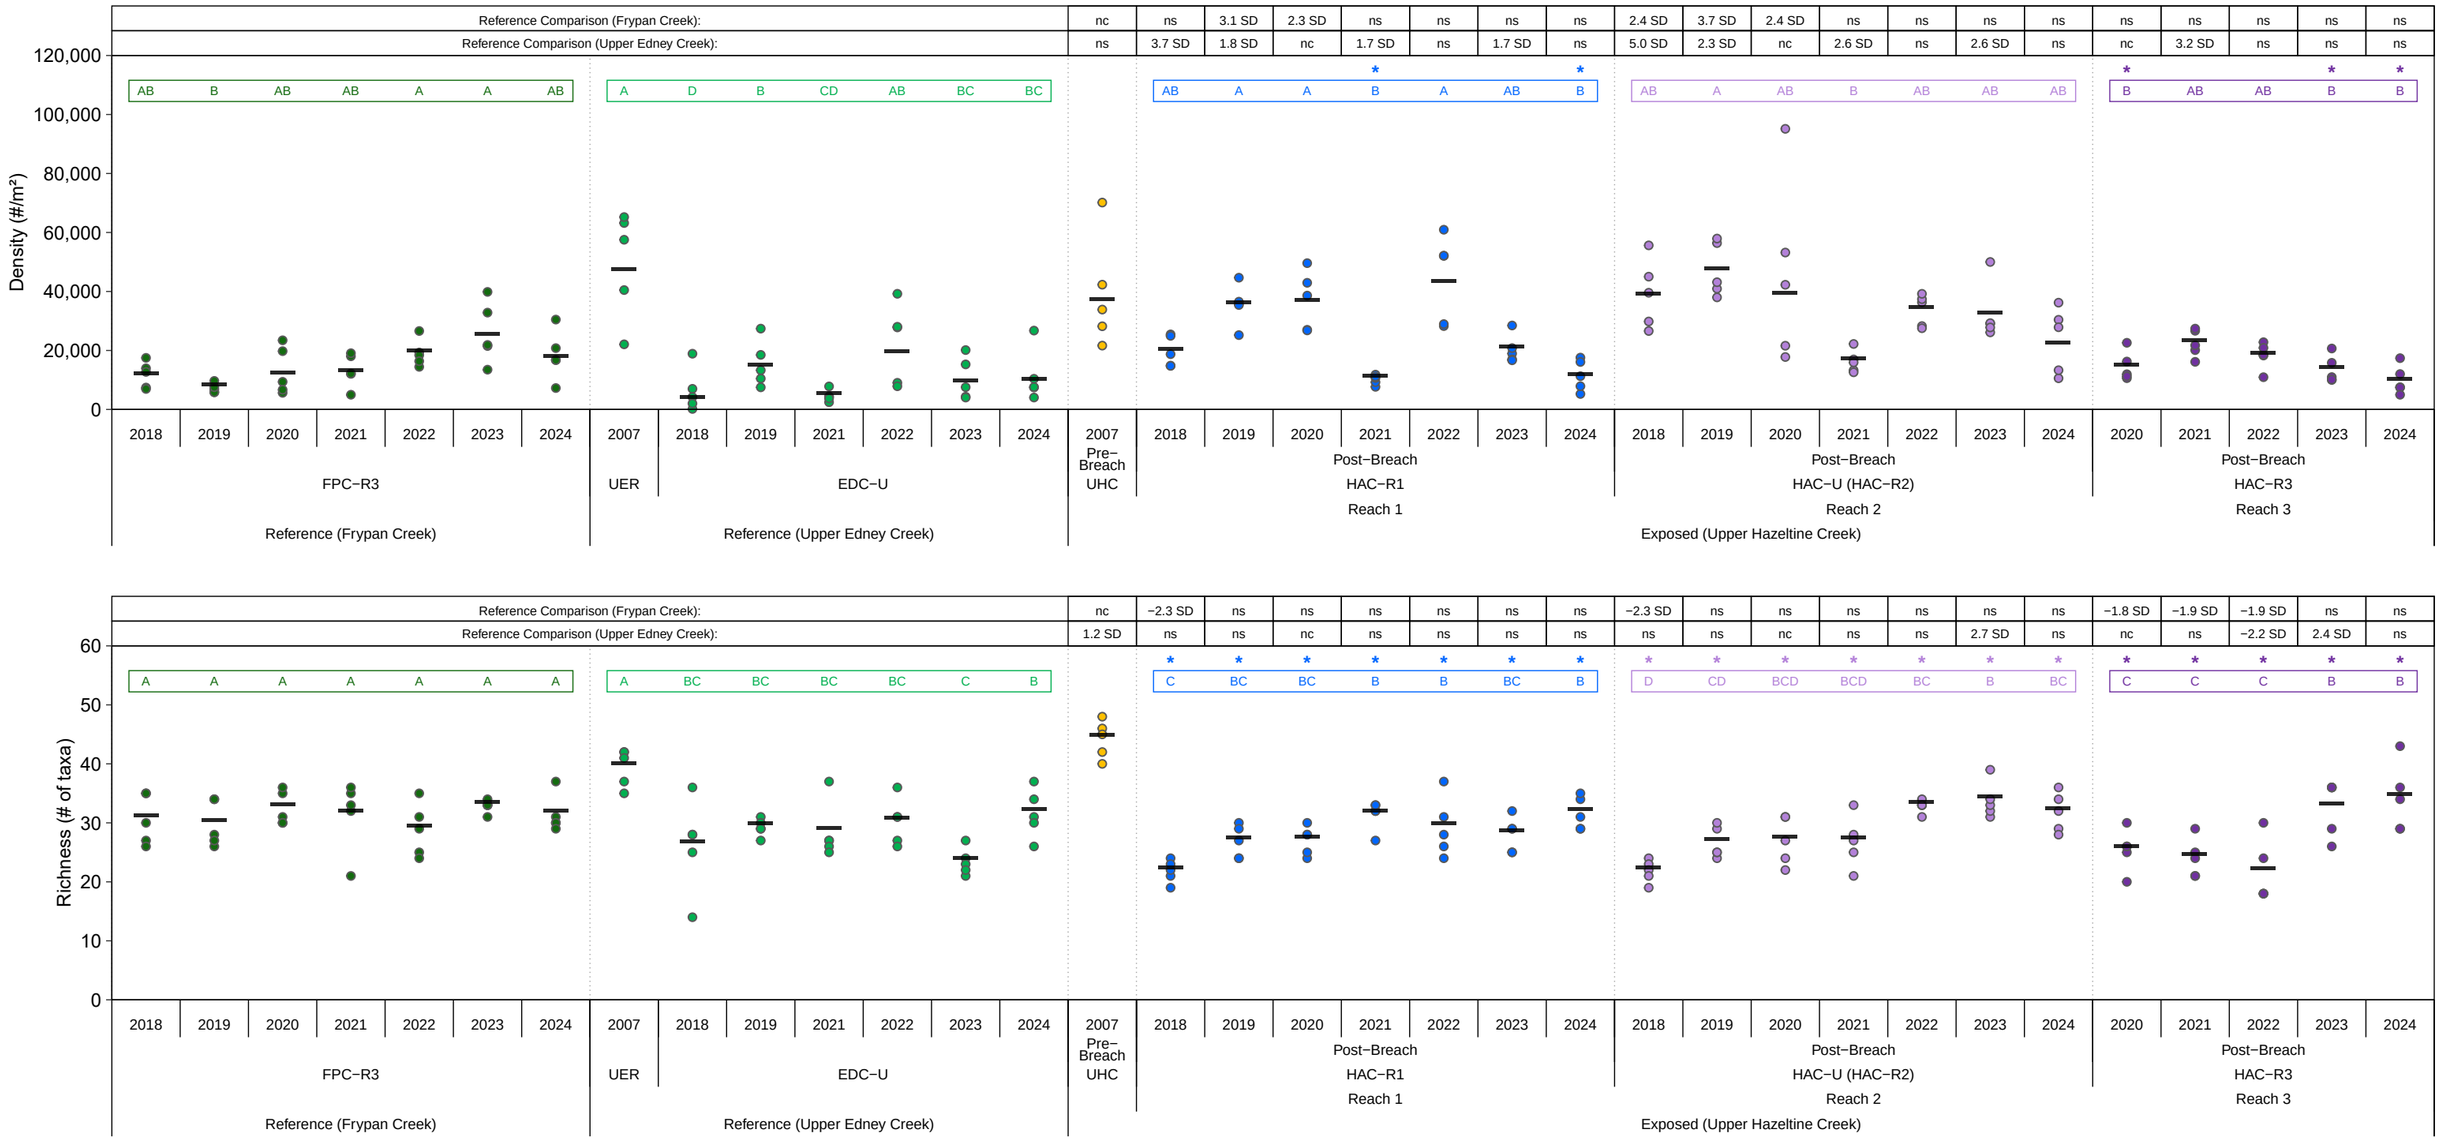

Figure 6.6: Benthic Invertebrate Community Metrics for the Upper Hazeltine Creek (HAC−R1, HAC−U [HAC−R2], HAC−R3; Exposed), Frypan Creek (FPC−R3; Reference), and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 2007 to 2024

Notes: #/m² = number per square metre. The EDC−U reference area was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC−R1, HAC−U (HAC−R2), and HAC−R3. Monitoring at area HAC−R3 was initiated in 2020. See Section 4.3 for details. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. Data from 2007 were used in the analyses to compare post−breach (2018 to 2024) to pre-breach conditions (2007). Post−breach data from HAC−R1, HAC−U (HAC−R2), and HAC−R3 were compared to pre−breach data from upper Hazeltine Creek (UHC), and post−breach data from EDC−U was compared to pre−breach data from upper Edney Creek (UER). An * indicates a significant difference between HAC−R1, HAC−U (HAC−R2), or HAC−R3 and UHC in 2007. HAC−R2 is the alternate name used for the HAC−U sampling area for Habitat Remediation Working Group (HRWG) reporting. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference.
A 'nc' indicates no comparisons were possible, and a 'ns' indicates a non−significant contrast.

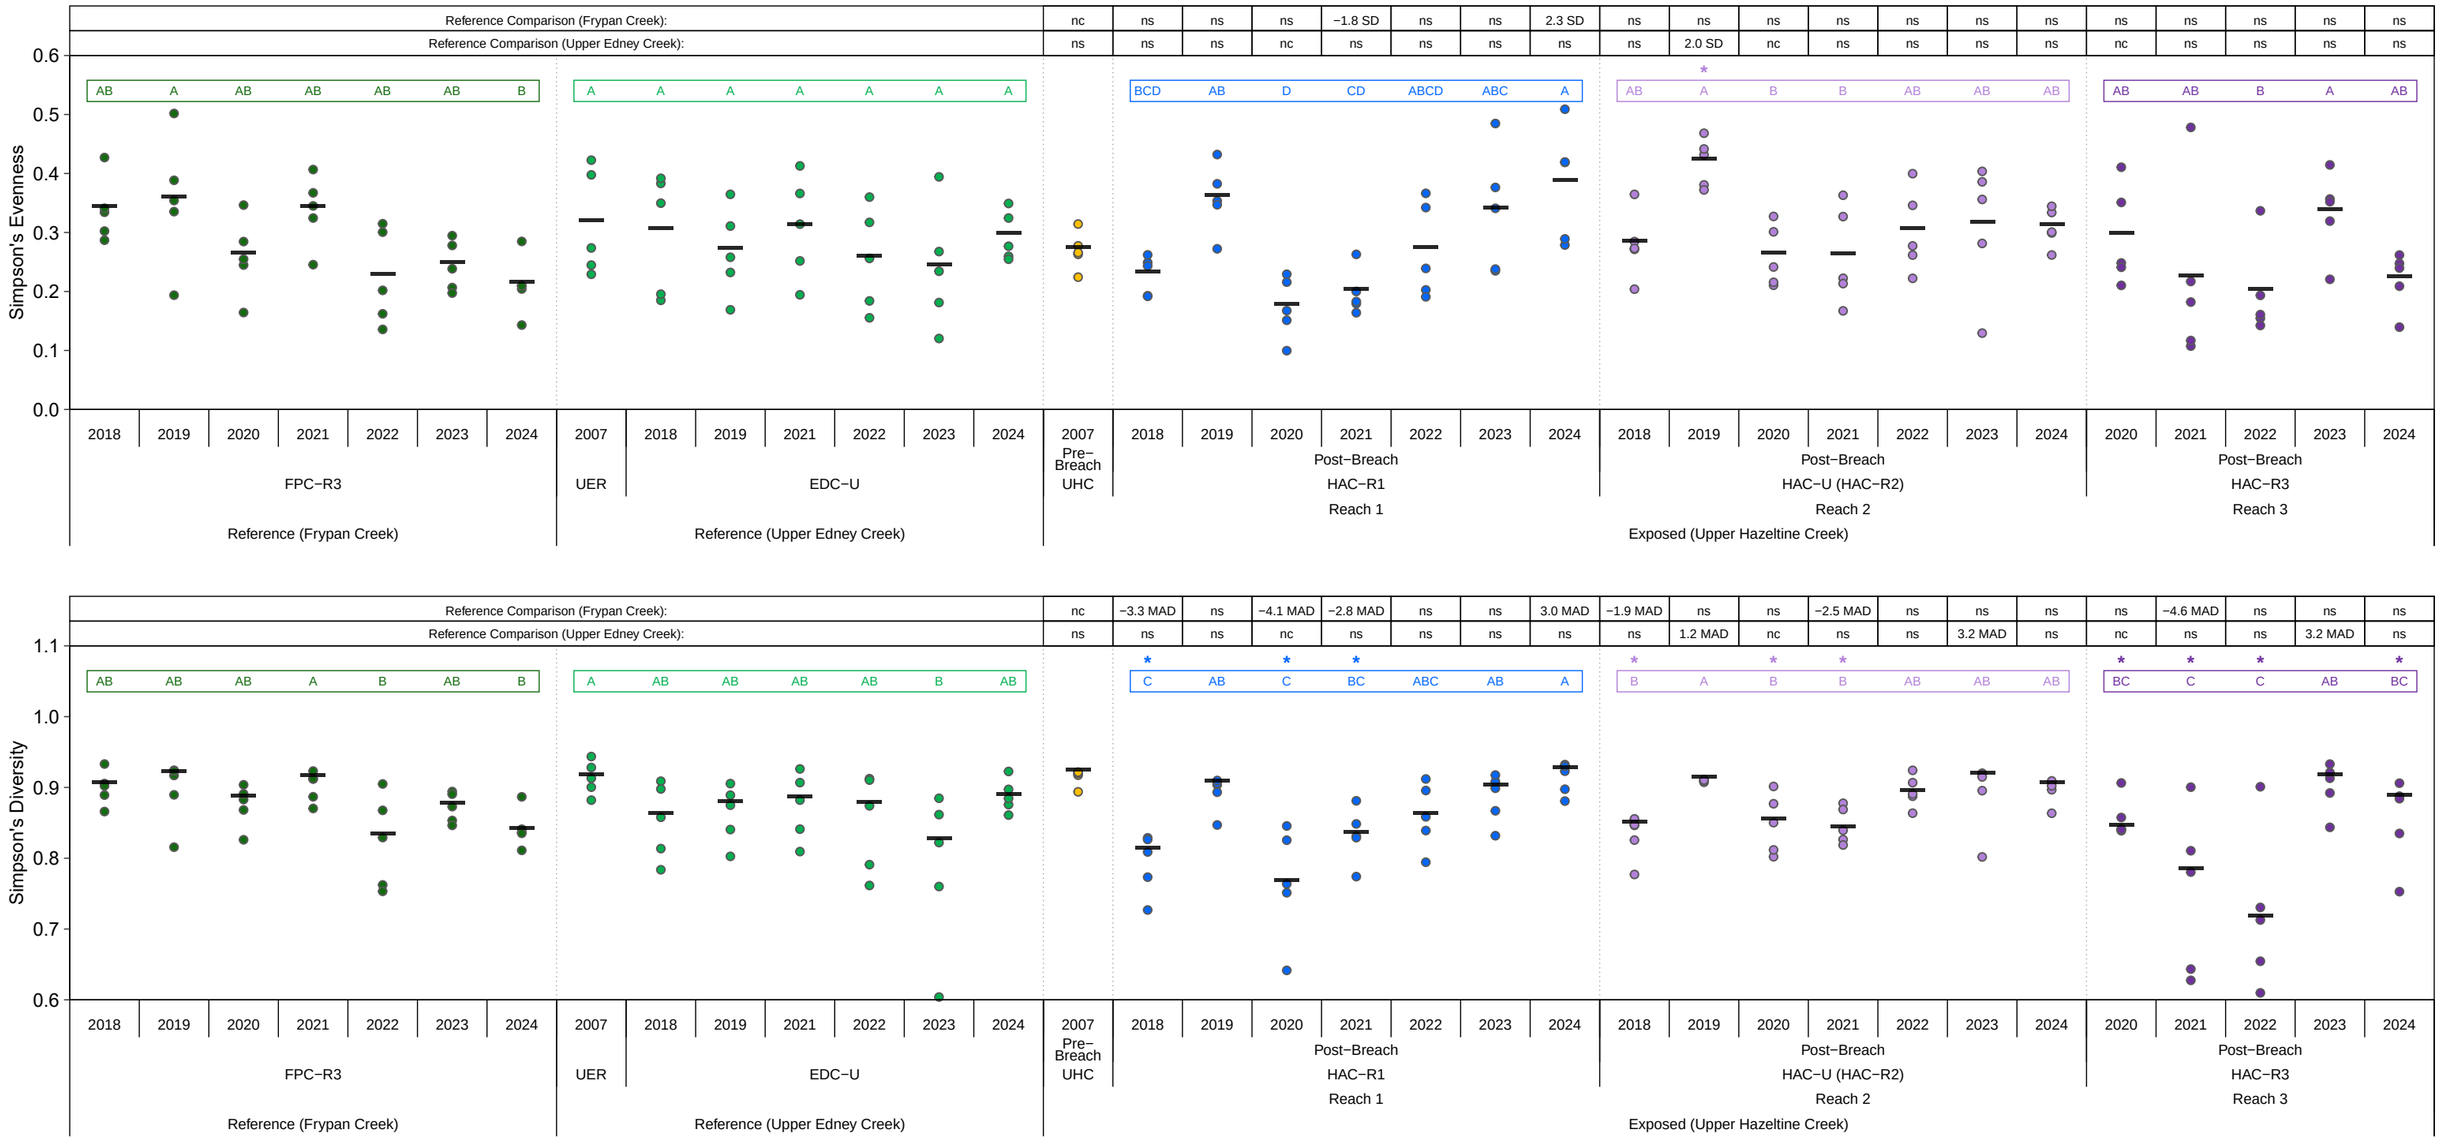

Figure 6.6: Benthic Invertebrate Community Metrics for the Upper Hazeltine Creek (HAC−R1, HAC−U [HAC−R2], HAC−R3; Exposed), Frypan Creek (FPC−R3; Reference), and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 2007 to 2024

Notes: #/m² = number per square metre. The EDC−U reference area was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC−R1, HAC−U (HAC−R2), and HAC−R3. Monitoring at area HAC−R3 was initiated in 2020. See Section 4.3 for details. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. Data from 2007 were used in the analyses to compare post−breach (2018 to 2024) to pre-breach conditions (2007). Post−breach data from HAC−R1, HAC−U (HAC−R2), and HAC−R3 were compared to pre−breach data from upper Hazeltine Creek (UHC), and post−breach data from EDC−U was compared to pre−breach data from upper Edney Creek (UER). An * indicates a significant difference between HAC−R1, HAC−U (HAC−R2), or HAC−R3 and UHC in 2007. HAC−R2 is the alternate name used for the HAC−U sampling area for Habitat Remediation Working Group (HRWG) reporting. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The magnitude of difference (MOD) for these significant *post hoc* comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference.
A 'nc' indicates no comparisons were possible, and a 'ns' indicates a non−significant contrast.

Table 6.6: **Statistical Comparisons of Benthic Invertebrate Community Metrics for the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], HAC-R3; Exposed), Frypan Creek (FPC-R3; Reference), and Upper Edney Creek (EDC-U; Reference) Monitoring Areas, 2007 to 2024**

P-value < 0.1.
Magnitude of Difference (MOD) < -2.
Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available. nc = no comparison. ns = non-significance. SD = Standard Deviation. nm = Contrast MODs could not be calculated because the Median Absolute Deviation (MAD) = 0. The EDC-U reference area was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC-R1, HAC-U (HAC-R2), and HAC-R3. Monitoring at area HAC-R3 was initiated in 2020. See Section 4.3 for details.

[a] Data from 2007 were used in the analyses to compare post-breach (2018 to 2024) to pre-breach conditions (2007). Post-breach data from HAC-R1, HAC-U (HAC-R2), and HAC-R3 were compared to pre-breach data from UHC, and post-breach data from EDC-U were compared to pre-breach data from UER.

[b] MCT = Measure of Central Tendency, which is the mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10-transformed, or rank-transformed data.

[c] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference

[d] Pairwise contrasts of post-breach (2018 to 2024) data from HAC-R1 and HAC-U (HAC-R2) against pre-breach (2007) data from UHC are indicated with an * in Figure 6.6.

[e] Spatial pairwise contrasts between HAC-R1, HAC-U (HAC-R2), and HAC-R3 in 2007 were not calculated because UHC in 2007 was used to represent pre-breach data for all three areas HAC-R1, HAC-U (HAC-R2), and HAC-R3.

[f] HAC-R2 is the alternate name used for the HAC-U sampling area for Habitat Remediation Working Group (HRWG) reporting.

Table 6.6: **Statistical Comparisons of Benthic Invertebrate Community Metrics for the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2], HAC-R3; Exposed), Frypan Creek (FPC-R3; Reference), and Upper Edney Creek (EDC-U; Reference) Monitoring Areas, 2007 to 2024**

MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference

[d] Pairwise contrasts of post-breach (2018 to 2024) data from HAC-R1 and HAC-U (HAC-R2) against pre-breach (2007) data from UHC are indicated with an * in Figure 6.6.

[e] Spatial pairwise contrasts between HAC-R1, HAC-U (HAC-R2), and HAC-R3 in 2007 were not calculated because UHC in 2007 was used to represent pre-breach data for all three areas HAC-R1, HAC-U (HAC-R2), and HAC-R3.

[f] HAC-R2 is the alternate name used for the HAC-U sampling area for Habitat Remediation Working Group (HRWG) reporting.

similar to pre-breach conditions, except for Simpson's Diversity at HAC-R3 which was significantly lower than pre-breach (Figure 6.6, Table 6.6). These results indicate that the benthic invertebrate community in upper Hazeltine Creek in 2024 was similar to reference conditions in terms of density and taxon richness, and similar to reference and pre-breach conditions in terms of Simpson's Evenness and Diversity (except for Simpson's Diversity at HAC-R3).

Mean benthic invertebrate densities at HAC-R1, HAC-U, and HAC-R3 were either similar to or significantly higher than those at FPC-R3 and EDC-U reference areas from 2018 to 2024 (Figure 6.6, Table 6.6). In addition, mean benthic invertebrate densities at the three upper Hazeltine monitoring areas have been similar to pre-breach densities except for HAC-R1 in 2021 and 2024, and HAC-R3 in 2020, 2023, and 2024, when densities were significantly lower than pre-breach conditions (Figure 6.6, Table 6.6). Lower mean densities at HAC-R1 in 2021 and 2024, relative to pre-breach, were primarily driven by significantly lower Chironomidae and Ephemeroptera densities, respectively, compared to most post-breach years. At HAC-R3, the lower total densities observed compared to pre-breach were the result of a relatively even decrease among several taxa (Appendix Figures F.3.1 and F.3.2, Appendix Table F.3.1). Taxon richness at HAC-R1 and HAC-U was similar to both reference areas from 2019 to 2024, except for richness at HAC-U being significantly higher than EDC-U in 2023; Figure 6.6, Table 6.6). Taxon richness at HAC-R3 in 2023 and 2024 was significantly higher than all prior years and similar to or significantly higher than both reference areas in these two years. In contrast, richness at HAC-R3 from 2020 to 2022 was significantly lower than one or both reference areas in each year (MOD = -2.2 to -1.8 SD; Figure 6.6, Table 6.6). Taxon richness at each of the three upper Hazeltine monitoring areas was significantly lower than pre-breach from 2018 to 2024 (Figure 6.6, Table 6.6). Mean Simpson's Evenness and Diversity at the three upper Hazeltine Creek areas were similar to one or both reference areas from 2018 to 2024 (no data were collected from EDC-U in 2020). Simpson's Evenness at the three exposed areas has been similar or significantly higher than pre-breach conditions over the post-breach period (i.e., 2018 to 2024). Simpson's Diversity was significantly lower than pre-breach conditions in 2018 and 2020 to 2021 at HAC-R1 and HAC-U, and in all years except 2023 at HAC-R3 (Figure 6.6, Table 6.6). Collectively, these results indicated the benthic invertebrate communities of upper Hazeltine Creek have been similar to one or both reference area in terms of all primary metrics (i.e., density, richness, and Simpson's Evenness and Diversity) since 2020 in Reaches 1 and 2 (HAC-R1 and HAC-U), and since 2023 in Reach 3 (HAC-R3). The benthic invertebrate communities of upper Hazeltine Creek in 2024 have recovered to pre-breach conditions in terms of density (at HAC-U), Simpson's Evenness (all three areas), and Simpson's Diversity (HAC-R1 and HAC-U).

The benthic invertebrate communities of the HAC-R1 and HAC-U in 2024 were similar to each other in terms of density, taxon richness, and Simpson's Evenness and Diversity, which was consistent with all prior post-breach years (i.e., 2018 to 2023; Figure 6.6, Table 6.6). The benthic community at HAC-R3 in 2024 had similar taxon richness to both HAC-R1 and HAC-U but had significantly lower density (relative to HAC-U) and Simpson's Evenness and Diversity (relative to HAC-R1) although differences were small (MOD = -2.1 to -1.4 SD; Figure 6.6, Table 6.6). The benthic invertebrate community at HAC-R3 has differed from HAC-R1 and/or HAC-U based on density, taxon richness, and Simpson's Evenness and Diversity for one or more years since 2020 (i.e., the initiation of monitoring at HAC-R3; Figure 6.6, Table 6.6). The similarity in these benthic invertebrate community metrics at the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) in 2024 and prior years indicates that recovery of the benthic invertebrate community in these two areas has been largely similar over the post-breach period. The greater frequency and magnitude of the differences in the benthic invertebrate community of HAC-R3 compared HAC-R1 and HAC-U suggests that the recovery at HAC-R3 has differed from the two upstream areas. This is consistent with the more recent completion of remediation works in Reach 3 of Hazeltine Creek (HAC-R3; 2019) compared to Reaches 1 and 2 (2016 and 2017, respectively; Table 4.3) and with the higher proportion of riffle habitat in Reach 3 compared to Reaches 1 and 2 (Minnow 2022b).

Chironomidae (non-biting midges) was the most abundant taxon present at HAC-R1 and HAC-U (mean = 50.7% and 41.2%) while Elmidae (riffle beetle) was the most abundant taxon present at HAC-R3 (mean = 34.9%) in 2024 (Figure 6.7; Appendix Tables D.4.1 and D.4.2). The remaining benthic community was predominantly comprised of Elmidae and Oligochaeta (aquatic worms) at HAC-R1 (mean = 8.67 and 8.26%, respectively), Elmidae at HAC-U (mean = 25.3%), and Ephemeroptera and Chironomidae at HAC-R3 (mean = 21.6% and 17.5%, respectively; Figure 6.7; Appendix Tables D.4.1 and D.4.2).

Chironomidae (%) at HAC-R1 and HAC-U in 2024 were significantly higher than pre-breach and FPC-R3 but similar to the EDC-U reference area. Conversely, Chironomidae (%) at HAC-R3 in 2024 were similar to pre-breach and FPC-R3 but was significantly lower than the EDC-U reference area (Figure 6.7; Appendix Figure F.3.1, Appendix Table F.3.1). Chironomidae (%) at HAC-R1 and HAC-U were temporally stable from 2022 to 2024 and have been significantly higher than pre-breach conditions since 2022 and 2023 at HAC-R1 and HAC-U, respectively. These results contrasted with those from 2021 when Chironomidae (%) at both exposed areas were similar to pre-breach and significantly lower than one or both reference areas. The significantly higher Chironomidae (%) in 2022 and 2024, compared to 2020 and 2021 at HAC-R1 and 2021 at HAC-U, reflected a return to conditions similar to 2018 (at HAC-R1 and HAC-U) and 2019 (at HAC-U only), when Chironomidae (%) were significantly

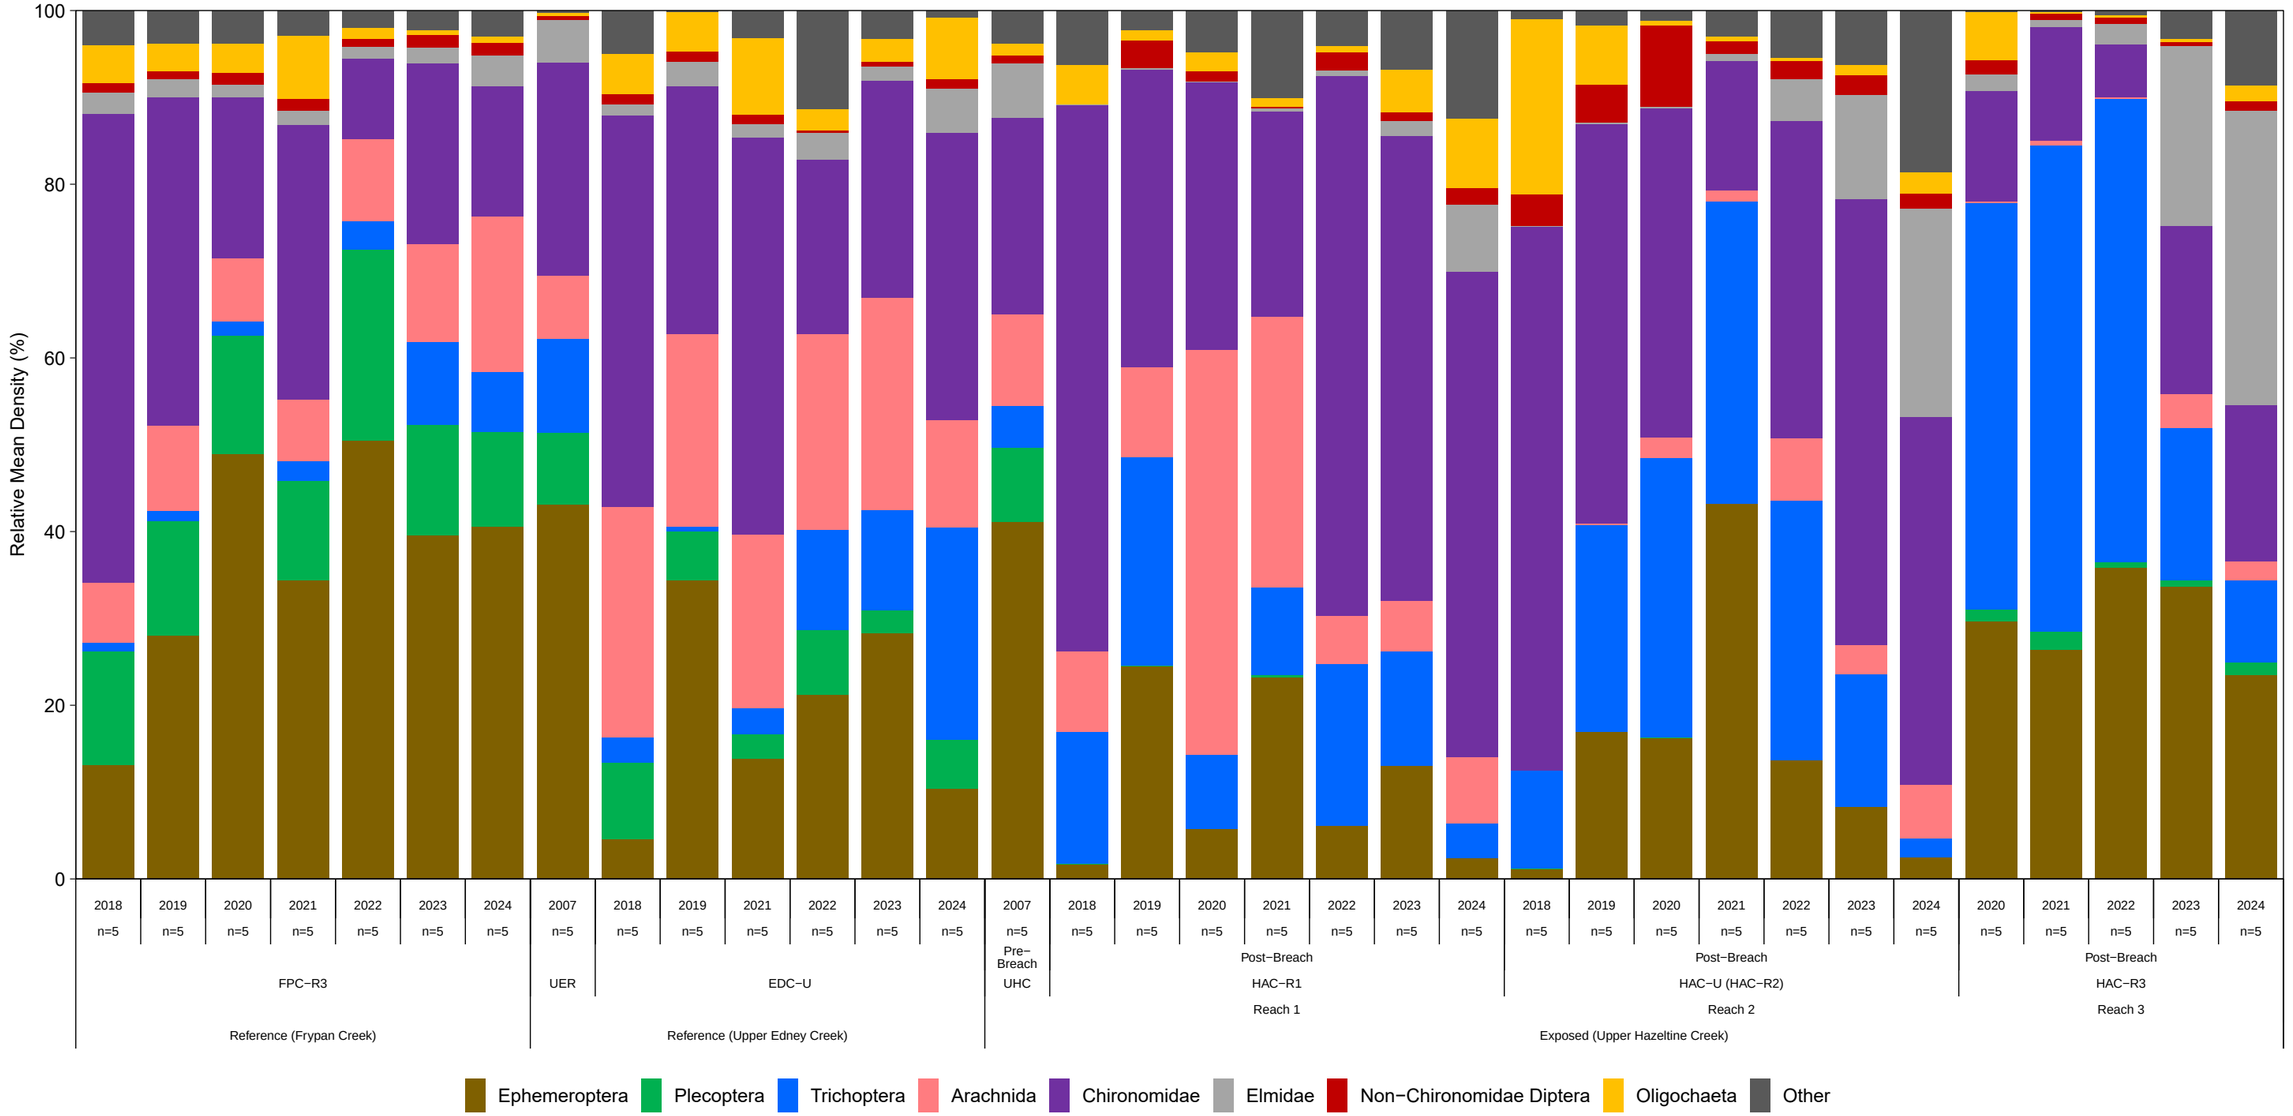

Figure 6.7: Relative Mean Densities of Major Benthic Invertebrate Taxa for the Upper Hazeltine Creek (HAC−R1, HAC−U [HAC−R2], HAC−R3; Exposed), Frypan Creek (FPC−R3; Reference), and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 2007 to 2024

Notes: The sampling area UHC (2007) is the pre−breach equivalent of the post−breach sampling areas HAC−R1, HAC−U (HAC−R2), and HAC−R3 (2018 to 2024). The sampling area UER (2007) is the pre−breach equivalent of the post−breach sampling area EDC−U (2018 to 2024). The EDC−U reference area was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC−R1, HAC−U (HAC−R2), and HAC−R3. HAC−R2 is the alternate name used for the HAC−U sampling area for Habitat Remediation Working Group (HRWG) reporting.

higher than pre-breach and similar to or significantly higher than at least one reference (Appendix Figure F.3.1, Appendix Table F.3.1). Chironomidae (%) at HAC-R3 have been similar to pre-breach and similar to or significantly lower than both reference areas since the start of monitoring in 2020. Chironomidae are tolerant of environmental stress (Mandaville 2002) and are generally expected to be present in greater proportion with increasing environmental disturbance (Barbour et al. 1999). The occurrence of Chironomidae (%) at HAC-R1 and HAC-U that were significantly higher than pre-breach conditions and higher than at least one reference area over at least the last two years (i.e., 2023 to 2024) suggests that benthic invertebrate communities at HAC-R1 and HAC-U communities have not yet fully recovered to pre-breach and reference conditions. Comparisons between the upper Hazeltine Creek monitoring areas in 2024 indicated that Chironomidae (%) at HAC-R1 were similar to HAC-U, while Chironomidae (%) at HAC-R3 were significantly lower than both HAC-R1 and HAC-U (Appendix Figure F.3.1, Appendix Table F.3.1). This was consistent with all post-breach years, except for 2022 when Chironomidae (%) at HAC-R1 were significantly higher than at HAC-U, and 2021 when HAC-R3 was similar to both HAC-R1 and HAC-U (Appendix Table F.3.1).

Elmidae (%) at the three upper Hazeltine Creek areas in 2024 were similar to pre-breach, which marked the first year that Elmidae (%) at HAC-R1 were similar to pre-breach. Elmidae (%) at HAC-R1 in 2024 were also similar to both reference areas, while Elmidae (%) at HAC-U and HAC-R3 were similar to the EDC-U area but significantly higher than the FPC-R3 area (Figure 6.7; Appendix Figure F.3.1, Appendix Table F.3.1). Elmidae (%) at the three upper Hazeltine Creek monitoring areas have been similar to pre-breach since 2024 at HAC-R1, since 2022 at HAC-U, and since 2023 at HAC-R3. The similarity to pre-breach conditions in these years at the exposed areas corresponded with Elmidae (%) that were significantly higher than all prior years at each of the three exposed areas; years in which Elmidae (%) were significantly lower than pre-breach conditions. Elmidae (%) at the exposed areas were also similar to or significantly higher than one or both reference areas since 2020 at HAC-U and HAC-R3, and since 2023 at HAC-R1, which differed from most prior years when Elmidae (%) were significantly lower than one or both reference areas (Appendix Figure F.3.1, Appendix Table F.3.1). Elmidae are relatively intolerant of environmental stress (Mandaville 2002), so are generally expected to decrease in prevalence with increasing environmental disturbance. Therefore, the temporal increase in Elmidae (%) at each of the three upper Hazeltine Creek areas to values in 2024 that were similar to pre-breach conditions, and similar to or significantly higher than reference conditions, suggests benthic invertebrate community recovery.

The mean relative densities (%) of EPT at HAC-R1, HAC-U, and HAC-R3 in 2024 (6.51%, 5.08%, and 35.0%, respectively) were significantly lower than pre-breach (54%), and both the FPC-R3 and EDC-U reference areas (65.2% and 37.7%, respectively; Appendix Table D.4.2),

with one exception. The one exception was EPT (%) at HAC-R3 in 2024, which was similar to EDC-U (Appendix Figure F.3.1, Appendix Tables F.3.1). Mean EPT (%) at HAC-R1 was significantly lower than pre-breach for most post-breach monitoring years except for 2019 (similar to pre-breach) while EPT (%) at HAC-U was similar to pre-breach for most post-breach monitoring years (i.e., 2019 to 2022) but has steadily decreased since 2021 to results in 2023 and 2024 that were significantly lower than pre-breach conditions. The relative densities (%) of EPT at HAC-R1 and HAC-U were significantly lower than one reference area (FPC-R3) in 2022 and 2023, and significantly lower than both reference areas in 2024. For HAC-U, this contrasted with 2021 when EPT (%) at HAC-U was significantly higher than both reference areas (Appendix Figure F.3.1, Appendix Table F.3.1). At HAC-R3, mean EPT (%) in 2024 was similar to 2023, but results for both of these years were significantly lower than all prior years. This significant decrease in EPT (%) at HAC-R3 in 2023 and 2024 corresponded with results that were similar to significantly lower than pre-breach and reference conditions, compared to EPT (%) at HAC-R3 that were similar to or significantly higher than pre-breach and reference conditions from in all prior years (i.e., 2020 to 2022; Appendix Figure F.3.1, Appendix Table F.3.1). The temporal decreases in EPT (%) at HAC-U and HAC-R3 described above corresponded with a significant decrease in EPT (density) in 2024 (compared to all prior years at HAC-U and compared to 2021 to 2022 at HAC-R3) and with a significant increase in Elmidae (density) in 2023 to 2024 compared to most prior years (excluding 2021). Therefore, the temporal decreases in EPT (%) observed at HAC-U and HAC-R3 were likely driven by a combination of the two factors; decreased EPT density and a change in community composition whereby Elmidae (% and density) increased and a concurrent decrease in EPT (%) occurred (Appendix Figure F.3.1, Appendix Table F.3.1). As indicated above, Elmidae are relatively intolerant of environmental stress (Mandaville 2002). Temporal changes in the individual EPT taxa that contributed to the observed decrease in EPT density are discussed in more detail below. The mean EPT (%) in 2024 was similar between HAC-R1 and HAC-U, which was consistent with results all post-breach years except 2020 and 2021, when EPT (%) at HAC-U was significantly higher than at HAC-R1. For HAC-R3, EPT (%) has been significantly higher relative to both HAC-R1 and HAC-U since monitoring at HAC-R3 began in 2020, except in 2021 when EPT (%) at HAC-R3 was significantly higher than HAC-R1 only (Appendix Figure F.3.1, Appendix Table F.3.1).

Within the EPT group, there were significant differences between areas and among years in the relative densities (%) and densities of Ephemeroptera, Plecoptera, and Trichoptera. Most notably, Plecoptera (stoneflies), which were present pre-breach and at the reference areas (FPC-R3 and EDC-U) were absent or near-absent from the three upper Hazeltine Creek areas for all post-breach monitoring years, including 2024 (Figure 6.7; Appendix Figures F.3.1 and

F.3.2, Appendix Table F.3.1). Plecoptera have narrow ecological requirements and are vulnerable to water pollution, habitat fragmentation, and alteration of water courses and their banks (Mandaville 2002). The absence or near-absence of Plecoptera from the upper Hazeltine Creek areas since initiation of post-breach monitoring suggested that habitat conditions in these remediated areas are currently better suited to the colonization taxa other than Plecoptera.

The relative densities (%) of Ephemeroptera (mayflies) at the three upper Hazeltine Creek areas in 2024 were significantly lower than pre-breach as well as both reference areas (FPC-R3 and EDC-U), except for Ephemeroptera (%) at HAC-R3 which were similar to the EDC-U reference area (Figure 6.7; Appendix Figure F.3.1, Appendix Table F.3.1). The lower Ephemeroptera (%) at HAC-R1 and HAC-U in 2024 (compared to reference and pre-breach) is consistent with 2023 results but contrasts with 2021 when Ephemeroptera (%) was similar to or higher than reference (HAC-U compared to EDC-U) for both areas and similar to pre-breach (Appendix Figure F.3.1, Appendix Table F. 3.1). Ephemeroptera (%) in 2024 at HAC-U were significantly lower than all prior years except 2018 and 2023, but at HAC-R1 were significantly lower than 2019 and 2021 only. Ephemeroptera (%) at HAC-R3 in 2024 was significantly lower than pre-breach and reference conditions (albeit FPC-R3 only) for the first time despite temporal stability in this metric since the start of monitoring (Appendix Figure F.3.1, Appendix Table F. 3.1). Ephemeroptera densities (organisms/m^2) at both HAC-R1 and HAC-U in 2024 were significantly lower than in all prior years except for the first year of monitoring (2018), which was consistent with the significantly lower Ephemeroptera (%) in 2024 compared to 2021 (but not in 2022 or 2023 compared to 2021). The Ephemeroptera densities at HAC-R3 have remained temporally stable, consistent with the relative density (%) results for this taxa (Appendix Figures F.3.1 and F.3.2, Appendix Table F.3.1).

The relative densities (%) of Trichoptera (caddisflies) at the three areas of upper Hazeltine Creek in 2024 were similar to pre-breach as well as the FPC-R3 reference area. Trichoptera (%) at HAC-R3 in 2024 were also similar to the EDC-U reference area, but at HAC-R1 and HAC-U were significantly lower than EDC-U although the difference was slight (-1.5 to -1.2 SD; Appendix Figure F.3.1, Appendix Table F.3.1). This represented a change from all previous years when Trichoptera (%) at these three areas were similar to or significantly higher than pre-breach and/or reference conditions. A similar temporal pattern was observed in Trichoptera densities at the upper Hazeltine Creek areas, with the results in 2024 being similar to pre-breach and reference conditions at each of the areas, representing a change from previous years when Trichoptera densities were significantly higher than one or both reference areas (Appendix Figure F.3.1, Appendix Table F.3.1). At HAC-U and HAC-R3, this temporal change in 2024 was accompanied by Trichoptera densities that were significantly lower than most (HAC-R3) or all (HAC-U)

prior years, whereas the density at HAC-R1 in 2024 was similar to most prior years. Collectively, these results indicated Trichoptera (% and density) at all upper Hazeltine Creek in 2024 were more similar to pre-breach and reference conditions than in prior post-breach years.

Given the observed temporal decreases in Ephemeroptera and Trichoptera (% and density) in 2024 compared to some or all prior years, the pollution tolerance of the observed taxa in upper Hazeltine Creek were investigated. This evaluation showed that the most abundant family of Ephemeroptera (Leptophlebiidae) at all of the upper Hazeltine Creek and reference areas are relatively intolerant to water pollution (Mandaville 2002; Appendix G). In addition, two of the Ephemeroptera families present at HAC-R3 are very intolerant of water pollution (i.e., Ameletidae and Ephemerellidae) and were present at higher densities at this exposed area than at the FPC-R3 reference area (Mandaville 2002; Appendix G). Several of the Trichoptera families present at one or more of the exposed areas were also considered very intolerant of water pollution (i.e., Lepidostomatidae, Rhyacophilidae, Glossosomatidae), some of which were more prevalent at the exposed areas compared to the reference areas (Mandaville 2002; Appendix G). The occurrence of sensitive Ephemeroptera and Trichoptera families at the upper Hazeltine Creek exposed areas, sometimes at higher densities than at the reference areas, suggests that the temporal decreases and/or significantly lower relative densities (%) of Ephemeroptera and Trichoptera at the exposed areas compared to reference and pre-breach conditions were likely primarily related to physical habitat conditions rather than chemical conditions (i.e., water quality).

Among the remaining taxa evaluated for upper Hazeltine Creek (Arachnida, non-Chironomidae Diptera, and Oligochaeta), only Arachnida (%) at HAC-R3 differed from pre-breach and reference conditions in 2024, while Oligochaeta (%) differed from reference (FPC-R3 only) but not pre-breach (Appendix Figure F.3.1, Appendix Table F.3.1). Arachnida (%) at HAC-R3 have been similar to or significantly lower than one or both reference areas and pre-breach conditions since the start of monitoring in 2020. The relative densities (%) of Arachnida in 2024 were similar between HAC-R1 and HAC-U but were significantly lower at HAC-R3 relative to HAC-R1 and HAC-U in 2024 Appendix Figure F.3.1, Appendix Table F.3.1). Reach 3 of Hazeltine Creek (where HAC-R3 is located) has a higher proportion of riffle habitat (i.e., a higher proportion of habitat with higher water velocity; Minnow 2022b). Arachnida mainly inhabit aquatic vegetation (Schatz and Behan-Pelletier 2008) which is more prevalent in creek areas with lower water velocity (i.e., pool habitat), therefore the lower Arachnida (%) at HAC-R3 in 2024 compared to pre-breach and reference conditions and HAC-R1, was likely reflective of the more limited recovery of aquatic vegetation in Reach 3 of Hazeltine Creek. This is also consistent with the more limited amount of time since completion of remediation works in Reach 3 of Hazeltine Creek compared to the upstream reaches (Table 4.3). Non-Chironomidae Diptera (%)

and Oligochaeta (%) at the upper Hazeltine Creek areas in 2024 were similar to pre-breach and reference conditions with one exception (Oligochaeta [%] at HAC-R1 were significantly higher than FPC-R3), therefore were not considered further (Appendix Figure F.3.1, Appendix Table F.3.1).

Multivariate analysis (CA) was used to further evaluate temporal changes in community composition from 2018 to 2024 for all three areas of upper Hazeltine Creek and the two reference areas. The first two axes of the CA explained a total of 39.4% of the benthic invertebrate community variation among the areas (29.0% and 10.4% for CA Axis 1 and 2, respectively; Appendix Figures F.3.1 and F.3.3, Appendix Tables D.4.1, D.4.2, F.3.1, and F.3.2). The community composition at HAC-R1, HAC-U, and HAC-R3 primarily differed from reference (both FPC-R3 and EDC-U) and pre-breach conditions along CA Axis 1 (from 2018 to 2024). In 2024, all three upper Hazeltine Creek monitoring areas differed from FPC-R3 reference area and pre-breach conditions along CA Axes 2 and 3 (except for HAC-R3 compared to FPC-R3 along CA Axis 2) but were similar to the EDC-U reference area (Appendix Figures F.3.1 and F.3.3; Appendix Tables F.3.1 and F.3.2). Evaluation of benthic invertebrate taxa with the greatest weightings on CA Axis 1 indicated lower relative densities of Sphaerridae (Pisidiidae; pea clams), Chironomidae (*Rheocricotopus*), Plecoptera (*Sweltsa,* Capniidae, and *Zapada*) and higher relative densities of Trichoptera (*Hydroptila* and *Cheumatopsyche*), and Gastropoda (Planorbidae and Lymnaeidae [snails]) at the exposed areas relative to reference and pre-breach conditions (Appendix Figure F.3.3, Appendix Tables F.3.1 and F.3.2). Some of the greatest differences observed along CA Axis 1 between the exposed and reference/pre-breach results were related to the absence of Sphaeriiidae from the exposed areas (taxa which prefer fine substrates and low velocity; Kubíková et al. 2011) and the absence of Lymnaeidae the from reference (a difference which was likely due to the presence of aquatic vegetation in Hazeltine Creek; Trondstad and Trondstad 2022). The absence or near-absence of Plecoptera at upper Hazeltine Creek areas in all post-breach years (discussed above) was corroborated by the lower prevalence of Plecoptera at the exposed areas compared to the reference/pre-breach along CA Axis 1.

The CA Axis 1 scores for HAC-R1 and HAC-U were similar from 2019 to 2024, whereas the CA Axis 1 score for HAC-R3 was lower relative to both HAC-R1 and HAC-U in most years from 2020 to 2024 (i.e., more similar to reference and pre-breach conditions), due to differences in community composition (e.g., significantly lower Chironomidae [%] and Arachnida [%] and significantly higher EPT [%] at HAC-R3 compared to HAC-R1 and HAC-U; Appendix Figure F.3.3, Appendix Table F.3.1). The axis scores for upper Hazeltine Creek along CA Axis 1 were temporally stable from at least 2021 to 2024 and were consistently higher at each exposed area compared to reference and pre-breach conditions throughout the post-breach period (i.e., from

2018 to 2024; Appendix Figure F.3.1, Appendix Table F.3.1). In contrast, temporal differences from 2021 to 2024 were observed for HAC-R1, HAC-U, and HAC-R3 along CA Axis 2 and 3 (which showed fewer and smaller differences to reference and pre-breach conditions than CA Axis 1), suggesting that the observed temporal changes in community composition within the exposed areas have been smaller in magnitude than the differences in community composition relative to reference and pre-breach conditions (Appendix Figure F.3.1, Appendix Table F.3.1).

Correlation analyses between benthic invertebrate community metrics and supporting physical and chemical measures for upper Hazeltine Creek and the reference areas indicated positive correlations of total density, and the density and/or relative densities (%) of several taxa (Ephemeroptera, Trichoptera, EPT, Chironomidae, and non-Chironomidae Diptera), wet and dry weight biomass, and CA Axis 1 scores with one or more of mean water depth, velocity, temperature, dissolved oxygen, pH, and specific conductivity (Appendix Figure F.3.4, Appendix Tables D.4.3, F.3.3). The positive correlations for Ephemeroptera and EPT were limited to water velocity only (Appendix Table F.3.3). Higher water velocity, dissolved oxygen (mg/L and % saturation), pH, and specific conductivity are characteristics of the upper Hazeltine Creek areas compared to the reference areas (FPC-R3 and EDC-U), with the higher water velocity specifically attributed to supplemental pumping from Polley Lake. Dissolved oxygen and water velocity at the EDC-U have been particularly low (<60% and 0 m/s from 2021 to 2024; Table 6.5; Appendix Figure F.3.4, Appendix Table F.3.3). The positive relationships observed for these benthic community metrics, with the positive direction of the correlations being largely represented by the exposed areas, suggested that the chemical and physical conditions at the exposed areas were not limiting the recovery of total density, Trichoptera, Chironomidae, and non-Chironomidae Diptera.

Correlation analysis also indicated negative correlations of taxon richness, and Plecoptera (density and %), Arachnida, EPT (% only), Ephemeroptera (% only), and Oligochaeta (% only) with one or more of mean water depth, velocity, temperature, dissolved oxygen, pH, and specific conductivity (Appendix Figure F.3.4, Appendix Tables D.4.3, F.3.3). For the correlations involving Plecoptera and Arachnida, these relationships were leveraged by the absence or near-absence of these taxa at all exposed areas for Plecoptera, and at HAC-R3 for Arachnida (Appendix Figure F.3.4). Negative correlations with specific conductivity occurred with Plecoptera (density and %) and Arachnida (density and %) and Ephemeroptera (%), but all other significant correlations with specific conductivity were positive (including with total density). This, along with the occurrence of Ephemeroptera families at the exposed areas that are of similar pollution tolerance to those at the reference area suggested the chemical conditions (i.e., water quality) of the exposed areas may not be a key limiting factor for the recovery of most taxa at the exposed areas. Water quality could be an influencing factor on Plecoptera recovery; however,

this cannot be separated from the other key habitat differences that exist between the exposed and reference areas that would also likely be influencing factors (i.e., water depth, velocity, temperature, and complete lack of canopy cover at the exposed areas). Collectively, these results suggest that physical correlates were the primary influencing factors on benthic invertebrate community condition in upper Hazeltine Creek.

Overall, the benthic invertebrate communities at the three areas of Upper Hazeltine Creek (HAC-R1, HAC-U, and HAC-R3) in 2024 were similar to reference conditions (i.e., one or both reference areas) in terms of density and taxon richness, and similar to reference and/or pre-breach conditions in terms of Simpson's Evenness and Diversity. The benthic invertebrate communities of HAC-R1 and HAC-U have been similar in terms of these four metrics in all post-breach years, while the community at HAC-R3 in 2024 had significantly lower density and Simpson's Evenness and Diversity than the upstream areas (although differences were small). The differences in the benthic invertebrate community at HAC-R3 compared to the upstream areas was consistent with the more recent completion of remediation works and habitat differences (i.e., greater proportion of riffles) at this area compared to upstream. The most abundant taxa in 2024 were Chironomidae at HAC-R1 and HAC-U and Elmidae at HAC-R3. Elmidae (%) at the three exposed areas in 2024 were similar to or significantly higher than pre-breach and reference conditions. Chironomidae (%) at the three exposed areas in 2024 were similar to reference and significantly higher than pre-breach at HAC-R1 and HAC-U (but not at HAC-R3). The sensitive EPT taxa (% and density) at the three exposed areas in 2024 were significantly lower than pre-breach. In addition, EPT taxa two of these exposed areas (HAC-R1 [% and density] and HAC-U [%]) were also significantly lower than both reference areas. Notable differences in EPT at all three Hazeltine Creek areas in 2024 relative to reference and pre-breach included a lack of Plecoptera and lower Ephemeroptera (%), while Trichoptera (%) were similar to reference and pre-breach. The occurrence of Ephemeroptera and Trichoptera families at the exposed areas that were of similar pollution tolerance to those at the reference areas suggested that chemical conditions (i.e., water quality) were not limiting the recovery of these taxa at the exposed areas. Multivariate analysis indicated community composition of the two upper Hazeltine Creek areas did not differ in 2024 or most years, suggesting similar recovery of the benthic invertebrate community in these areas. Correlation analysis indicated that physical characteristics of the upper Hazeltine Creek areas (mean water depth, velocity, temperature) were the primary influencing factors on benthic invertebrate community condition and composition in these exposed areas. Collectively, results indicated that the benthic invertebrate communities at the three areas of upper Hazeltine Creek have recovered since remediation efforts to a condition that was similar to at least one reference area based on density, taxon richness, and Simpson's Evenness and Diversity, and largely similar to pre-breach conditions for Simpson's

Evenness and Diversity. However, there were some key remaining differences in the community composition of upper Hazeltine Creek compared to reference and/or pre-breach (particularly for the sensitive EPT taxa) that suggested ongoing recovery.

6.1.3.2.2 Productivity

Mean wet and dry weight biomass of benthic invertebrates in 2024 at HAC-R1, HAC-U, and HAC-R3 were similar to those at the two reference areas (FPC-R3 and EDC-U) except for significantly lower mean biomass (wet and dry) at HAC-R3 compared to FPC-R3. In previous years, mean benthic biomass at all three upper Hazeltine Creek areas has been similar to or significantly higher than both reference areas (Figure 6.8; Appendix Table F.3.1). Despite significantly lower mean biomass (wet and dry) at HAC-R3 compared to FPC-R3 in 2024, biomass (wet and dry) at HAC-R3 not decrease significantly in 2024. Dry weight biomass at HAC-R1, HAC-U, and HAC-R3 in 2024 was similar to all prior years, while wet weight biomass at each area in 2024 was similar to most prior years but significantly higher in 2024 relative to 2022 (Figure 6.8; Appendix Table D.4.2, F.3.1). The similarity in mean biomass at HAC-R1 and HAC-U relative to both reference areas, and in mean biomass at HAC-R3 relative to EDC-U, were consistent with the similarity in total density between the exposed and reference areas (Figure 6.6, Table 6.6). Mean biomass (wet and dry) for HAC-R1, HAC-U, and HAC-R3 in 2024 was similar between areas, which was consistent with prior years except 2020, when HAC-R3 had significantly lower biomass (wet and dry) relative to HAC-R1 and HAC-U; Figure 6.8; Appendix Table F.3.1, Appendix Tables D.4.1 and D.4.2). The consistently higher benthic invertebrate wet and dry biomass at the exposed areas of upper Hazeltine Creek, relative to at least one reference area, indicated benthic invertebrate productivity has recovered to or exceeded reference conditions.

6.1.3.3 Lower Hazeltine Creek

Benthic invertebrate community and productivity monitoring was conducted at a remediated (exposed) area of lower Hazeltine Creek (HAC-D) in 2023, with an unimpacted area of lower Edney Creek (EDC-D) serving as reference (Minnow 2024a). The results of this monitoring are summarized briefly herein with detailed methods and results presented in Minnow (2024a).

6.1.3.3.1 Community

In 2023, the benthic invertebrate community in lower Hazeltine Creek (HAC-D) was similar to reference (EDC-D) and pre-breach (2007) in terms of density, taxon richness, and Simpson's Evenness and Diversity. The similarity of density, taxon richness, and Simpson's Diversity at HAC-D in 2023 relative to reference and pre-breach reflected substantial improvement compared to 2021, when these metrics were significantly lower than reference and pre-breach. The benthic

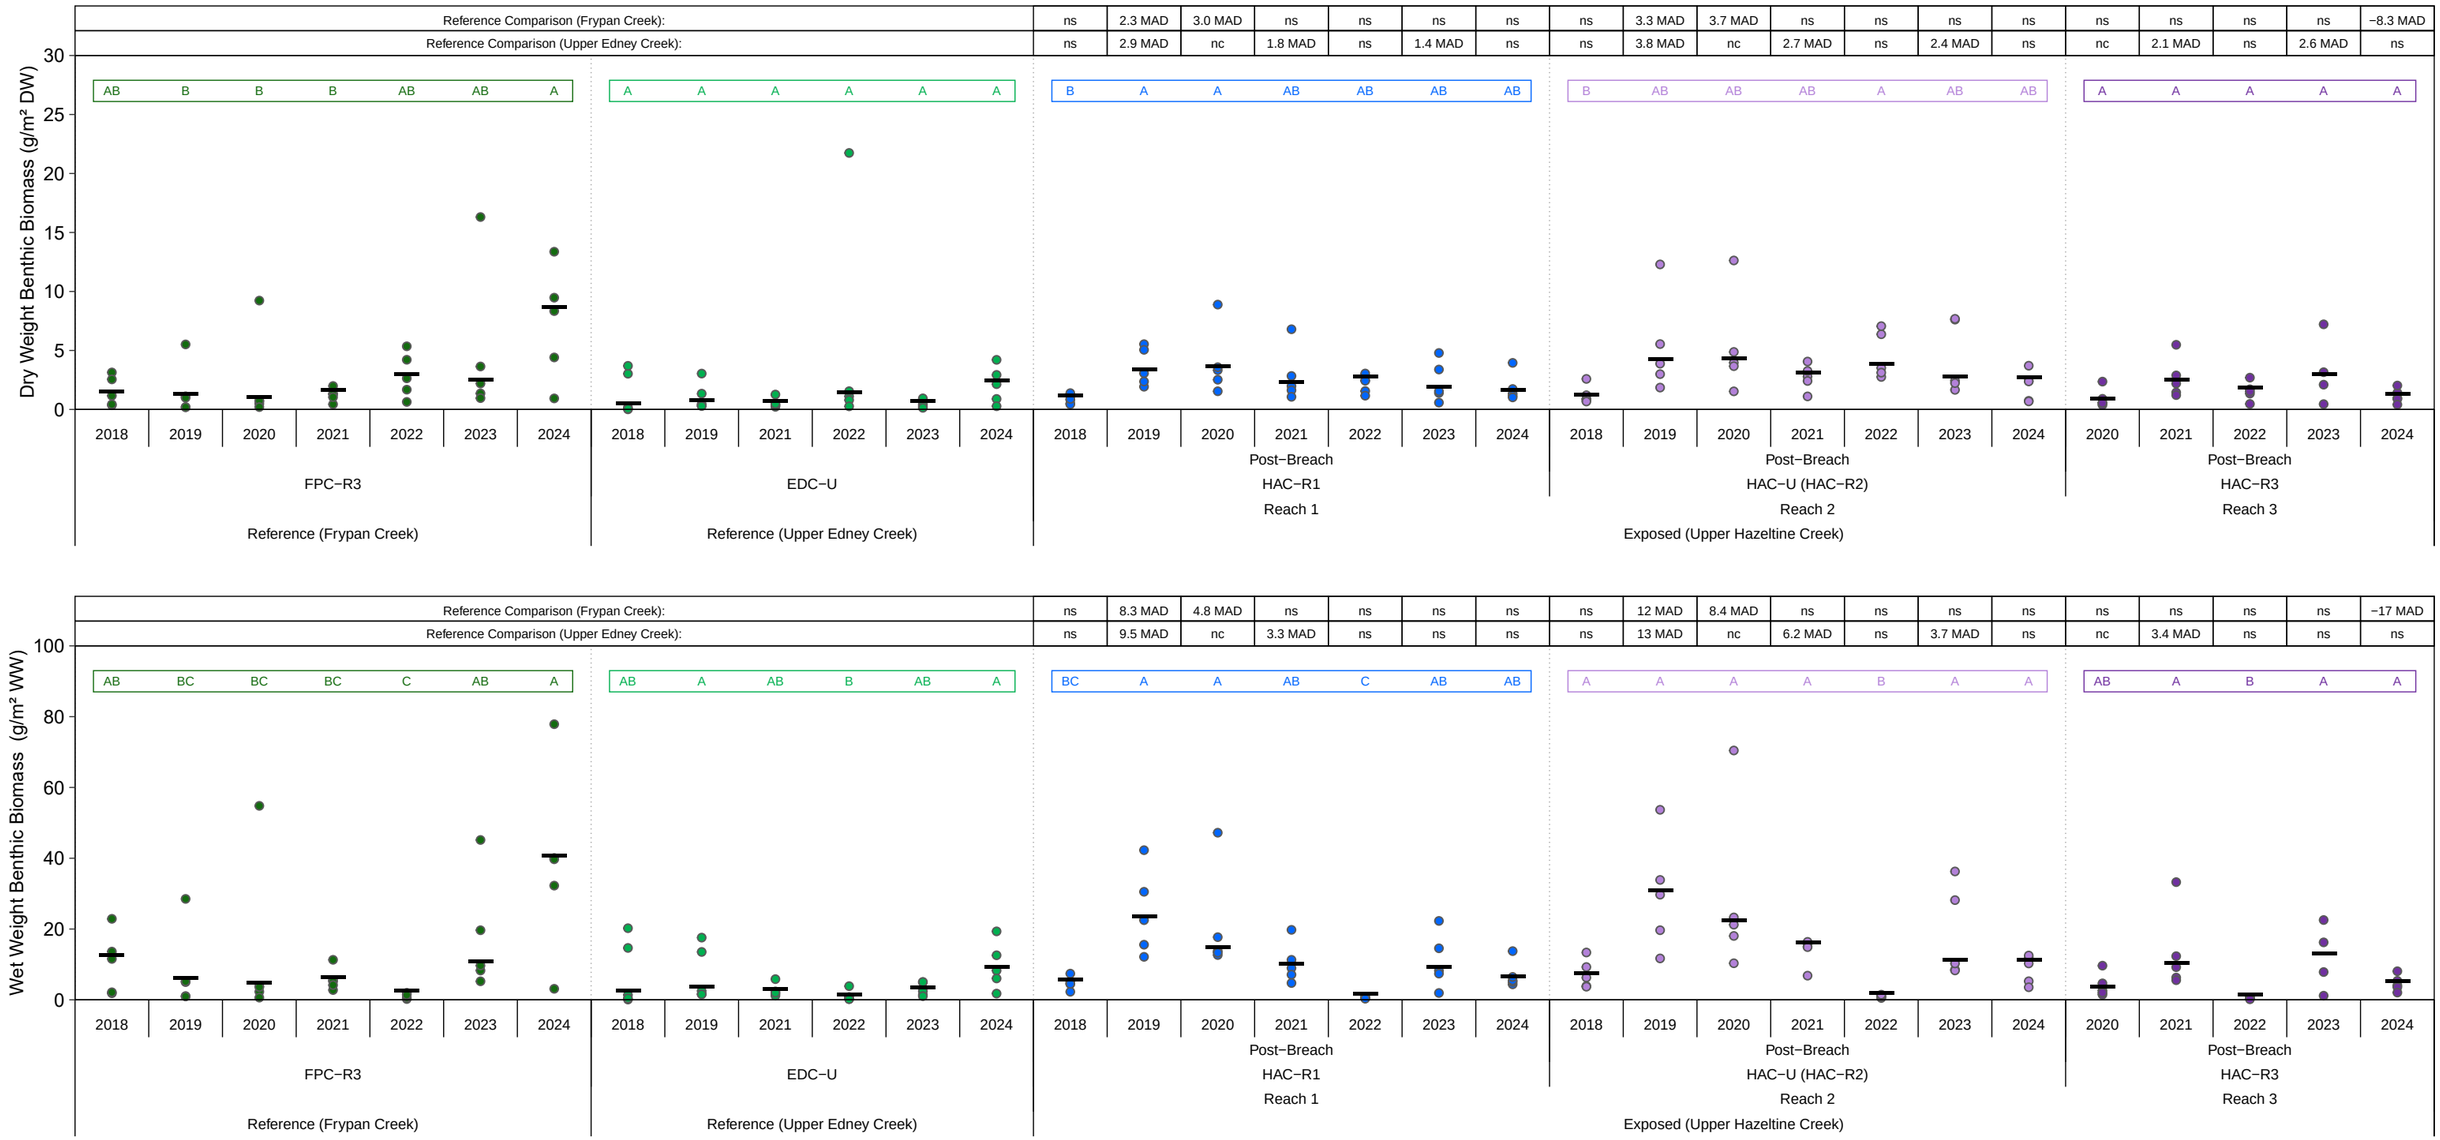

Figure 6.8: Benthic Invertebrate Biomass for the Upper Hazeltine Creek (HAC−R1, HAC−U [HAC−R2], HAC−R3; Exposed), Frypan Creek (FPC−R3; Reference), and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 2018 to 2024

Notes: DW = dry weight. WW = wet weight. g/m² = grams per square metre. The EDC−U reference area was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC−R1, HAC−U (HAC−R2), and HAC−R3. Monitoring at area HAC−R3 was initiated in 2020. See Section 4.3 for details. HAC−R2 is the alternate name used for the HAC−U sampling area for Habitat Remediation Working Group (HRWG) reporting. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) *post hoc* comparisons within areas over time. Letter colours and boxes indicate the area contrasted. A number above the plot indicates significant exposed vs. reference *post hoc* comparisons within a given year. The Magnitude of Difference (MOD) for these significant *post hoc* comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank− transformed prior to analysis) relative to reference. A 'nc' indicates no comparisons were possible, a 'ns' indicates a non−significant contrast.

invertebrate community at HAC-D in 2021 represented the community weeks after completion of final remediation works in this area. For taxon richness and Simpson's Diversity, the similarity to reference and pre-breach in 2023 represented a return to conditions observed in 2017. For density, the similarity to reference and pre-breach in 2023 represented an improvement relative to all prior years. Simpson's Evenness was temporally stable and similar to reference and pre-breach from 2017 to 2023.

The community composition (%) of lower Hazeltine Creek was dominated by Chironomidae (%) and to a lesser extent EPT (%), which were significantly more and less prevalent, respectively, than reference. Within EPT, Ephemeroptera (%) and Plecoptera (%) at HAC-D were significantly lower, and Trichoptera (%) at HAC-D were significantly higher, than reference and pre-breach from 2017 to 2023 with few exceptions. Although EPT (%) in lower Hazeltine Creek in 2023 remained lower than reference, the difference from reference was smaller in 2023 than in 2021 (immediately following the remediation works), owing to a significant increase in Ephemeroptera and Trichoptera (% and density) from 2021 to 2023. The differences in dominant benthic invertebrate taxa between HAC-D and the reference area in 2023 were consistent with the ongoing recovery of community composition following habitat remediation efforts in lower Hazeltine Creek in 2021. Correlation analysis indicated that physical characteristics of the exposed lower Hazeltine Creek area (water depth, velocity, temperature, and substrate size) were the most likely influencing factors on benthic invertebrate community condition and composition rather than water quality parameters.

Collectively, the results indicated substantial recovery of benthic invertebrate community in lower Hazeltine Creek since 2021 (after final remediation works), with density, taxon richness, and Simpson's Diversity and Evenness having recovered to a condition similar to reference and pre-breach. However, the differences in community composition that remained in lower Hazeltine Creek compared to reference and pre-breach conditions suggested that recovery of the community in this remediated area was still ongoing.

6.1.3.3.2 Productivity

Mean total dry biomass of benthic invertebrates at lower Hazeltine Creek (HAC-D) in 2023 was significantly higher than reference (EDC-D), which differed from results in 2017 to 2021 when mean biomass at HAC-D was significantly lower than reference. Compared to previous monitoring years, mean dry and wet biomass at HAC-D did not change significantly over time. Mean wet benthic invertebrate biomass at HAC-D was similar to reference in 2023 and 2019, but significantly lower in than reference in 2017 and 2021. The similar (wet) or higher (dry) benthic invertebrate biomass at E1 relative to reference in 2023, indicated benthic invertebrate productivity at this area had recovered to reference conditions.

6.1.4 Periphyton and Benthic Invertebrate Tissue Quality

Periphyton and benthic invertebrate tissue quality monitoring was completed annually between 2022 and 2024, with monitoring in each year including two exposed areas of upper Hazeltine Creek (HAC-R1 and HAC-U [HAC-R2]) with upper Edney Creek (EDC-U) serving as reference, and one exposed area of lower Hazeltine Creek (HAC-D [HAC-R5]) with an unimpacted area of lower Edney Creek (EDC-D [EDC-REF]) serving as reference (Figure 4.2; Table 4.4).[68]

A review of the 2024 periphyton and benthic invertebrate tissue quality results (Appendix B) indicated that the data largely met the established DQOs. Specifically, the data were characterized by appropriate detectability, negligible analyte concentrations in MB samples, and excellent laboratory accuracy. Laboratory duplicate samples failed the DQO in 6.90% of results. Periphyton and benthic invertebrate tissue field duplicate samples generally had low agreement, and the recommended DQO for field precision was exceeded in 87% of field duplicate pairs. Reanalysis was requested for several duplicate pairs and the results generally confirmed poor agreement between the parent and duplicate samples. Low precision between field duplicate samples was a result of sample heterogeneity (e.g., taxonomic variability in composite-taxa samples or natural variability within a single taxon); however, the collection of replicated samples (n = 8 per area in accordance with the CEMP; MPMC 2019) helped to characterize this variability. Overall, the tissue quality data can be used with a high level of confidence for interpretation, although the occurrence of some natural heterogeneity in analyte results were considered during data interpretation. A review of 2024 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

Data interpretation was focused on primary and secondary analytes (Table 2.4) with a significant positive relative (exposed-reference) difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2024 (if the analysis *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant[69]) for at least one tissue type (periphyton, caddisfly, or composite-taxa benthic invertebrate) in at least one area.

Data interpretations were further focused by integrating the results of water quality monitoring (i.e., bioconcentration) and TTFs of benthic invertebrate tissue analyte concentrations.

[68] For HRWG reporting, HAC-R2, HAC-R5, and EDC-REF are the alternate names used for the HAC-U, HAC-D, and EDC-D sampling areas. The original area names only (i.e., HAC-U, HAC-D, and EDC-D) are used throughout the remainder of this report section (Section 6.1.4).

[69] If no significant change was detected in the relative (exposed-reference) difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

Specifically, water quality data (and BCFs) for the analytes selected for data interpretation were examined to determine whether the significantly higher analyte concentrations in exposed tissues (relative to reference) were related to water quality. The TTFs for the analytes selected for data interpretation were also evaluated to determine if these analytes were bioaccumulating in the aquatic biota in Hazeltine Creek. Combined, these approaches were used to identify analytes for which concentrations in biota and TTFs at the exposed areas have increased at a rate that differs from reference and that may represent a potential risk to aquatic biota. This interpretive approach was completed separately for upper and lower Hazeltine Creek areas because the results for these areas differed slightly. Results for composite-taxa benthic invertebrate tissue samples are referred to as composite-taxa for the remainder of this section.

6.1.4.1 Upper Hazeltine Creek

For most analytes evaluated, there was no increase in concentrations in periphyton and/or benthic invertebrate tissues at the exposed areas of upper Hazeltine Creek (HAC-R1 and HAC-U) relative to the reference area (EDC-U) over time (Appendix Figures F.4.1 to F.4.6, Appendix Tables D.5.1 to D.5.3, F.4.1 to F.4.10). Three primary analytes (arsenic, copper, and selenium) and seven secondary analytes (barium, calcium, manganese, molybdenum, strontium, titanium, and vanadium) met the criteria for inclusion in data interpretation outlined above (i.e., had concentrations in at least one tissue type from at least one area of the exposed upper Hazeltine Creek areas that were significantly higher than reference in 2024 or in all years; Figures 6.9 and 6.10, Table 6.7). Of these analytes, copper and titanium did not show a significant *Area×Year* interaction for at least one tissue type from upper Hazeltine Creek.

MPMC implements routine water quality monitoring in upper Hazeltine Creek at HAC-13 (a station within the sampling area of HAC-R1) and at HAC-05a (a station downstream of HAC-U; Figure 4.2). Results from these routine water quality monitoring stations indicated that only aqueous concentrations of dissolved copper and total selenium exceeded the chronic BCWQG during the preceding year (i.e., September 2023 to August 2024), while the remaining analytes remained below the applicable BCWQG. Specifically, the chronic BCWQG for dissolved copper, which is based on the BLM (BCMOWLRS 2025) was exceeded in 92% and 75% of the samples collected from station HAC-13 (HAC-R1) and station HAC-05a (HAC-U), respectively. Further, the chronic BCWQG for total selenium was exceeded in 8.3% and 33% of the samples collected from station HAC-13 and station HAC-05a, respectively (Appendix Tables D.1.3 and D.1.4). Temporal analysis of routine water quality data from HAC-13, and HAC-05a from 2015 to 2024 indicated that, of the primary and secondary analytes identified for data interpretation (above), only concentrations of total vanadium (at HAC-13 only) and dissolved vanadium (at both HAC-13 and HAC-05a) increased significantly

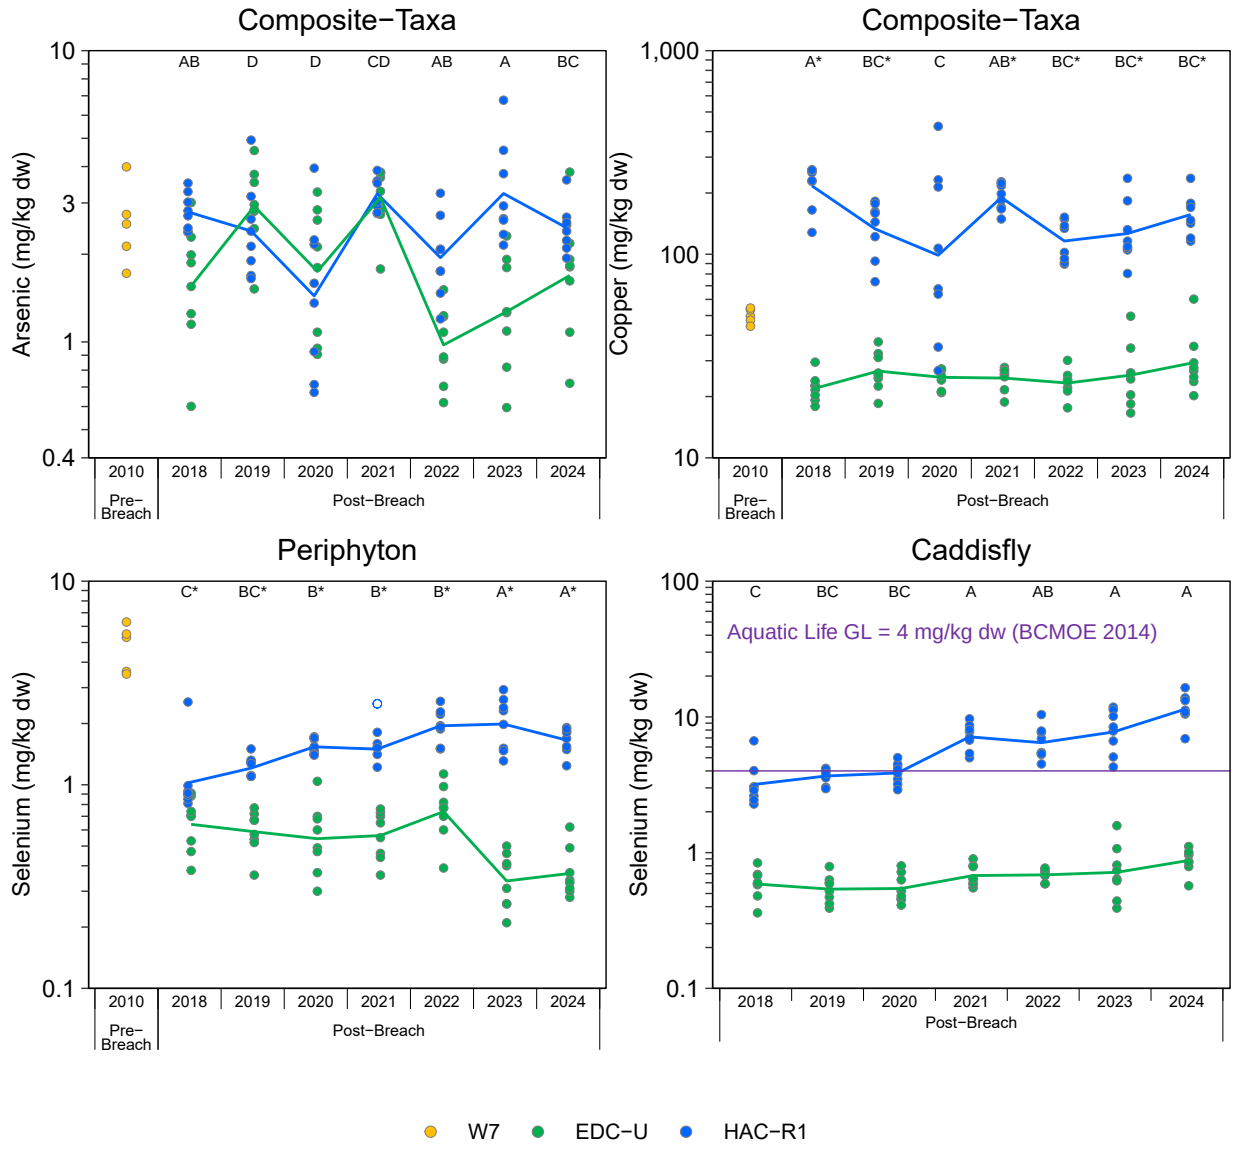

Figure 6.9: Periphyton, Caddisfly, and Composite−Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for the Upper Hazeltine Creek (HAC−R1; Exposed) and Upper Edney Creek (EDC−U; Reference) Monitoring Areas, 2010 to 2024

Notes: GL = Guideline, mg/kg dw = milligrams per kilogram dry weight. Green represents reference areas and blue represents exposed areas. W7 (2010) is the pre−breach equivalent of HAC−R1. Plots are only included for primary and secondary analytes with a significant positive exposed−reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant). Data are not available for all years within the date range identified, only years with available data are displayed and these are analyte−dependent. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log −normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Letters with a * designate years where the exposed site is different than pre −breach conditions, as determined using a one−way temporal ANOVA. Only years with samples from both reference and exposed areas are plotted.

Indicates significantly higher tissue concentration at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

(↑) = Indicates significantly higher tissue concentration relative to pre-breach in 2010 (α = 0.05).

(↓) = Indicates significantly lower tissue concentration relative to pre-breach in 2010 (α = 0.05).

(ns) = no significant different in analyte concentration relative to pre-breach in 2010 (α = 0.05).

Notes: "-" = no statistical comparison could be made because data were not available or all results below Laboratory Reporting Limit (LRL), refer to Appendix Tables F.4.1 to F.4.10 and F.4.17 to F.4.21 for statistical analyses results and magnitude of difference calculations. Data were analysed in units of mg/kg dry weight. <LRL = greater than 50% LRL data for both stations so the time period was omitted from the analysis. HAC-R2, EDC-REF, and HAC-R5 are the alternate names for the HAC-U, EDC-D, and HAC-D sampling areas, respectively, for HRWG reporting.

[a] This table only presents results for primary and secondary analytes with a significant positive exposed-reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant) for one or more tissue types (periphyton, caddi or composite benthic invertebrate) in at least one area. Years that share a letter (e.g., A,B,C) had ratios of analyte concentrations (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

(Appendix Figures D.1.1 to D.1.3, Appendix Table D.1.9). Evaluation of aqueous selenium speciation parameters was initiated in 2024 (see Section 4.6 for details) to investigate possible causes of the temporal increases of selenium concentrations in periphyton and benthic invertebrate tissues from Hazeltine Creek (Minnow 2024a). This monitoring indicated that mean concentrations of selenate at HAC-13 and HAC-05a were 2.2- and 13-times those reported at the reference area (EDC-U), respectively, which was generally consistent with the aqueous total selenium concentrations discussed below. Mean concentrations of selenite at HAC-13 and HAC-05a were 1.7- and 2.5-times those reported at the reference area, respectively, and concentrations of the remaining measured selenium species (selenocyanate and unknown selenium species) were below the LRL at all sampling stations (Appendix Tables D.1.2 to D.1.4, Appendix Figure D.1.4).

Of the three primary and seven secondary analytes identified for inclusion in data interpretation, mean dissolved aqueous concentrations of copper and selenium were elevated (greater than 2-times reference) at HAC-R1 and HAC-U in 2024 relative to reference, as were the secondary analytes calcium, molybdenum, strontium, uranium (Table 6.8, Appendix Tables D.1.3 and 1.4).[70] Specifically, mean aqueous dissolved concentrations of copper at HAC-R1 and HAC-U were higher than reference by 4.1- and 4.4-times, respectively, while dissolved selenium concentrations were more elevated compared to reference (5.6- and 13.2-times, respectively; Table 6.8). Despite dissolved aqueous concentrations of copper and selenium being elevated relative to reference, BCFs for primary analytes in tissues from upper Hazeltine Creek were lower than reference or only slightly elevated (< 2-times) relative to reference in most cases in 2024, as expected[71], with few exceptions. These exceptions were for the BCFs for arsenic in composite-taxa tissues from HAC-R1 and HAC-U (2.1- and 3.1-times reference, respectively) and for the BCF for selenium from HAC-R1 (2.4-times reference; Table 6.8). For the secondary analytes identified, the BCFs were between 2- and 10-times greater than reference for barium, calcium, manganese, and strontium, in at least one tissue type for at least one area of upper Hazeltine Creek, while the composite-taxa BCF for manganese were also 17.6-times higher than reference at HAC-U (Table 6.8).

Mean copper concentrations in most tissue types from upper Hazeltine Creek were consistently elevated relative to the reference area (EDC-U) from 2018 to 2024, with the exception of caddisfly tissues at HAC-R1 (in 2022 and 2024) and HAC-U (in 2020 and 2021), and periphyton tissues

[70] Elevated analytes were identified as those with mean concentrations at the exposed station that were at least twice the mean concentration at the reference station.

[71] Both BCFs and trophic TTFs are generally expected to decrease with increasing concentration. Increased BCFs and TTFs with increasing concentrations can be suggestive of enhanced bioavailability or reduced ability of organisms to regulate analytes.

Table 6.8: Summary of Primary and Secondary Analyte Concentrations in Water, Periphyton, Caddisfly, and Composite-Taxa Tissues, BCFs, and TTFs for the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D [HAC-R5]; Exposed), and Lower Edney Creek (EDC-D [EDC-REF]; Reference) Monitoring Areas, 2024

Dissolved concentration at exposed area exceeded reference area by less than 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 5-times.
Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05).
Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05).
BCF for exposed area exceeded reference area by less than 2-times.
BCF for exposed area exceeded reference area by at least 2-times.
BCF for exposed area exceeded reference area by at least 10-times.
Mean TTF exceeds 1.
Mean TTF at exposed area exceeds 1 and the corresponding reference area TTF for a given year.
Mean TTF at exposed area exceeds 1, the corresponding reference area TTF for a given year, and mean TTFs for all previous years (pre-breach and 2017 when applicable).

BOLD = mean tissue selenium value exceeds long-term benthic invertebrate tissue guideline for selenium (4 mg/kg dw; BCMOE 2014).

BOLD/ITALICS = Indicates dissolved water value greater than the long-term average British Columbia Water Quality Guideline (BCMOWRLS 2024, 2025).

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., those with a significant positive exposed - reference difference in 2024 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = no data for dissolved water concentration/ BCF was not calculated for analytes due to no data for dissolved water concentration. "na" = not applicable. Summary statistics reported to 3 significant figures for display purposes. HAC-R2, HAC-R5, and EDC-REF are the alternate names for the HAC-U, HAC-D, and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Monitoring stations included W10, HAC-13, HAC-05a, and HAC-08 for corresponding tissue sampling stations EDC-D, HAC-R1, HAC-U, and HAC-D, respectively (refer to Appendix Tables D.1.3, D.1.4, D.1.6, and D.1.7). For EDC-U routine water quality data were not available, so BCFs were calculated using spot water quality samples taken during tissue collection.

[b] Sample sizes for water quality monitoring for EDC-U (EDC-U spot water quality monitoring), EDC-D (W10), HAC-R1 (HAC-13), HAC-U (HAC-05a), and HAC-D (HAC-08) were 1, 1, 8, 8, and 9, respectively.

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2024 and the time of sampling in August 2024 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a, 2023a).

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L), if the dissolved water concentration was reported as below the Laboratory Reporting Limit (LRL), then the LRL was substituted for the BCF calculation.

[f] Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

Table 6.8: Summary of Primary and Secondary Analyte Concentrations in Water, Periphyton, Caddisfly, and Composite-Taxa Tissues, BCFs, and TTFs for the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D [HAC-R5]; Exposed), and Lower Edney Creek (EDC-D [EDC-REF]; Reference) Monitoring Areas, 2024

Dissolved concentration at exposed area exceeded reference area by less than 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 5-times.
Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05).
Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05).
BCF for exposed area exceeded reference area by less than 2-times.
BCF for exposed area exceeded reference area by at least 2-times.
BCF for exposed area exceeded reference area by at least 10-times.
Mean TTF exceeds 1.
Mean TTF at exposed area exceeds 1 and the corresponding reference area TTF for a given year.
Mean TTF at exposed area exceeds 1, the corresponding reference area TTF for a given year, and mean TTFs for all previous years (pre-breach and 2017 when applicable).

BOLD = mean tissue selenium value exceeds long-term benthic invertebrate tissue guideline for selenium (4 mg/kg dw; BCMOE 2014).

BOLD/ITALICS = Indicates dissolved water value greater than the long-term average British Columbia Water Quality Guideline (BCMOWRLS 2024, 2025).

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., those with a significant positive exposed - reference difference in 2024 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = no data for dissolved water concentration/ BCF was not calculated for analytes due to no data for dissolved water concentration. "na" = not applicable. Summary statistics reported to 3 significant figures for display purposes. HAC-R2, HAC-R5, and EDC-REF are the alternate names for the HAC-U, HAC-D, and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Monitoring stations included W10, HAC-13, HAC-05a, and HAC-08 for corresponding tissue sampling stations EDC-D, HAC-R1, HAC-U, and HAC-D, respectively (refer to Appendix Tables D.1.3, D.1.4, D.1.6, and D.1.7). For EDC-U routine water quality data were not available, so BCFs were calculated using spot water quality samples taken during tissue collection.

[b] Sample sizes for water quality monitoring for EDC-U (EDC-U spot water quality monitoring), EDC-D (W10), HAC-R1 (HAC-13), HAC-U (HAC-05a), and HAC-D (HAC-08) were 1, 1, 8, 8, and 9, respectively.

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2024 and the time of sampling in August 2024 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a, 2023a).

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L), if the dissolved water concentration was reported as below the Laboratory Reporting Limit (LRL), then the LRL was substituted for the BCF calculation.

[f] Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

from HAC-R1 (from 2019 to 2021 and in 2024; Figures 6.9 and 6.10, Table 6.7; Appendix Tables D.5.1 to D.5.3, F.4.1 to F.4.10). The relative (exposed-reference) differences of copper concentrations for all tissue types from HAC-R1 and HAC-U in each year were similar to or significantly lower than the first or second year of post-breach monitoring (i.e., 2018 or 2019) with one exception (Figures 6.9 and 6.10, Table 6.7). The one exception was the relative difference of copper concentrations in in composite-taxa tissues from HAC-U that steadily increased from 2020 to 2022 then decreased significantly between 2022 to 2023 and remained unchanged in 2024 (Figure 6.10, Table 6.7). Copper concentrations in composite-taxa tissue from both areas of upper Hazeltine Creek have consistently been significantly higher than pre-breach conditions from 2021 to 2024, but in periphyton tissues were similar to or significantly lower than pre-breach conditions for all years (2018 to 2024; Figures 6.9 and 6.10, Table 6.7). The TTFs for copper in caddisfly tissues were significantly higher than reference in 2018, 2019, and 2021 at HAC-R1 and did not differ from reference at HAC-U (in any years). However, copper TTFs in exposed composite-taxa tissues were significantly higher than reference in all years (i.e., 2018 to 2024) at HAC-R1, and in most years (except 2018 and 2020) at HAC-U (Table 6.9; Appendix Figures F.4.7 to F.4.10, Appendix Tables F.4.11 to F.4.16). The copper TTFs for caddisfly and composite-taxa tissues from HAC- R1 and HAC-U in each year were similar to or significantly lower than the first year of post-breach monitoring (2018), except for the TTF for composite-taxa tissues at HAC-U in 2022 (Table 6.9). Combined, these results indicate that there has been no sustained increase in copper concentrations in the periphyton and benthic invertebrate tissues from upper Hazeltine Creek (or in the trophic transfer of copper to benthic invertebrates) since 2019 or earlier.

Mean concentrations of selenium in all tissue types from upper Hazeltine Creek were consistently elevated relative to the reference area (EDC-U) from 2018 to 2024 (Figures 6.9 and 6.10, Table 6.7; Appendix Tables F.4.1 to F.4.10). In 2024, the relative difference in selenium concentrations for all tissues from upper Hazeltine Creek was significantly higher than in the first year of post-breach monitoring (2018), except for composite-taxa tissues from HAC-R1. The relative (exposed-reference) difference of selenium concentrations decreased significantly between 2023 and 2024 in composite-taxa tissues from HAC-R1 and caddisfly tissues from HAC-U. For composite-taxa tissues from HAC-R1, this significant decrease between 2023 and 2024 resulted in selenium concentrations in 2024 that were similar to the first year of post-breach monitoring (2018; as well as 2019 and 2022), and for caddisfly tissues from HAC-U this resulted in selenium concentrations in 2024 that were similar to those in 2021 and 2022 (Figures 6.9 and 6.10, Table 6.7). The relative difference of selenium concentrations in most remaining tissues from upper Hazeltine Creek have been stable since at least 2021, except for periphyton tissue from HAC-R1. For periphyton tissue at HAC-R1, the relative difference in

Table 6.9: Summary of Statistical Contrasts for Caddisfly and Composite-Taxa Benthic Invertebrate Tissue Trophic Transfer Factors of Primary and Secondary Analytes with a Significant Positive Exposed - Reference Relative Difference for the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D [HAC-R5]; Exposed), and Lower Edney Creek (EDC-D [EDC-REF]; Reference) Monitoring Areas, 2018 to 2024[a]

Indicates significantly higher TTF at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

(↑) = Indicates significantly higher tissue concentration relative to pre-breach in 2010 (α = 0.05).

(↓) = Indicates significantly lower tissue concentration relative to pre-breach in 2010 (α = 0.05).

(ns) = no significant different in analyte concentration relative to pre-breach in 2010 (α = 0.05).

Notes: "-" = no statistical comparison could be made since data were not available or all results were below Laboratory Reporting Limit (LRL). Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated. Refer to Appendix Tables F.4.11 to F.4.16 and F.4.22 to F.4.24 for statistical analyses results and magnitude of difference calculations. HAC-R2, HAC-R5, and EDC-REF are the alternate names for the HAC-U, HAC-D, and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., those with a significant positive exposed - reference difference in 2024 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). Years that share a letter (e.g., A,B,C) had ratios of TTFs (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

selenium concentrations was temporally stable from 2019 to 2022, then increased significantly in 2023 and remained unchanged in 2024, largely owing to a decrease in reference concentrations in 2023 and 2024 (Figures 6.9 and 6.10, Table 6.7). Mean concentrations of selenium in caddisfly (11.7 mg/kg dw at HAC-R1 and 14.0 mg/kg dw at HAC-U) and composite-taxa (4.61 mg/kg dw at HAC-R1 and 9.58 mg/kg dw at HAC-U) tissues from upper Hazeltine Creek in 2024 were above the BC interim guideline for aquatic life (4 mg/kg dw; BCMOE 2014; Table 6.8; Appendix Tables D.5.2 and D.5.3), which is consistent with most results from 2020 to 2023 (Figures 6.9 and 6.10). The selenium concentrations in caddisfly tissues from HAC-U in 2024 were notable, with a mean concentration that was 3.5-times the guideline (14.0 mg/kg dw), and a maximum concentration 5-times the guideline (20.1 mg/kg dw; Figure 6.10; Appendix Table D.5.2). Similar to previous monitoring years, selenium concentrations in periphyton and composite-taxa tissues[72] remained significantly lower than or similar to pre-breach conditions for both areas of upper Hazeltine Creek (Figures 6.9 and 6.10, Table 6.7; Appendix Tables D.5.1 to D.5.3, F.4.1 to F.4.10).

The TTFs for selenium in caddisfly and composite-taxa tissues from upper Hazeltine Creek were consistently higher than reference (from 2018 to 2024), except for composite-taxa tissue at HAC-R1 in 2023 and 2024 which was similar to reference (Table 6.9). Evaluation of temporal changes showed that selenium TTFs from upper Hazeltine Creek in 2024 were similar to or significantly lower than the first year of post-breach monitoring (2018) and also similar to prebreach conditions (Table 6.9). The TTFs for selenium in caddisfly tissues from HAC-R1 and composite-taxa tissues from HAC-U were temporally stable from 2018 to 2024. In contrast, the selenium TTFs in composite-taxa tissues from HAC-R1 in 2024 were similar to 2023 but significantly lower than all other prior years, while the selenium TTFs for caddisfly tissues from HAC-U decreased significantly between 2023 and 2024 to a result that was similar to all prior years. These decreases in the selenium TTFs for composite-taxa and caddisfly tissues from HAC-R1 and HAC-U, respectively, in 2024 compared to prior years corresponded with significantly decreased selenium concentrations in these benthic invertebrate tissues.

Collectively, temporal evaluations of tissue selenium results from upper Hazeltine Creek indicated an increase in post-breach periphyton and benthic invertebrate tissue selenium concentrations and trophic transfer of selenium to benthic invertebrates, particularly in caddisfly tissues, relative to reference. The increased selenium concentrations in benthic invertebrate tissues in upper Hazeltine Creek over the post-breach period (and increased TTFs for caddisfly tissue) have corresponded with increases in sediment selenium concentrations compared to reference (see Section 6.1.1.1 for sediment results), but not with aqueous total and dissolved selenium

[72] Caddisfly tissue results cannot be compared to pre-breach values because monitoring of this tissue type was initiated in 2018.

concentrations (which have not changed or decreased significantly from 2015 to 2024; Appendix Figures D.1.1. to D.1.3, Appendix Table D.1.9). In addition, the greater elevation of selenium concentrations in benthic invertebrate tissues from HAC-U compared to HAC-R1 in 2024 (and prior years) corresponded with the higher aqueous concentrations of total and dissolved concentrations of selenium, selenate, and selenite at this area (Appendix Figures D.1.1 to D.1.4, Appendix Tables D.1.3 and D.1.4). Dietary exposure is a more likely predictor of selenium bioaccumulation in benthic invertebrates (Mendes et al. 2023) than sediment exposure and primary benthic invertebrate consumers (e.g., scrapers, shredders, filterers, and collector-gatherer feeding groups of periphyton) typically have higher tissue selenium concentrations than predatory benthic invertebrate consumers. Caddisflies, in particular, have been shown to be 'hyper-accumulators' of selenium (Wayland and Crosley 2006; Mendes et al. 2022; Mendes et al. 2023) which is consistent with the higher selenium concentrations observed in caddisfly tissue compared to composite-taxa tissue samples. An increase in the selenium concentrations of any benthic invertebrate tissues did not occur over the last year (i.e., since 2023), and has not occurred in most benthic invertebrate tissues since at least 2021, with the notable exception of caddisflies from HAC-U in 2022 and 2023. Rather, the concentrations of selenium in exposed tissues and the trophic transfer of selenium to benthic invertebrates in 2024 were both lower than at least one prior year for composite-taxa and caddisfly tissues from HAC-R1 and HAC-U, respectively.

The third primary analyte, arsenic, had significantly higher concentrations relative to reference for composite-taxa tissues in 2024 at both HAC-R1 and HAC-U (Figures 6.9 and 6.10, Table 6.7). The relative difference for arsenic in composite-taxa tissues has not increased significantly compared to the first year of post-breach monitoring (2018), except for at HAC-U in 2022 (Figures 6.9 and 6.10, Table 6.7). Concentrations of arsenic in composite-taxa tissues concentrations from both areas of upper Hazeltine Creek in all post-breach years were similar to or significantly lower than pre-breach concentrations (Table 6.7; Appendix Tables F.4.7 and F.4.10). The TTFs for arsenic in composite-taxa tissues from both upper Hazeltine Creek areas have been significantly higher than reference and pre-breach conditions (for composite-taxa tissues) for all monitoring years, but have not increased significantly compared to the first year of monitoring (i.e., 2018) except for in 2022 at HAC-U (Table 6.9). Although composite-taxa tissue BCFs and TTFs were elevated relative to reference in 2024 (Tables 6.8 and 6.9), the absence of significantly increased concentrations of arsenic in these tissue in 2024 compared to the first year of post-breach monitoring (2018), relative to reference, indicate there was no sustained increase in arsenic concentrations in periphyton or benthic invertebrate tissues or in the trophic transfer of arsenic to benthic invertebrates over the post-breach period.

Concentrations of the seven secondary analytes identified for data interpretation in exposed tissues (barium, calcium, manganese, molybdenum, strontium, titanium, and vanadium) varied among tissue types (Figures 6.9 and 6.10, Table 6.7; Appendix Figures F.4.1 to F.4.6, Appendix Tables D.5.1 to D.5.3, F.4.1 to F.4.10). Periphyton tissues from both upper Hazeltine Creek areas only had concentrations of calcium and strontium that were consistently higher than reference and pre-breach conditions in all years (2018 to 2024; Table 6.7). However, the relative (exposed-reference) difference of calcium and strontium concentrations in periphyton tissues in each year has not increased significantly compared to 2019 or earlier (Figures 6.9 and 6.10, Table 6.7). Composite-taxa tissues from both upper Hazeltine Creek areas also had concentrations of calcium and strontium in 2024 that were significantly higher than reference and pre-breach conditions, except for strontium at HAC-U which was similar to pre-breach conditions. Temporally, the relative difference of calcium and strontium concentrations in composite-taxa tissues at HAC- R1 and HAC-U have varied but in 2024 were significantly lower or similar compared to the first year of post-breach monitoring (Figures 6.9 and 6.10, Table 6.7). The TTFs for calcium and strontium in composite-taxa tissues from both upper Hazeltine Creek areas in 2024 were similar to or significantly lower than reference and pre-breach in 2024 (Table 6.9), although the BCFs for both analytes in composite-taxa tissues were higher compared to reference at both HAC-R1 and HAC-U in 2024 (Table 6.8). These observations indicate that while calcium and strontium concentrations were significantly higher in composite-taxa tissues from upper Hazeltine Creek, there has been no sustained increase in the concentrations of these analytes in exposed tissues over the post-breach period, relative to reference, and the trophic transfer of these analytes to benthic invertebrates has remained lower than reference conditions (Table 6.9; Appendix Figures F.4.7 to F.4.10, Appendix Tables F.4.11 to F.4.16).

Caddisfly and composite-taxa tissues from both areas of upper Hazeltine Creek had concentrations of molybdenum that were significantly higher than reference in most years, excluding 2022 for both tissue types from both areas, 2019 for caddisfly tissues from both areas, and 2023 for caddisfly tissues from HAC-R1 only (Figures 6.9 and 6.10, Table 6.7; Appendix Tables F.4.5 and F.4.10). Although the relative difference of molybdenum concentrations in caddisfly and composite-taxa tissues have varied temporally, the relative difference in 2024 was similar to or significantly lower than the first year of post-breach monitoring. In addition, molybdenum concentrations in composite-taxa tissues from both exposed areas were similar to or significantly lower than pre-breach conditions, except for 2020 at HAC-U (Figures 6.9 and 6.10, Table 6.7). The TTFs for molybdenum in caddisfly and composite-taxa tissues from both areas of upper Hazeltine Creek were significantly higher than at the reference area in most years (including 2024), but for composite-taxa tissues were similar to pre-breach conditions (for which pre-breach data exist), except for at HAC-R1 in 2021 (Table 6.9). The relative differences of the

TTFs in 2024 were similar to the first or second year of post-breach monitoring (i.e., 2018 or 2019), except for the TTFs for caddisfly tissues from HAC-U in 2024 which were significantly higher than most prior years (except 2020; Table 6.9; Appendix Figures F.4.7 to F.4.10, Appendix Tables F.4.11 to F.4.16). However, the relative difference of molybdenum concentrations in caddisfly tissues from HAC-U in 2024 were not similarly higher than most previous years (Figure 6.10, Table 6.7). Collectively, the results for molybdenum indicate there has been no sustained increase in the concentrations of this analyte in periphyton and benthic invertebrate tissues over the post-breach period, and the trophic transfer of molybdenum to benthic invertebrates also did not increase over this period, except for caddisfly tissues from HAC-U.

Concentrations of four secondary analytes in composite-taxa tissues from upper Hazeltine Creek were significantly higher than reference in 2024, including barium concentrations at both areas (HAC-R1 and HAC-U), titanium and vanadium concentrations at HAC-R1, and manganese concentrations at HAC-U (Figures 6.9 and 6.10, Table 6.7). For each of these analytes, the concentrations in composite-taxa tissues from both exposed areas throughout the post-breach monitoring period (i.e., 2018 to 2024) have remained similar to or significantly lower than pre-breach conditions, with one exception (vanadium concentrations at HAC-R1 in 2021). In addition, the relative differences in the concentrations of these analytes in 2024 were similar to the first or second years of post-breach monitoring (i.e., 2018 or 2019), indicating there has been no consistent increase over the post-breach period. For titanium, the relative differences in the concentrations of this analyte in composite-taxa tissues were also temporally stable over the post-breach monitoring period (i.e., no significant *Area*×*Year* interaction). The TTFs for barium in composite-taxa tissues from both upper Hazeltine Creek areas were significantly higher than at the reference area from 2022 to 2024, and in 2019 and 2020 at HAC-R1, and 2019 at HAC-U. Similarly, composite-taxa tissues from HAC-R1 had TTFs for titanium and vanadium that were significantly higher than reference in all years (i.e., 2018 to 2024), as did the composite-taxa TTFs for manganese at HAC-U (Table 6.9). The TTFs for these four analytes were significantly higher than pre-breach conditions in most post-breach monitoring years; however, in all cases the TTFs in 2024 for these analytes in composite-taxa tissues were similar to either the first or second year of post-breach monitoring (Table 6.9; Appendix Figures F.4.7 to F.4.10, Appendix Tables F.4.11 to F.4.16). Combined, these results indicate that there has been no sustained increase over the post-breach period in the concentrations of these four secondary analytes in periphyton and benthic invertebrate tissues or in the trophic transfer of these analytes to benthic invertebrates.

Overall, the results of tissue quality monitoring in upper Hazeltine Creek indicated that while copper concentrations in periphyton and benthic invertebrate tissues in 2024 were significantly higher than reference (all tissue types) and pre-breach (composite-taxa tissues only), there was no consistent increase in the concentrations of copper in exposed tissues over the

post-breach period (i.e., compared to 2019 or earlier), or in the trophic transfer of copper to benthic invertebrates. Selenium concentrations in periphyton and benthic invertebrates (caddisfly and composite-taxa) from upper Hazeltine Creek were consistently higher than reference throughout the post-breach period (i.e., 2018 to 2024). While results indicated a temporal increase in the concentrations of selenium in exposed tissues as well as the trophic transfer of selenium to benthic invertebrates over the post-breach period, relative to reference, no increase occurred over the last year (i.e., since 2023) in any benthic invertebrate tissues from upper Hazeltine Creek. Additionally, most benthic invertebrate tissues have shown no increase in selenium concentrations since at least 2021, with the notable exception of caddisflies from HAC-U in 2022 and 2023. Rather, the concentrations of selenium in exposed tissues, and the trophic transfer of selenium to benthic invertebrates, were lower in 2024 than at least one prior year for composite-taxa and caddisfly tissues from HAC-R1 and HAC-U, respectively. Mean selenium concentrations in benthic invertebrate tissues from upper Hazeltine Creek have been above the guideline for the protection of aquatic life since 2020 or 2021, despite remaining lower than pre-breach conditions (where pre-breach data are available). The magnitude of the selenium guideline exceedance in 2024 was higher at HAC-U than at HAC-R1, which corresponded with the higher aqueous concentrations of total and dissolved concentrations of selenium, selenate, and selenite at this area, as well as increasing concentrations of selenium in sediments over time, relative to reference. For the remaining primary and secondary analytes, there was no sustained increase in the concentrations of these analytes in exposed tissues, relative to reference, or in the trophic transfer of the analytes to benthic invertebrates, over the post-breach period as evidenced by results that were similar to the first or second year of post-breach monitoring (i.e., 2018 or 2019).

6.1.4.2 Lower Hazeltine Creek

For most analytes evaluated, concentrations in periphyton and/or benthic invertebrate tissues at the lower Hazeltine Creek area have not increased relative to the reference area over time (Appendix Figures F.4.11 to F.4.13, Appendix Tables D.5.4 to D.5.6, F.4.17 to F.4.21). Three primary analytes (copper, iron, and selenium) and 11 secondary analytes (barium, cadmium, calcium, cobalt, manganese, mercury, molybdenum, strontium, titanium, uranium, and vanadium) met the criteria for inclusion in data interpretation (i.e., had concentrations in at least one tissue type from the exposed lower Hazeltine Creek area that were significantly higher than reference in 2024 or in all years; Figure 6.11, Table 6.7).

MPMC implements routine water quality monitoring in lower Hazeltine Creek at HAC-08 (a station upstream of HAC-D; Figure 4.2). Results from this routine water quality monitoring station indicated that of the primary and secondary analytes, only aqueous concentrations of dissolved

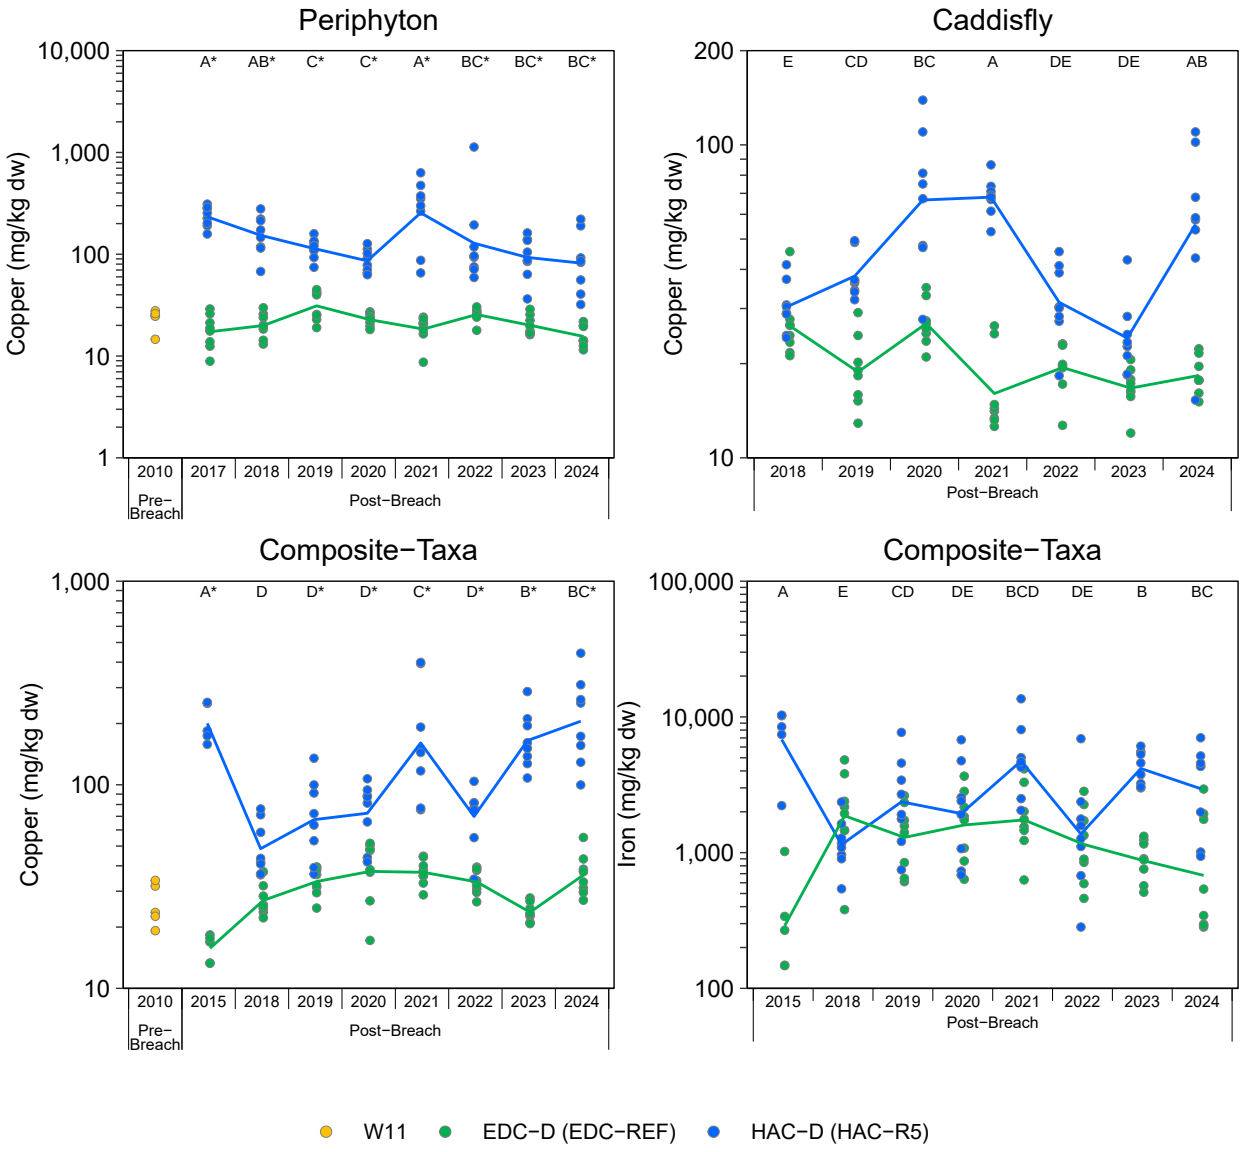

Figure 6.11: Periphyton, Caddisfly, and Composite−Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for the Lower Hazeltine Creek (HAC−D [HAC−R5]; Exposed) and Lower Edney Creek (EDC−D [EDC−REF]; Reference) Monitoring Areas, 2010 to 2024

Notes: GL = Guideline, mg/kg dw = milligrams per kilogram dry weight. Green represents reference areas and blue represents exposed areas. W11 (2010) is the pre−breach equivalent of HAC−D (HAC−R5). HAC-R5 and EDC-REF are the alternate names for the HAC-D and EDC-D sampling areas, respectively, for HRWG reporting. Plots are only included for primary and secondary analytes with a significant positive exposed−reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant). Data are not available for all years within the date range identified, only years with available data are displayed and these are analyte−dependent. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least −squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log-normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Letters with a * designate years where the exposed site is different than pre-breach conditions, as determined using a one-way temporal ANOVA. Only years with samples from both reference and exposed areas are plotted.

copper and total selenium exceeded the BCWQG during the year preceding sampling (i.e., September 2023 to August 2024). Specifically, concentrations of dissolved copper consistently exceeded the chronic BCWQG (100% of samples) and total selenium exceeded the chronic BCWQG in 7.7% of samples (Appendix Table D.1.6). Temporal analysis of routine water quality data from HAC-08 from 2015 to 2024 indicated that, of the three primary and 11 secondary analytes identified for data interpretation (above), only concentrations of dissolved vanadium increased significantly (Appendix Figures D.1.1 to D.1.3, Appendix Table D.1.9). Evaluation of aqueous selenium speciation parameters was initiated in 2024 (see Section 4.6 for details) to investigate possible causes of the temporal increases of selenium concentrations in periphyton and benthic invertebrate tissues from Hazeltine Creek (Minnow 2024a). This monitoring indicated that mean concentrations of selenate and selenite at HAC-08 were 8.3- and 2.6-times those reported at the reference area (EDC-D), respectively. Concentrations of the remaining measured selenium species (selenocyanate and unknown selenium species) were below the LRL at all sampling stations (Appendix Tables D.1.2 and D.1.6, Appendix Figure D.1.4).

Of the three primary and 11 secondary analytes identified for inclusion in data interpretation, only dissolved aqueous concentrations of copper, selenium, calcium, molybdenum, strontium, and uranium were elevated (greater than 2-times reference) at HAC-D relative to the reference area (Table 6.8)[73]. BCFs were slightly (<2-times) higher than reference for copper in caddisfly tissues and for iron in periphyton tissues, were between 2- and 10-times higher than reference for copper in periphyton and composite-taxa tissues and for iron in caddisfly tissues, and were >10-times higher than reference for iron in composite-taxa tissues (Table 6.8). The BCFs for barium and strontium were slightly elevated relative to reference (<2-times), while BCFs were between 2- and 10-times greater than reference for cadmium, calcium, cobalt, manganese, and vanadium, in one or more tissue type (periphyton, caddisfly or composite-taxa) from lower Hazeltine Creek. In addition, the BCF for cadmium in composite-taxa tissues was >10-times greater than reference (Table 6.8).

Mean copper concentrations in periphyton, caddisfly, and composite-taxa tissues from lower Hazeltine Creek (HAC-D) were consistently elevated relative to the reference area (EDC-D) from 2019 onwards (Figure 6.11, Table 6.7; Appendix Tables D.5.4 to D.5.6, F.4.17 to F.4.21). In addition, copper concentrations in periphyton and composite-taxa tissues were consistently higher than pre-breach in most sampling years, except 2018 for composite-taxa tissues (pre-breach data do not exist for caddisfly tissues; Figure 6.11, Table 6.7). Temporally, the relative (exposed-reference) differences in copper concentrations for periphyton

[73] Elevated analytes were identified as those with mean concentrations at the exposed station that were at least twice the mean concentration at the reference station.

and composite-taxa tissue in 2024 were similar to or significantly lower than in the first post-breach year of monitoring (i.e., 2018), and for caddisfly tissues in 2024 were significantly higher than most prior years (including 2018) but were similar to 2020 and 2021 (Figure 6.11, Table 6.7). The TTFs for copper in caddisfly and composite-taxa tissues were similar to or significantly lower than reference and pre-breach conditions in all years (pre-breach data do not exist for caddisfly tissues; Table 6.9; Appendix Tables F.4.22 to F.4.24). Overall, copper concentrations in all three tissue types were significantly higher than reference and pre-breach (where pre-breach data exist), and the BCFs only slightly exceeded the reference conditions in periphyton (2.3-times), composite-taxa (2.3-times), and caddisfly (1.3-times) tissues (Table 6.8). However, copper TTFs were similar to or lower than reference and pre-breach. Combined, these results indicated there was no sustained increase in the concentrations of copper in periphyton and composite-taxa tissues, or in the trophic transfer of copper to benthic invertebrates (caddisfly or composite-taxa), over the post-breach period. The significant increase in the copper concentrations of caddisfly tissues in 2024, relative to reference, represented a return to copper concentrations that were observed during final remediation works in this area (i.e., 2020 and 2021). Continued monitoring will help to determine whether this increase represented a single anomalous year or is part of a long-term trend.

Mean selenium concentrations in caddisfly and composite-taxa tissues from lower Hazeltine Creek (HAC-D) were consistently elevated relative to the reference area (EDC-D) over the post-breach period (i.e., 2018 to 2024), while selenium concentrations in periphyton tissues from HAC-D were significantly higher than reference in 2020, 2022, and 2024 only (Figure 6.11, Table 6.7; Appendix Tables D.5.4 to D.5.6, F.4.17 to F.4.21). The relative (exposed-reference) difference of selenium concentrations in composite-taxa and periphyton tissues in 2024 were significantly higher than all prior monitoring years. Selenium concentrations in these tissues were also significantly higher than pre-breach conditions from 2023 to 2024 for periphyton tissue, and from 2022 to 2024 for composite-taxa tissue (Figure 6.11, Table 6.7). In caddisfly tissues, the relative (exposed-reference) difference of selenium concentrations was stable from 2020 to 2022, then increased significantly in 2023 to higher than all prior years, and decreased again in 2024 to a result that was intermediary to the 2022 and 2023 results (Figure 6.11, Table 6.7). Mean concentrations of selenium in caddisfly (9.12 mg/kg dw) and composite-taxa (6.46 mg/kg dw) tissues from lower Hazeltine Creek in 2024 were above the BC interim guideline for aquatic life (4 mg/kg dw; BCMOE 2014) which is similar to 2021 to 2023, but differs from prior years (2015 to 2020) when mean concentrations were below the guideline (Figure 6.11, Tables 6.7 and 6.8; Appendix Tables D.5.4, D.5.6, D.5.8, and D.5.9). In contrast to the results for selenium concentrations in tissues, the TTFs for selenium in caddisfly and composite-taxa tissues from lower Hazeltine Creek were significantly lower than reference in

2024, similar to 2022, which differs from all other post-breach years when the TTFs for these tissues were significantly higher than reference (Table 6.9; Appendix Tables F.4.22 to F.4.24). For composite-taxa and caddisfly tissues, the relative differences of selenium TTFs in 2024 were similar to 2022 and 2020 but significantly lower than all other prior years. The TTFs for selenium in composite-taxa tissues did not differ significantly from pre-breach conditions in all post-breach monitoring years (pre-breach data do not exist for caddisfly tissues; Table 6.9). The selenium TTF results in 2024 for lower Hazeltine Creek were consistent with the selenium BCFs from this area in 2024, which were also lower than at the reference area for all tissue types (periphyton, caddisfly, and composite-taxa; Table 6.8).

Collectively, evaluations of lower Hazeltine Creek data indicated a temporal increase in post-breach periphyton and benthic invertebrate tissue selenium concentrations, but not in the trophic transfer of selenium to benthic invertebrates, relative to reference. The temporal increase in tissue selenium concentrations was particularly pronounced in caddisfly tissues between 2022 and 2023, which was then followed by a decrease between 2023 and 2024. The selenium concentrations in all three tissue types (periphyton, caddisfly, and composite-taxa) in 2024 were significantly higher than all prior years, relative to reference, except for caddisfly tissues in 2023. In addition, selenium concentrations in periphyton and composite-taxa tissues (tissues for which pre-breach data exist) have been significantly higher than pre-breach conditions since 2023 for periphyton tissues, and since 2022 for composite-taxa tissues. The temporal increases in tissue selenium concentrations in lower Hazeltine Creek over the post-breach period corresponded with increases in sediment selenium concentrations in this area (see Section 6.1.1.2 for sediment results), but not higher BCFs or TTFs compared to reference, or aqueous total and dissolved selenium concentrations (which have not changed or decreased significantly from 2015 to 2024; Appendix Figures D.1.1. to D.1.3, Appendix Table D.1.9). Selenium concentrations in benthic invertebrates from lower Hazeltine Creek have been higher than pre-breach conditions since 2022 and higher than the BC interim guideline for aquatic life since 2021.

For the third primary analyte, iron, mean concentrations in composite-taxa tissues from lower Hazeltine Creek (HAC-D) in 2024 were significantly higher than reference (pre-breach data does not exist for iron; Figure 6.11, Table 6.7). Temporally, the relative differences of iron concentrations in composite-taxa tissues in 2024 were significantly higher than 2018, 2020 and 2022, and similar to or significantly lower than all remaining prior years (including the first year of post-breach monitoring [2015]; Figure 6.11, Table 6.7; Appendix Table F.4.20). The BCFs for iron in composite-taxa tissues from lower Hazeltine Creek in 2024 were higher than reference by 11.8-times (Table 6.8), which was consistent with the TTFs for iron in composite-taxa tissues from HAC-D that were also significantly higher than reference in 2024 (similar to most prior years except for 2018 and 2020). The relative difference of iron TTFs for composite-taxa tissues in

2024 was significantly higher than the first year of monitoring (i.e., 2018), but similar to the second year of monitoring (i.e., 2019; Table 6.9; Appendix Figure F.4.15, Appendix Table F.4.23). The significant increase in TTFs in 2024 compared to 2018 was not reflected in the iron concentrations of composite-taxa tissues, which were significantly lower in 2024 than in the first year of post-breach monitoring (i.e., 2015; Table 6.7). In addition, the TTFs for iron in exposed composite-taxa tissues remained below one, indicating a decrease in iron concentrations between the increasing trophic levels (i.e., between periphyton and benthic invertebrates; Table 6.8). Combined, these results indicate that for those exposed tissues with iron concentrations greater than reference (i.e., composite-taxa), there has not been a sustained increase in the tissue iron concentrations, or in the trophic transfer of iron to benthic invertebrates, compared to at least the second year of post-breach monitoring.

Temporal changes in the 11 secondary analytes identified for data interpretation (barium, cadmium, calcium, cobalt, manganese, mercury, molybdenum, strontium, titanium, uranium, and vanadium) differed between tissue types from lower Hazeltine Creek (HAC-D; Figure 6.11, Table 6.7; Appendix Figures F.4.11 to F.4.13, Appendix Tables D.5.4 to D.5.6, F.4.17 to F.4.21). Mean concentrations of cadmium, calcium, and strontium in periphyton, caddisfly, and composite-taxa tissues from lower Hazeltine Creek (HAC-D) were significantly higher than at the reference area in 2024. For periphyton and composite-taxa tissues from HAC-D (for which there are pre-breach data), the concentrations of these three analytes in 2024 were also significantly higher than pre-breach conditions, except for strontium in composite-taxa tissues (Figure 6.11, Table 6.7). For each of these three analytes, the relative (exposed-reference) differences have varied over time but in 2024 were similar to the first or second year of post-breach monitoring, with three exceptions. The three exceptions were calcium in periphyton and caddisfly tissues and strontium in caddisfly tissues. The relative differences of calcium concentrations in periphyton tissues in 2024 were similar to 2019 but were significantly higher than the prior two years of post-breach sampling (Figure 6.11, Table 6.7). The relative differences of calcium and strontium concentrations in caddisfly tissues were significantly higher in 2024 compared to all previous monitoring years except for 2021 (Figure 6.11, Table 6.7). These results indicated an increase in the cadmium and strontium concentrations in caddisfly tissues at lower Hazeltine Creek in 2024, relative to reference, but this was isolated to caddisfly tissue (i.e., not similarly observed in periphyton or composite-taxa samples). The TTFs for calcium, cadmium, and strontium in the three tissue types (periphyton, caddisfly, and composite-taxa) from HAC-D were similar to or significantly lower than reference in all years (except for cadmium in caddisfly tissue in 2021; Table 6.9; Appendix Tables F.4.22 to F.4.24), indicating no potential mine-related influence on the trophic transfer of these analytes to benthic invertebrates. The BCFs for these three tissue types from HAC-D in 2024 were relatively

similar to those from the reference area for strontium and calcium (except for the BCF for calcium in periphyton tissue which was 3.8-times reference). The BCFs for cadmium in tissues from HAC-D in 2024 were more elevated compared to reference (3.9-, 3.5-, and 11.5-times higher than reference in periphyton, caddisfly, and composite-taxa tissues; Table 6.8), however as indicated above, the concentrations of cadmium in these three tissue types from HAC-D have not increased relative to the first or second year of post-breach monitoring.

Mean concentrations of barium and manganese in periphyton and composite-taxa tissues from HAC-D were significantly higher than reference in 2024 and were similar to or significantly lower than pre-breach conditions in all post-breach years (Figure 6.11, Table 6.7). The relative differences of these two analytes in periphyton and composite-taxa tissues in 2024 were similar to or significantly lower than the first year of monitoring, except for manganese in periphyton which had a relative difference in 2024 that was significantly higher than all prior years (Figure 6.11, Table 6.7). These results indicated an increase in the manganese concentrations of periphyton tissues from lower Hazeltine Creek in 2024, relative to reference, but this was isolated to periphyton tissues only. The TTFs for barium and manganese in composite-taxa tissues from HAC-D in 2024 were similar to both reference and pre-breach conditions (Table 6.9; Appendix Tables F.4.22 to F.4.24). The BCFs for composite-taxa tissues from HAC-D in 2024 were similarly only slightly (1.5-times) higher than reference for barium, while the BCFs for manganese were more elevated compared to reference in 2024 (3.7-times; Table 6.8).

In addition to the secondary analytes discussed above, the composite-taxa tissues from lower Hazeltine Creek in 2024 also had concentrations of the secondary analytes cobalt, mercury, molybdenum, titanium, uranium, and vanadium that were significantly higher than reference but similar to or significantly lower than pre-breach conditions, except for mercury concentrations which were significantly higher than pre-breach (Figure 6.11, Table 6.7, Appendix Tables F.4.20, and F.4.21). For five of these six analytes (excluding mercury), the relative difference in analyte concentrations in 2024 was similar to or significantly lower than the first or second year of monitoring, indicating there has been no sustained increase in the concentrations of these analytes in exposed composite-taxa tissues over this period, relative to reference. For mercury, the relative difference of concentrations in composite-taxa tissues in 2024 was significantly higher than all prior years (i.e., 2018 to 2023; Figure 6.11, Table 6.7).

The TTFs for these six secondary analytes in composite-taxa tissues from lower Hazeltine Creek in 2024 (cobalt, mercury, molybdenum, titanium, uranium, and vanadium) were significantly higher than reference but similar to pre-breach (where pre-breach data exists; Table 6.9; Appendix Figure F.4.15, Appendix Tables F.4.22 to F.4.24). The relative (exposed-reference) difference of TTFs for the majority of these six analytes in each year has been similar to or

significantly lower compared to the second year of post-breach monitoring (i.e., 2019). This was not true for titanium and vanadium, which had significantly higher relative differences in 2024 when compared to 2021 (and earlier) for vanadium, and 2020 (and earlier) for titanium (Table 6.9; Appendix Figure F.4.15). The BCF for titanium in composite-taxa tissues was 4.6-times higher than the reference, while the BCF for vanadium was 4.9-times higher (Table 6.8). While aqueous concentrations of total vanadium significantly increased in lower Hazeltine Creek (from 2015 to 2024), no significant temporal increase in titanium concentrations was observed over the same period (Appendix Table D.1.9). However, TTFs for both titanium and vanadium in composite-taxa tissues in 2024 remained similar to pre-breach and were below a value of one, indicating that concentrations of these analytes decreased between with increasing trophic levels (i.e., between periphyton and benthic invertebrates; Tables 6.8 and 6.9). Overall, the results indicated that the relative differences of concentrations of these six analytes in composite-taxa tissues from HAC-D (cobalt, mercury, molybdenum, titanium, uranium, and vanadium) did not show a sustained increase over the post-breach period (i.e., compared to the first or second year of post-breach monitoring), with one exception. The one exception was mercury in composite-taxa tissues which had significantly higher relative differences of concentrations in 2024 compared to all prior years, but this was isolated to composite-taxa tissues. Continued monitoring will help to determine whether the increased concentrations of mercury in composite-taxa tissues represent a single anomalous year or are part of a long-term trend. Although the trophic transfer of titanium and vanadium to composite-taxa tissues in 2024 was higher compared to prior years, this did not correspond with an increase in the concentrations of these two analytes in composite-taxa tissues, and trophic transfer was similar to pre-breach conditions.

Overall, the results of tissue quality monitoring in lower Hazeltine Creek indicated that copper concentrations in periphyton and benthic invertebrate tissues were significantly higher than reference and pre-breach (where pre-breach data exist). However, the copper concentrations in these tissues, and the trophic transfer of copper to benthic invertebrates, have not shown sustained increases over the post-breach period, except for the copper concentrations in caddisfly tissues. In caddisfly tissues, copper concentrations increased significantly between 2023 and 2024, relative to reference, representing a return to the concentrations observed during final remediation works in this area (i.e., 2020 and 2021), but this increase was limited to caddisfly tissues only. Temporal evaluations indicated a temporal increase in the selenium concentrations in periphyton and benthic invertebrate tissues from lower Hazeltine Creek over the post-breach period to concentrations that were higher than pre-breach conditions (where data exist). Selenium concentrations in periphyton and benthic invertebrate tissues from lower Hazeltine Creek were consistently higher than reference throughout the post-breach period, and in 2024

were significantly higher than all prior years, except for caddisfly tissues in 2023. The temporal increases in tissue selenium concentrations in lower Hazeltine Creek over the post-breach period corresponded with temporal increases in sediment selenium concentrations in this area, but not higher BCFs or TTFs for selenium compared to reference, or aqueous total and dissolved selenium concentrations. Selenium concentrations in benthic invertebrates from lower Hazeltine Creek have been higher than pre-breach conditions since 2022 and higher than the BC interim guideline for aquatic life since 2021. For the remaining primary and secondary analytes, there were no increases in the concentrations of these analytes compared to 2020 or earlier in more than one tissue type. Concentrations of four secondary analytes (calcium, manganese, mercury, and strontium) in 2024 were significantly higher than all prior years, but these increases were isolated to a single tissue-type for each analyte and were not supported by similar increases in the trophic transfer of these analytes to benthic invertebrates over time or compared to the reference area. Continued monitoring will help to determine whether the increased concentrations of cadmium, manganese, mercury, and strontium represented a single anomalous year or are part of a long-term trend.

6.1.4.3 Tissue-Type Comparison

A comparison between benthic invertebrate (caddisfly and composite) tissue findings was completed to evaluate if results were consistent between the two tissue types. This qualitative comparison focused on analytes with a significant positive relative (exposed-reference) difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2024 or in all monitoring years for at least one tissue type in at least one area.

Among the primary analytes, the significant positive exposed-reference differences detected in analyte concentrations and TTFs for caddisfly tissues in 2024 were largely a subset of those detected for composite-taxa tissues from Hazeltine Creek (upper and lower creek areas; Table 6.10). This means that the significant elevation of analyte concentrations and TTFs in the exposed caddisfly tissues, relative to reference, was largely captured by the results of the composite-taxa monitoring, while the reverse was not true (i.e., caddisfly monitoring generally captured fewer significant exposed-reference differences for primary analytes than composite-taxa monitoring). Any instances in which the significant positive exposed-reference differences in the analyte concentrations or TTFs for caddisfly tissues in 2024 were not captured by composite-taxa tissue results were detailed below (including the MODs).

There were five instances in which a positive exposed-reference difference was detected for caddisfly tissue results in 2024 that was not detected in composite-taxa tissues. Specifically, these occurred for selenium TTFs for caddisfly tissues from HAC-R1, and copper,

Table 6.10: Summary Magnitude of Difference (MOD)[a] of Exposed - Reference Contrasts of Primary and Secondary Analyte Concentrations and Trophic Transfer Factors (TTFs) in Caddisfly and Composite-Taxa Benthic Invertebrate Tissues for the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D [HAC-R5]; Exposed), and Lower Edney Creek (EDC-D [EDC-REF]; Reference) Monitoring Areas, 2024

Indicates significantly higher tissue concentration or TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly higher tissue concentration or TTF at exposed compared to reference area (α = 0.05), without a significant (Area x Year) interaction of the two-way ANOVA. Values represent the MOD exposed:reference, which did not change significantly among monitoring years.

Notes: ns = not significant. Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., analytes that had a significant positive exposed - reference difference i 2024 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). ns = no significant difference between exposed at reference area. TTF calculated as (benthic invertebrate tissue analyte concentration) / (periphyton tissue analyte concentration). HAC-R2, HAC-R5, and EDC-REF are the alternate names for the HAC-U, HAC-D, and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Magnitude of difference (MOD) calculated on backtransformed least-squares means as (Exp-Ref)/Ref x 100%.

barium, cobalt, and manganese TTFs for caddisfly tissues from HAC-U (Table 6.10). There were an additional five instances in which a significant *Area x Year* interaction was detected for the TTFs for composite-taxa tissues (indicating a significant change in the exposed-reference differences of TTFs over time) but a significant *Area x Year* interaction was not detected for the TTFs for caddisfly tissues (indicating temporal stability in the exposed-reference differences of TTFs). These five instances occurred for arsenic and titanium TTFs for caddisfly tissues from HAC-R1, as well as iron, selenium, and vanadium TTFs for caddisfly tissues from HAC-U (Table 6.10). The remaining observed differences between the results for caddisfly tissues compared to composite-taxa tissues (for either analyte concentrations or TTFs) were limited to the magnitude of the observed exposed-reference differences, and these are discussed in more detail below.

The MODs for selenium concentrations in 2024 were consistently higher for caddisfly tissues than for composite-taxa tissues across all three exposed areas (by 1.5- to 4.8-times). Of the secondary analytes, cadmium, mercury, and molybdenum were the only analytes with higher MODs observed for caddisfly tissues compared to composite-taxa tissues. The MODs for molybdenum concentrations in caddisfly tissues in 2024 were slightly higher than those composite-taxa tissues at both HAC-R1 and HAC-U (by 1.02- to 1.2-times), as was the MOD for the molybdenum TTFs in caddisfly tissues (1.6-times higher than composite-taxa tissues). The MODs for the TTFs of mercury and cadmium in caddisfly tissues from HAC-R1 and HAC-U, respectively, were also higher than those observed for composite-taxa tissues (by 1.3- to 1.6-times; Table 6.10).

Overall, results from both upper and lower Hazeltine Creek indicate that the significant elevations in the concentrations and TTFs and analytes in exposed caddisfly tissues, relative to reference, were largely captured by composite-taxa monitoring. However, the magnitude of the differences between the exposed and reference results for selenium were often higher in caddisfly tissues than in composite-taxa tissues. As such, the results indicated that if monitoring were limited to composite-taxa samples only for tissue quality monitoring, most changes in the concentrations and TTFs of primary and secondary analytes in caddisfly tissues would still be captured, but the higher magnitude of the differences in selenium results that was observed in caddisfly tissues would not be fully captured. This is consistent with findings from 2020, 2021 and 2022 (Minnow 2021a, 2022a, 2023a) but not 2023 (Minnow 2024a).

6.1.5 Fish Tissue Quality

Tissue quality monitoring of juvenile fish was completed in creek habitats in 2024 in response to observed temporal increases in the selenium concentrations of benthic invertebrate tissues from Hazeltine Creek (Minnow 2024a), and to satisfy Condition 3(g) for the draft CEMP approval conditions dated May 16, 2024 (BCMOECCS 2024; see Section 4.5.1). Specifically, post-breach

tissue quality monitoring of juvenile whole-body fish was initiated in 2018 and 2024 in upper and lower creek areas, respectively. Whole-body samples of juvenile rainbow trout were collected from upper Hazeltine Creek (HAC-U [HAC-R2])[74] with Frypan Creek (FPC- R2) serving as reference in 2018 and 2024 (Figure 4.4, Table 4.5) [75]. Whole-body samples of juvenile rainbow trout and juvenile coho salmon were targeted for monitoring in lower Hazeltine Creek (HAC-D [HAC-R5]), with the unimpacted area of lower Edney Creek (EDC-D [EDC-REF]) serving as reference in 2024. Only one rainbow trout was captured from HAC-D (HAC-R5), limiting statistical comparisons for this species. However, the target number of coho salmon (n=8) were collected from HAC-D (HAC-R5) and the associated reference area (EDC-D [EDC-REF]; Figure 4.4, Table 4.5) and were therefore the focus of the statistical analyses for the lower creek areas (see Section 4.5.3.1 for details).

A review of the 2024 fish tissue quality results (Appendix B) indicated that these data can be used with an acceptable level of confidence for interpretation, although the occurrence of some natural heterogeneity in analyte results were considered during data interpretation. A review of the 2024 fish aging results (Appendix B) indicated that laboratory accuracy for aging data can be used with a high level of confidence for interpretation (see Section 5.1.7 for details).

6.1.5.1 Comparisons to Guidelines

Mean selenium and mercury concentrations in juvenile whole-body rainbow trout samples from upper Hazeltine Creek (HAC-U) in 2018 and 2024 were below consumption guidelines for the protection of human health, while mean selenium concentrations in these samples exceeded the guideline for the protection of aquatic life (4 mg/kg dw; BCMOE 2014) in 2018 (4.39 mg/kg dw) and 2024 (6.42 mg/kg dw; Figure 6.12, Table 6.11). The rate of guideline exceedances in these rainbow trout samples from HAC-U was the same in 2018 and 2024 (87.5% of samples; Table 6.11; Appendix Tables D.7.1 and D.7.2) although the mean concentrations differed. Detailed statistical analyses of the temporal changes in the selenium concentration of rainbow trout from HAC-U are discussed in Section 6.1.5.1. In both 2018 and 2024, selenium concentrations in all juvenile whole-body rainbow trout samples from the reference area (FPC-R2) were below the aquatic life guideline (Figure 6.12, Table 6.11).

In the single juvenile whole-body rainbow trout sample from lower Hazeltine Creek (HAC-D) and in all eight rainbow trout samples from the reference site (EDC-D) the selenium concentrations were below the guideline for the protection of aquatic life in 2024 (4 mg/kg dw; Table 6.11;

[74] Rainbow Trout from upper Hazeltine Creek in 2018 were captured from two stations in HAC-R1 and two stations in HAC-U (HAC-R2). See Appendix Table D.6.1 and Minnow (2019d) for details of sampling locations within these two areas.

[75] HAC-R2, HAC-R5, and EDC-REF are the alternate names used for the HAC-U, HAC-D, and EDC-D sampling areas for HRWG reporting. The original area names only (i.e., HAC-U, HAC-D, and EDC-D) are used throughout the remainder of this report section (Section 6.1.5).

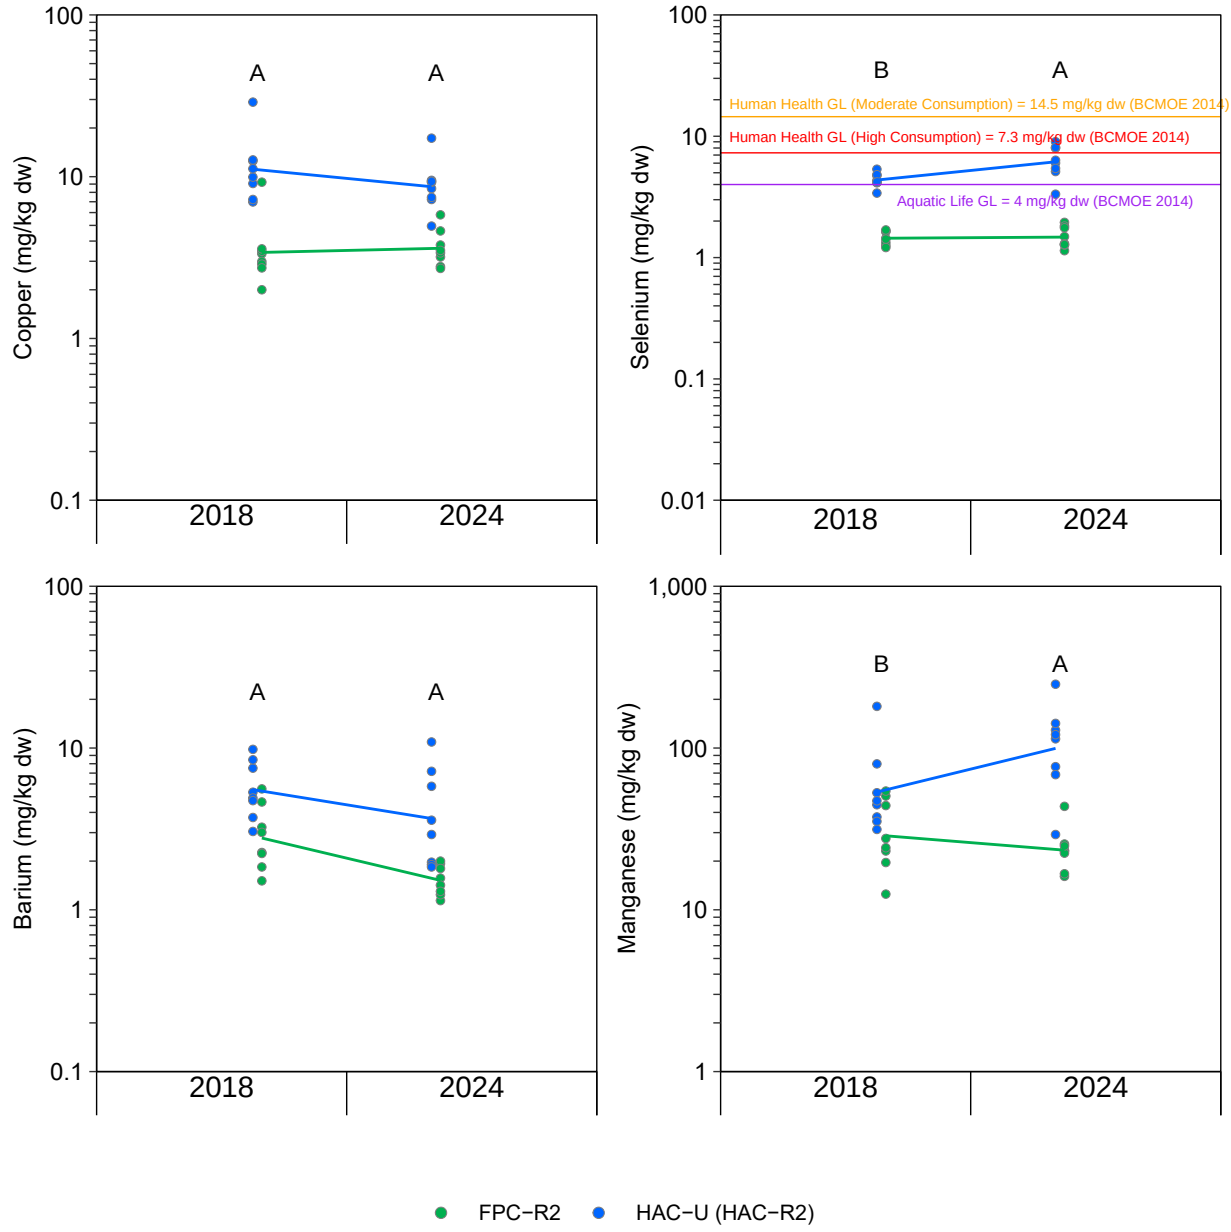

Figure 6.12: Juvenile Rainbow Trout Whole−body Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for the Upper Hazeltine Creek (HAC−U [HAC−R2]; Exposed) and Frypan Creek (FPC−R2; Reference) Monitoring Areas, 2018 to 2024

Notes: GL = Guideline, dw = dry weight. HAC−R2 is the alternate name for the HAC−U sampling area for HRWG reporting. Green represents reference areas and blue represents exposed areas. Rainbow trout from Upper Hazeltine Creek were collected from HAC−R1 and HAC−U (HAC−R2) in 2018 and only from HAC−U (HAC−R2) in 2024. Plots are only included for primary and secondary analytes that had a significant Area × Time interaction term and were higher at exposed than reference areas in 2024. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g.,A,B,C) have ratios of concentrations (HAC−U:FPC−R2) that do not differ significantly (p−value <0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (HAC−U:FPC−R2).

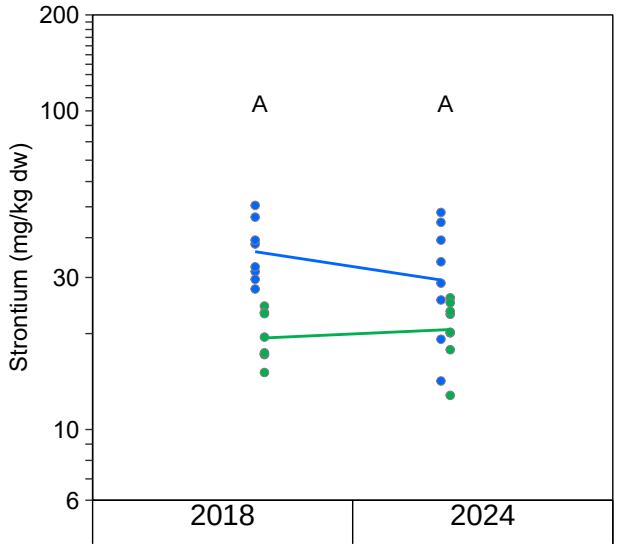

Figure 6.12: Juvenile Rainbow Trout Whole−body Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for the Upper Hazeltine Creek (HAC−U [HAC−R2]; Exposed) and Frypan Creek (FPC−R2; Reference) Monitoring Areas, 2018 to 2024

Notes: GL = Guideline, dw = dry weight. HAC−R2 is the alternate name for the HAC−U sampling area for HRWG reporting. Green represents reference areas and blue represents exposed areas. Rainbow trout from Upper Hazeltine Creek were collected from HAC−R1 and HAC−U (HAC−R2) in 2018 and only from HAC−U (HAC−R2) in 2024. Plots are only included for primary and secondary analytes that had a significant Area × Time interaction term and were higher at exposed than reference areas in 2024. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g.,A,B,C) have ratios of concentrations (HAC−U:FPC−R2) that do not differ significantly (p−value <0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (HAC−U:FPC−R2).

Table 6.11: **Juvenile Fish Whole-body Selenium and Mercury Concentrations from the Upper Hazeltine Creek (HAC-R1, HAC-U [HAC-R2]; Exposed), Frypan Creek (FPC-R2; Reference), and Edney Creek (EDC-D [EDC-REF]; Reference) Monitoring Areas Relative to the British Columbia Guideline for the Protection of Aquatic Life, 2018 to 2024**

Waterbody or Area [a]		Type	Species	Season/ Year[b]	Sample Size	Mercury		Selenium			
						Human Health (CFIA 2015) Guideline = 0.5 mg/kg ww		Mean	Aquatic Life Guideline (4 mg/kg dw)	Human Health (BCMOE 2014) High Consumption = 7.3 mg/kg dw Moderate Consumption = 14.5 mg/kg dw	
						Mean	Frequency > Guideline		Frequency > Guideline	Frequency > Moderate	Frequency > High

			Coho Salmon		8	0.0197	0%	4.42	50%	13%	0%

Indicates mean selenium concentration greater than the BC Aquatic Life guideline for muscle tissue or whole-body in fish (4 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than the Guideline for Human Health, general population, high consumption (7.3 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than the Guideline for Human Health, general population, moderate consumption (14.5 mg/kg dw; BCMOE 2014).

Indicates mean mercury concentration greater than the Guideline for Human Health (0.5 mg/kg ww; CFIA 2015).

Notes: mg/kg dw = milligrams per kilogram dry weight. ">" = greater than. "%" = percent.

[a] HAC-R2, EDC-REF, and HAC-R5 are the alternate names used the for the HAC-U, EDC-D, and HAC-D sampling areas, respectively, for HRWG reporting.

[b] See Appendix Tables D.6.1, D.6.2, and D.6.3 for detailed catch information.

Appendix Table D.7.3). However, the mean selenium concentration (4.42 mg/kg dw) in juvenile whole-body coho salmon samples from lower Hazeltine Creek (HAC-D) exceeded the guideline in 2024 in 50% of samples, whereas no exceedances were observed at the reference area (EDC-D; maximum = 3.04 mg/kg dw; Figure 6.13, Table 6.11; Appendix Table D.7.4).

Rainbow trout and coho salmon only reside in Hazeltine Creek during their juvenile life stages; rainbow trout typically return to Polley Lake within their first year of life (e.g., Minnow 2019d, 2024b) and coho salmon return to coastal marine waters after 1 to 2 years of life (Scott and Crossman 1998) via the Quesnel River to the Fraser River (which flows to the Pacific Ocean). Therefore, the period of exposure of rainbow trout and coho salmon exposure to selenium in Hazeltine Creek (via dietary exposure) is limited to the juvenile life stages before most tissue growth occurs, and before reproductive development and potential selenium transfer to ovary tissues occur (ovary tissues are recommended for assessing the effects of selenium on fish; see Section 5.1.7.1). This is supported by selenium concentrations in the tissues rainbow trout from Polley Lake which have not increased over the post-breach period or have decreased in some cases (see Section 5.1.7).

6.1.5.2 Spatial and Temporal Comparisons

Statistical comparisons of morphological measures (fork length and body weight) of juvenile rainbow trout from upper Hazeltine Creek indicated there were no significant differences in fish size between years (i.e., 2018 and 2024; Appendix Tables D.6.4, D.6.5, and F.5.1). Juvenile coho salmon from lower Hazeltine Creek (HAC-D [HAC-R5]) were significantly longer and heavier (by 21% and 71%, respectively), but not older, than those from the reference area (EDC-D) in 2024 (Appendix Tables D.6.6, D.6.7, and F.5.2).

Data interpretation of juvenile whole-body rainbow trout samples from upper Hazeltine Creek (for which there are data from 2018 and 2024) was focused on primary and secondary analytes (Table 2.4) with a significant positive relative (exposed-reference) difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2024 (if the analysis *Area×Year* interaction was significant) or in all monitoring years (if the *Area×Year* interaction was not significant[76]). Increasing analyte concentrations at the exposed area (HAC-U) relative to reference area (FPC-R2) over time, or consistently elevated analyte concentrations at the exposed area relative to reference, were not detected for most analytes (Figure 6.12; Appendix Figure F.5.1, Appendix Table F.5.1). Two primary analytes (copper and selenium) and three secondary analytes (barium, manganese, and strontium) met the criteria for inclusion in data interpretation outlined above.

[76] If no significant change was detected in the relative (exposed-reference) difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

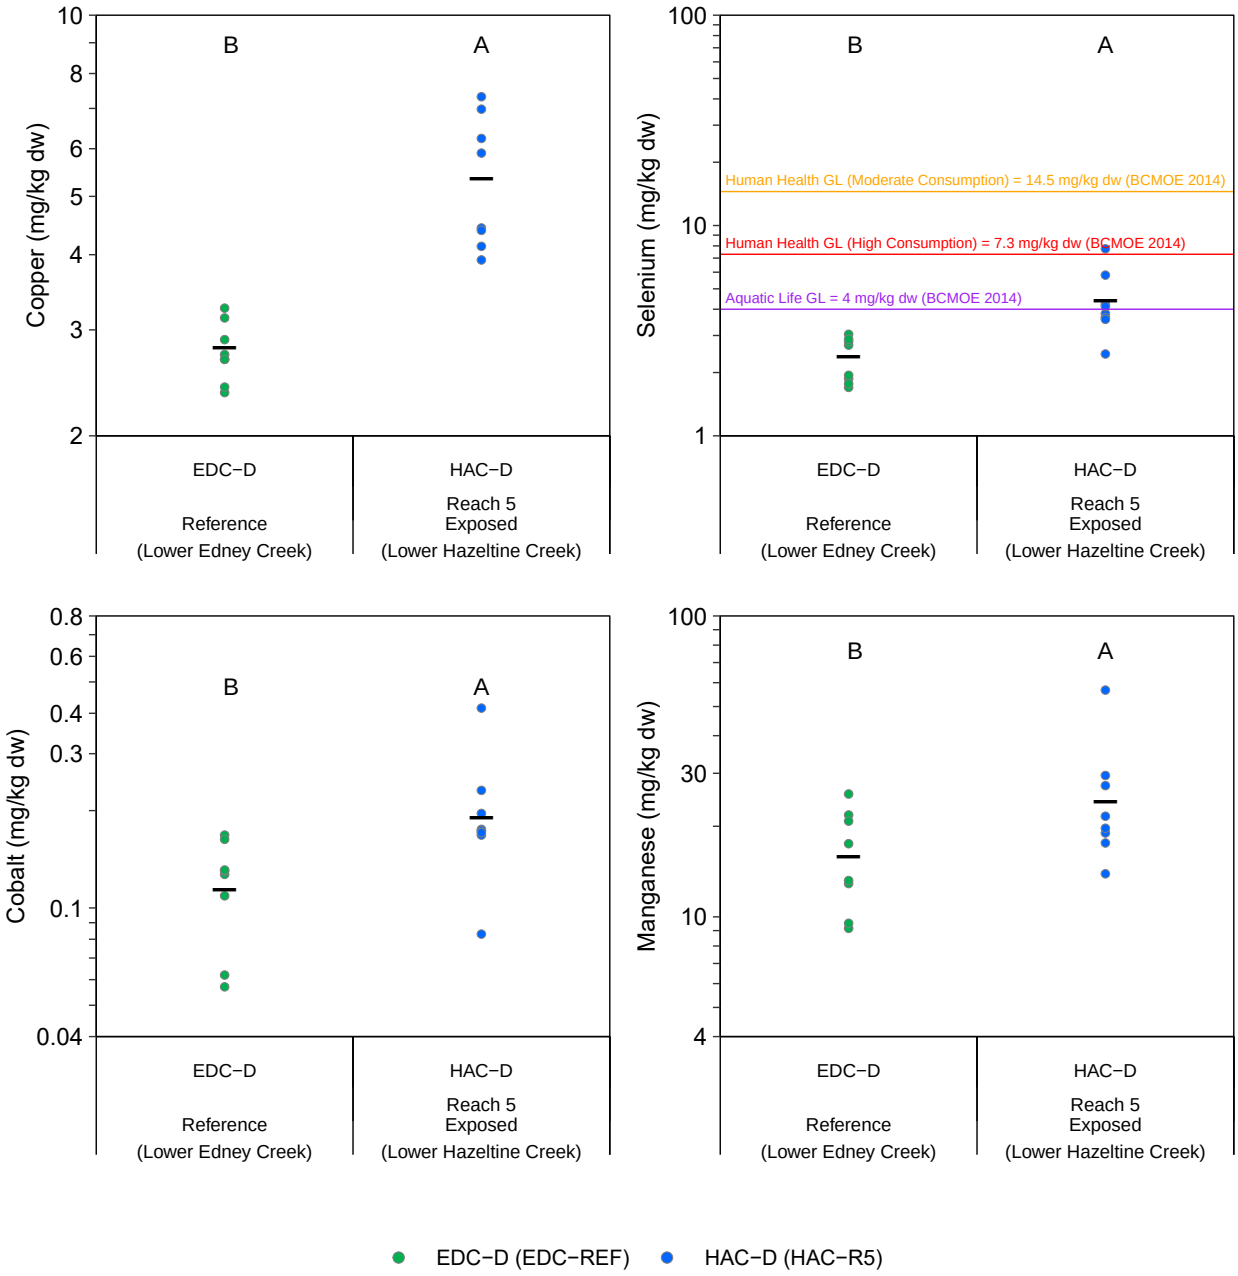

Figure 6.13: Juvenile Coho Whole−body Tissue Primary and Secondary Analyte Concentrations with a Significant Area Difference Between the Lower Hazeltine Creek (HAC−D [HAC−R5]; Exposed) and Lower Edney Creek (EDC−D [EDC−REF]; Reference) Monitoring Areas, 2024

Notes: GL = Guideline, dw = dry weight. HAC−R5 and EDC−REF are the alternate names for the HAC−D and EDC−D sampling areas, respectively, for HRWG reporting. Green represents reference areas and blue represents exposed areas. Plots are only included for primary and secondary analytes that had a significant Area differences in 2024. Individual samples are plotted and lines join the least−squares estimated mean values for areas included in the statistical analysis. Statistical analyses were conducted using a one−way ANOVA with the factor Area. The model was fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Areas that share a letter (e.g., A,B,C) do not differ significantly. Letter A was assigned to the area with the highest analyte concentration.

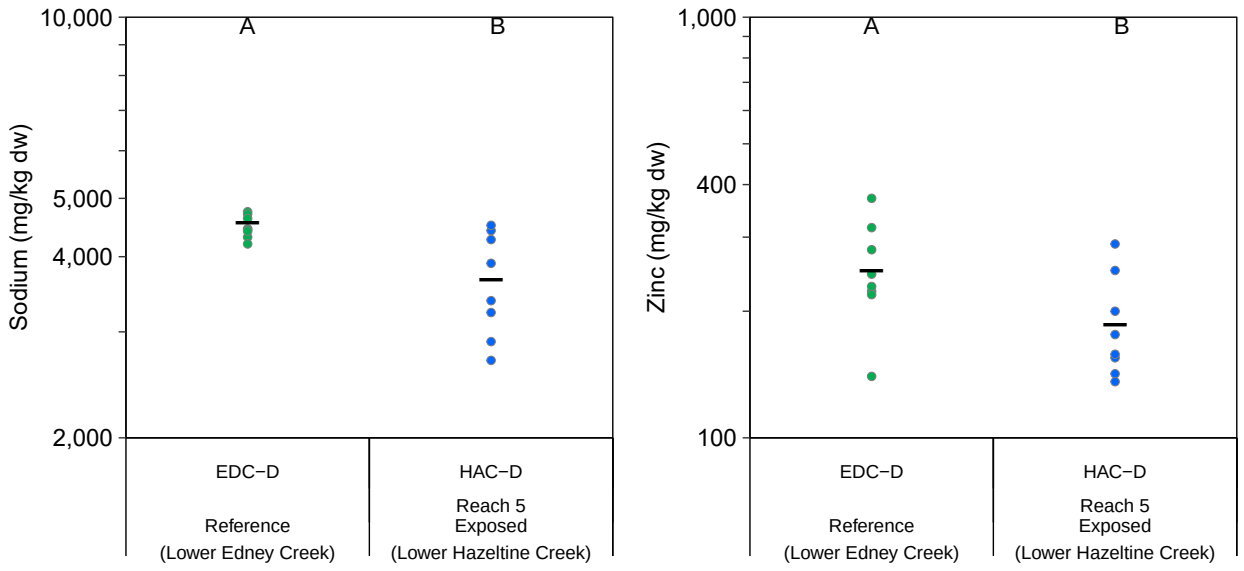

Figure 6.13: Juvenile Coho Whole−body Tissue Primary and Secondary Analyte Concentrations with a Significant Area Difference Between the Lower Hazeltine Creek (HAC−D [HAC−R5]; Exposed) and Lower Edney Creek (EDC−D [EDC−REF]; Reference) Monitoring Areas, 2024

Notes: GL = Guideline, dw = dry weight. HAC−R5 and EDC−REF are the alternate names for the HAC−D and EDC−D sampling areas, respectively, for HRWG reporting. Green represents reference areas and blue represents exposed areas. Plots are only included for primary and secondary analytes that had a significant Area differences in 2024. Individual samples are plotted and lines join the least−squares estimated mean values for areas included in the statistical analysis. Statistical analyses were conducted using a one−way ANOVA with the factor Area. The model was fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Areas that share a letter (e.g., A,B,C) do not differ significantly. Letter A was assigned to the area with the highest analyte concentration.

Selenium was the only primary analyte with a significant *Area×Year* interaction, which indicates that the relative (exposed-reference) difference in selenium concentrations changed significantly between 2018 and 2024 (i.e., the geometric mean concentrations at the exposed area were not trending the same as the geometric mean concentrations at the reference area). Specifically, the relative (exposed-reference) difference in selenium concentrations of juvenile whole-body rainbow trout from the upper creek areas increased significantly from 2018 to 2024 (by 38%; Figure 6.12; Appendix Table F.5.1). For copper, the *Area×Time* interaction was not significant, indicating that the relative (exposed-reference) difference of concentrations of this analyte in the rainbow trout samples remained consistent across both years. Therefore, although copper concentrations in juvenile whole-body rainbow trout from HAC-U were significantly higher than those at the reference areas (by 180%), this difference was temporally stable between the 2018 and 2024 (Figure 6.12; Appendix Table F.5.1). These results indicated significantly higher concentrations of selenium and copper in juvenile rainbow trout from upper Hazeltine Creek in 2018 and 2024 compared to reference, and increased selenium concentrations in the tissues of exposed fish over time relative to reference.

Of the three secondary analytes identified in data interpretation for upper Hazeltine Creek (i.e., barium, manganese, and strontium), manganese was the only analyte with a significant *Area×Year* interaction term. Manganese concentrations in juvenile whole-body rainbow trout samples from upper Hazeltine Creek were significantly higher than those from the reference area in both 2018 and 2024, and the relative (exposed-reference) difference of these concentrations increased significantly between 2018 and 2024 (by 128%; Figure 6.12; Appendix Table F.5.1). In contrast, the *Area×Year* interaction term was not significant for barium and strontium, indicating that concentrations of these analytes in exposed tissues have remained consistently elevated relative to reference tissues in both years (119% and 63% higher in exposed tissues for barium and strontium, respectively, relative to reference; Figure 6.12; Appendix Table F.5.1). These findings indicate that while the relative difference of barium and strontium concentrations remained stable between 2018 and 2024, manganese concentrations in juvenile rainbow trout increased significantly over this period at upper Hazeltine Creek, relative to reference.

Data analysis and interpretation of juvenile whole-body coho salmon samples from the lower creek areas focused on spatial differences of primary and secondary analyte concentrations in 2024 since there were no data available from prior years (i.e., temporal comparisons were not possible). Analyte concentrations in juvenile whole-body coho salmon samples from lower Hazeltine Creek (HAC-D) showed few differences relative to the reference area (EDC-D) in 2024 (Figure 6.13; Appendix Table F.5.2). Two primary analytes (copper and selenium) and four secondary analytes (cobalt, manganese, sodium, and zinc) showed a significant *Area* effect in the spatial analyses, indicating that concentrations of these analytes differed significantly between

the exposed and reference area in 2024. These six analytes therefore met the criteria for inclusion in data interpretation.

Concentrations of both copper and selenium in juvenile whole-body coho salmon samples from HAC-D in 2024 were significantly higher (by 91% and 84% respectively) than those from the reference area (EDC-D; Figure 6.13; Appendix Table F.5.2). The significantly higher selenium concentrations of the juvenile coho salmon, relative to reference, was consistent with the selenium tissue guideline exceedances observed for these fish from HAC-D but not at EDC-D (Section 6.1.5.1).

Four secondary analytes were identified for inclusion in data interpretation for lower creek areas (cobalt, manganese, sodium, and zinc). Of these, concentrations of sodium and zinc in juvenile whole-body coho salmon samples from lower Hazeltine Creek (HAC-D) were significantly lower than those from the reference area (EDC-D), indicating no potential mine-related effect (Figure 6.13; Appendix Table F.5.2). In contrast, concentrations of cobalt and manganese were significantly higher in exposed compared to reference coho (by 67% and 53%, respectively; Figure 6.13; Appendix Table F.5.2) in 2024. Evaluation of temporal changes in the concentrations of these analytes in juvenile fish tissues from lower Hazeltine Creek will be possible following continued data collections.

Overall, fish tissue quality monitoring in upper Hazeltine Creek indicated that concentrations of two primary analytes (copper and selenium) and three secondary analytes (barium, manganese, and strontium) in juvenile whole-body rainbow trout were significantly higher than those from the reference area in 2024. Of these five analytes, results indicated temporal increase in the selenium and manganese concentrations in juvenile rainbow trout between 2018 and 2024. In lower Hazeltine Creek, concentrations of two primary analytes (copper and selenium) and two secondary analytes (cobalt and manganese) in juvenile whole-body coho salmon were significantly higher than those from the reference area in 2024. Temporal analyses for lower Hazeltine Creek fish tissue quality results will be possible following continued data collections.

6.1.5.3 Comparison to Benthic Invertebrate Tissue

The spatial and temporal (where possible) analysis of juvenile whole-body rainbow trout and coho salmon indicated that the concentrations of two primary analytes (copper and selenium) were significantly higher in these fish from Hazeltine Creek (exposed) compared to the associated reference areas (see Section 6.1.5.2). These results were consistent with significantly higher copper and selenium concentrations in periphyton and benthic invertebrate tissues from upper and lower Hazeltine Creek, relative to reference areas (see Section 6.1.4). In addition, the concentrations of selenium in periphyton and benthic invertebrate tissues from both upper and lower Hazeltine Creek have increased significantly over the post-breach period, relative to

reference, which is consistent with the significant increase in juvenile whole-body rainbow trout tissue selenium concentrations from upper Hazeltine Creek over the post-breach period (i.e., 2018 to 2024), relative to reference (see Section 6.1.5.2).

The primary route of selenium accumulation in fish is through dietary exposure with an average TTF between benthic invertebrates and fish of approximately 1.1 (and a range of 0.6 to 1.6 based on 25 fish species; Presser and Luoma 2010). As such, the relationship between selenium concentrations observed in juvenile whole-body fish tissues and benthic invertebrates (their primary food source) were evaluated for rainbow trout (2018 and 2024) and coho salmon (2024) relative to composite-taxa and caddisfly benthic invertebrate tissue samples collected at corresponding sampling areas and dates. A line representing a one-to-one relationship was included on each plot to represent an average selenium TTF of approximately one between fish and benthic invertebrate tissues (Presser and Luoma 2010).

The relationships between selenium concentrations in juvenile whole-body rainbow trout samples compared to those in benthic invertebrate tissues (i.e., representing dietary exposure) from upper Hazeltine Creek differed over time and differed from those observed at the reference area (FPC-R2). At the reference area, the selenium concentrations in juvenile whole-body rainbow trout samples in 2018 were similar to those from benthic invertebrates from this area (i.e., results were close to the one-to-one line; Figure 6.14), consistent with the literature-based average TTF of 1.1 (Presser and Luoma 2010). In upper Hazeltine Creek (HAC-U) in 2018, the selenium concentrations in juvenile whole-body rainbow trout samples were higher, on average, than those in benthic invertebrate tissues from the same area (i.e., were above the one-to-one line; Figure 6.14), similar to the results described by Cianciolo et al. (2020). In contrast, the selenium concentrations in juvenile whole-body rainbow trout samples from upper Hazeltine Creek in 2024 were lower, on average, than those in benthic invertebrates from the same area (i.e., were below the one-to-one line; Figure 6.14).

In the lower Hazeltine Creek, the relationships between selenium concentrations in juvenile whole-body coho salmon samples compared to those in benthic invertebrates also differed from those observed at the reference area (EDC-D). Comparisons between tissue selenium concentrations in the lower creek areas were limited to 2024 because earlier juvenile fish tissue quality data do not exist. At the reference area, the selenium concentrations in juvenile whole-body coho salmon samples were slightly higher, on average, than those in benthic invertebrates from this area (Figure 6.15). The opposite was observed in lower Hazeltine Creek (exposed), with selenium concentrations in juvenile whole-body coho salmon samples that were slightly lower, on average, than those in benthic invertebrates from this area (Figure 6.15).

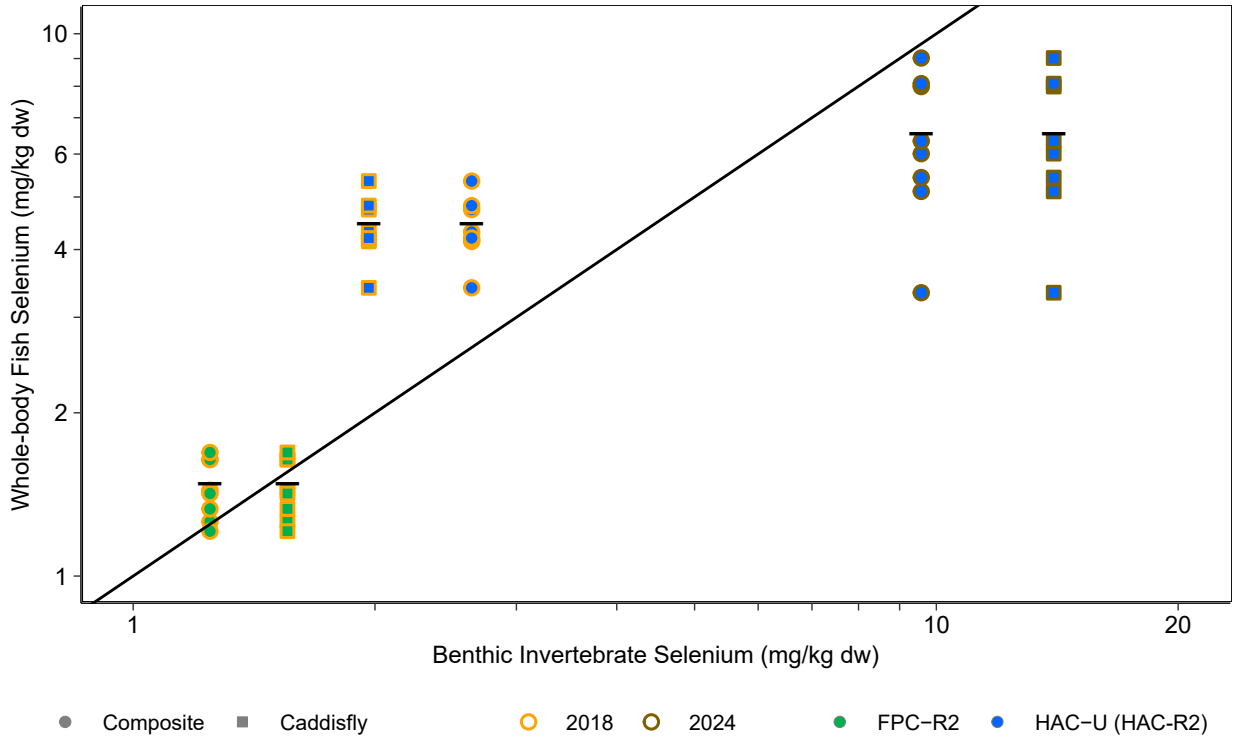

Figure 6.14: Juvenile Rainbow Trout Whole-body Tissue Selenium Concentrations Compared to Caddisfly and Composite-Taxa Benthic Invertebrate Tissue Selenium Concentrations for the Upper Hazeltine Creek (HAC-U [HAC-R2]; Exposed) and Frypan Creek (FPC-R2; Reference) Monitoring Areas, 2018 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. HAC-R2 is the alternate name for the HAC-U sampling area for HRWG reporting. Benthic invertebrate tissue quality data plotted for Frypan Creek in 2018 were from Reach 3 (i.e., FPC-R3), which were the only available data (i.e., data were not available for Reach 2 [FPC-R2] in 2018). Benthic invertebrate tissue quality at Frypan Creek was not collected after 2018 (see Table 4.4). Green represents reference areas and blue represents exposed areas. Black bars denote mean fish selenium concentrations. Mean benthic invertebrate tissue selenium concentrations for each area and year were used for comparison to fish tissue selenium concentrations.

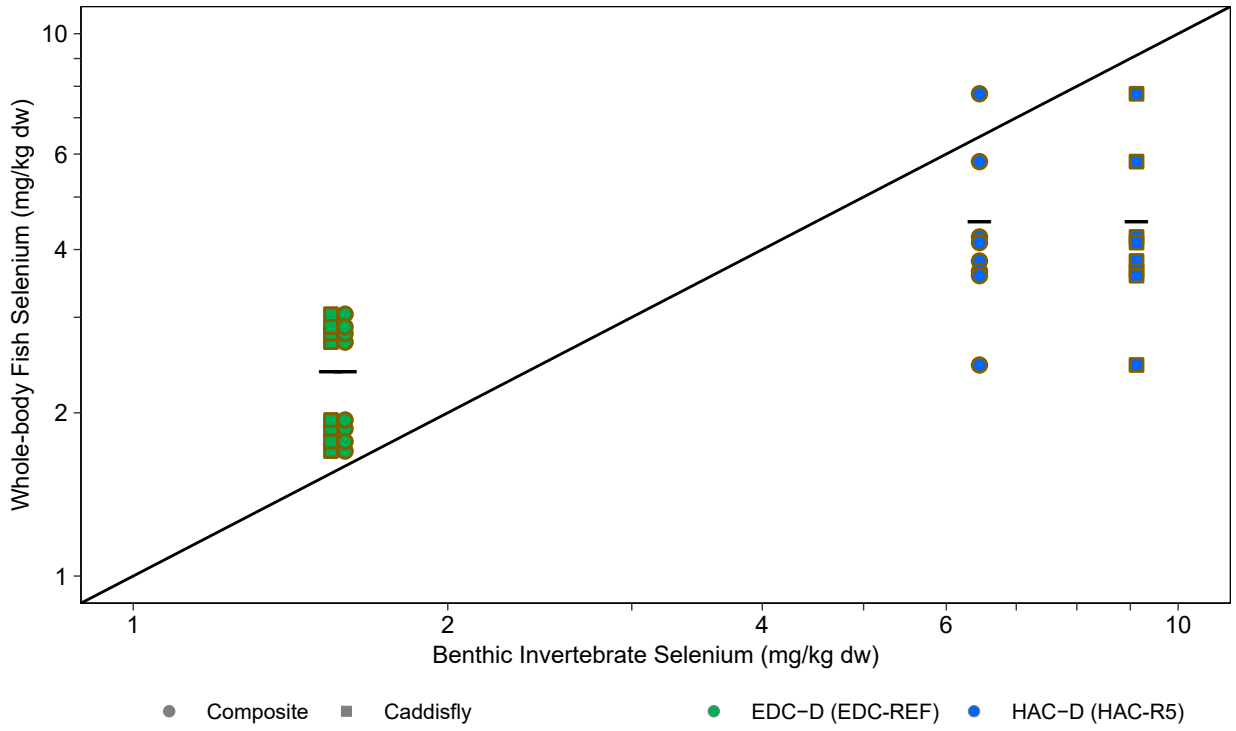

Figure 6.15: Juvenile Coho Whole-body Tissue Selenium Concentrations Compared to Caddisfly and Composite-Taxa Benthic Invertebrate Tissue Selenium Concentrations for the Lower Hazeltine Creek (HAC-D [HAC-R5]; Exposed) and Lower Edney Creek (EDC-D [EDC-REF]; Reference) Monitoring Areas, 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. HAC-R5 and EDC-REF are the alternate names for HAC-D and EDC-D sampling areas, respectively, for HRWG reporting. Green represents reference areas and blue represents exposed areas. Black bars denote mean fish selenium concentrations. Mean benthic invertebrate tissue selenium concentrations for each area were used for comparison to fish tissue selenium concentrations.

Benthic invertebrate tissue selenium concentrations were evaluated for both caddisfly and composite-taxa tissue sample types (see Section 4.4.1 for details). Mean selenium concentrations in caddisfly tissues in 2024 and prior years were often higher than those in composite-taxa tissues, consistent with caddisflies being known as 'hyper-accumulators' of selenium (Wayland and Crosley 2006; Mendes et al. 2022; Mendes et al. 2023; see Section 6.1.4.1). While the selenium concentrations in both caddisfly and composite-taxa benthic invertebrate tissues were higher than those measured in juvenile whole-body rainbow trout and coho salmon samples in 2024, this difference was greater for caddisfly tissues than for composite-taxa benthic invertebrate samples. This suggests that selenium concentrations in juvenile whole-body rainbow trout and coho salmon samples were more reflective of dietary exposure to composite-taxa benthic invertebrates (i.e., a mix of benthic invertebrate taxa) than to caddisfly tissues.

Overall, the selenium concentrations measured in juvenile whole-body rainbow trout and coho salmon from Hazeltine Creek in 2024 were lower than those measured in benthic invertebrates from corresponding monitoring areas (representing dietary selenium exposure); a difference that was larger for caddisfly tissues than for composite-taxa benthic invertebrate tissues. These results suggested that the selenium concentrations in juvenile fish from Hazeltine Creek were more reflective of dietary exposure to composite-taxa benthic invertebrates (i.e., a mix of benthic invertebrate taxa) than caddisfly tissues.

6.2 Edney Creek

6.2.1 Periphyton Community and Productivity

Periphyton community and productivity monitoring was conducted at a remediated (exposed) area of lower Edney Creek (E1 [EDC-EXP]) in 2023, with an unimpacted area of lower Edney Creek (EDC-D [EDC-REF]) serving as reference (Minnow 2024a).[77] The results of this monitoring are summarized briefly herein with detailed methods and results presented in Minnow (2024a).

6.2.1.1 Community

In 2023, the periphyton community of the exposed area (E1) of lower Edney Creek had significantly lower density and significantly higher total taxon richness than at the reference area (EDC-D) and similar Diatom richness, Simpson's Evenness, and Simpson's Diversity to the reference area. Density at E1 was consistently significantly lower than at EDC-D from 2019 to

[77] For HRWG reporting, EDC-EXP and EDC-REF are the alternate names used for the E1 and EDC-D sampling areas. The original area names only (i.e., E1 and EDC-D) are used throughout the remainder of this report section (Section 6.2.1).

2023; however, density increased at E1 in 2023 relative to all prior years. Total taxon richness and Diatom richness increased significantly from 2021 to 2023, from lower than reference in 2021 to similar to reference in 2023. Simpson's Evenness and Diversity decreased significantly at both E1 and EDC-D in 2023 compared to 2021, but these metrics at E1 remained similar to reference from 2019 to 2023. The temporal variability in community metrics at E1 between 2021 and 2023 was likely related to the remediation efforts in this area that were concluded in 2021 (after 2021 biological sampling) and substrate transport that occurred in this area due to high spring freshet flows.

Periphyton community composition at both the exposed (E1) and reference (EDC-D) areas were dominated by Cyanobacteria and to a lesser extent Diatoms, Chlorophytes, and Rhodophytes from 2019 to 2023. Periphyton community composition at E1 was similar to reference conditions from 2019 to 2023 in terms of the relative densities (%) of taxa. The consistent similarity in periphyton community composition between E1 and EDC-D in all years suggested these communities have likely been similarly affected by physical and chemical factors (e.g., light exposure, water temperature, nutrient availability) within the creek.

Combined, the results indicated that the periphyton community at the exposed area of lower Edney Creek had largely recovered to reference conditions, while recovery of density was ongoing.

6.2.1.2 Productivity

Mean periphyton chlorophyll-a concentrations (mg/m²) in E1 in 2023 were well below the BCWQG of 100 mg/m² (BCMOWLRS 2025) and below the threshold indicative of moderately enriched streams (21 mg/m²; Biggs 1996). Periphyton productivity (as measured by chlorophyll-a concentrations and AFDM) at E1 were consistently lower than at the reference area (EDC-D) from 2017 to 2023. Similar temporal changes at the exposed area compared to reference suggested temporal variability at both areas was related to natural changes in physical and chemical factors (e.g., light exposure, water temperature, nutrient availability). The consistently lower periphyton productivity at E1 compared EDC-D from 2017 to 2023 was likely related to the remediation efforts that concluded in this area in 2021 (after 2021 biological sampling) and substrate transport that occurred in this area due to high spring freshet flows.

6.2.2 Benthic Invertebrate Community and Productivity

Benthic invertebrate community and productivity monitoring in lower Edney Creek in 2023 was completed at a remediated (exposed) area (E1 [EDC-EXP]), with an unimpacted area of lower

Edney Creek (EDC- D [EDC-REF]) serving as reference (Minnow 2024a).[78] The results of this monitoring are summarized briefly herein with detailed methods and results presented in Minnow (2024a).

6.2.2.1 Community

The benthic invertebrate community at the exposed lower Edney Creek (E1) area in 2023 was similar to the reference area (EDC-D) in terms of density and Simpson's Diversity. Taxon richness and Simpson's Evenness were slightly but significantly higher and lower, respectively, at E1 in 2023 relative to reference. Mean density at E1 was similar to reference over the 2016 to 2023 period. Taxon richness at E1 was significantly higher than reference in 2023, which reflected an improvement from 2016 to 2021, when taxon richness was significantly lower at E1 compared to EDC-D. Simpson's Diversity and Evenness at E1 similarly showed improvement from prior years (i.e., 2021) to 2023, with Simpson's Diversity increasing from significantly lower than reference (EDC-D) in 2021 to similar to reference in 2023. Simpson's Evenness at E1 was lower than EDC-D in both 2021 and 2023 but was similar to reference in 2023 than 2021. Overall, the benthic invertebrate community at the exposed area of lower Edney Creek (E1) showed recovery following the remediation efforts in 2020 and 2021, with taxon richness and Simpson's Diversity changing from lower than reference in 2021 to similar to or higher than reference in 2023, and Simpson's Evenness that was more similar to reference in 2023 than in 2021.

Benthic invertebrate community composition at E1 in 2023 was dominated by Chironomidae followed by EPT, which differed from reference (EDC-D) where the community was dominated by EPT followed by Chironomidae. For these dominant taxa, Chironomidae (%) at E1 was significantly higher than reference for most years (except being significantly lower than reference in 2017. EPT (%) at E1 was similar to reference from 2016 to 2023. Within EPT, Ephemeroptera (%) and Trichoptera (%) at E1 were significantly lower and higher, respectively, than reference in 2023, and Plecoptera (%) was similar to reference from 2016 to 2023. The lower Ephemeroptera (%) at E1 than reference in 2023 was not owing to a significant temporal change in Ephemeroptera (% or density) which were unchanged from 2022 to 2023 but rather to a significant increase in other taxa (non-Chironomidae Diptera).

Collectively, the results indicated recovery of the benthic invertebrate community at E1 following the completion of final remediation works in 2020 and 2021 (after biological monitoring occurred in 2021), including similar dominance of sensitive EPT taxa to reference. However, the remaining

[78] For HRWG reporting, EDC-EXP and EDC-REF are the alternate names used for the E1 and EDC-D sampling areas. The original area names only (i.e., E1 and EDC-D) are used throughout the remainder of this report section (Section 6.2.2).

differences in community composition relative to reference suggested that recovery of the community was still ongoing.

6.2.2.2 Productivity

Mean dry benthic invertebrate biomass at E1 in 2023 was significantly higher than 2019 but similar to other years, and similar to reference from 2017 to 2023. Mean wet weight benthic invertebrate biomass in 2023 was similar to all prior years, and similar to reference from 2017 to 2023 (Minnow 2024a). The higher mean benthic invertebrate dry biomass in 2023 than in 2019 at E1 is consistent with the higher total density results (i.e., significantly higher in 2023 than 2019). For both wet and dry biomass, the similarity at E1 to reference in each year is also consistent with the total density results (i.e., similar total density at E1 in each year relative to reference Minnow 2024a).

6.2.3 Periphyton and Benthic Invertebrate Tissue Quality

Periphyton and benthic invertebrate tissue quality monitoring was completed annually between 2022 and 2024, with monitoring in each year including an exposed section of lower Edney Creek (E1 [EDC-EXP]), with an unimpacted area of Edney Creek (EDC-D [EDC-REF]) serving as reference (Figure 4.2, Table 4.4).[79]

A review of the 2024 periphyton and benthic invertebrate tissue quality results (Appendix B) indicated that the data largely met the established DQOs and can be used with a high level of confidence for interpretation, although field precision was low and natural heterogeneity in analyte results were considered during data interpretation (see Section 6.1.4.1 for details). A review of 2024 supporting water data quality indicated that these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details).

Data interpretation was focused on primary and secondary analytes (Table 2.4) with a significant positive relative (exposed-reference) difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2024 (if the analysis *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant[80]) for at least one tissue type (periphyton, caddisfly, or composite-taxa benthic invertebrate).

[79] EDC-EXP and EDC-REF are the alternate names used for the E1 and EDC-D sampling areas for HRWG reporting. The original area names only (i.e., E1 and EDC-D) are used throughout the remainder of this report section (Section 6.2.3).

[80] If no significant change was detected in the relative (exposed-reference) difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

Data interpretation was further focused by integrating the results of water quality monitoring (i.e., bioconcentration) and TTFs of benthic invertebrate tissue analyte concentrations as detailed in Section 6.1.4.1. Combined, these approaches were used to identify analytes for which concentrations in biota and TTFs at the exposed area have increased at a rate that differs from reference and that may represent a potential risk to aquatic biota. Results for composite-taxa benthic invertebrate tissue samples are referred to as composite-taxa for the remainder of this section.

For most analytes evaluated, there was no increase in concentrations in periphyton and/or benthic invertebrate tissues from the exposed (E1) area relative to the reference (EDC-D) area over time (Appendix Figure F.4.15, Appendix Tables D.5.4 to D.5.6, F.4.25 to F.4.27). Two primary analytes (copper and iron) and eight secondary analytes (barium, cadmium, calcium, cobalt, sodium, titanium, uranium and vanadium) met the criteria for inclusion in data interpretation (i.e., had concentrations in at least one tissue type from the lower Edney Creek exposed area that were significantly higher than reference in 2024 or in all years; Table 6.12). None of the primary or secondary analytes showed a significant *Area×Year* interaction and a significant positive relative (exposed-reference) difference in 2024 for all three tissue types from lower Edney Creek (E1; Table 6.12; Appendix Figure F.4.16; Appendix Tables F.4.25 to F.4.27).

MPMC implements routine water quality monitoring in lower Edney Creek at EDC-01a (a station near sampling area E1; Figure 4.2).[81] Results from this routine water quality monitoring station indicated that only aqueous concentrations of dissolved copper exceeded the BCWQG (BCMOWLRS 2025). Dissolved copper exceeded the chronic BCWQG in 38% of samples in the preceding year (i.e., September 2023 to August 2024; Appendix Table D.1.8; BCMOWLRS 2025). Temporal analysis of routine water quality data from EDC-01a from 2021 to 2024 indicated that dissolved copper and dissolved manganese have decreased significantly over this period, but there were no other temporal changes in total and dissolved aqueous primary and secondary analyte concentrations over this period (Appendix Figures D.1.1 to D.1.3, Appendix Table D.1.9). Evaluation of aqueous selenium speciation parameters was initiated in 2024 (see Section 4.6 for details) to investigate possible causes of the temporal increases of selenium concentrations in periphyton and benthic invertebrate tissues from Hazeltine Creek (Minnow 2024a). Monitoring results from 2024 indicated that mean concentrations of selenate and selenite at EDC-01a were 2.7- and 1.3-times those reported at the reference area (EDC-D), respectively, while concentrations of the remaining measured selenium species

[81] Data collected at EDC-01 from 2015 to 2020 were excluded from analyses since EDC-01 was relocated and renamed as EDC-01a in 2021 (following the completion of remediation works in this area).

Table 6.12: Summary of Statistical Contrasts for Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Relative Difference for the Lower Edney Creek (E1 [EDC-EXP]; Exposed and EDC-D [EDC-REF]; Reference) Monitoring Areas, 2019 to 2024[a]

Indicates significantly higher tissue concentration at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Notes: "-" = no statistical comparison could be made because data were not available or all results below Laboratory Reporting Limit (LRL), refer to Appendix Tables F.4.25 to F.4.27 for statistical analyses results and magnitude of difference calculations. Data were analysed in units of mg/kg dry weight. <LRL = greater than 50% LRL data for both stations so the time period was omitted from the analysis. EDC-EXP and EDC-REF are the alternate names used the for the E1 and EDC-D sampling areas, respectively, for HRWG reporting.

[a] This table only presents results for primary and secondary analytes with a significant positive exposed-reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant) for one or more tissue types (periphyton, caddisfly, or composite benthic invertebrate) in at least one area. Years that share a letter (e.g., A,B,C) had ratios of analyte concentrations (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

(selenocyanate and unknown selenium species) were below the LRL at all sampling stations (Appendix Tables D.1.2 and D.1.8, Appendix Figure D.1.4).

Of the two primary analytes and the eight secondary analytes identified above for further evaluation, dissolved aqueous concentrations of copper, barium, calcium, sodium, and vanadium were slightly (<2-times) higher than reference area conditions, while uranium concentrations were <5-times higher than at the reference area (EDC-D; Table 6.13).[82] Overall, this indicates similar water quality between the exposed and reference areas (except for elevated dissolved uranium concentrations), and no temporal increase in analyte concentrations at E1 since 2021. Mean BCFs were slightly (<2-times) higher than reference for cobalt and vanadium and up to approximately 4-times greater than reference for copper, iron, barium, cadmium, and titanium for at least one tissue type (Table 6.13).

Copper concentrations in caddisfly and composite-taxa were significantly higher at the exposed area of lower Edney Creek (E1) in 2024 relative to reference (EDC-D) and had a significant *Area×Year* interaction (Table 6.12). Mean concentrations of copper in periphyton tissues from E1 were consistently higher than reference (EDC-D) from 2019 to 2024, but the relative (exposed-reference) difference was temporally stable (i.e., *Area×Year* interaction was not significant; Figure 6.16, Table 6.12; Appendix Table F.4.25). Copper concentrations in composite-taxa tissues from E1 were higher than reference from 2021 to 2024, however, the relative difference of copper concentrations in 2024 was similar to or significantly lower than all prior post-breach years (Figure 6.16, Table 6.12; Appendix Table F.4.27). In caddisfly tissues from E1, copper concentrations were higher than reference in most years from 2020 to 2024 (except 2023) but the relative difference in 2024 was similar to or significantly lower than all prior years except 2019 (Figure 6.16, Table 6.12; Appendix Table F.4.26). Despite the tissue copper concentrations being higher than reference for all tissue types, the TTFs for caddisfly and composite-taxa tissues from E1 were lower than reference in all years (Table 6.14; Appendix Tables F.4.28 and F.4.29). Therefore, the concentrations of copper in the aquatic biota in lower Edney Creek, and the trophic transfer of copper to benthic invertebrates, have not increased compared to 2020 or earlier.

For the other identified primary analyte, iron, only composite-taxa tissues from the exposed area of lower Edney Creek (E1) had concentrations that were significantly higher than reference in 2024, but the relative difference was temporally stable (i.e., *Area×Year* interaction was not

[82] Elevated analytes were identified as those with mean concentrations at the exposed station that were at least twice the mean concentration at the reference station.

Table 6.13: Summary of Primary and Secondary Analyte Concentrations in Water, Periphyton, Caddisfly, and Composite-Taxa Tissues, BCFs, and TTFs for the Lower Edney Creek (E1 [EXP-EXP]; Exposed and EDC-D [EDC-REF]; Reference) Monitoring Areas, 2024

Dissolved concentration at exposed area exceeded reference area by less than 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 5-times.
Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05).
Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05).
BCF for exposed area exceeded reference area by less than 2-times.
BCF for exposed area exceeded reference area by at least 2-times.
BCF for exposed area exceeded reference area by at least 10-times.
Mean TTF exceeds 1.
Mean TTF at exposed area exceeds 1 and the corresponding reference area TTF for a given year.
Mean TTF at exposed area exceeds 1, the corresponding reference area TTF for a given year, and mean TTFs for all previous years (pre-breach and 2017 when applicable).

BOLD = mean tissue selenium value exceeds long-term benthic invertebrate tissue guideline for selenium (4 mg/kg dw; BCMOE 2014).

BOLD/ITALICS = Indicates dissolved water value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.12 (i.e., those with a significant positive exposed - reference difference in 2024 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = no data for dissolved water concentration and BCF was not calculated for analytes due to no data for dissolved water concentration. "na" = not applicable. Summary statistics reported to 3 significant figures for display purposes. EDC-EXP and EDC-REF are the alternate names used the for the E1 and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Monitoring stations included W10 and EDC01a for corresponding tissue sampling stations EDC-D and E1, respectively (refer to Appendix Tables D.1.7 and D.1.8).

[b] Sample sizes for water quality monitoring was n=2 for EDC-D (W10) and n=13 for EDC-01a (E1).

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWRLS 2024, 2025) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2024 and the time of sampling in August 2024 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a, 2023a, 2024a).

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L), if the dissolved water concentration was reported as below the Laboratory Reporting Limit (LRL), then the LRL was substituted for the BCF calculation.

[f] Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

Table 6.13: Summary of Primary and Secondary Analyte Concentrations in Water, Periphyton, Caddisfly, and Composite-Taxa Tissues, BCFs, and TTFs for the Lower Edney Creek (E1 [EXP-EXP]; Exposed and EDC-D [EDC-REF]; Reference) Monitoring Areas, 2024

Summary statistics reported to 3 significant figures for display purposes. EDC-EXP and EDC-REF are the alternate names used the for the E1 and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Monitoring stations included W10 and EDC01a for corresponding tissue sampling stations EDC-D and E1, respectively (refer to Appendix Tables D.1.7 and D.1.8).

[b] Sample sizes for water quality monitoring was n=2 for EDC-D (W10) and n=13 for EDC-01a (E1).

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWRLS 2024, 2025) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2024 and the time of sampling in August 2024 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a, 2023a, 2024a).

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L), if the dissolved water concentration was reported as below the Laboratory Reporting Limit (LRL), then the LRL was substituted for the BCF calculation.

[f] Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

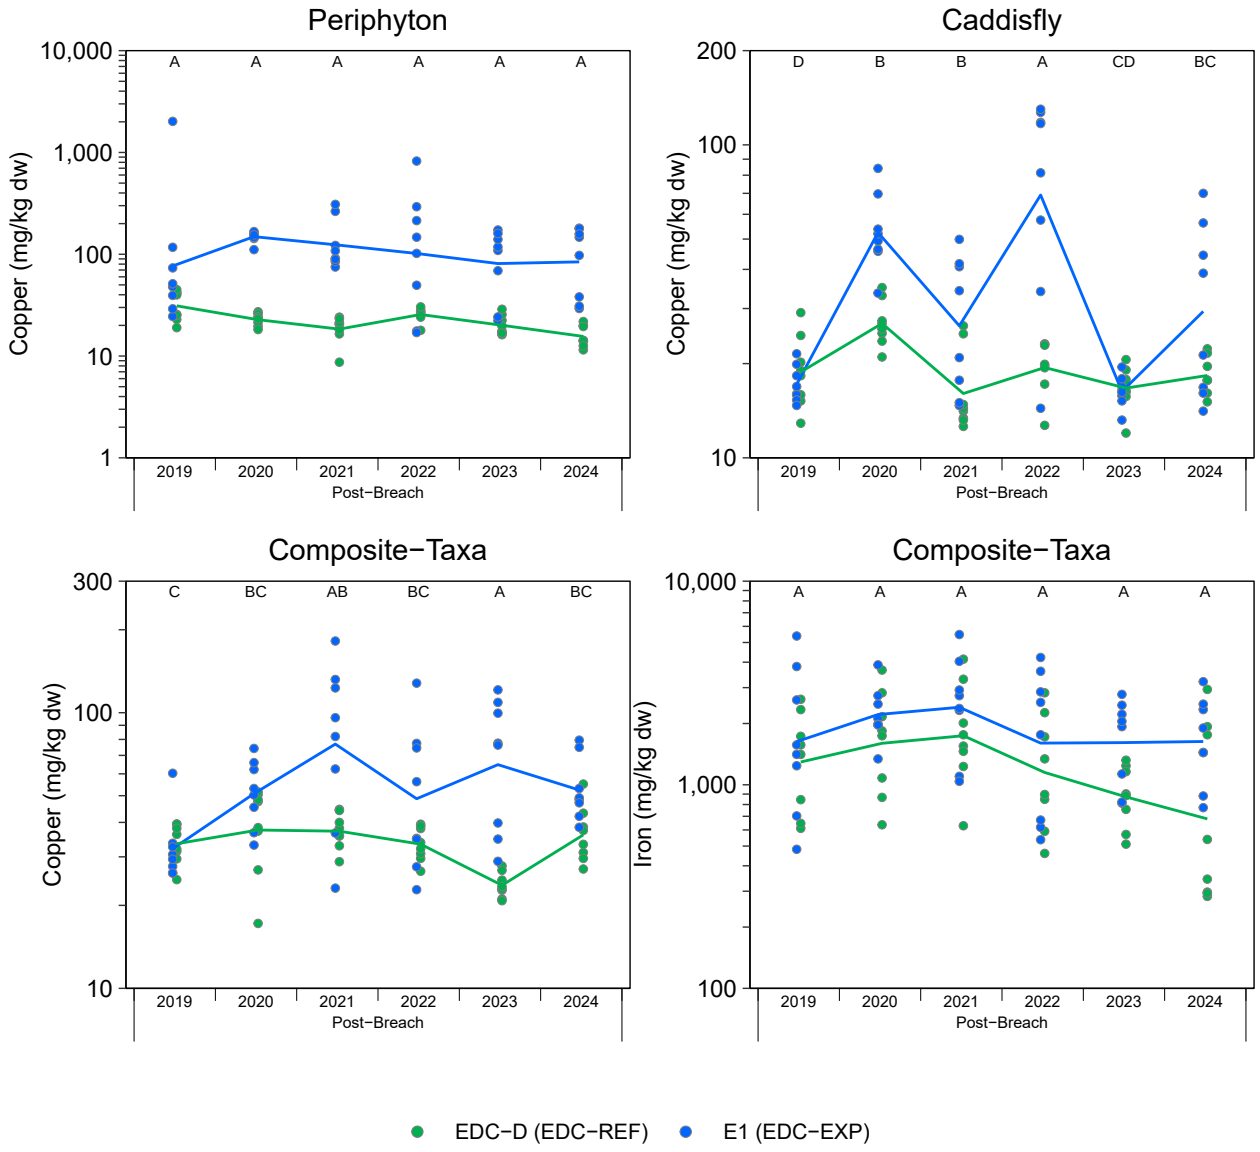

Figure 6.16: Periphyton, Caddisfly, and Composite−Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed − Reference Difference for the Lower Edney Creek (E1 [EDC−EXP; Exposed]; EDC−D [EDC −REF; Reference]) Monitoring Areas, 2019 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. Green represents reference areas and blue represents exposed areas. EDC-REF and EDC-EXP are the alternate names for the EDC-D and E1 sampling areas, respectively, for HRWG reporting. Plots are only included for primary and secondary analytes with a significant positive exposed −reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2024 (if the analysis Area×Year interaction was significant) or in all monitoring years (if the Area×Year interaction was not significant). Data are not available for all years within the date range identified, only years with available data are displayed and these are analyte−dependent. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

Data are not available for all years within the date range identified, only years with available data are displayed and these are analyte−dependent. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

Table 6.14: Summary of Statistical Contrasts for Caddisfly and Composite-Taxa Benthic Invertebrate Tissue Trophic Transfer Factors of Primary and Secondary Analytes with a Significant Positive Exposed - Reference Relative Difference for the Lower Edney Creek (E1 [EXP-EXP]; Exposed and EDC-D [EDC-REF]; Reference) Monitoring Areas, 2019 to 2024[a]

Analytes		Lower Edney Creek (E1; Exposed) / Lower Edney Creek (EDC-D; Reference)											
		Caddisfly						Composite-Taxa Benthic Invertebrate					
		2019	2020	2021	2022	2023	2024	2019	2020	2021	2022	2023	2024
Primary Analytes	Copper	A	A	A	A	A	A	A	A	A	A	A	A
	Iron	A	A	A	A	A	A	A	A	A	A	A	A
Secondary Analytes	Barium	AB	B	B	A	B	B	A	AB	B	A	A	A
	Cadmium	C	ABC	AB	A	BC	BC	A	A	A	A	A	A
	Calcium	B	B	C	A	B	B	B	B	C	A	AB	AB
	Cobalt	A	A	A	A	A	A	A	A	A	A	A	A
	Sodium	AB	AB	B	A	AB	A	A	AB	B	A	A	A
	Titanium	BC	BC	C	A	AB	ABC	A	A	A	A	A	A
	Uranium	A	A	A	A	A	A	A	A	A	A	A	A
	Vanadium	A	A	A	A	A	A	A	A	A	A	A	A

Indicates significantly higher TTF at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Notes: "-" = no statistical comparison could be made since data were not available or all results were below Laboratory Reporting Limit (LRL). Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated. Refer to Appendix Tables F.4.28 to F.4.29 for statistical analyses results and magnitude of difference calculations. EDC-EXP and EDC-REF are the alternate names used for the for the E1 and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Results are shown for primary and secondary analytes that are presented in Table 6.12 (i.e., those with a significant positive exposed - reference difference in 2024 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). Years that share a letter (e.g., A,B,C) had ratios of TTFs (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

significant; Figure 6.16, Table 6.12; Appendix Tables F.4.25 to F.4.27). Similarly, the TTFs for iron in composite-taxa tissues from E1 were temporally stable from 2019 to 2024 (i.e., *Area×Year* interaction was not significant; Table 6.14; Appendix Figure F.4.18). Selenium concentrations in all three tissue types from E1 in 2024 (periphyton, caddisfly, and composite-taxa) did not differ significantly from the reference area (EDC-D; Appendix Tables F.4.25 to F.4.27), therefore temporal changes in tissue selenium concentrations and selenium TTFs were not evaluated. Selenium concentrations in benthic invertebrate tissues from E1 in 2024 (maximum = 2.20 and 3.27 mg/kg dw in caddisfly and composite-taxa tissues, respectively; Appendix Tables D.5.5 and D.5.6) were below the BC interim guideline for the protection of aquatic life (4 mg/kg dw; BCMOE 2014).

Of the eight secondary analytes identified for data interpretation, barium, sodium, titanium, and vanadium were significantly higher in periphyton tissues from lower Edney Creek (E1) in 2024 than those from the reference area (EDC-D; Figure 6.16, Table 6.12; Appendix Table F.4.25). For sodium concentrations, the relative (exposed-reference) difference in periphyton tissues was temporally stable from 2019 to 2024 (i.e., *Area×Year* interaction was not significant). The relative (exposed-reference) differences of barium and vanadium concentrations in periphyton in 2024 were similar to the first year of post-breach monitoring (2019), while titanium concentrations in 2024 were significantly higher compared to 2019 and 2022 but similar to remaining prior years (Figure 6.16, Table 6.12). None of the eight secondary analytes (identified above) were significantly higher in caddisfly tissues from E1 in 2024 compared to the reference area (Figure 6.16, Table 6.12; Appendix Figure F.4.15, Appendix Table F.4.26). Concentrations of barium, cobalt, sodium, titanium, uranium, and vanadium in composite-taxa tissues were significantly higher at the exposed area relative to reference in all years (2019 to 2024) but the relative differences of these analyte concentrations were temporally stable over this period (i.e., no significant *Area×Year* interaction; Figure 6.16, Table 6.12; Appendix Table F.4.27). Concentrations of cadmium and calcium in composite-taxa tissues from E1 in 2024 were also significantly higher than reference, but the relative differences of the analyte concentrations in 2024 were similar to the first or second (i.e., 2019 or 2020) year of monitoring for cadmium and calcium, respectively (Figure 6.16, Table 6.12; Appendix Table F.4.27). The TTFs for cadmium, cobalt, titanium, uranium, and vanadium in composite-taxa tissue from E1 were elevated relative to reference from 2019 to 2024 but were temporally stable over this period (Table 6.14; Appendix Figure F.4.18, Appendix Table F.4.29). The TTFs for caddisfly tissues from E1 in 2024 were similar to or significantly lower than those from the reference area for each of the primary and secondary analytes identified for discussion. The evaluation of secondary analytes in periphyton, caddisfly, and composite-taxa tissues in 2024 indicates there was no significant increase in the tissue analyte concentrations, or trophic transfer of these analytes to benthic invertebrates, in the

exposed area of lower Edney Creek compared to the first (i.e., 2019) or second (i.e., 2020) year or monitoring, relative to reference.

Overall, the results of tissue quality monitoring in the exposed area of lower Edney Creek in 2024 indicated that copper concentrations in periphyton and benthic invertebrate tissues and iron concentrations in composite-taxa tissues were significantly higher than reference. However, there was no increase in the copper or iron concentrations of these tissues compared to the first or second year of post-breach monitoring (i.e., 2019 or 2020). Selenium concentrations in exposed tissues (periphyton and benthic invertebrates) were similar to reference results, indicating no potential mine-related influence, and remained below the guideline for the protection of aquatic life in benthic invertebrate tissues. Although the tissue analyte concentrations of eight secondary analytes were significantly higher at the exposed area compared to reference area in 2024, there was no sustained increase in the concentrations of these analytes in exposed tissues, or in the trophic transfer of these analytes to benthic invertebrates (relative to reference), with results in 2024 being similar to the first (2019) or second (2020) year of monitoring.

6.2.3.1 Tissue-Type Comparisons

A comparison between benthic invertebrate (caddisfly and composite-taxa) tissue findings was completed to evaluate if results were consistent between the two tissue types. This qualitative comparison focused on analytes with a significant positive exposed-reference difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2024 or in all monitoring years for at least one tissue type in at least one area.

Among the primary and secondary analytes evaluated benthic invertebrate tissues from lower Edney Creek in 2024, the significant positive exposed-reference differences in analyte concentrations and TTFs identified for caddisfly tissues were a subset of those identified for composite-taxa tissues (Table 6.15). This indicates that the analyte concentrations and TTFs in exposed caddisfly tissues that were significantly elevated relative to reference were captured by composite-taxa monitoring, while the reverse was not true (i.e., caddisfly monitoring identified fewer significant relative differences for both primary and secondary analytes than composite-taxa monitoring; Table 6.15). These results indicate that composite-taxa tissue sampling effectively detected all changes also occurring in caddisflies for both tissue analyte concentrations and TTFs. Overall, results from lower Edney Creek suggest that if monitoring were limited to composite-taxa tissue samples, changes in caddisfly tissue analyte concentrations and TTFs would still be captured.

Table 6.15: Summary Magnitude of Difference (MOD)[a] of Exposed - Reference Contrasts of Primary and Secondary Analyte Concentrations and Trophic Transfer Factors (TTFs) in Caddisfly and Composite-Taxa Benthic Invertebrate Tissue for the Lower Edney Creek (E1 [EDC-EXP]; Exposed and EDC-D [EDC-REF]; Reference) Monitoring Areas, 2024

Analytes		Lower Edney Creek (E1 [EDC-EXP]; Exposed) / Lower Edney Creek (EDC-D [EDC-REF]; Reference)			
		Tissue		TTF	
		Caddisfly	Composite-Taxa	Caddisfly	Composite-Taxa
Primary Analytes	Copper	60	45	-65	-66
	Iron	-35	57	-38	50
Secondary Analytes	Barium	ns	32	-74	ns
	Cadmium	ns	299	ns	173
	Calcium	ns	35	-45	ns
	Cobalt	ns	63	ns	88
	Sodium	ns	50	ns	ns
	Titanium	ns	105	ns	50
	Uranium	-39	39	ns	52
	Vanadium	ns	95	-50	53

Indicates significantly higher tissue concentration or TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly higher tissue concentration or TTF at exposed compared to reference area (α = 0.05), without a significant (Area x Year) interaction of the two-way ANOVA. Values represent the MOD exposed:reference, which did not change significantly among monitoring years.

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.12 (i.e., analytes that had a significant positive exposed - reference difference in 2024 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). ns = no significant difference between exposed at reference area. TTF calculated as (benthic invertebrate tissue analyte concentration) / (periphyton tissue analyte concentration). EDC-EXP and EDC-REF are the alternate names used the for the E1 and EDC-D sampling areas, respectively, for HRWG reporting.

[a] Magnitude of difference (MOD) calculated on backtransformed least-squares means as (Exp-Ref)/Ref x 100%.

7 SUMMARY OF FINDINGS

This section provides an overall summary of the findings of sediment and aquatic biological monitoring completed under the Mount Polley CEMP from 2022 to 2024, drawing on additional historical monitoring results for data interpretation as required. As identified in Section 2, this section considers multiple lines of evidence to identify well supported findings versus those that are not fully supported and/or those for which uncertainty exists. Throughout the following sub-sections, each monitoring component builds on evidence from others, typically over the line of evidence sequence from sediment quality to primary producer to secondary producer/benthic invertebrates to fish. Where temporal changes in sediment and tissue quality results are discussed in the following sub-sections, these are relative to reference results.[83] The discussion of temporal and spatial differences in the following sub-sections are limited to those differences that were statistically significant.

7.1 Polley Lake

7.1.1 Sediment Quality

Sediments from the deep basins of Polley Lake in 2024 remained clearly influenced by breach material, based on chemical and physical characteristics. Sediments from the deep areas of Polley Lake in 2024 were characterized by concentrations of arsenic and copper greater than pre-breach/reference conditions and BCWSQG. Copper was the most substantially elevated analyte, with mean concentrations in 2024 that exceeded the upper BCWSQG by 2.5- and 2.9-times in the Northwest (POL-P1) and Southeast (POL-P2) basins, respectively. Copper concentrations in sediments from both basins of Polley Lake, relative to reference, have been temporally stable (i.e., no significant change) from 2018 to 2024 and during this period have been similar to or significantly lower than immediate post-breach conditions (i.e., 2014). Arsenic concentrations of Polley Lake deep sediments have been stable since 2021 at POL-P1 and since 2018 at POL-P2, relative to reference, and have been significantly lower than immediate post-breach conditions (i.e., 2014) since at least 2018. The TOC content of deep Polley Lake sediments was slightly higher in 2024 than in previous-post breach monitoring years (except for 2021), suggesting early evidence of recovery of TOC content, but this change was not yet statistically significant. Overall, the 2024 sediment quality results indicated that temporal changes in the physical and chemical characteristics of sediments in both the Northwest and Southeast basins of Polley Lake have been limited since the breach in 2014, and no significant

[83] Temporal changes were assessed in the relative (exposed-reference) difference among years. See Section 3.1.3.2 for detailed methods.

changes in sediment characteristics or analyte concentrations have occurred since at least 2021, but recovery is occurring slowly.

Sediments from the shallow areas of Polley Lake, which were last sampled in 2022, had mean arsenic, copper, and iron concentrations that exceeded reference conditions and BCWSQG. Specifically, mean arsenic concentrations in the exposed sediment exceeded the lower BCWSQG by 2.4-times, and mean copper and iron concentrations exceeded the upper BCWSQG by 3.4--and 1.5-times, respectively. Of the analytes with concentrations that exceeded reference conditions and BCWSQG in 2024 (i.e., arsenic, copper, and iron), copper was the only analyte with concentrations in reference sediments that exceeded the BCWSQG (i.e., exceeded the lower BCWQG by 2.4-times). The TOC content, arsenic, copper, and iron concentrations in shallow Polley Lake sediments in 2022 were similar to those reported in the previous sampling event (i.e., 2019) indicating temporal stability of these analyte concentrations.

Sediment toxicity testing was conducted for deep and shallow areas of Polley Lake (and reference; Bootjack Lake) in 2024 and 2022, respectively. Test organisms (*C. dilutus*) exposed to sediments from deep areas of Polley Lake in 2024 showed no unacceptable responses of survival or growth relative to the sand control or reference sediments, using a weight-of evidence approach associated with endpoints of survival and growth compared to reference results. Similarly, test organisms (*H. azteca)* exposed to sediments from shallow areas of Polley Lake in 2022 showed no unacceptable response of survival and growth relative to the reference area or the sand control. Sediment toxicity testing of deep and shallow sediments from Polley Lake has consistently shown no unacceptable responses of test organisms since the initiation of post-breach monitoring. Conditions of the CEMP outlined that sediment toxicity testing of the shallow Polley Lake area must be continued "*unless MPMC can clearly show that copper concentrations in all Polley Lake shallow sediment samples are below the 95th percentile of the copper concentrations in the Bootjack Lake reference area shallow sediment samples."* (BCMOECCS 2021). This condition was not met in 2022 in Polley Lake shallow sediments, indicating that toxicity testing of these shallow sediments must be completed in 2025.

7.1.2 Aquatic Life

Phytoplankton community and productivity monitoring in Polley Lake indicated that phytoplankton productivity (assessed by chlorophyll-a concentrations) was significantly lower than at the reference area (Bootjack Lake) in 2024, and lower than most prior years (except 2021). The chlorophyll-a results in 2024 characterized both Polley Lake and Bootjack Lake as oligotrophic, which was similar to results from 2020 to 2021, but differed from when the lakes were classified as mesotrophic (i.e., in 2019, 2022, and 2023). The phytoplankton community in Polley Lake in 2024 was characterized by total density and taxon richness that were significantly

lower, and Simpson's Diversity and Evenness that were significantly higher, compared to the reference area. Phytoplankton density has varied temporally, which is attributable to significant changes in Cyanobacteria densities in both lakes that were likely driven by natural changes in environmental parameters. Taxon richness in Polley Lake has consistently been significantly lower than at the reference area (except in 2020), while Simpson's Diversity and Evenness have been similar to or significantly higher than at the reference area in all years. Cyanobacteria (the dominant taxa in both lakes) has shown similar or significantly lower relative densities (%) in Polley Lake compared to the reference area in all years, while Chrysophytes and Cryptomonads (%) have been consistently higher and lower, respectively, compared to the reference area. Collectively, the lack of directional consistency in the differences of the Polley Lake community endpoints, relative to the reference area (i.e., no consistent increasing or decreasing patterns), suggests that the observed differences were likely related to environmental factors (e.g., light exposure, water temperature, nutrient availability).

Zooplankton community and productivity monitoring in Polley Lake in 2024 indicated that zooplankton biomass (dw) was significantly higher than at the reference area (Bootjack Lake). In most prior years (2019 to 2022), biomass was either similar to or significantly higher than reference (except 2023). The zooplankton community in Polley Lake in 2024 was characterized by total density, and Simpson's Diversity and Evenness that were significantly lower than at the reference area, and taxon richness that was similar to the reference area. These community metrics have varied temporally, both within Polley Lake (excluding Simpson's Evenness which has been temporally stable), and relative to the reference area, without obvious directional consistency (i.e., no obvious temporal increase or decrease in the endpoints). The zooplankton community in Polley Lake has consistently had higher dominance of Cyclopoida (%) and lower dominance of Rotifera (%) than Bootjack Lake throughout the monitoring period (excluding 2022 for Cyclopoida), while Copepod Nauplii (%) in Polley Lake were significantly higher than Bootjack Lake from 2019 to 2022 but were similar to the reference area in 2023 and 2024. Collectively, the observed temporal variability in most endpoints at both the exposed and reference areas, and the lack of directional consistency in the differences of the Polley Lake community metrics, relative to reference, suggested that the observed differences were likely related to environmental factors (e.g., water temperature, nutrient availability, phytoplankton community, and predation).

Zooplankton tissue quality monitoring in Polley Lake in 2024 indicated that concentrations of primary and secondary analytes in zooplankton were similar to or lower than reference. Although temporal variability has been observed over the post-breach monitoring period (i.e., 2019 to 2024), the primary and secondary analyte concentrations of zooplankton tissues from Polley Lake in 2024 were not significantly higher than the first year of monitoring that included

sample replicates (i.e., 2019), indicating no sustained increase over this period. Rather, the concentrations of several analytes (copper, manganese, mercury, molybdenum, nickel, and tin) in zooplankton tissues from Polley Lake in 2024 were significantly lower than in 2019. The mean selenium concentration in zooplankton tissues from Polley Lake in 2024 was approximately 1.1-times the BC guideline for the protection of aquatic life but did not differ significantly from reference in 2024. Selenium concentrations in exposed zooplankton tissues have not increased significantly since 2019 (i.e., the first year of monitoring). Surface water quality data from Polley Lake (2015 to 2024) corroborated the zooplankton tissue quality results and showed stable or decreasing concentrations for all aqueous primary and secondary analytes except dissolved copper and dissolved and total vanadium.

Benthic invertebrate community monitoring in Polley Lake in 2024 indicated that the community of the two basins of Polley Lake differed from one another. The benthic invertebrate community at the Northwest basin (POL-P1) was characterized by total density, taxonomic richness, and Simpson's Evenness that were similar to both pre-breach (1999) and reference conditions (or significantly higher than pre-breach for density). At the Southwest basin (POL-P2) density and Simpson's Evenness were significantly lower compared to POL-P1 and reference, and Simpson's Evenness was also significantly lower than pre-breach (1999) conditions. Although taxon richness at both basins of Polley Lake in 2024 was similar to pre-breach and reference conditions (and was similar between the basins), Simpson's Diversity at both basins in 2024 was significantly lower than reference and pre-breach conditions, and was significantly lower at POL-P2 (which is closer to the breach location) compared to POL-P1. Total density in both basins decreased significantly from 2018 to 2024 but has remained similar to or significantly higher than reference and/or pre-breach conditions in all years since 2016. The benthic invertebrate community of both Polley Lake basins in 2024 was dominated by Chironomidae and, to a lesser extent, Oligochaeta. Although the community composition at two Polley Lake basins in 2024 differed significantly in terms of Chironomidae (%) and Oligochaeta (%), the relative density (%) and density of all major taxa groups in both basins were similar to reference and/or pre-breach (1999) conditions. Overall, the benthic invertebrate community at deep basins of Polley Lake in 2024 were largely comparable to the communities documented in Polley Lake in 1999 (pre-breach) and/or the reference area communities (Bootjack Lake) in 2024, excluding Simpson's Evenness at POL-P2, and Simpson's Diversity at both POL-P1 and POL-P2. This indicated that the benthic invertebrate community structure of Polley Lake in 2024 has mostly recovered to pre-breach and/or reference conditions since the breach in 2014. Remaining differences between the two Polley Lake basins indicate that recovery is more advanced at the Northwest basin (POL-P1), which is consistent with its greater distance from the location of the breach impact.

Fish community and population health assessments undertaken annually from 2019 to 2024 documented the influence of the temporary loss of Hazeltine Creek due to the breach (August 2014 to April 2018), which supports most of the fish recruitment to Polley Lake. Following consecutive years of increases in spring rainbow trout CPUE (2022 and 2023) which featured the highest recorded values since 2016 (28.4 fish/trap/day in 2023), CPUE in 2024 (28.2 fish/trap/day) was almost unchanged from the previous year. Increased spring CPUE from 2022 to 2024 compared to 2017 to 2021 suggests that most of the remaining 2018 to 2020 rainbow trout cohorts, resulting from restoration of fish access to Hazeltine Creek in 2018, have reached maturity. In the fall of 2024, when fishing was randomized in Polley Lake, CPUE for rainbow trout was lower than in all previous years of monitoring. Following three years of elevated rainbow trout fall CPUE when the population lacked older age classes (i.e., 2019 to 2021), the population in 2024 may have returned to an abundance and age-size structure more comparable to 2016. The assessment of rainbow trout size distribution provides further insight into the population trends observed in Polley Lake. Length frequency distributions for rainbow trout over time showed a proportional shift towards smaller and younger fish in 2019 and a subsequent shift towards a more even distribution among size classes with the survival of the 2018 and 2019 cohorts. In 2022 and 2023, a more balanced distribution among size classes was observed than in previous years, and in 2024 the distribution most closely resembled that in 2016 (two years post-breach). These temporal changes in length frequency distributions may also help to explain the trends observed in rainbow trout CPUE, with higher CPUE from 2019 to 2021 (reflecting a period of higher population density resulting from restoration of fish access to Hazeltine Creek in 2018) and a subsequent decrease in CPUE from 2022 to 2024 (reflecting a lower density population with more representation from older age classes). CPUE for longnose sucker in the spring has declined over the past four years, and was lowest in 2024 since monitoring began in 2016, while CPUE in the fall of 2024 was the second lowest recorded since 2016. The CPUE for longnose sucker in spring and fall has shown temporal variability, which might be attributable to several factors that can affect the success of netting efforts (e.g., temperature driven activity effects and/or gear efficacy). Length frequency distributions of longnose sucker in 2024 showed fewer age-1 fish and more age-3 fish relative to 2023 with both years more closely resembling the size structure in 2016 than in prior years (i.e., 2020 to 2022).

Fish tissue quality monitoring of rainbow trout and longnose sucker from Polley Lake in 2024 indicated that fish muscle analyte concentrations were below the guidelines for the protection of human health (which exist for mercury and selenium), indicating that these fish were safe for human consumption. Mean selenium concentrations in rainbow trout and longnose sucker muscle in 2024 were moderately (1.1- and 1.5-times, respectively) greater than the BC guideline for the protection of aquatic life, consistent with prior years. Evaluation of ovary tissue is

recommended for the assessment of potential selenium-associated effects on fish, and mean selenium concentrations in the ovary tissues of both fish species from Polley Lake in 2024 were below the BC guideline for the protection of aquatic life and the threshold for reproductive effects. Selenium concentrations in most rainbow trout and longnose sucker tissues from Polley Lake have remained elevated relative to reference since the uncontrolled surface runoff to Polley Lake from 2006 to 2009 but the difference has not increased over the post-breach period. In fact, selenium concentrations in rainbow trout liver tissues and longnose sucker kidney tissues from Polley Lake did not differ significantly from the reference area in 2024, marking the first time this has occurred in any fish tissues from Polley Lake fish since the start of mining operations. In addition, selenium concentrations in rainbow trout muscle tissue and longnose sucker muscle and ovary tissues in 2024 were significantly lower than pre-breach (2012) results. The observed decreases in fish tissue selenium concentrations in Polley Lake corresponded with the absence of increased selenium concentrations in zooplankton tissue (i.e., dietary exposure) over the monitoring period (2019 to 2024) and with a significant decrease in both total and dissolved selenium concentrations in surface waters of Polley Lake from 2015 to 2024. Concentrations of the remaining primary analytes and 15 secondary analytes were significantly higher in exposed tissues relative to reference in 2024 in at least one tissue type in one or both species. However, the results for most of these analytes were inconsistent among tissues and species, were temporally stable, and/or were similar to the first or second year of monitoring, indicating there has been no sustained increase of analyte concentrations in fish tissues from Polley Lake since the initiation of post-breach monitoring. Cobalt was the only analyte that showed higher concentrations in multiple fish tissues (longnose sucker liver and kidney) in 2024 compared to all prior years; continued monitoring will help to determine whether the increased tissue cobalt concentrations represented a single anomalous year or are part of a long-term trend.

7.1.3 Key Findings

Key findings of CEMP monitoring of Polley Lake from 2022 to 2024 (Table 7.1) were:

- Sediment Quality (shallow areas: 2022; deep areas: 2024):
    - Concentrations of arsenic and copper in deep Polley Lake sediments in 2024 were higher than BCWSQG and reference/pre-breach conditions while TOC content was much lower than reference. Limited changes in the sediments have occurred over the post-breach period, with no significant changes in sediment arsenic and copper concentrations since at least 2021, but recovery is occurring slowly. The TOC content of the deep Polley Lake sediments has been temporally stable over the post-breach period.

		Quality[b]	Toxicity[c]		Productivity	Community[d]	Zooplankton Tissue Quality[e]	Community[d]	Usage and Population Health	Tissue Quality[f]
			Survival	Growth						
Shallow	POL-S	**2022** Analytes of Interest = As, Cu, Fe Mean Cu and Fe > upper BCWSQG and ref 95th; Mean As > lower BCWSQG and ref 95th; TOC < ref **Temporal Evaluation (2019 to 2022)** As, Cu, Fe in 2022 = 2019 TOC in 2022 = 2019	***H. azteca* (14-day)** **2022** No unacceptable response (97% of Control; 104% of Reference) **Temporal Evaluation (2019 to 2022)** No unacceptable / Moderate response (2019); No unacceptable response (2022)	***H. azteca* (14-day)** **2022** No unacceptable response (126% of Control; 114% of Reference) **Temporal Evaluation (2019 to 2022)** No unacceptable response	-	-	-	-	**Temporal Evaluation (2016 to 2024)** CPUE Spring: RB CPUE in 2024 < 2016, > 2017 to 2022, = 2023; LSU CPUE in 2024 < 2016 to 2023 (all years) CPUE Fall: RB CPUE in 2024 < 2016 to 2023 (all years); LSU in 2024 < 2016 to 2021 and 2023, > 2022 Condition (Spring/Fall; All): RB in spring 2024 = 2016 to 2021, > 2022 to 2023; LSU in spring 2024 < 2016 to 2023; RB in fall 2024 < 2016 to 2021, = 2022 to 2023; LSU in fall 2024 < 2014 to 2020, = 2021 to 2023 Weight-at-age (Spring; females): RB in 2024 = 2016 to 2019 and 2022, 2023, < 2020 to 2021; LSU in 2024 = 2016 to 2017 and 2020 to 2023, < 2018 to 2019 Fall Length Frequency Distributions: RT size distribution in 2024 most closely resembled that in 2016 (two years following the breach). In prior post-breach years, RT size distribution in 2019 showed the highest frequency of smaller and younger fish, and in 2022 and 2023 showed more even distribution among size classes (and more similarity to the 2016 distribution). LSU size distribution in 2024 showed fewer age-1 fish and more age-3 fish compared to 2023 with both years more closely resembling the size structure in 2016 than in 2020 to 2022.	**Temporal Evaluation (2015 to 2024)** Guidelines and Thresholds: RB and LSU (MU) mean [Hg] and [Se] < Human Health GL in all years; RB (MU) and LSU (MU) mean [Se] > Aquatic Life GL in all years (except for RB in 2023); RB (OV) and LSU (OV) mean [Se] < Aquatic Life GL in all years (except 2015, 2017, 2019 for RB); RB (OV) mean [Se] > Effects threshold in 2015, but otherwise < threshold in all years Spatial and Temporal Analysis: [As] in RB (MU, OV, LI, KI) and LSU (MU, LI, KI) in 2024 > ref but = 2018 or earlier; [Cu] in RB (OV, KI) and LSU (LI) in 2024 > ref but = first year of monitoring; [Fe] in RB (LI, KI) and LSU (LI) in 2024 > ref but temporally stable except for LSU (LI) in 2024 > all prior years; [Se] in RB (MU, OV, KI) and LSU (MU, OV, LI) in 2024 > ref but ≤ first year of post-breach monitoring; Concentration of most secondary analytes in RB and LSU tissues in 2024 ≤ ref. Analytes > ref in 2024 for two or more tissues within a fish species (RB and LSU) included Ca, Co, Mn,, Mo, Ni, P, Na, Sr, Ti, V, Zn. For these analyte-tissue combinations, concentrations were either temporally stable or did not exhibit sustained temporal increases in more than one tissue type. [Co] in LSU (LI, KI) was the only analyte in multiple fish tissues in 2024 > all prior years.
Deep	POL-P1 (North Basin)	**2024** Analytes of Interest = As, Cu Mean [Cu] > upper BCWSQG, and ref and pre-breach 95th; Mean [As] > lower BCWSQG, and ref and pre-breach 95th; TOC < ref **Temporal Evaluation (2014 to 2024)** [As] in 2024 < from 2014 to 2018, = 2021; [Cu] in 2024 < 2014, = from 2016 to 2021; TOC in 2024 = from 2014 to 2021	***C. dilutus* (10-day)** **2024** No unacceptable response (109% of Control; 98% of Reference); **Temporal Evaluation (2014 to 2024)** No unacceptable response	***C. dilutus* (10-day)** **2024** No unacceptable response (132% of Control; 114% of Reference); **Temporal Evaluation (2014 to 2024)** No unacceptable response (2014, 2016, 2021 to 2024); No unacceptable / Moderate response (2018)	-	-	-	**2024** Density = ref, > pre-breach, > POL-P2; Richness = ref, = pre-breach, = POL-P2 **Temporal Evaluation (2014 to 2024)** Density < ref in 2014 (Highly) and 2016 (Slightly), > ref in 2018 and 2021 (Slightly to Moderately), = ref in 2024; Density < pre-breach in 2014 = pre-breach in 2016, > pre-breach from 2018 to 2024; Density > POL-P2 in 2014 and 2024, = POL-P2 from 2016 to 2021; Richness = ref and POL-P2 from 2016 to 2024; Richness < pre-breach 2014, 2018, and 2021, = pre-breach in 2016 and 2024		
	POL-P2 (South Basin)	**2024** Mean [Cu] > upper BCWSQG, and ref and pre-breach 95th; Mean [As] > lower BCWSQG, and ref and pre-breach 95th; TOC < ref **Temporal Evaluation (2014 to 2024)** [As] in 2024 < 2014 to 2016, = 2018 to 2021; [Cu] in 2024 = 2014, and 2016 to 2021, < 2015; TOC in 2024 = from 2014 to 2021	***C. dilutus* (10-day)** **2024** No unacceptable response (102% of Control; 92% of Reference); **Temporal Evaluation (2014 to 2024)** No unacceptable response	***C. dilutus* (10-day)** **2024** No unacceptable response (131% of Control; 113% of Reference); **Temporal Evaluation (2014 to 2024)** No unacceptable response	**Phytoplankton** **2024** Chl-a < ref (Moderately); Classified as oligotrophic **Temporal Evaluation (2019 to 2024)** Chl-a = ref in 2019 and 2020, < ref in 2021 and 2024 (Moderately), > ref in 2022 and 2023 (Moderately) **Zooplankton** **2024** Biomass (dry) > ref (Moderately) **Temporal Evaluation (2019 to 2024)** Biomass (dry) > ref in 2019 and 2024 (Moderately), = ref from 2020 to 2022, < ref in 2023 (Slightly)	**Phytoplankton** **2024** Density < ref (Slightly); Richness < ref (Moderately) **Temporal Evaluation (2019 to 2024)** Density = ref in 2019, < ref in 2020 and 2024 (Slightly to Moderately); > ref from 2021 to 2023 (Moderately) Richness < ref in 2019 (Slightly), = ref in 2020, > ref 2021 to 2024 (Moderately) **Zooplankton** **2024** Density < ref (Slightly); Richness = ref **Temporal Evaluation (2019 to 2024)** Density > ref in 2019 (Slightly), = ref in 2020 and 2022, < ref in 2021, 2023, and 2024 (Slightly to Moderately) Richness = ref in 2019, 2021, 2022 and 2024, < ref in 2020 (Slightly), > ref in 2023 (Slightly)	**2024** Mean [Se] > BCWQG Aquatic Life GL; Primary and secondary analyte concentrations ≤ ref **Temporal Evaluation (2019 to 2024)** Mean [Se] > BCWQG Aquatic Life GL in 2021, 2023, and 2024; For primary analytes, [Se] > ref from 2019 to 2021 and 2023, = ref 2022 and 2024; For secondary analytes, [Cd] > ref in 2020, 2021, and 2023, = ref in 2019, 2022, and 2024; Concentrations of remaining primary and secondary analytes ≤ ref from 2022 to 2024	**2024** Density < ref (Moderately), = pre-breach; Richness = ref, = pre-breach **Temporal Evaluation (2014 to 2024)** Density < ref in 2014 (Highly), < ref in 2015 and 2024 (Moderately), > ref in 2018 (Slightly), = ref in 2016 and 2021; Density < pre-breach in 2014 and 2015, = pre-breach in 2016 and 2024, > pre-breach in 2018 and 2021; Richness = ref from 2015 to 2024; Richness < pre-breach in 2014, = pre-breach from 2015 to 2024		

Notes: **"-"** = no data available. CEMP = Comprehensive Environmental Monitoring Program. BCWSQG = British Columbia Working Sediment Quality Guidelines. BCWQG = British Columbia Water Quality Guideline. TOC = total organic carbon. Chl-a = Chlorophyll-a. ref = reference. 95th = 95th Percentile (applicable to sediment quality evaluation). [ ] = concentration. CPUE = catch-per-unit-effort. YOY = young-of-the-year. RB = rainbow trout. LSU = longnose sucker. MU = muscle tissue. OV = ovary tissue. KI = kidney tissue. LI = liver tissue. GL = guideline. Temporal changes presented for sediment quality, zooplankton tissue quality, and fish tissue quality refer to changes in the relative (exposed-reference) difference over time as evaluated using a 2-way Analysis of Variance (ANOVA). For sediment quality, results are presented for Analytes of Interest (see Section 3.1.3.1 for details of Analyte of Interest selection). For zooplankton and fish tissue quality, results are presented for primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2024 or in all monitoring years.

[a] Findings from 2022 to 2024 are included at minimum. Additional years are displayed (as available) to support temporal comparisons.

[b] BCWSQG Lower = Lower BC Working Sediment Guideline; BCWSQG Upper = Upper BC Working Sediment Quality Guideline (BCMOWLRS 2024, 2025).

[c] Toxicity tests were completed using *Hyalella azteca* (14-day test) for shallow monitoring areas and using *Chironomus dilutus* (10-day test) for deep monitoring areas. Significant reductions in survival and growth are classed as high response (>50% reduction compared to control/reference); moderate response (20-50% reduction compared to control/reference, and significantly different than control and reference); low response (20-50% reduction compared to control/reference, and not significantly different than control and reference), and no unacceptable response (< 20% reduction compared to control/reference). Results relative to control or reference are shown in parentheses.

[d] Magnitude of significant differences in organism density and taxonomic richness relative to reference areas classed as highly different (> 5x SD), moderately different (5x to 2x SD), and slightly different (< 2x SD), where SD is the absolute value of the pooled standard deviation.

[e] BCWQG Aquatic Life GL = British Columbia Water Quality Guideline for the protection of aquatic life: interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

[f] Human Health guideline for Hg in muscle tissue of fish (0.5 mg/kg dw; CFIA 2015); Human Health guideline for Se in fish muscle (moderate consumption; 14.5 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in muscle tissue or whole body of fish (4 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in fish ovary tissue (11 mg/kg dw; BCMOE 2014).

  - Arsenic, copper, and iron concentrations in shallow Polley Lake sediments in 2022 were higher than BCWSQG and reference conditions while TOC content was lower than reference. Copper concentrations in all shallow Polley Lake sediment samples in 2022 were greater than the reference 95th percentile value, indicating a continued requirement for sediment toxicity testing of these shallow sediments every three years (i.e., next in 2025) in accordance with Condition 9 of the CEMP approval letter dated February 10, 2021 (BCMOECCS 2021). Arsenic, copper, and iron concentrations and TOC content were stable between 2019 (the initiation of monitoring) and 2022.

- Sediment Toxicity (shallow areas: 2022; deep areas: 2024):
  - Sediments from the deep areas of Polley Lake (POL-P1 and POL-P2) showed no unacceptable survival or growth responses of *C. dilutus* relative to both field reference and laboratory controls.
  - Sediments from the shallow area of Polley Lake (POL-S) showed no unacceptable survival or growth responses of *H. azteca* relative to both field reference and laboratory controls.
- Plankton Community and Productivity (2022, 2023, 2024):
  - Phytoplankton productivity (chlorophyll-a) in Polley Lake (POL-P2) in 2024 was significantly lower than reference and most prior years (except 2021). Chlorophyll-a measures in 2024 resulted in the classification of Polley Lake (and the reference area) as oligotrophic, similar to 2020 and 2021, but differing from the remaining years when the lakes were classified as mesotrophic. The phytoplankton community in 2024 had significantly lower density and taxon richness, and significantly higher Simpson's Diversity and Evenness compared to reference. Temporally, density has been variable, richness has been significantly lower (in most years), and Simpson's Diversity and Evenness have been similar to or significantly higher than reference. Phytoplankton community composition was similar to reference in most years for the dominant taxa (Cyanobacteria) and had relatively consistent differences to relative to reference for less dominant taxa.
  - Zooplankton productivity (biomass) in Polley Lake (POL-P2) in 2024 was significantly higher than reference, and in prior years was similar to or significantly higher than reference (except 2023). The zooplankton community in 2024 had taxon richness that was similar to reference, but significantly lower density and

Simpson's Evenness and Diversity metrics than reference. These community metrics have varied temporally, both within Polley Lake and relative to the reference area, without obvious directional consistency. Zooplankton community composition differed from reference in terms of the dominant taxa, but these differences were relatively temporally consistent.

- Zooplankton Tissue Quality (2022, 2023, 2024):
    - Concentrations of primary and secondary analytes in zooplankton tissues from Polley Lake (POL-P2) were consistently similar to or lower than reference in 2024. The analyte concentrations of zooplankton tissue from Polley Lake have shown some temporal variability, but in 2024 were similar to or significantly lower than the first year of monitoring with replication (i.e., 2019). Between 2022 and 2024, mean selenium concentrations in Polley Lake zooplankton tissues were higher than the BC guideline for the protection of aquatic life by <1.1-times in 2023 and 2024.
- Benthic Invertebrate Community (2024):
    - Benthic invertebrate communities at the deep areas of Polley Lake (POL-P1 and POL-P2) in 2024 were similar to reference and/or pre-breach conditions, except for Simpson's Evenness at POL-P2 and Simpson's Diversity at both POL-P1 and POL-P2 which were significantly lower than reference and pre-breach. Community composition at both deep basins of Polley Lake in 2024 has largely recovered to pre-breach and/or reference conditions when considering major taxa. The benthic invertebrate community at the Northwest basin (POL-P1) has largely recovered to pre-breach and/or reference conditions while the recovery at the Southwest basin (POL-P2) was less advanced, consistent with its closer proximity to the location of the breach impact.
- Fish Usage and Population Health (2022, 2023, 2024):
    - The CPUE of rainbow trout in the spring in Polley Lake was higher from 2022 to 2024 than in 2017 to 2021, suggesting that rainbow trout cohorts from 2018 to 2020 have reached maturity (i.e., cohorts resulting from the reinstatement of fish access to Hazeltine Creek in 2018). Although rainbow trout CPUE in the fall was lower in 2024 than all prior years, the length frequency distribution in 2024 showed a more balanced distribution among size classes and more closely resembled that in 2016 (two years post-breach) than in all prior years. This more balanced distribution among size classes suggested ongoing recruitment success, and that

the lower CPUE observed from 2022 to 2024 (which was lowest in 2024) was likely related to greater representation of older age classes than in 2019 to 2021. For longnose sucker, CPUE in the spring has declined over the past four years, with 2024 marking the lowest since monitoring began (i.e., 2016), while CPUE in the fall of 2024 was the second lowest observed since 2016. Length frequency distributions for longnose sucker in the fall of 2024 showed fewer age-1 fish and more age-3 fish relative to 2023 with both years more closely resembling the size structure in 2016 than in prior years (i.e., 2020 to 2022).

- Fish Tissue Quality (2022, 2023, 2024):
    - Mercury and selenium concentrations in fish muscle samples from Polley Lake in 2024 were below applicable human health guidelines. Mean selenium concentrations in rainbow trout and longnose sucker muscle samples in 2024 were above the BC guideline for the protection of aquatic life (by 1.1- and 1.5-times, respectively). Selenium concentrations in the ovary tissues of both species were below the threshold for reproductive effects. Concentrations of primary and secondary analytes in fish tissues that were significantly higher than reference in 2024 have largely not shown a sustained increase over the post-breach period, while selenium concentrations have been stable or decreasing over the post-breach period. Cobalt was the only analyte that had significantly higher concentrations in multiple exposed fish tissues (longnose sucker liver and kidney) in 2024 compared to all prior years.

7.2 Quesnel Lake

7.2.1 Sediment Quality

Sediments from the deep areas of Quesnel Lake in 2024 remained clearly influenced by breach material, based on chemical and physical characteristics. In the deep near-field (QUL-PNF) and far-field (QUL-PFF1) areas in 2024, sediments were characterized by mean arsenic, copper, and manganese concentrations greater than 95th percentile pre-breach/reference concentrations and BCWSQG. Iron concentrations in deep near-field sediments (but not deep far-field sediments) were also greater than pre-breach/reference conditions and BCWSQG. Copper was the most substantially elevated analyte in 2024 (consistent with prior years), with mean concentrations 4.1- and 3.5-times the upper BCWSQG at the deep near-field and far-field areas, respectively. Temporal analyses of deep near-field sediments indicated concentrations of these four analytes have not changed significantly since at least 2019, with arsenic, copper, iron, and manganese concentrations in 2024 that were similar to or lower than

those in most prior years (i.e., at least 2015 to 2023). In sediments from the deep far-field area, arsenic concentrations have been stable since 2018. However, copper and manganese concentrations in the deep far-field sediments increased significantly between 2018 and 2021 and remained elevated in 2024 (i.e., did not differ significantly from 2021), with concentrations in 2024 that were significantly higher than those in 2016 and 2018. The increase in copper and manganese concentrations in deep far-field sediments, corresponded with changes in the physical characteristics of these sediments (i.e., clay content) which may be indicative of the mobilization of breach-related fines from the deep near-field area towards the deep far-field area of Quesnel Lake. There has been a steady increase in the TOC content of the deep exposed sediments, which was statistically significant at the near-field, but not the far-field, relative to immediate post-breach conditions (i.e., 2014), but the TOC content of the deep exposed sediments in 2024 (0.425 to 0.635%) remained significantly lower than reference.

Sediments from the shallow near-field area (QUL-LNF1) in 2024 had a very high sand content (96.8%), and were characterized by concentrations of arsenic, copper, iron, manganese, and silver that were greater than reference/pre-breach conditions as well as BCWSQG. Copper was the most substantially elevated analyte, with mean concentrations 8.7-times the upper BCWSQG. The exposed shallow sediments in 2024 had parameter concentrations that were similar to all prior years (2014 to 2023) in the case of TOC, arsenic, and iron, and similar to most prior years (2015 to 2023) in the case of manganese, relative to reference. Concentrations of copper and silver in 2024 were similar to 2023 and 2019 but were significantly higher than most (for copper) or all (for silver) remaining prior years, indicating no significant increase compared to when sampling stations in this area were relocated in 2019.

Toxicity testing of *C. dilutus* using sediments from the deep near-field area of Quesnel Lake (QUL-PNF) in 2024 resulted in a low to moderate response for survival (23 to 46% mortality) and growth showed no response or a low response (0 to 25% reduction). The survival response in 2024 was similar to 2018, but showed lower survival (i.e., greater mortality) than other prior years, while growth in 2024 was higher than in prior years. It is apparent that low TOC and high sediment copper concentrations in deep near-field sediments of Quesnel Lake continue to be effective descriptors of growth responses in sediment toxicity tests of *C. dilutus*.

Toxicity testing of *H. azteca* using sediments from the shallow near-field area of Quesnel Lake (QUL-LNF1) in 2024 resulted in a moderate survival response (31 to 38% mortality) and a moderate to high growth response (48 to 63% reduction). The responses of *H. azteca* in 2024 were similar or showed fewer effects than in prior years. Concentrations of dissolved copper in overlying waters of the toxicity test vessels for shallow near-field sediments in 2024 were 168-times higher than those documented in field-collected water from the same area and were

3.4-times higher than the acute BCWQG. A substantial difference in dissolved copper concentrations of the overlying water of toxicity test vessels compared to *in situ* field conditions has been consistently observed for these shallow near-field sediments, suggesting copper mobilization in the test setup that has either not occurred or has attenuated over time in the field. Under these conditions, the observed survival and growth responses are consistent with dissolved copper concentrations in overlying water, particularly given that *H. azteca* have been documented to derive little nutrition from sediment and respond primarily to contaminants in overlying water. This observation was corroborated by significant regression relationships that indicated lower *H. azteca* survival and growth at higher overlying water dissolved copper concentrations and higher sediment copper concentrations. Overall, the toxicity test results from the shallow near-field area cannot be reliably extrapolated to the field but suggested potential copper mobilization with disturbance to this area.

7.2.2 Aquatic Life

Phytoplankton community and productivity monitoring in Quesnel Lake indicated that productivity (in terms of chlorophyll-a concentrations) at the exposed area has been significantly different from the reference area throughout the monitoring period (2019 to 2024). However, the differences in chlorophyll-a concentrations between the areas have been slight in most years (including 2024), except in 2022 and 2023 when chlorophyll-a concentrations at the exposed area were significantly lower and higher, respectively, than at the reference area. Mean chlorophyll-a results in 2024 characterized both the exposed and reference areas of Quesnel Lake as ultraoligotrophic, which was similar to earlier post-breach years (i.e., 2016 to 2018) but differed from the classifications in more recent years (oligotrophic in 2019 to 2023, mesotrophic in 2022). The phytoplankton community at the exposed area of Quesnel Lake from 2019 to 2024 has been characterized by total density, taxon richness, and Simpson's Diversity that were similar to or significantly higher than at the reference area, with few exceptions (density in 2023, taxon richness in 2022 and 2023, and Simpson's Diversity in 2022). Simpson's Evenness of the phytoplankton community at the exposed area has consistently been similar to the reference area since 2021. The composition of the phytoplankton community at the exposed area has been consistently similar to the reference area from 2019 to 2024 in terms of the relative densities (%) of most taxa (i.e., Diatoms, Chlorophytes, and Cyanobacteria), and statistically significant differences between the areas for other taxa (i.e., Chrysophytes) have been small. The similarities between the phytoplankton communities at exposed and reference areas over time suggested an influence of local environmental factors on the phytoplankton community of Quesnel Lake.

Zooplankton community and productivity monitoring in Quesnel Lake indicated that biomass (dw) at the exposed area has been similar to the reference area throughout the monitoring period

(2019 to 2024). The zooplankton community at the exposed area of Quesnel Lake in 2024 was characterized by total density, taxon richness, and Simpson's Diversity that were similar to the reference area, and Simpson's Evenness that was only slightly higher than at the reference area. Throughout the monitoring period (2019 to 2024), total density and taxon richness at the exposed area have been similar to the reference area, while Simpson's Diversity has been similar to or significantly higher than reference. Simpson's Evenness at the exposed area has been slightly higher than at the reference area since 2021. The composition of the zooplankton community at the exposed area has been largely similar to the reference area from 2020 to 2024, except for consistent but slight differences in Copepod Nauplii (density and %) and Rotifera (%), which were significantly higher and lower, respectively, compared to the reference area. The similarity between the exposed and reference areas for most endpoints over the monitoring period (i.e., since at least 2020) suggested a lack of mine-related influence on the zooplankton community and productivity in Quesnel Lake.

Zooplankton tissue quality monitoring in Quesnel Lake in 2024 indicated that concentrations of the primary analyte copper and the secondary analytes molybdenum, tin, and titanium were significantly higher in tissues from the exposed area compared to reference. Analyte concentrations that were significantly higher in exposed zooplankton tissues compared to reference results have not been previously observed in Quesnel Lake. In 2024, concentrations of these four analytes in zooplankton tissues were significantly higher than most (molybdenum) or all (copper, tin, and titanium) prior years (i.e., 2019 to 2023), relative to reference; this change was driven at least in part by a decrease in concentrations in reference tissues. Continued monitoring will help to determine whether the observed results are part of a long-term trend or a single anomalous year. For most analytes, surface water quality data did not support the temporal increases observed in analyte concentrations of exposed zooplankton tissues, except for molybdenum. Increasing trends in the aqueous analyte concentrations in surface waters (from 2015 to 2024) were observed for total and dissolved molybdenum, total and dissolved selenium, and dissolved sodium. Although a significant increase in molybdenum concentrations in exposed zooplankton tissues was observed in 2024, aqueous total molybdenum concentrations were approximately 20,000-times lower than BCWQG (from 2015 to 2024). Combined, these results indicated little to no evidence that the increase in molybdenum concentrations in water and zooplankton tissues might present a risk to aquatic life. Despite the increasing trend in aqueous selenium concentrations, zooplankton tissue selenium concentrations were below the guideline for the protection of aquatic life at the exposed area in 2024 (similar to 2018 to 2023), and tissue selenium concentrations at the exposed area did not differ significantly from the reference area from 2019 to 2024.

The benthic invertebrate community at the deep near-field (QUL-PNF) and far-field (QUL-PFF1) areas of Quesnel Lake in 2024 were characterized by taxon richness, Simpson's Evenness, and Simpson's Diversity, that were similar to the reference area and similar between the two exposed areas. Total density at the two deep exposed areas in 2024 remained significantly lower than at the reference area and was also similar between the exposed areas. Although the benthic invertebrate communities at the deep near-field and far-field areas have shown recovery since 2014 (in terms of density, taxon richness, and Simpson's Evenness and Diversity), they remained similar to 2015 conditions. Despite this, some recovery towards reference conditions has occurred at both the exposed areas; taxon richness, Simpson's Evenness, and Simpson's Diversity have been similar to reference conditions since 2019 or earlier at the near-field area and since 2021 or 2024 at the far-field area. At the deep far-field area, recovery of the benthic invertebrate community towards reference conditions occurred despite the potential mobilization of breach-related fines to this area from the deep near-field area. Total density at both exposed areas was significantly lower in 2024 than in 2021 (at the far-field area this was due to a significant decrease in Chironomidae density) but remained similar to all other years since 2015, and density has remained significantly lower than reference in all post-breach years. The continued lower total density at the deep exposed areas compared to reference was consistent with the continued low TOC content of the deep exposed sediments (mean = 0.635% and 0.425% at the near-field and far-field areas, respectively) which is below the documented intolerance level of <1% sediment TOC for Chironomidae. The community composition at the exposed areas in 2024 (dominated by Chironomidae) was similar to all prior years (and has been stable since 2020) and has consistently shown significantly lower Oligochaeta (%) than at the reference area. Correlation results indicated that the differences in benthic invertebrate densities and communities between reference and exposed areas were related to sediment conditions at the exposed area that were less favourable the benthic invertebrates (especially to the dominant Chironomidae) such as lower TOC content, greater proportions of fines, and higher metal concentrations; sediment properties which were consistent with the presence of breach-impacted sediments at this deep exposed near-field area.

Fish tissue quality monitoring in 2024 included three species from Quesnel Lake (peamouth chub, northern pikeminnow, and lake trout) and rainbow trout from Quesnel River. Analyte concentrations in fish muscle samples from Quesnel Lake and Quesnel River in 2024 were below guidelines for the protection of human health (which exist for mercury and selenium), indicating that these fish were safe for human consumption. The mean selenium concentrations in fish muscle or whole-body samples in 2024 were also below the BC guideline for the protection of aquatic life. Evaluation of ovary tissue is recommended for the assessment of potential selenium-associated effects on fish. Mean selenium concentrations in rainbow ovary tissues in

2024 exceeded the BC guideline for the protection of aquatic life (by 2.5-times) and the threshold for potential reproductive effects (by 1.4-times). However, high variability in the selenium concentrations of these samples was observed in 2024, potentially related to the early development stage of the collected tissues (which is known to be related to higher selenium concentrations) and/or sample heterogeneity reported by the laboratory. Continued monitoring will help to determine whether the 2024 rainbow trout ovary selenium concentration results are part of a long-term trend. Despite the guideline and threshold exceedances in 2024 for selenium concentrations in ovary tissues, the selenium concentrations of rainbow trout tissues (muscle, ovary, and liver) in 2024 were similar to all prior years, or most prior years in the case of kidney (excluding 2015 and 2020). Selenium concentrations in the tissues of peamouth chub, northern pikeminnow, and lake trout in 2024 were similar to or significantly lower than the first year of monitoring. These results indicate that selenium concentrations in exposed fish tissues from Quesnel Lake and Quesnel River have not increased over time, when considering at least the last eight years (i.e., since 2017), which is consistent with the temporal stability of selenium concentrations in exposed zooplankton tissues (i.e., dietary exposure) from Quesnel Lake. Concentrations of all primary analytes and 13 secondary analytes were significantly higher in exposed tissues relative to reference in 2024 for at least one tissue type in at least one species or showed a significant temporal change (if reference data were not collected). However, the results for most of these analytes were inconsistent among tissues and species, and/or were temporally stable, indicating there has been no sustained increase of analyte concentrations in fish tissues from Quesnel Lake or Quesnel River since the initiation of post-breach monitoring.

7.2.3 Key Findings

Key findings of CEMP monitoring of Quesnel Lake from 2022 to 2024 (Table 7.2) were:

- Sediment Quality (shallow and deep areas: 2022, 2023, 2024 [2024 only for far-field and reference deep areas])
    - Concentrations of arsenic, copper, iron, and manganese in deep near-field (QUL-PNF) and far-field (QUL-PFF1) sediments of Quesnel Lake in 2024 were higher than BCWSQG and reference conditions (except for iron in the far-field area). At the deep near-field area, concentrations of these analytes have not changed significantly since at least 2019. At the deep far-field area, arsenic concentrations have been stable since 2018. Copper and manganese concentrations of deep far-field sediments increased significantly between 2018 and 2021 and remained elevated in 2024, which may indicate the mobilization of

Table 7.2: Summary of Mount Polley CEMP Sediment and Aquatic Life Results for Quesnel Lake, 2022 to 2024[a]

Analytes > ref in 2024 for two or more tissues within a fish species included Ba, Cd, Ca, Mn, Hg (ww), Mo, P, Sr, V, Zn. Concentrations of these analytes were either temporally stable or inconsistent among tissues and species, indicating there has been no sustained increase over the post-breach period. Most secondary analytes in RB and LT (OV) in 2024 ≤ first or second year of monitoring
			Dissolved Cu concentrations in overlying water during laboratory testing were substantially higher in 2024 (168x) than *in situ* field-collected measures (compared to 74- to 175-times higher than *in situ* in 2019 to 2023). This indicated that toxicity test results cannot be reliably extrapolated to the field but also that there is a potential for copper mobilization in this area with disturbance.							
Deep	QUL-PNF (Near-field; QUL-ZOO-1 for plankton)	**2024** Analytes of Interest = As, Cu, Fe, Mn Mean [Cu] and [Mn] > upper BCWSQG and ref 95th; Mean [As] and [Fe] > lower BCWSQG and ref 95th; TOC < ref **Temporal (2014 to 2024)** [As] in 2024 = from 2014 to 2018 and 2021, < 2019; [Cu] and [Fe] in 2024 = from 2014 to 2021; [Mn] in 2024 > 2014, = from 2015 to 2021; TOC in 2024 > from 2014 to 2018 and 2021, = 2019	***C. dilutus* (10-day)** **2024** Low / Moderate response (54% of Control, 77% of Reference) **Temporal Evaluation (2014 to 2024)** No unacceptable response (2015, 2016, 2021); Moderate response (2018); Low/ Moderate response (2014, 2024)	***C. dilutus* (10-day)** **2024** No unacceptable / Low response (147% of Control, 75% of Reference) **Temporal Evaluation (2014 to 2024)** No unacceptable/ Low response (2024); No unacceptable / Moderate response (2021); Low / Moderate response (2014, 2015); Moderate response (2016); Moderate/High response (2018)	**Phytoplankton** **2024** Chl-a > ref (Slightly); Classified as ultraoligotrophic **Temporal Evaluation (2019 to 2024)** Chl-a > ref in 2019, 2020, 2024 (Slightly), < ref in 2021 and 2022 (Slightly to Moderately), > ref in 2023 (Moderately) **Zooplankton** **2024** Biomass (dry) = reference **Temporal Evaluation (2019 to 2024)** Biomass (dry) = ref from 2019 to 2024	**Phytoplankton** **2024** Density and richness = ref **Temporal Evaluation (2019 to 2024)** Density = ref from 2019 to 2021 and 2024, > ref in 2022 (Moderately), < ref in 2023 (Slightly); Richness = ref from 2019 to 2021 and 2024, < ref in 2022 (Moderately) and 2023 (Slightly) **Zooplankton** **2024** Density and richness = ref **Temporal Evaluation (2019 to 2024)** Density and richness = ref from 2019 to 2024	**2024** Mean [Se] in 2024 < BCWQG Aquatic Life GL; [Cu], [Mo], [Sn], [Ti] > ref **Temporal Evaluation (2019 to 2024):** Mean [Se] < BCWQG Aquatic Life GL in 2019 to 2024; Primary and secondary analyte tissue concentrations ≤ ref from 2019 to 2024 except Cu, Mo, Sn, Ti in 2024; [Cu], [Mo], [Sn], [Ti] in 2024 > all prior years due in part to decrease in ref analyte concentrations	**2024** Density < ref (Moderately), = QUL-PFF1; Richness = ref, = QUL-PFF1 **Temporal Evaluation (2014 to 2024)** Density < ref from 2014 to 2024 (Moderately to Highly); Density < QUL-PFF1 in 2014, = QUL-PFF1 from 2016 to 2024; Richness < ref 2014, 2016 (Slightly to Moderately), = ref 2015 and 2018 to 2024; Richness = QUL-PFF1 in 2014, 2016, 2024, < QUL-PFF1 from 2018 and 2021

Notes: "-" = no data available. CEMP = Comprehensive Environmental Monitoring Program. BCWSQG = British Columbia Working Sediment Quality Guidelines. BCWQG = British Columbia Water Quality Guideline. TOC = total organic carbon. Chl-a = Chlorophyll-a. ref = reference. exp = exposed. 95th = 95th Percentile (applicable to sediment quality evaluation). CPUE = catch-per-unit-effort. LT = lake trout. NSC = northern pikeminnow. PCC = peamouth chub. RB = rainbow trout. MU = muscle tissue. OV = ovary tissue. LI = liver tissue. KI = kidney tissue. WB = whole-body. GL = guideline. Temporal changes presented for sediment quality, zooplankton tissue quality, and fish tissue quality refer to changes in the relative (exposed-reference) difference over time as evaluated using a 2-way Analysis of Variance (ANOVA) except for LT (OV) and RB tissues, which were evaluated using a 1-way ANOVA. For sediment quality, results are presented for Analytes of Interest (see Section 3.1.3.1 for details of Analyte of Interest selection). For zooplankton and fish tissue quality, results are presented for primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2024 or in all monitoring years.

[a] Data collected from 2022 to 2024 are included at minimum. Additional years are displayed (as available) to support temporal comparisons. Results of sampling completed for Environment Effects Monitoring in 2024 are excluded from this table; these results will be included in a separate report due in October 2025.

[b] Lower BCWSQG = Lower BC Working Sediment Guideline; Upper BCWSQG = Upper BC Working Sediment Quality Guideline (BCMOWLRS 2024, 2025).

[c] Toxicity tests were completed using *Hyalella azteca* (14-day test) for shallow monitoring areas and using *Chironomus dilutus* (10-day test) for deep monitoring areas. Significant reductions in survival and growth are classed as high response (>50% reduction compared to control/reference); moderate response (20-50% reduction compared to control/reference, and significantly different than control and reference); low response (20-50% reduction compared to control/reference, and not significantly different than control and reference), and no unacceptable response (< 20% reduction compared to control/reference). Results relative to control or reference are shown in parentheses.

[d] Magnitude of significant differences in organism density and taxonomic richness relative to reference areas classed as highly different (> 5x SD), moderately different (5x to 2x SD), and slightly different (< 2x SD), where SD is the absolute value of the pooled standard deviation.

[e] BCWQG Aquatic Life GL = British Columbia Water Quality Guideline for the protection of aquatic life: interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

[f] Human Health guideline for Hg in muscle tissue of fish (0.5 mg/kg dw; CFIA 2015); Human Health guideline for Se in fish muscle (moderate consumption; 14.5 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in muscle tissue or whole body of fish (4 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in fish ovary tissue (11 mg/kg dw; BCMOE 2014); Effects Threshold indicates mean selenium concentration greater than DeForest et al. (2012) threshold for ovary tissue in fish (20 mg/kg dw) and the BCMOE guideline.

breach-related fines from the deep near-field area towards the deep far-field area. The TOC content of the deep near-field and far-field sediments in 2024

  - (0.425 to 0.635%) was significantly lower than reference, but the TOC content of these sediments has steadily increased over the post-breach period (i.e, compared to 2014). This increase was significant at the near-field but not the far-field area.
  - Concentrations of arsenic, copper, iron, manganese, and silver in shallow near-field (QUL-LNF1) sediments of Quesnel Lake in 2024 were higher than BCWSQG and reference/pre-breach conditions. Arsenic, iron, and manganese concentrations in these sediments in 2024 were similar to first or second year of monitoring (i.e., 2014 or 2015) and have been stable since 2020 or earlier. Copper and silver concentrations in these sediments in 2024 were similar to 2019 and 2023, but significantly higher than most (copper) or all (silver) remaining prior years. Mean TOC content (0.421%) of the shallow near-field sediments in 2024 were significantly lower than reference and temporally stable over the post-breach period.

- Sediment Toxicity (shallow areas: 2022, 2023, 2024; deep areas: 2024)
  - Sediments from the deep near-field (QUL-PNF) area of Quesnel Lake in 2024 showed a low to moderate response for survival (23 to 46% mortality) and showed no response or a low response for growth (0 to 25% reduction) of *C. dilutus* relative to field reference and laboratory controls. The responses of *C. dilutus* in 2024 had lower survival (i.e., greater mortality) than in prior years (except for 2018) and higher growth than in prior years.
  - Sediments from the shallow near-field (QUL-LNF1) area of Quesnel Lake in 2024 showed a moderate survival response (31 to 38% mortality) and a moderate to high growth response (48 to 63% reduction) of *H. azteca* relative to field and laboratory controls. The *H. azteca* responses in 2024 were similar to or showed fewer effects than in prior years. Concentrations of dissolved copper in overlying waters of the toxicity test vessels in 2024 were highly dissimilar (an average of 168-times greater) than in field-collected water from these sites, consistent with previous years of monitoring. This suggests that the sediment toxicity test results cannot be reliably extrapolated to the field and that copper mobilization in this area may occur with disturbance.

- Plankton Productivity and Community (2022, 2023, 2024):

- Phytoplankton productivity (measured as chlorophyll-a) in the exposed area of Quesnel Lake (QUL-ZOO-1) differed from reference throughout the post-breach period but the differences were mostly small. Chlorophyll-a measures resulted in the classification of Quesnel Lake as ultraoligotrophic (at exposed and reference areas), which was similar to earlier post-breach years but a lower classification than more recent years (i.e., 2019 to 2022). The phytoplankton community was similar to reference in terms of density, taxon richness, and Simpson's Diversity and Evenness metrics in 2024, and these metrics have been similar to or significantly higher than reference in prior years (with few exceptions). Phytoplankton community composition was similar to reference for most taxa over the post-breach period.
- Zooplankton productivity (biomass) in the exposed area of Quesnel Lake (QUL-ZOO-1) was similar to reference throughout the post-breach period. The zooplankton community had density, taxon richness, and Simpson's Diversity and Evenness metrics that were similar to or significantly higher than reference throughout the post-breach period. Zooplankton community composition was largely similar to reference from 2020 to 2024.

- Zooplankton Tissue Quality (2022, 2023, 2024):
  - Concentrations of primary and secondary analytes in zooplankton tissues from the exposed area of Quesnel Lake (QUL-ZOO-1) in 2024 were similar to or lower than reference except for copper, molybdenum, tin, and titanium, which was the first time in the post-breach period that analyte concentrations in exposed zooplankton tissues were significantly higher than reference. Concentrations of these four analytes in exposed zooplankton tissues were significantly higher in 2024 than all prior years (relative to reference) but this was related in part to decreased analyte concentrations in reference tissues. Mean selenium concentrations in exposed zooplankton samples throughout the post-breach period were below the BC guideline for the protection of aquatic life.
- Benthic Invertebrate Community (2022, 2023, 2024 [2024 only for far-field and reference areas):
  - The benthic invertebrate communities at the deep near-field (QUL-PNF) and far-field (QUL-PFF1) areas in 2024 were similar to reference and to each other in terms of taxon richness and Simpson's Evenness and Diversity, but had densities that remained significantly lower than reference. Excluding density, these metrics at the exposed areas have been similar to reference since 2019 or

earlier at the near-field area and since 2024 or earlier at the far-field area. Within each of the deep exposed areas there has been no significant change in communities since 2015. Community composition at the deep exposed areas has consistently been dominated by Chironomidae, with significantly lower dominance of Oligochaeta than reference.

- Fish Tissue Quality (2022, 2023, 2024):
    - Mean analyte concentrations in fish muscle samples from Quesnel Lake and Quesnel River in 2024 were below applicable human health guidelines (which exist for mercury and selenium), indicating that these fish were safe for human consumption. Mean selenium concentrations in fish muscle or whole-body tissues were also below the BC guideline for the protection of aquatic life in 2024. Mean selenium concentrations in ovary tissues of exposed rainbow trout were above the BC guideline for the protection of aquatic life and the threshold for reproductive effects. Despite these guideline/threshold exceedances, selenium concentrations in fish tissues from Quesnel Lake and Quesnel River have not increased significantly over at least the last eight years (i.e., since 2017). Concentrations of primary and secondary analytes in fish tissues that were significantly higher than reference in 2024 have not shown a sustained increase over the post-breach period.

7.3 Hazeltine Creek

7.3.1 Sediment Quality

Sediment quality in upper and lower Hazeltine Creek in 2024 was characterized by concentrations of several analytes that were greater than reference/pre-breach concentrations and BCWSQG values: copper, iron, manganese, and selenium in upper Hazeltine Creek, and arsenic, copper, iron, and selenium in lower Hazeltine Creek. Sediment analyte concentrations in 2024 were most elevated for copper and manganese in upper Hazeltine Creek (2.6- and 3.4-times the upper BCWSQG, respectively), and for arsenic and copper in lower Hazeltine Creek (1.6- and 1.5-times the upper BCWSQG, respectively). The TOC content of upper Hazeltine Creek sediments has been temporally stable from 2021 to 2024, following a period of temporal variability from 2018 to 2020. The TOC content of lower Hazeltine Creek sediments in 2024 was significantly lower than in 2021 and 2023, but similar to all other prior years. Iron concentrations in upper Hazeltine Creek sediments in 2024 were similar to or significantly lower than all previous years. Concentrations of copper, manganese, and selenium in upper Hazeltine Creek sediments did not change significantly from 2022 to 2024 but were significantly higher than two or more prior years.

In lower Hazeltine Creek sediments, arsenic, copper, and iron concentrations in 2024 were similar to or significantly lower than all prior years. Sediment selenium concentrations in lower Hazeltine Creek did not change significantly between 2022 and 2024 but were significantly higher in 2022 to 2024 than most prior years (i.e., 2018 to 2020). Analyte concentrations continued to be significantly correlated to the chemical and physical characteristics of these sediments, which is likely driven by a combination of required opportunistic sampling methods and continued sediment accumulation in upper and lower Hazeltine Creek. Collectively, results indicated a temporal increase in sediment concentrations of copper, selenium, and to a lesser extent manganese in upper Hazeltine Creek, and selenium in lower Hazeltine Creek, over the post-breach period. Benthic invertebrate community and tissue quality monitoring both provide more directly applicable approaches for evaluating the potential effects of increased analyte concentrations to aquatic life in these erosional creek habitats, compared to sediment monitoring (see Section 7.3.2 for the benthic invertebrate community and tissue quality monitoring summaries).

7.3.2 Aquatic Life

Periphyton monitoring indicated that primary productivity of upper Hazeltine Creek (Reaches 1 to 3), as assessed by mean chlorophyll-a concentrations, was below the BCWQG but above the threshold indicative of moderate enrichment in streams. Periphyton chlorophyll-a concentrations in upper Hazeltine Creek in 2024 were similar to reference and baseline/pre-breach conditions with few exceptions and decreased with increasing distance downstream (i.e., were lowest in Reach 3). This spatial gradient was likely related to differences in the amount of time since completion of remediation works in these areas. Periphyton productivity, as measured by AFDM in upper Hazeltine Creek 2024, was higher than reference, which was the first time this occurred at in Reach 3 of upper Hazeltine Creek (HAC-R3). Overall, periphyton productivity in upper Hazeltine Creek increased following remediation efforts and has largely remained greater than or similar to the reference area and baseline/ pre-breach productivity levels. *In situ* measures of dissolved oxygen in upper Hazeltine Creek in 2024 were consistently higher than the acute and long-term BCWQG indicating no potential adverse effects to aquatic life from dissolved oxygen depletion related to periphyton growth. The periphyton community of upper Hazeltine Creek (Reaches 1 and 2) was characterized by taxon richness, Diatom richness, and Simpson's Diversity and Evenness that were similar to or higher than reference conditions in most years since 2018 (and similar to reference in 2024). Periphyton densities in 2024 in upper Hazeltine Creek were lower than reference (due to an increase in density at the reference area) but have remained relatively stable since 2018. Periphyton community composition in upper Hazeltine Creek differed from the reference area in 2024 based on Phaeophytes (%) and Rhodophytes (%) only. Except for density, the periphyton communities in upper Hazeltine

Creek have recovered to reference conditions (or to conditions that are indicative of healthy periphyton communities).

Periphyton community and productivity monitoring in lower Hazeltine Creek (Reach 5), which was last completed in 2023, indicated that periphyton chlorophyll-a concentrations were below both the BCWQG and the threshold for moderately enriched streams. Mean chlorophyll-a concentrations in lower Hazeltine Creek were significantly lower than reference in most years since 2017 (except 2019), while AFDM was similar to reference in 2021 and 2023. Chlorophyll-a and AFDM results in 2023 indicated that recovery of periphyton productivity in the lower Hazeltine Creek area was ongoing following the completion of remediation works in this area in 2021. The periphyton community of lower Hazeltine Creek (HAC-D) in 2023 was characterized by total taxon richness, Diatom richness, Simpson's Diversity, and Simpson's Evenness that were similar to reference and total density that was higher than reference, which represented substantial recovery since 2021. The remaining differences in the periphyton community of lower Hazeltine Creek compared to the reference area in 2023 (i.e., higher Cyanobacteria [%] and lower Diatom and Chlorophyte [%]) suggested that recovery of community composition was still ongoing.

Benthic invertebrate community monitoring in the three areas of Upper Hazeltine Creek (HAC-R1 [Reach 1], HAC-U [Reach 2], and HAC-R3 [Reach 3]) in 2024 indicated that the communities of these areas were similar to reference (i.e., one or both reference areas) in terms of density and taxon richness, and similar to reference and pre-breach conditions in terms of Simpson's Evenness and Diversity (except for Simpson's Diversity at HAC-R3). The benthic invertebrate communities of HAC-R1 and HAC-U have been similar in terms of these four metrics in all post-breach years, while the community at HAC-R3 in 2024 had significantly lower density and Simpson's Evenness and Diversity than the upstream areas (although differences were small) consistent with the more recent completion of remediation works at this area. The most abundant taxa in 2024 were Chironomidae at HAC-R1 and HAC-U and Elmidae (riffle beetle) at HAC-R3. Sensitive EPT taxa (% and density) at the three exposed areas in 2024 were significantly lower than pre-breach. In addition, EPT taxa two of these exposed areas (HAC-R1 [% and density] and HAC-U [%]) were also significantly lower than both reference areas. Notable differences in EPT at all three Hazeltine Creek areas in 2024 relative to reference and pre-breach included a lack of Plecoptera and lower Ephemeroptera (%), while Trichoptera (%) were similar to reference and pre-breach. The occurrence of Ephemeroptera and Trichoptera families at the exposed areas that were of similar pollution tolerance to those at the reference areas suggested that chemical conditions (i.e., water quality) were not limiting the recovery of these taxa at the exposed areas. Benthic invertebrate productivity (as measured by dry and wet weight biomass) in upper Hazeltine Creek was similar to or significantly higher than at least one

(or both) reference areas throughout the post-breach period, indicating recovery to or exceedance of reference conditions. Correlation analysis indicated that physical characteristics of the upper Hazeltine Creek areas (mean water depth, velocity, temperature) were the primary influencing factors on benthic invertebrate community condition and composition in these exposed areas. Collectively, results indicated that the benthic invertebrate communities at the three areas of upper Hazeltine Creek have recovered since remediation efforts to a condition that was similar to at least one reference area based on density, taxon richness, and Simpson's Evenness and Diversity, and largely similar to pre-breach conditions for Simpson's Evenness and Diversity. However, there were some key remaining differences in the community composition of upper Hazeltine Creek compared to reference and/or pre-breach (particularly for the sensitive EPT taxa) that suggested ongoing recovery.

Benthic invertebrate community monitoring in lower Hazeltine Creek (HAC-D), which was last completed in 2023, indicated that the community was characterized by total density, richness, and Simpson's Evenness and Diversity that were similar to reference and pre-breach conditions. These results represented substantial recovery of the benthic invertebrate community in lower Hazeltine Creek compared to 2021 (immediately following remediation works). The benthic invertebrate community in lower Hazeltine Creek in 2023 was dominated by Chironomidae (%) and to a lesser extent EPT (%), which were significantly more and less prevalent, respectively, than reference. Although EPT (%) remained lower than reference, the difference from reference was smaller in 2023 than in 2021 owing to significant increases in Ephemeroptera and Trichoptera (% and density) from 2021 to 2023. In lower Hazeltine Creek in 2023, Ephemeroptera (%) were lower, Trichoptera (%) were higher, and Plecoptera (%) were similar to reference. Benthic invertebrate productivity (as measured by dry and wet weight biomass) was similar in lower Hazeltine Creek to reference, which indicated recovery from 2021. Correlation analyses indicated that physical characteristics were the primary influencing factors on the benthic invertebrate community of lower Hazeltine Creek rather than water quality parameters. Collectively, the results indicated that benthic invertebrate community and productivity (biomass) in lower Hazeltine Creek recovered substantially following remediation works to conditions that were similar to reference and/or pre-breach for several metrics, but that recovery of community composition was still ongoing.

Periphyton and benthic invertebrate (caddisfly and composite-taxa) tissue quality monitoring in upper and lower Hazeltine Creek in 2024 indicated that concentrations of the primary analytes arsenic, iron, copper, and selenium were higher than reference in at least one tissue type from at least one of the exposed monitoring areas. Copper concentrations in exposed periphyton and benthic invertebrate tissues in 2024 were also higher than pre-breach conditions (in at least one tissue type per area), however, these were not significantly higher in 2024 when compared to

2019 or earlier with one exception. The one exception was copper concentrations of caddisfly tissue from lower Hazeltine Creek which increased significantly between 2023 and 2024, representing a return to conditions similar to 2020 and 2021. Selenium concentrations in exposed periphyton and in benthic invertebrate tissues in 2024 were consistently higher than reference and pre-breach conditions in lower Hazeltine Creek (but not upper Hazeltine Creek). Mean selenium concentrations in benthic invertebrates from upper and lower Hazeltine Creek areas were higher than the BC guideline for the protection of aquatic life in 2024 (2.3- to 3.5-times the guideline [caddisfly] and 1.2- to 2.4-times the guideline [composite-taxa]) and were highest in benthic invertebrate tissues (particularly caddisflies) from HAC-U (Reach 2) of upper Hazeltine Creek. This is consistent with caddisflies being known as 'hyper-accumulators' of selenium. Selenium concentrations in periphyton and benthic invertebrate tissues from upper and lower Hazeltine Creek have increased over the post-breach period. Despite this, the selenium concentrations of most benthic invertebrate tissues from upper Hazeltine Creek have not increased since at least 2021, with the notable exception of caddisflies from Reach 2 in 2022 and 2023. Rather, the concentrations of selenium in tissues from upper Hazeltine Creek were lower in 2024 than at least one prior year. In lower Hazeltine Creek, the selenium concentrations of periphyton and benthic invertebrate tissues in 2024 were significantly higher than all prior years, except for caddisfly tissues in 2023. The temporal increases in tissue selenium concentrations in Hazeltine Creek over the post-breach period corresponded with increases in sediment selenium concentrations at these areas compared to reference, but not aqueous total or dissolved selenium concentrations in surface waters (which have not increased from 2015 to 2024). Evaluation of aqueous selenium speciation parameters in surface waters, which was initiated in 2024, indicated that mean selenate and selenite concentrations in Hazeltine Creek were highest in Reach 2, and below detection for all other aqueous selenium species. For the remaining primary analytes (arsenic and iron) and most secondary analytes, there were no increases in the concentrations compared to 2020 or earlier in more than one tissue type. Concentrations of four secondary analytes (calcium, manganese, mercury, and strontium) in 2024 were significantly higher than all prior years, but these increases were isolated to a single tissue-type for each analyte. A comparison of results between the two types of benthic invertebrate tissues collected (caddisfly and composite-taxa) indicated that monitoring of both tissue types may be required to fully capture the magnitude of potential changes in all analyte concentrations of benthic invertebrate tissues from Hazeltine Creek.

Tissue quality monitoring of juvenile whole-body fish was completed in creek habitats in 2024 in response to observed temporal increases in the selenium concentrations of benthic invertebrate tissues from Hazeltine Creek and to satisfy draft CEMP approval requirements. This monitoring showed that mean selenium concentrations in juvenile whole-body rainbow trout and coho salmon

from upper and lower Hazeltine Creek, respectively, exceeded the BC guideline for the protection of aquatic life in 2024 (1.6-times the guideline [upper Hazeltine Creek]; 1.1-times the guideline [lower Hazeltine Creek]). In upper Hazeltine Creek, concentrations of two primary analytes (copper and selenium) and three secondary analytes (barium, manganese, and strontium) in juvenile whole-body rainbow trout were significantly higher than those from the reference area in 2024. Of these five analytes, the concentrations selenium and manganese in juvenile whole-body rainbow trout increased significantly over the post-breach period (i.e., 2018 and 2024). In lower Hazeltine Creek, concentrations of two primary analytes (copper and selenium) and two secondary analytes (cobalt and manganese) in juvenile whole-body coho salmon were significantly higher than those from the reference area in 2024. Temporal analyses for lower Hazeltine Creek fish tissue quality results will be possible following continued data collections (i.e., 2024 represented the first year of post-breach monitoring at this area). Rainbow trout and coho salmon only reside in Hazeltine Creek during their juvenile life stages; rainbow trout typically return to Polley Lake within their first year of life and coho salmon return to coastal marine waters after 1 to 2 years of life via the Quesnel River to the Fraser River (which flows to the Pacific Ocean). Therefore, the period of exposure of rainbow trout and coho salmon exposure to selenium in Hazeltine Creek (via dietary exposure) is limited to the juvenile life stages before most tissue growth occurs, and before reproductive development and potential selenium transfer to ovary tissues occur (ovary tissues are recommended for assessing the effects of selenium on fish). This is supported by selenium concentrations in the tissues rainbow trout from Polley Lake which have not increased over the post-breach period or have decreased in some cases (see Section 7.1.2). Selenium concentrations in the tissues of fish from Quesnel Lake and Quesnel River have also not increased temporally, when considering at least the last eight years (see Section 7.2.2). Selenium concentrations in juvenile fish from Hazeltine Creek in 2024 were lower than those measured in benthic invertebrates from corresponding monitoring areas (i.e., dietary exposure), and this difference was larger for caddisfly tissues than for composite-taxa benthic invertebrate tissues. These results suggested that the selenium concentrations in juvenile whole-body fish from Hazeltine Creek were more reflective of dietary exposure to composite-taxa benthic invertebrates (i.e., a mix of benthic invertebrate taxa) than to caddisfly tissues.

To evaluate whether the operation of the Mount Polley Mine was the likely the source of the temporal increase in tissue selenium concentrations in Hazeltine Creek, WSP conducted an evaluation of groundwater results and provided the following interpretation of results for inclusion in the present report (WSP 2024, 2025). WSP evaluated data from the groundwater monitoring wells located between the Tailings Storage Facility (TSF) and Hazeltine Creek, the groundwater wells located along Hazeltine Creek and the Perimeter Embankment Till Borrow Pond (PETBP), which is a flow equalization pond feeding into the water treatment plant (WSP 2024, 2025).

Groundwater selenium chemistry in the wells outside of the TSF has been stable and concentrations low since shortly after the breach. The shallow (but not the deep) well at monitoring well 16-2 shows the presence of selenium at concentrations that are higher than all other wells around the TSF regardless of well depth. Monitoring well 16-2 is located near the PETBP where, although selenium concentrations are below the permit criteria, they are higher than the very low concentrations in the TSF wells. There is a positive gradient between the PETBP surface water level and well 16-2 with an elevation difference of approximately 8.5 m. The PETBP collects surface runoff water from the site. Although its concentrations of selenium are not high (well below the effluent permit limits), they are higher than the TSF groundwater. WSP inferred that this provided an explanation of the chemistry of that one shallow well (well 16-2). Groundwater data for these wells are provided in WSP (2025). In addition to the groundwater wells that are located between the TSF and Hazeltine Creek, there are several wells located along Hazeltine Channel. In those wells, the concentration of selenium in groundwater has been consistently below the BC Contaminated Sites Regulation (CSR) Fresh Water Aquatic Life (AW) standards, with the exception of a single sample. WSP indicated that single sample may have been an artefact of sampling as it returned to historical levels in the next sampling event. The monitoring data from the Hazeltine Creek wells are provided in WSP (2024). WSP concluded that the data reviewed suggested that operation of the Mount Polley Mine is not a source of selenium.

7.3.3 Key Findings

Key findings of CEMP monitoring of Hazeltine Creek from 2022 to 2024 (Table 7.3) were:

- Sediment Quality (upper and lower areas: 2022, 2023, 2024):
    - Concentrations of copper, iron, manganese, and selenium in upper Hazeltine Creek (HAC-U) sediments in 2024 were higher than BCWSQG and reference/pre-breach conditions. Iron concentrations in upper Hazeltine Creek sediments from 2021 to 2024 were similar to or significantly lower than those in the 2018, while copper, manganese, and selenium concentrations did not change significantly from 2022 to 2024 but were significantly higher than two or more prior years, and TOC content has been temporally stable from 2021 to 2024.
    - Concentrations of arsenic, copper, iron, and selenium in lower Hazeltine Creek (HAC-D) sediments in 2024 were higher than BCWSQG and reference/pre-breach conditions. Arsenic, copper, and iron concentrations in lower Hazeltine Creek sediments since 2022 (or earlier) were similar to or significantly lower than those in 2018, and TOC content was significantly lower than in 2023 but similar to most prior years. Selenium concentrations in lower

Notes: "-" = no data available. CEMP = Comprehensive Environmental Monitoring Program. BCWSQG = British Columbia Working Sediment Quality Guidelines. BCWQG = British Columbia Water Quality Guideline. TOC = total organic carbon. Chl-a = Chlorophyll-a. AFDM = Ash Free Dry Mass. RB = rainbow trout. CO = coho salmon. WB = whole-body. 95th = 95th Percentile (applicable to sediment quality evaluation). [ ] = concentration. BCF = Bioconcentration Factor. TTF = Trophic Transfer Factor. Peri = Periphyton. Caddis = Caddisfly. BIC = Composite-taxa benthic invertebrate. GL = guideline. ref = reference. Temporal changes presented for sediment quality and tissue quality (periphyton, benthic invertebrates, fish) within the post-breach period refer to changes in the relative (exposed-reference) difference over time as evaluated using a 2-way Analysis of Variance (ANOVA). For sediment quality, results are presented for Analytes of Interest (see Section 3.1.3.1 for details of Analyte of Interest selection). For tissue quality (periphyton, benthic invertebrates, fish) results are presented for primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2024 or in all monitoring years.

[a] Data collected from 2022 to 2024 are included at minimum. Additional years are displayed (as available) to support temporal comparisons. Fish habitat and usage monitoring from 2022 to 2024 in Hazeltine Creek are summarized in a separate report (Minnow 2025) and are excluded from this table. HAC-R2 and HAC-R5 are the alternate names for HAC-U and HAC-R5, respectively, used for HRWG reporting (Minnow 2025).

[b] BCWSQG Lower = Lower BC Working Sediment Guideline; BCWSQG Upper = Upper BC Working Sediment Quality Guideline (BCMOWLRS 2024, 2025).

[c] Magnitude of significant differences in organism density and taxonomic richness relative to reference areas classed as highly different (> 5x SD), moderately different (5x to 2x SD), and slightly different (< 2x SD), where SD is the absolute value of the pooled standard deviation.

[d] BCWQG Aquatic Life GL = British Columbia Water Quality Guideline for the protection of aquatic life: interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

Notes: "-" = no data available. CEMP = Comprehensive Environmental Monitoring Program. BCWSQG = British Columbia Working Sediment Quality Guidelines. BCWQG = British Columbia Water Quality Guideline. TOC = total organic carbon. Chl-a = Chlorophyll-a. AFDM = Ash Free Dry Mass. RB = rainbow trout. CO = coho salmon. WB = whole-body. 95th = 95th Percentile (applicable to sediment quality evaluation). [ ] = concentration. BCF = Bioconcentration Factor. TTF = Trophic Transfer Factor. Peri = Periphyton. Caddis = Caddisfly. BIC = Composite-taxa benthic invertebrate. GL = guideline. ref = reference. Temporal changes presented for sediment quality and tissue quality (periphyton, benthic invertebrates, fish) within the post-breach period refer to changes in the relative (exposed-reference) difference over time as evaluated using a 2-way Analysis of Variance (ANOVA). For sediment quality, results are presented for Analytes of Interest (see Section 3.1.3.1 for details of Analyte of Interest selection). For tissue quality (periphyton, benthic invertebrates, fish) results are presented for primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2024 or in all monitoring years.

[a] Data collected from 2022 to 2024 are included at minimum. Additional years are displayed (as available) to support temporal comparisons. Fish habitat and usage monitoring from 2022 to 2024 in Hazeltine Creek are summarized in a separate report (Minnow 2025) and are excluded from this table. HAC-R2 and HAC-R5 are the alternate names for HAC-U and HAC-R5, respectively, used for HRWG reporting (Minnow 2025).

[b] BCWSQG Lower = Lower BC Working Sediment Guideline; BCWSQG Upper = Upper BC Working Sediment Quality Guideline (BCMOWLRS 2024, 2025).

[c] Magnitude of significant differences in organism density and taxonomic richness relative to reference areas classed as highly different (> 5x SD), moderately different (5x to 2x SD), and slightly different (< 2x SD), where SD is the absolute value of the pooled standard deviation.

[d] BCWQG Aquatic Life GL = British Columbia Water Quality Guideline for the protection of aquatic life: interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

Hazeltine Creek sediments have been stable since 2022, and in 2023 and 2024 were significantly higher than all prior years. The temporal changes in analyte concentrations in sediments from upper and lower Hazeltine Creek were related to the physical and chemical sediment characteristics, factors which are likely

  - influenced by a combination of required opportunistic sampling methods and continued sediment accumulation in upper and lower Hazeltine Creek.

- Periphyton Community and Productivity (upper areas: 2022, 2023, 2024; lower areas: 2023):
  - Periphyton productivity (measured as chlorophyll-a) in the three upper Hazeltine Creek areas (HAC-R1, HAC-U, HAC-R3) was below the BCWQG in all post-breach years and in 2024 was similar to reference and baseline/pre-conditions with few exceptions. Periphyton chlorophyll-a in decreased significantly with increasing distance downstream in Hazeltine Creek in most years (including 2024). Periphyton community metrics of taxon richness, Diatom richness, and Simpson's Evenness and Diversity were similar to or higher than reference conditions in most post-breach years, including 2024. Periphyton densities were significantly lower than reference since 2022 or earlier but have remained relatively stable over the post-breach period. The periphyton community composition in 2024 was indicative of a healthy community (relative to reference).
  - Periphyton productivity (measured as chlorophyll-a) in lower Hazeltine Creek (HAC-D) was below the BCWQG in all years and significantly lower than reference but similar to pre-breach conditions in most years (including 2023). Periphyton community density taxon richness, Diatom richness, and Simpson's Evenness and Diversity were similar to or higher than reference in 2023. Some remaining differences in periphyton community composition in 2023 compared to reference suggested ongoing community recovery.
- Benthic Invertebrate Community and Productivity (upper areas: 2022, 2023, 2024; lower areas: 2023):
  - Benthic invertebrate communities in upper Hazeltine Creek (HAC-R1, HAC-U, HAC-R3) were similar to one or both references in terms of density and taxon richness and were also similar to pre-breach conditions in terms of Simpson's Evenness and Diversity (excluding Diversity at HAC-R3). Some key differences in the benthic community structure remained compared to pre-breach

and reference conditions, particularly in terms of lower prevalence of sensitive taxa (% and density), which suggested ongoing recovery. The benthic invertebrate communities in Reaches 1 and 2 of upper Hazeltine Creek (HAC-R1 and HAC-U) were similar to each other in 2024, indicating similar recovery, while the community in Reach 3 (HAC-R3) differed from the upstream reaches.

- Benthic invertebrate community in lower Hazeltine Creek (HAC-D) in 2023 was similar to reference and pre-breach conditions in terms of density, richness, Simpson's Evenness and Diversity. Benthic invertebrate productivity (biomass) in 2023 was similar to or significantly higher than reference. Some remaining differences in the benthic community composition compared to reference and pre-breach and reference conditions suggested ongoing community recovery.

- Periphyton and Benthic Invertebrate Tissue Quality (2022, 2023, 2024):
  - Concentrations of copper in most and selenium in all periphyton and benthic invertebrate tissues from upper and lower Hazeltine Creek (HAC-R1, HAC-U, HAC-D) in 2024 were higher than reference. Copper concentrations in benthic invertebrate (composite-taxa) tissues from all areas and in periphyton tissues from HAC-D in 2024 were significantly higher than pre-breach, as were selenium concentrations in periphyton and benthic invertebrate (composite-taxa) tissues from lower (but not upper) Hazeltine Creek in 2024. There was no sustained increase of copper concentrations in tissues from Hazeltine Creek over the post-breach period, except for copper in caddisfly tissues from HAC-D, which increased in 2024 to concentrations similar to 2020 and 2021. Selenium concentrations in periphyton and benthic invertebrate tissues from upper and lower Hazeltine Creek have increased significantly over the post-breach period but have not increased since at least 2021 in most benthic invertebrate tissues from upper Hazeltine Creek (except for caddisfly tissues from HAC-U in 2022 and 2023). In lower Hazeltine Creek, the selenium concentrations of periphyton and benthic invertebrate tissues in 2024 were significantly higher than all prior years, except for caddisfly tissues in 2023. Mean selenium concentrations in benthic invertebrates from upper and lower Hazeltine Creek areas were higher than the BC guideline for the protection of aquatic life in 2024 (1.2- to 2.4-times guideline [composite-taxa]; 2.3- to 3.5-times guideline [caddisfly]) and were highest in benthic invertebrate tissues (particularly caddisflies) from HAC-U. This is consistent with caddisflies being known as 'hyper-accumulators' of selenium. Concentrations of the remaining

primary and secondary analytes largely showed no increases compared to 2020 or earlier, and analyte concentrations in 2024 that were higher than all prior years were limited to a single tissue-type.

- Juvenile Fish Tissue Quality (2024):
    - Concentrations of the primary analytes copper and selenium, and the secondary analytes barium, manganese, and strontium in juvenile whole-body rainbow trout from upper Hazeltine Creek (HAC-U) in 2024 were significantly higher than reference. Of these, selenium and manganese concentrations increased significantly between 2018 and 2024. Concentrations of the primary analytes copper and selenium, and the secondary analytes cobalt, and manganese in juvenile whole-body coho salmon from lower Hazeltine Creek (HAC-D) in 2024 were also significantly higher than reference; temporal analyses for this area are not yet possible. Mean selenium concentrations in juvenile whole-body rainbow trout and coho salmon from Hazeltine Creek exceeded the BC guideline for the protection of aquatic life in 2024 (by 1.6- and 1.1-times). Selenium concentrations in juvenile whole-body fish tissues from Hazeltine Creek were lower than those in benthic invertebrates from corresponding areas (i.e., dietary exposure), and this difference was larger for caddisfly compared to composite-taxa benthic invertebrate tissues. Rainbow trout and coho salmon only reside in Hazeltine Creek during rearing, so the dietary exposure to selenium in Hazeltine Creek is limited to juvenile life stages only. Selenium concentrations in the tissues of fish from waterbodies connected to Hazeltine Creek (i.e., Polley Lake, Quesnel Lake, and Quesnel River) have not increased when considering at least the last eight years.

7.4 Edney Creek

7.4.1 Aquatic Life

Periphyton monitoring completed in lower Edney Creek (E1), which was last completed in 2023, indicated that primary productivity (as measured by chlorophyll-a) was lower than reference, below the BCWQG, and below the threshold for moderately enriched streams. Primary productivity (as measured by both chlorophyll-a and AFDM) was significantly lower at E1 than reference from 2017 to 2023. The continued lower periphyton productivity at E1 compared to reference indicated that recovery was ongoing which was likely related to a combination of the remediation efforts that concluded in 2021 (after 2021 biological sampling) and substrate transport that occurred in most years due to high spring freshet flows. The periphyton community

of the exposed area of lower Edney Creek (E1) in 2023 was characterized by significantly lower total density, significantly higher total taxon richness, and similar Diatom richness and Simpson's Diversity and Evenness, compared to reference. Simpson's Diversity and Evenness, and the dominance of taxa at the exposed area, were consistently similar to the reference area from 2019 to 2023 indicating similar community composition to reference. Combined, these results indicated the periphyton community composition at the exposed area of lower Edney Creek had largely recovered to reference conditions; however, the consistently lower density and productivity metrics compared to reference suggested that recovery of periphyton productivity was ongoing.

Benthic invertebrate community monitoring in lower Edney Creek (E1), which was last completed in 2023, indicated that total density and Simpson's Diversity were similar to the reference area (EDC-D), while taxon richness and Simpson's Evenness were slightly higher and lower, respectively, than reference. The occurrence of these metrics at E1 in 2023 at values that were similar to or higher than at the reference area represented recovery in the benthic invertebrate community at this area compared to 2021. Benthic invertebrate community composition at E1 differed from reference in terms of higher Chironomidae (%) and lower Arachnida (%) in most years, while sensitive EPT taxa (%) at E1 were similar to reference from 2016 to 2023. Within the EPT taxa, Plecoptera (%) were similar to reference from 2016 to 2023, Trichoptera (%) were consistently higher than reference from 2017 to 2023, and Ephemeroptera (%) were lower than reference in 2023 but not in prior years (i.e., 2017 to 2021). Lower Ephemeroptera (%) at E1 than reference in 2023 was not due to a decrease in the prevalence of Ephemeroptera (% and density) in 2023, but rather due to an increase in non-Chironomidae Diptera (%) from 2022 to 2023 (from lower than to higher than reference). Benthic invertebrate productivity (as measured by dry and wet weight biomass) at E1 was similar to reference from 2017 to 2023. These results indicated that recovery of the benthic invertebrate community at E1 had occurred following the completion of final remediation works in this area in 2020 and 2021, including similar dominance of sensitive EPT taxa at E1 to reference. However, the differences in community composition that remained relative to reference suggested that recovery of the community was still ongoing.

Periphyton and benthic invertebrate tissue quality monitoring in lower Edney Creek in 2024 indicated that concentrations of two primary analytes (copper and iron) and eight secondary analytes were significantly higher at the exposed area compared to the reference area in at least one tissue type. However, there was no sustained increase in the concentrations of these primary or secondary analytes in the tissues since the first (i.e., 2019) or second (i.e., 2020) year of post-breach monitoring. Selenium concentrations in exposed tissues (periphyton and benthic invertebrates) were similar to reference, indicating no potential mine-related influence, and remained below the BC guideline for the protection of aquatic life in benthic invertebrate

tissues. A comparison of results between the two types of benthic invertebrate tissues collected in 2024 (i.e., caddisfly and composite-taxa) indicated that composite-taxa tissue sampling detected all changes occurring in caddisflies, suggesting that monitoring of composite-taxa may be sufficient to determine potential changes in analyte concentrations of benthic invertebrate tissues from lower Edney Creek.

7.4.2 Key Findings

Key findings of CEMP monitoring of Edney Creek from 2022 to 2024 (Table 7.4) were:

- Periphyton Community and Productivity (2023):
    - Periphyton productivity (measured as chlorophyll-a) in lower Edney Creek (E1) from 2017 to 2023 was consistently lower than reference, below the BCWQG, and temporally stable. The periphyton community in 2023 was characterized by significantly lower total density, higher taxon richness, and similar Diatom richness and Simpson's Diversity and Evenness compared to the reference area. Taxon richness and Diatom richness were significantly higher in 2023 than in 2021 which reflected recovery after the completion of remediation works in 2020 and 2021. Similarity in the relative densities of major taxa from 2019 to 2023 to the reference area indicated that community composition had recovered to reference conditions, while recovery of periphyton density and productivity was still ongoing.
- Benthic Invertebrate Community and Productivity (2023):
    - Benthic invertebrate community in lower Edney Creek (E1) in 2023 was characterized by slightly higher richness, slightly lower Simpson's Evenness, and similar density, Simpson's Diversity, and productivity (biomass) to the reference area. The similar or higher results for most of these metrics were indicative of community recovery, while differences remaining in community composition (relative to the reference area) suggested ongoing recovery of the community.
- Periphyton and Benthic Invertebrate Tissue Quality (2022, 2023, 2024):

Periphyton and benthic invertebrate tissues from lower Edney Creek (E1) in 2024 had concentrations of copper (in all tissue types) and iron (in composite-taxa benthic invertebrate tissues only) that were significantly higher than at the reference area. However, there was no increase in tissue concentrations of these primary analytes compared to the first or second year of post-breach monitoring (2019 or 2020). Mean selenium concentrations in periphyton and

Table 7.4: Summary of Mount Polley CEMP Sediment and Aquatic Life Results for Lower Edney Creek, 2022 to 2024 [a]

Notes: "-" = no data available. CEMP = Comprehensive Environmental Monitoring Program. BCWQG = British Columbia Water Quality Guideline. Chl-a = Chlorophyll-a. AFDM = Ash Free Dry Mass. [ ] = concentration. BCF = Bioconcentration Factor. TTF = Trophic Transfer Factor. Peri = Periphyton. Caddis = Caddisfly. BIC = Composite-taxa benthic invertebrate. GL = guideline. ref = reference. Temporal changes presented for periphyton and benthic invertebrate tissue quality within the post-breach period refer to changes in the relative (exposed-reference) difference over time as evaluated using a 2-way Analysis of Variance, and are presented for primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2024 or in all monitoring years.

[a] Data collected from 2022 to 2024 are included at minimum. Additional years are displayed (as available) to support temporal comparisons. Fish habitat characterization and fish usage monitoring (for spawning and rearing purposes) from 2022 to 2024 in lower Edney Creek is summarized in a separate report (Minnow 2024). EDC-EXP and EDC-REF are the alternate names for E1 and EDC-D, respectively, used for HRWG reporting (Minnow 2025).

[b] Magnitude of significant differences in organism density and taxonomic richness relative to reference areas classed as highly different (> 5x SD), moderately different (5x to 2x SD), and slightly different (< 2x SD), where SD is the absolute value of the pooled standard deviation.

[c] BCWQG Aquatic Life GL = British Columbia Water Quality Guideline for the protection of aquatic life: interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

benthic invertebrate tissues in 2024 were significantly lower than at the reference area, and were well below the BC guideline for the protection of aquatic life in benthic invertebrate tissues. Concentrations of secondary analytes in exposed tissues that were significantly higher than reference in 2024 have not increased compared to the first or second year of post-breach monitoring.

APPENDIX A
SAMPLING LOCATIONS AND SUPPORTING INFORMATION

APPENDIX A.1

LAKES

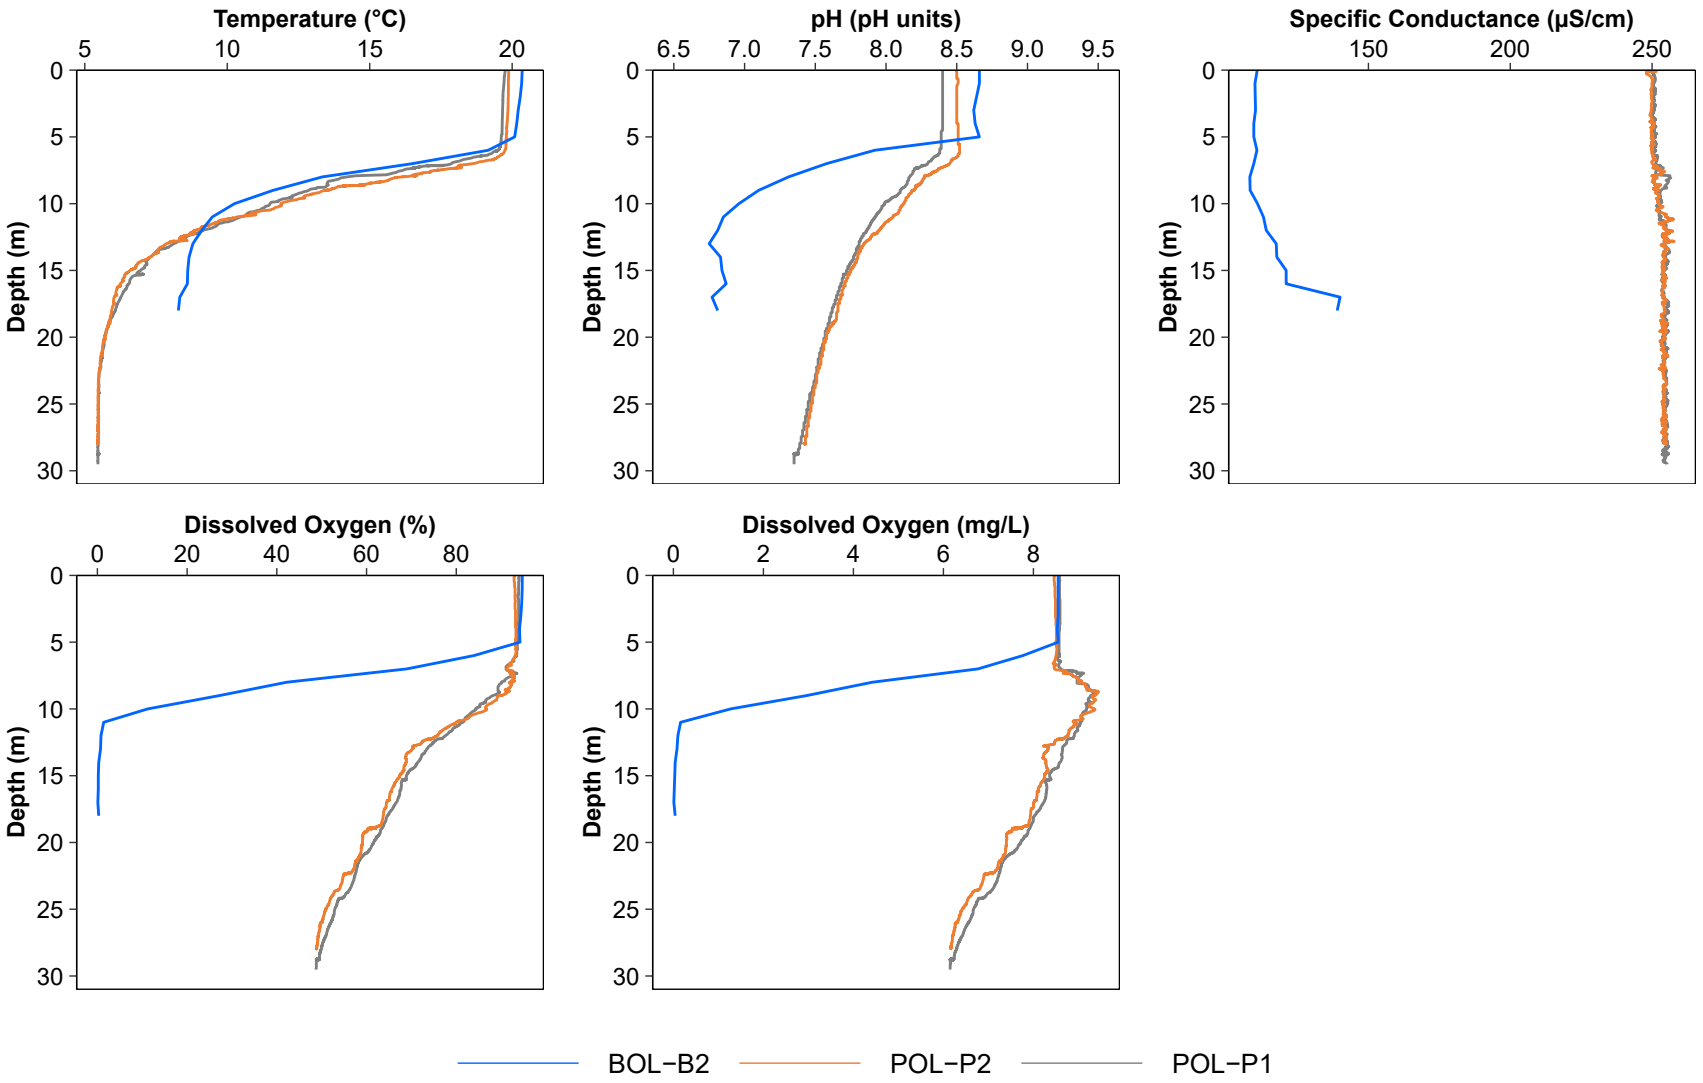

Figure A.1.1: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Sediment Quality and Benthic Invertebrate Community Monitoring at the Polley Lake (POL-P2, POL-P1; Exposed) and Bootjack Lake (BOL-B2; Reference) Deep Monitoring Areas, August 2024

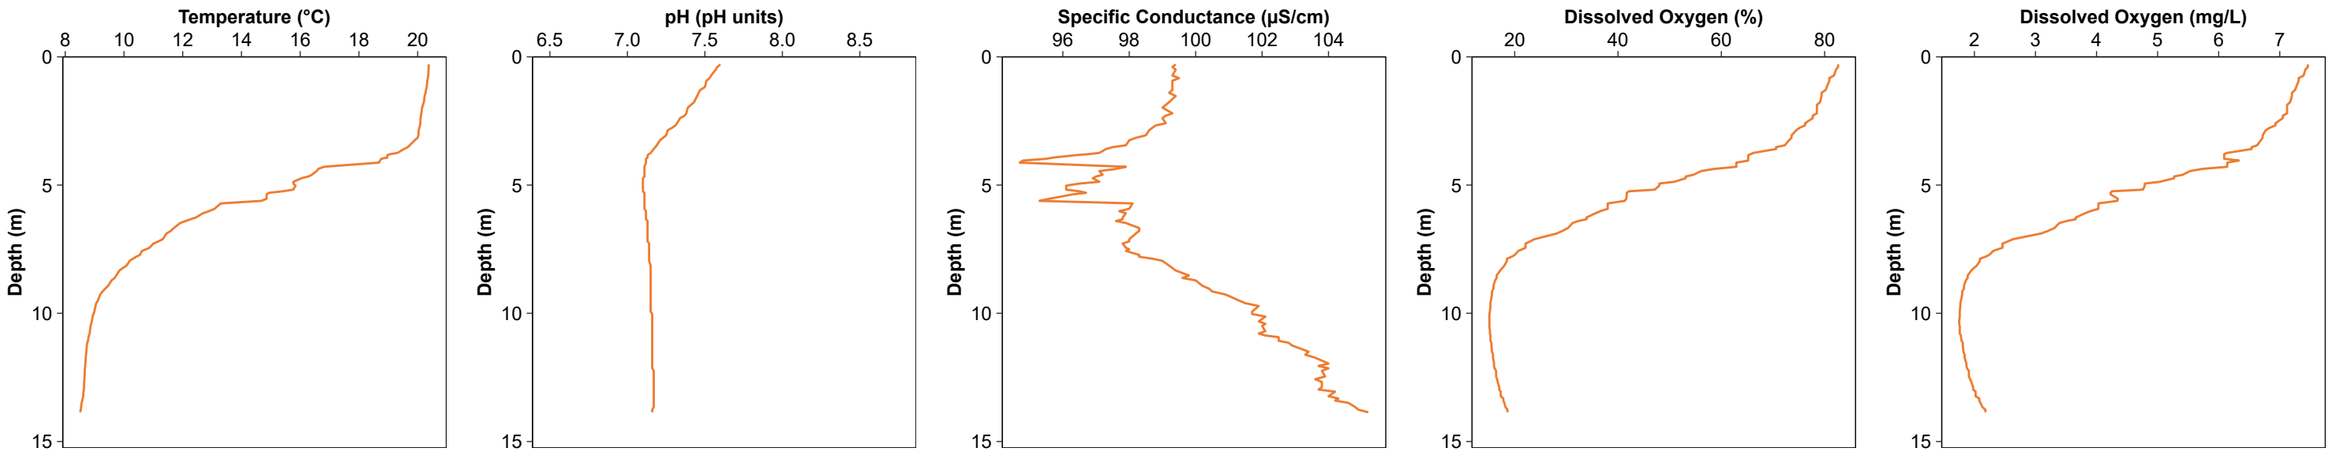
Notes: m = metres. mg/L = milligrams per litre. µS/cm = microSiemens per centimeter. °C = degrees Celsius. % = percent.

Bootjack Lake (BOL−B2; Reference)



Polley Lake (POL−P2; Exposed)

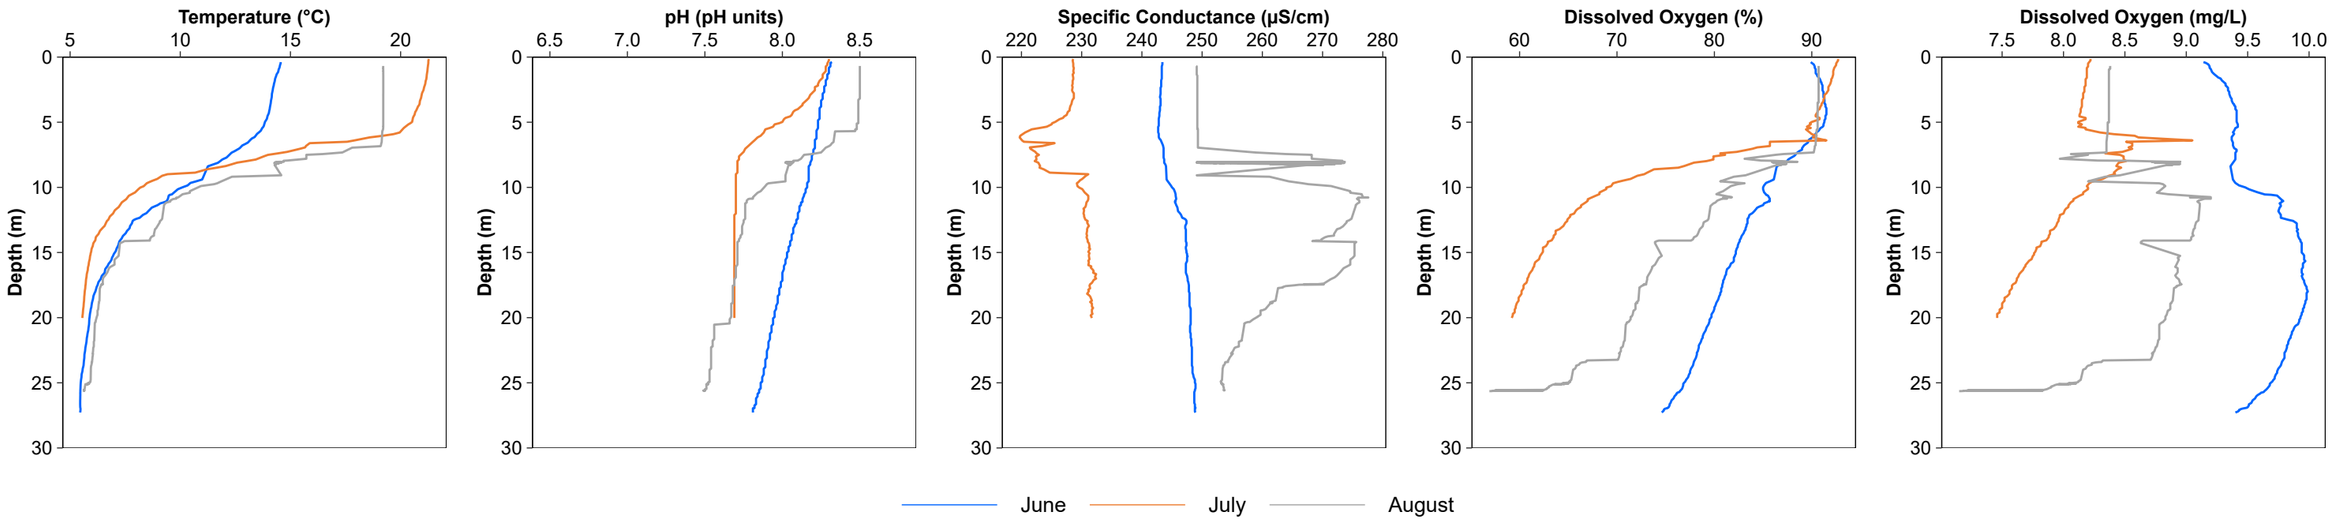


Figure A.1.2: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Plankton Monitoring at the Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, June to August, 2024

Notes: m = metres. mg/L = milligrams per litre. µS/cm = microSiemens per centimeter. °C = degrees Celsius. % = percent. Vertical profiles were not collected for Bootjack Lake in June and August due to equipment malfunction.

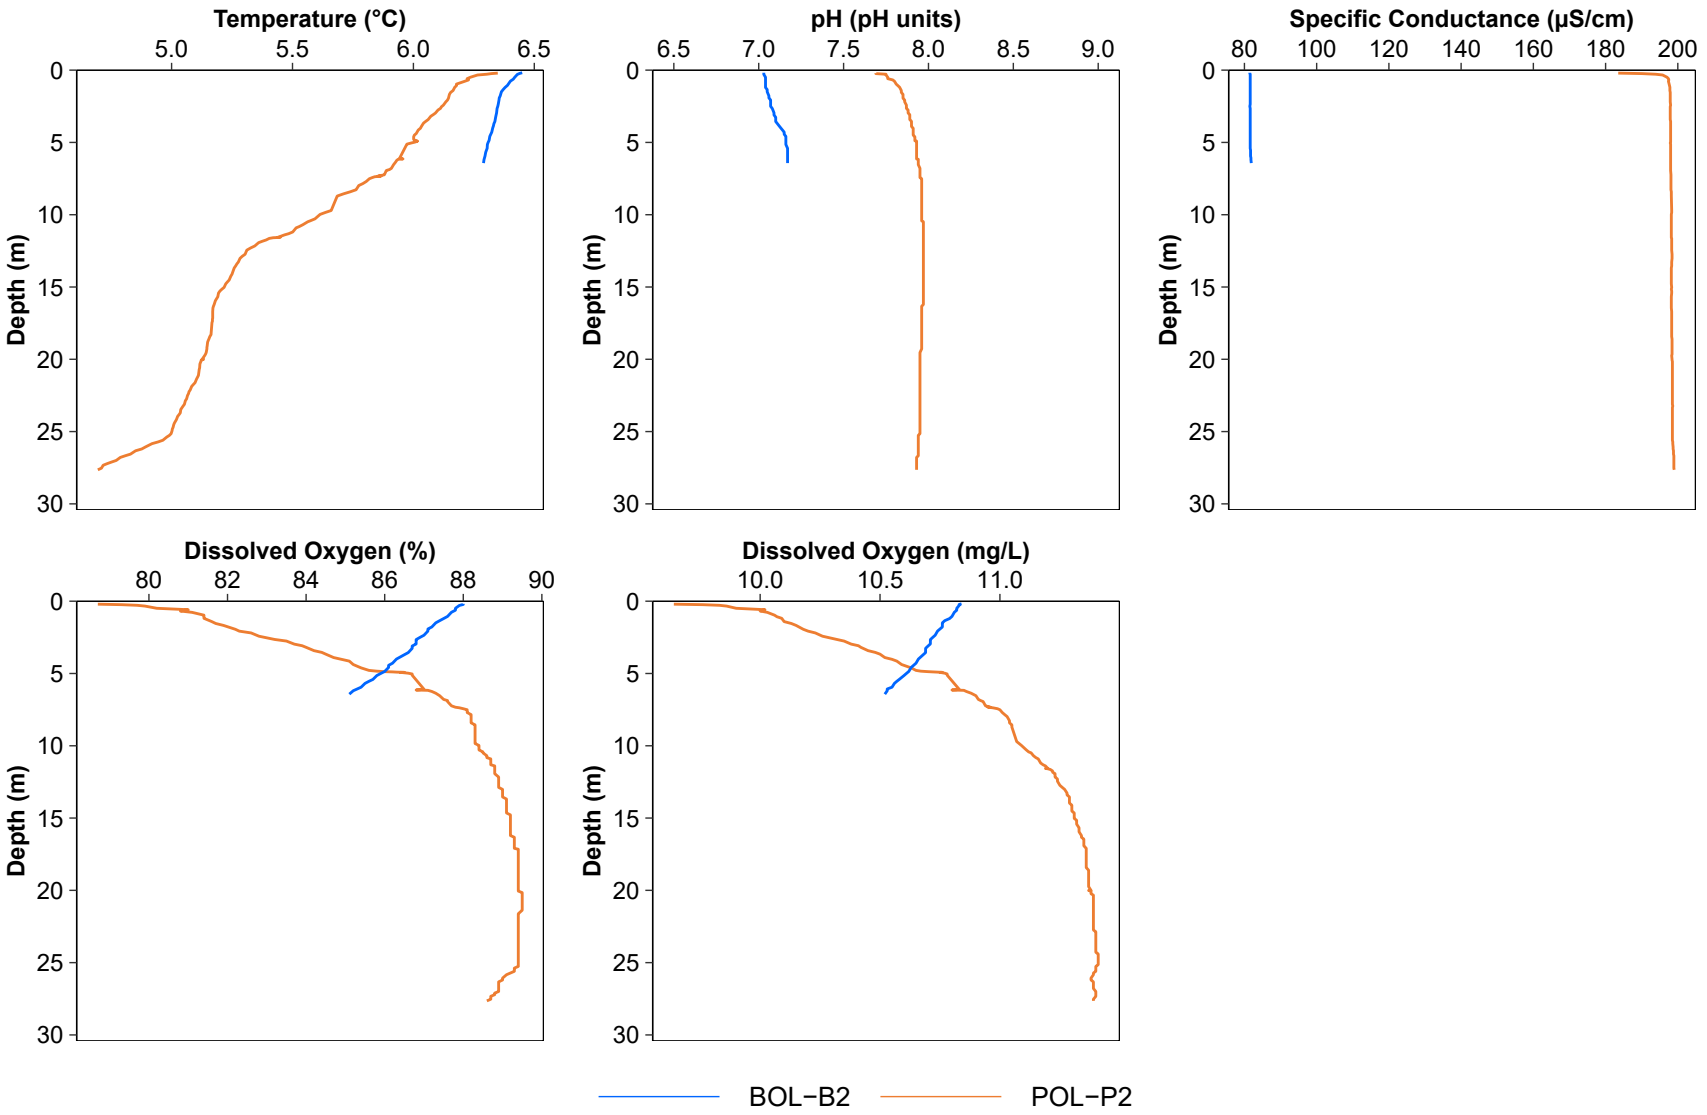

Figure A.1.3: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Fish Monitoring at the Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, Spring 2024

Notes: m = metres. mg/L = milligrams per litre. µS/cm = microSiemens per centimeter. °C = degrees Celsius. % = percent. Due to equipment malfunction, the vertical profile for Bootjack Lake was only partially completed.

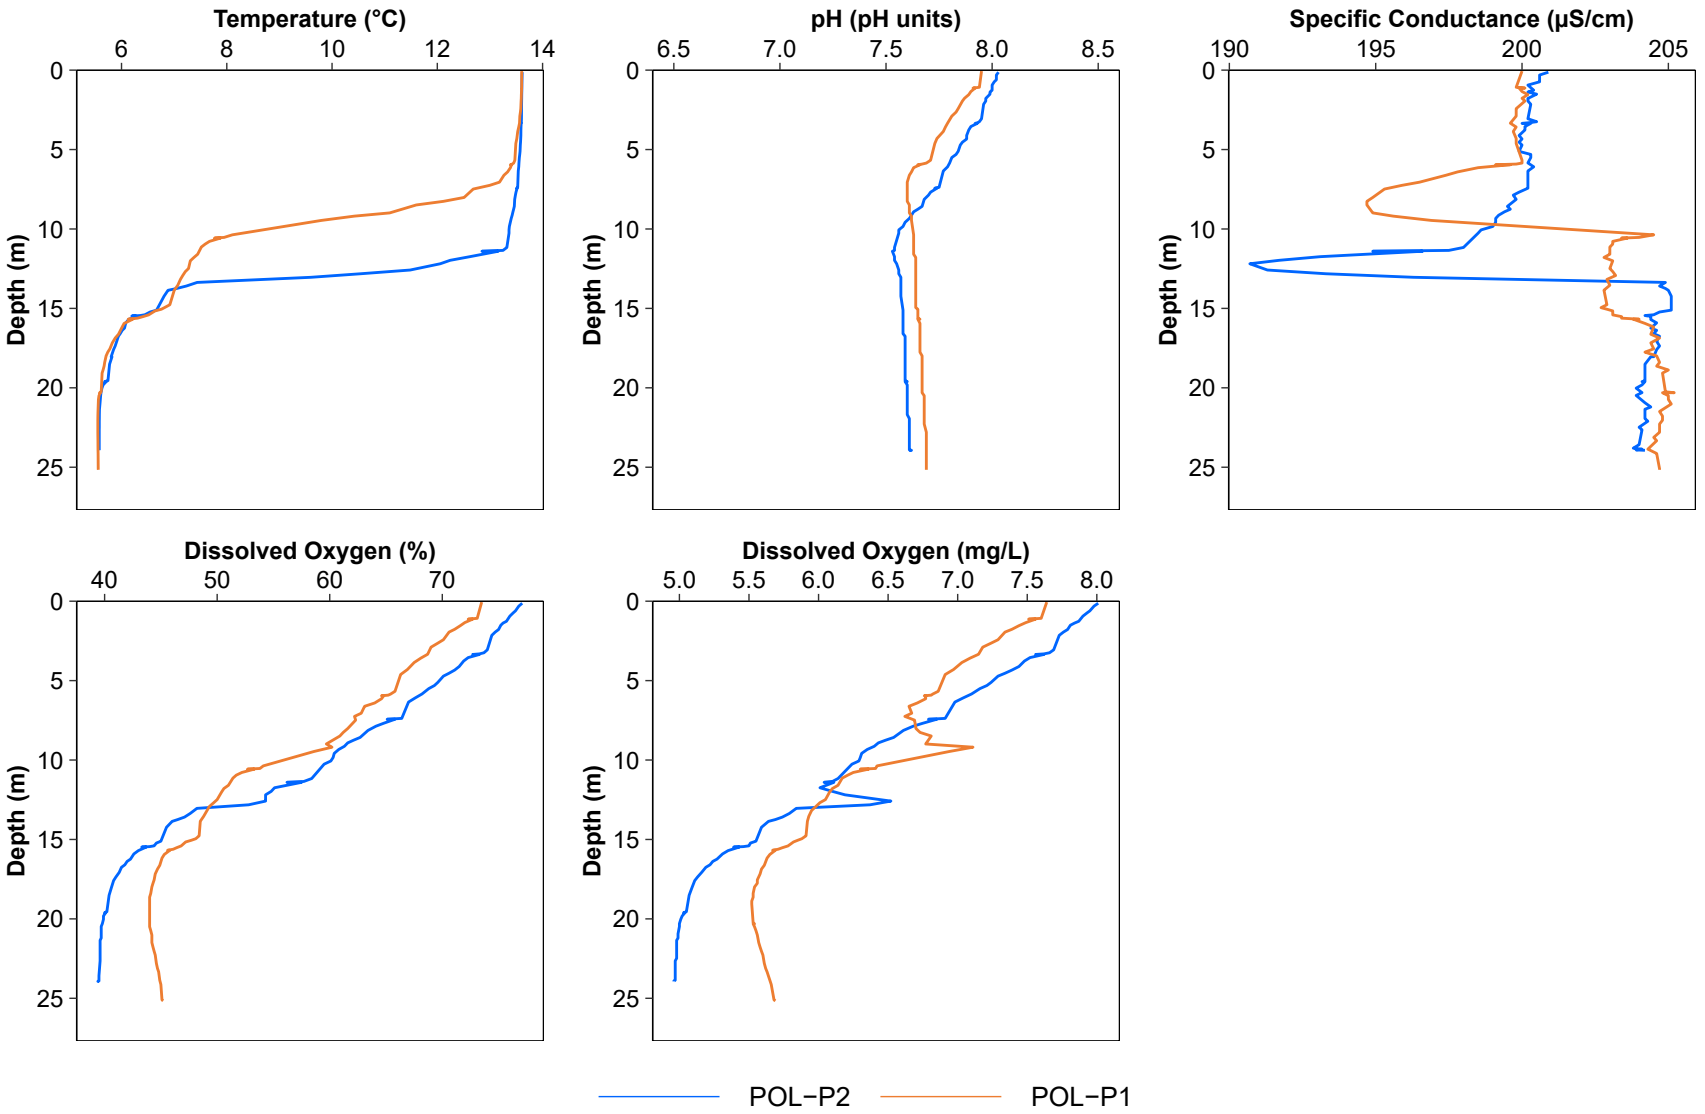

Figure A.1.4: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Fish Monitoring for Polley Lake (POL−P2 and POL−P1; Exposed), September 2024

Notes: m = metres. mg/L = milligrams per litre. µS/cm = microSiemens per centimeter. °C = degrees Celsius. % = percent.

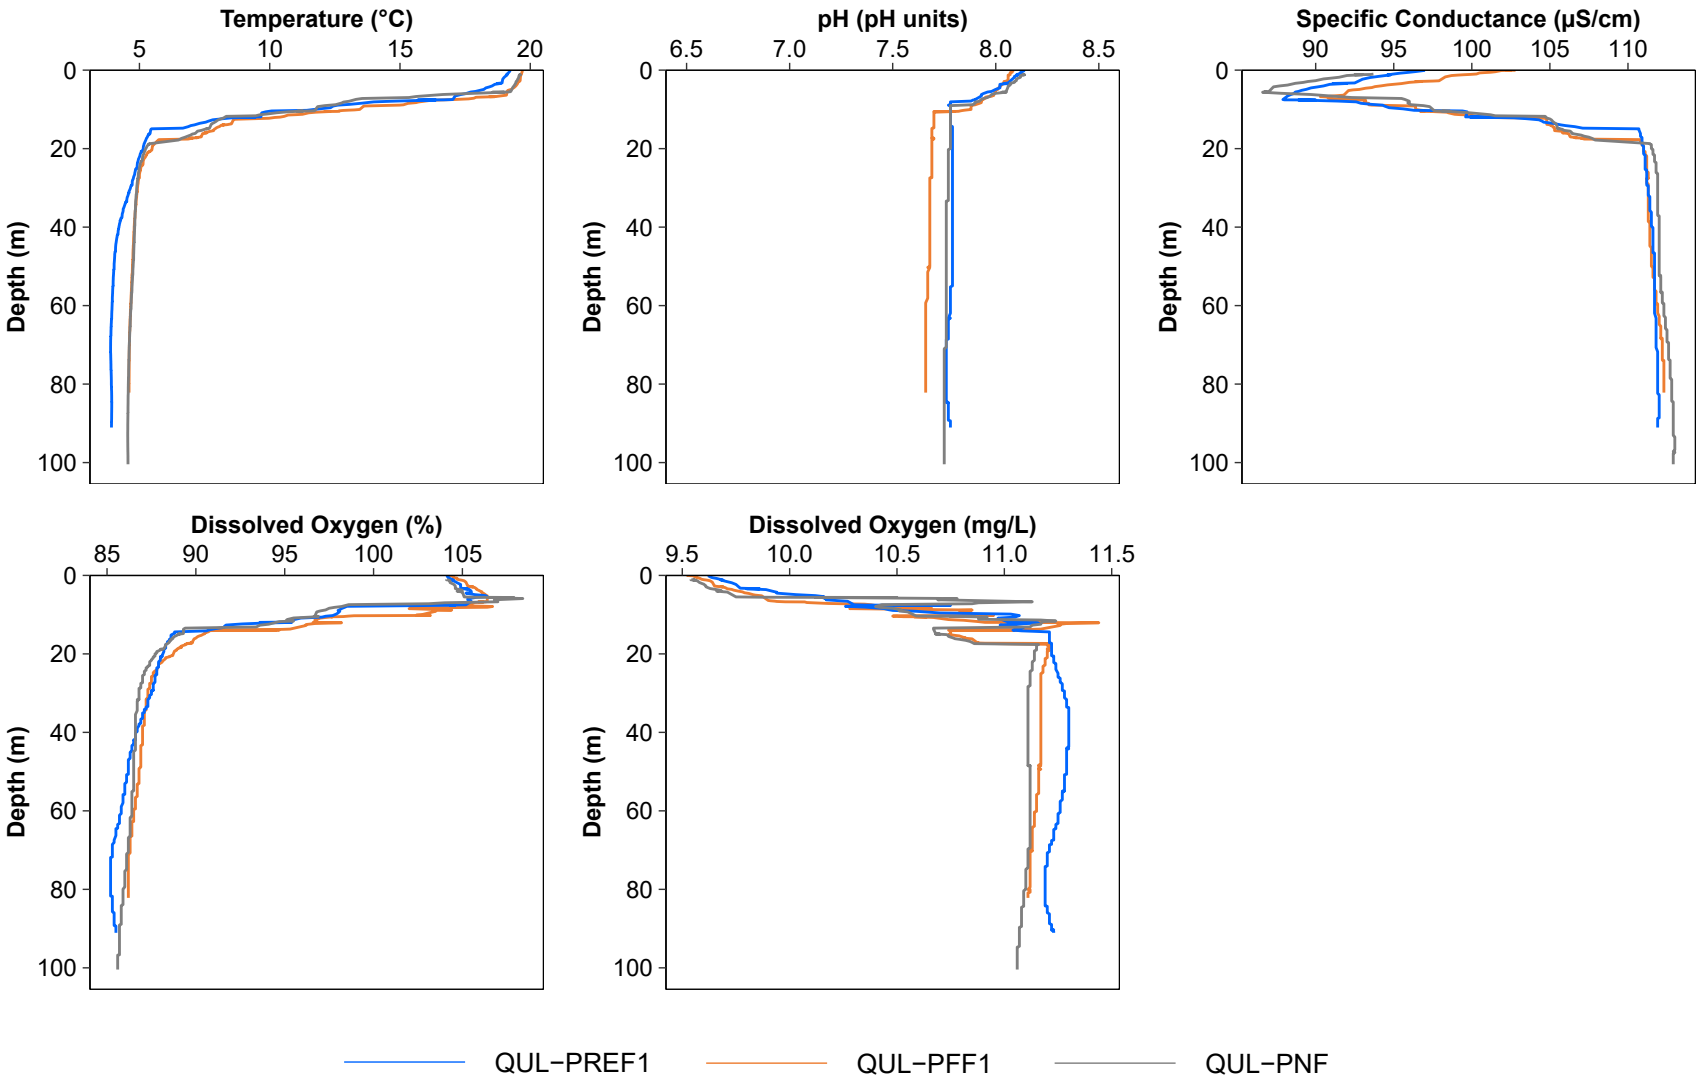

Figure A.1.5: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Sediment Quality and Benthic Invertebrate Monitoring at the Quesnel Lake (QUL−PNF, QUL−PFF1; Exposed and QUL−PREF1; Reference) Deep Monitoring Areas, August 2024

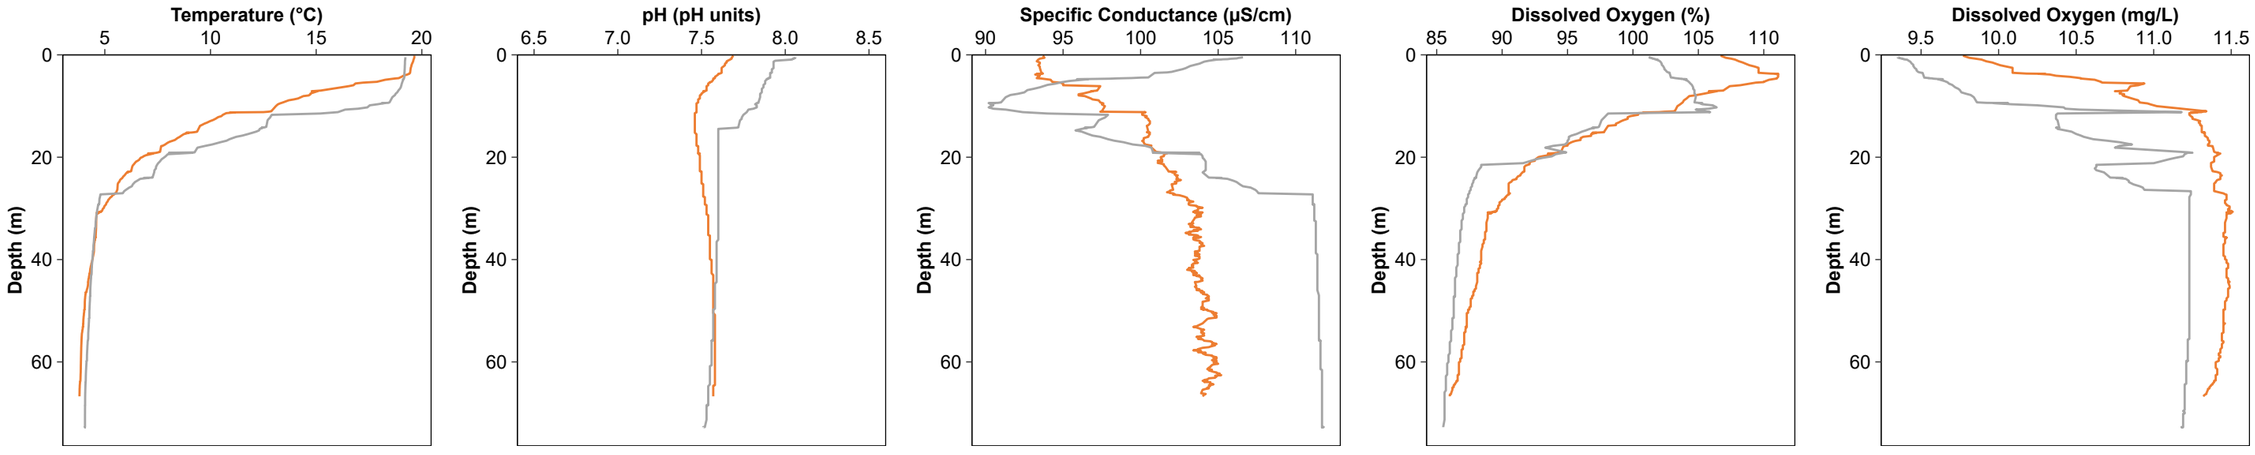
Notes: m = metres. mg/L = milligrams per litre. µS/cm = microSiemens per centimeter. °C = degrees Celsius. % = percent.

Quesnel Lake (QUL−ZOO−7; Reference)



Quesnel Lake (QUL−ZOO−1; Exposed)

Figure A.1.6: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Plankton Monitoring at the Quesnel Lake (QUL−ZOO−1; Exposed and QUL−ZOO−7; Reference) Monitoring Areas, June to August, 2024

Notes: m = metres. mg/L = milligrams per litre. µS/cm = microSiemens per centimeter. °C = degrees Celsius. % = percent. Vertical profiles were not collected in June due to equipment malfunction.

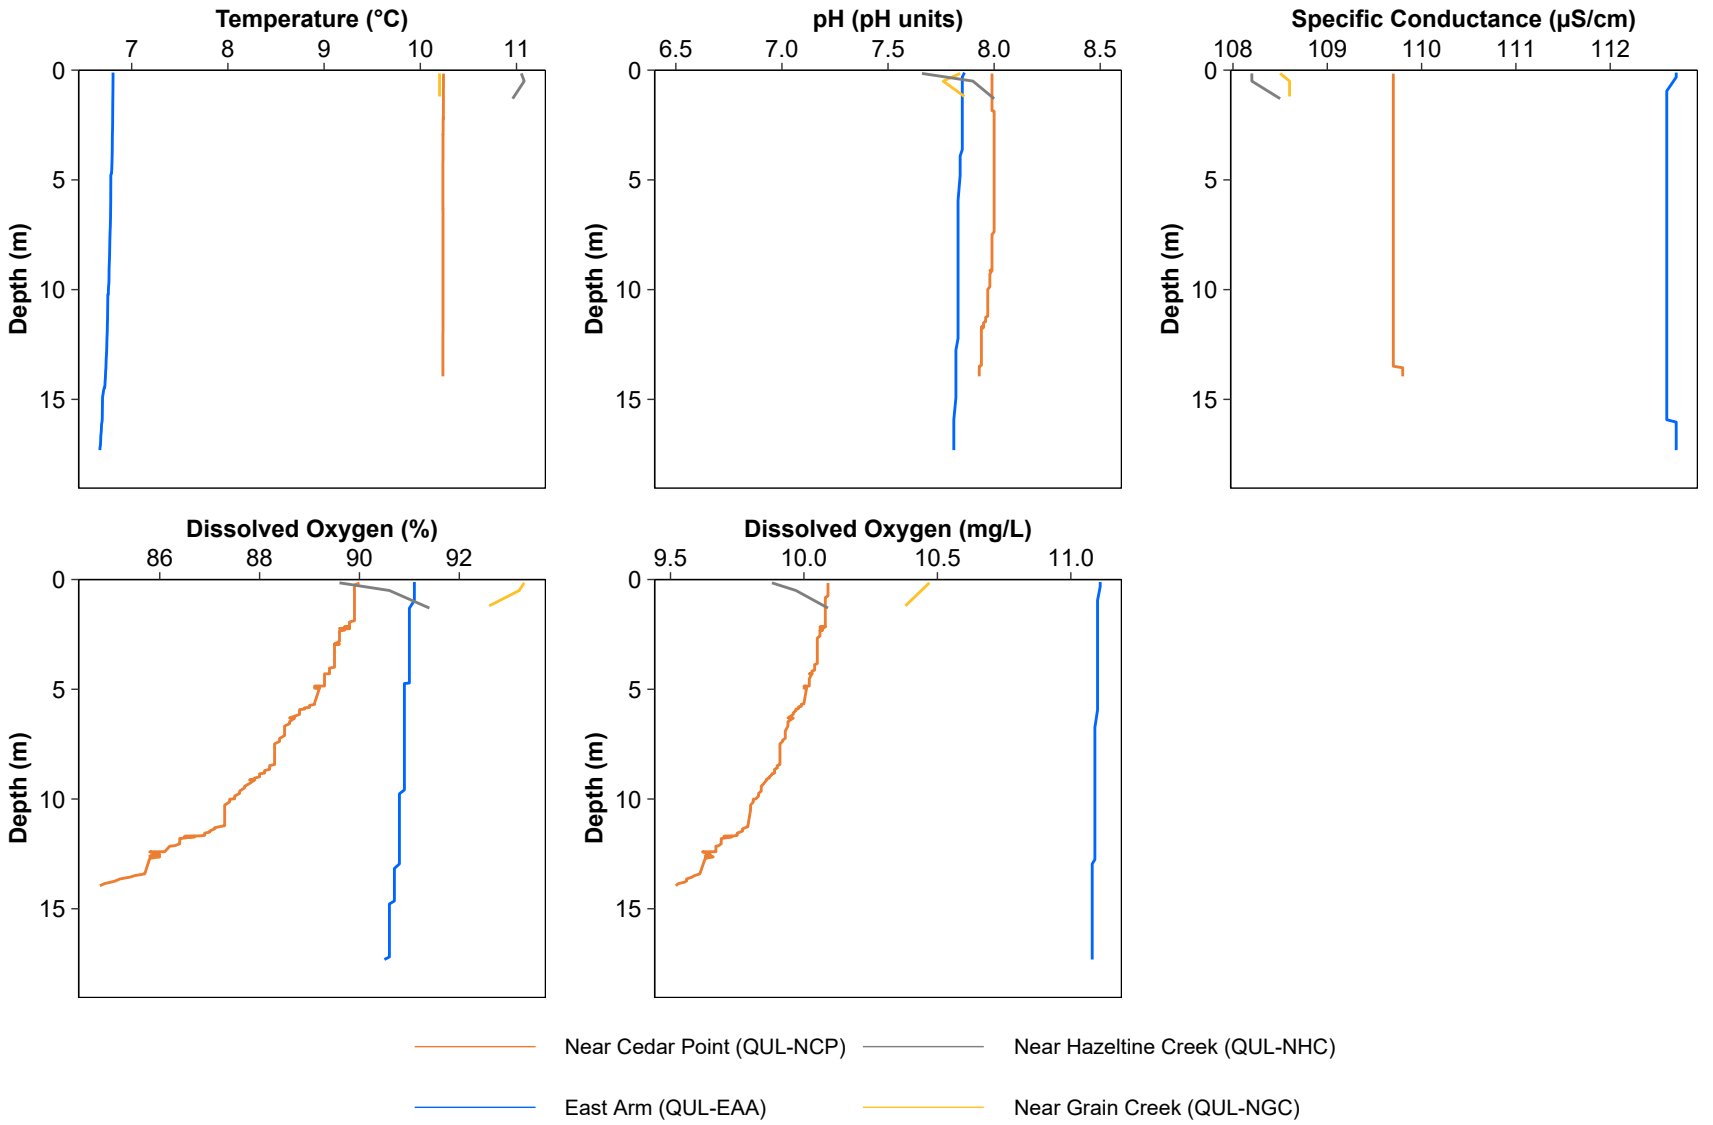


Figure A.1.7: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Fish Monitoring at the Quesnel Lake (QUL-NCP, QUL-NHC; Exposed and QUL-EAA, QUL-NGC; Reference) Monitoring Areas, October 2024

Notes: m = metres. mg/L = milligrams per litre. µS/cm = microSiemens per centimeter. °C = degrees Celsius. % = percent.

Table A.1.1: Sediment and Benthic Invertebrate Community Monitoring Methods and Locations at the Polley Lake (POL-P1, POL-P2; Exposed), Bootjack Lake (BOL-B2; Reference) Deep Monitoring Areas and the Quesnel Lake Deep (QUL-PNF and QUL-PFF1; Exposed and QUL-PREF1; Reference) and Shallow (QUL-LNF1; Exposed and QUL-LREF1; Reference) Monitoring Areas, August 2024

[a] Secchi depth could not be recorded due to windy weather.

Table A.1.4: Habitat Information Associated with Fish Population Monitoring in Polley Lake, September 2024

Station ID		Exposed
		Polley Lake
Date Sampled		19-Sep-24
UTM (NAD83, Zone 10U)	Easting	595166
	Northing	5822183
Habitat Characteristics		
Surrounding Land Use		Mining, forest, recreation
Riparian Vegetation (decreasing dominance)		Coniferous (cedar, spruce), alder, aspen
Evidence of Anthropogenic Disturbances		TSF breach 2014, recreation site with boat launch, cabins at north end of lake
Aquatic Vegetation	% Emergent	5
	% Submergent	20
	% Floating	5
	% Attached Algae	0
Shoreline (% area coverage)	% Bedrock	0
	% Boulder	0
	% Cobble	10
	% Gravel	20
	% Sand / Finer	50
	% Organic Debris	20
Littoral Substrate (% area coverage)	% Bedrock	-
	% Boulder	-
	% Cobble	-
	% Gravel	-
	% Sand / Finer	-
	% Organic Debris	-
Comments	Emergent vegetation: Typha and sedges at south end of lake. Floating vegetation: Polygonum (water smartweed) in multiple areas. Submerged vegetation: Ranunculus (water-crowfoot) in multiple areas and Chara (muskgrass) at the south end of lake.	

Notes: " - " indicates no data available. Littoral assessment omitted as majority of lake could not be observed.

Table A.1.5: Habitat Information Associated with Fish Tissue Collections in Quesnel Lake, October 2024

[a] HAC-R2, EDC-REF, EDC-EXP, and HAC-R5 are alternate names used the for HAC-U, EDC-D, E1, and HAC-D sampling areas, respectively, for HRWG reporting.

[b] Water flows of 0 m/s were recorded throughout the EDC-U monitoring area. Low flow at EDC-U was likely related to drought conditions in the Cariboo Region: Severe Drought (Level D2) from August 2023 through April 2024, and either Moderate Drought (Level D1) or Abnormally Dry (Level D0) from May to August 2024 (Agriculture and Agri-Foods Canada 2025). Flow conditions should be considered in data interpretation.

[c] Hazeltine Reach 1 stations 1 through 4 were relocated in 2024 due to disturbances to riffle crest substrate from electrofishing monitoring.

[a] HAC-R2, EDC-REF, EDC-EXP, and HAC-R5 are alternate names used the for HAC-U, EDC-D, E1, and HAC-D sampling areas, respectively, for HRWG reporting.

[b] Water flows of 0 m/s were recorded throughout the EDC-U monitoring area. Low flow at EDC-U was likely related to drought conditions in the Cariboo Region: Severe Drought (Level D2) from August 2023 through April 2024, and either Moderate Drought (Level D1) or Abnormally Dry (Level D0) from May to August 2024 (Agriculture and Agri-Foods Canada 2025). Flow conditions should be considered in data interpretation.

[c] Hazeltine Reach 1 stations 1 through 4 were relocated in 2024 due to disturbances to riffle crest substrate from electrofishing monitoring.

B1 INTRODUCTION

B1.1 Background

A variety of factors can influence the physical, chemical, and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Depending on their magnitude, inaccuracy and/or imprecision have the potential to affect the reliability of conclusions made from data; therefore, it is important to ensure that programs incorporate appropriate steps to control non-natural sources of data variability (i.e., minimize variability that does not reflect authentic spatial and temporal variability in the environment) and thus assure the quality of the data. Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. A data quality review (DQR) involves the comparison of field and laboratory measurement performance to Data Quality Objectives (DQOs) established for a particular study, such as evaluation of Laboratory Reporting Limits (LRL), blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). Trusted analytical laboratories certified by the Canadian Association for Laboratory Accreditation (CALA) or the National Environmental Laboratory Accreditation Program (NELAP), with a rigorous internal quality assurance program, were selected to ensure the highest possible data quality. Data quality objectives were established a priori to reflect reasonable and achievable performance expectations. Programs involving many samples and analytes may sometimes yield results that exceed DQOs, which is particularly true for multi-element scans, as the analytical conditions are not necessarily optimal for every element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the parameters fail to meet DQOs. Overall, the intent of a DQR is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of the project.

B1.2 Quality Control Samples

A DQR was conducted on all laboratory data collected as part of the Mount Polley Mine Comprehensive Environmental Monitoring Program (CEMP) 2024 and involves the examination of analytical results associated with several types of Quality Control (QC) samples collected (or prepared) in the field and laboratory. General QC samples collected for this project, and a description of each, include the following:

- **Blanks** are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed in the same way as regular samples. These samples will reflect any contamination of samples occurring in the field (in the case of field or trip blanks) or in the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be non-detectable.
- **Laboratory Duplicates** are replicate sub-samples created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.
- **Field Duplicates** are samples collected from a randomly selected field station that are homogenized to the extent possible, split and analyzed separately in the laboratory. The duplicate samples are handled and analyzed in an identical manner in the laboratory.
- **Spike Recovery Samples** are created in the laboratory by adding a known amount/concentration of a given analyte (or mixture of analytes) to a randomly selected test sample previously divided to create two sub-samples. The spiked and regular sub-samples are then analyzed in an identical manner. The spike recovery represents the difference between the measured spike amount (total amount in the spiked sample minus the amount in the original sample) relative to the known spike amount (as a percentage). Two types of spike recovery samples are commonly analyzed. Spiked blanks (or blank spikes) are created by adding a known concentration of analytes to an uncontaminated blank (e.g. resin gel, distilled water) whereas matrix spikes (MS) are created using field-collected samples. The analysis of spiked samples provides an indication of the accuracy of analytical results.
- **Certified Reference Materials (CRM) or Reference Materials (RM)** are commercially prepared (or commercially homogenized) samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to target results to provide a measure of analytical accuracy. The results are reported as the percent of the known concentration that was recovered in the analysis.
- **Laboratory Control Samples** are created in the laboratory to have a known analyte concentration in a matrix free of interferences, such as deionized water or reference sand. The sample results are compared to the target results to confirm that the analytical method is accurate in a purified reference sample. The results are reported as the percent of the known concentration that was recovered in the analysis.

- **Reference Toxicant Tests** are toxicity tests run concurrent to the sediment toxicity test where a reference toxicant with laboratory-developed limits are used. The results of the reference toxicant testing should fall within the developed limits. This testing ensures that internal test systems are in check and that the sensitivity of the test organisms are within an expected range.

- **Laboratory Sorting Duplicates** are randomly selected grabs of the initially sorted community material from benthic invertebrate, zooplankton, or phytoplankton samples. These samples are recounted to determine the number (benthic invertebrates) or density (zooplankton, phytoplankton, and periphyton) of organisms that were not recovered during the initial sort. In order to reduce bias, the recount was conducted by an analyst uninvolved in the initial sample processing. This check was performed on 10% of samples and measures laboratory accuracy through assessment of recovery (sorting) efficiency and quantifies any under-estimation of organism enumeration.

- **Taxonomic Quality Control Samples** were measured on 10% of community (benthic invertebrate, plankton, and periphyton) samples, which were assessed by the laboratory through an internal quality control audit. A blind re-enumeration and re-identification of random samples is performed by an analyst uninvolved in the original sample processing. This assessment quantifies taxonomic misidentification among laboratory analysts and ensures accurate organism identities are reported.

- **Laboratory Subsamples** are community samples prepared by the laboratory to ensure that the fraction of the total sample examined was an accurate representation of the total number of organisms. By comparing the amount recovered between at least two sub-samples, one can assess the analytical precision. In addition, comparisons of the sub-samples from the whole community sample allows for an evaluation of sub-sampling accuracy.

B2 WATER QUALITY

B2.1 Laboratory Reporting Limits

The analytical reports for water quality from ALS Environmental (ALS; VA24B4763, VA24B8050, VA24B8516, VA24C0557, VA24C1387, VA24C1718, VA24C2066, and VA24C2329; Appendix G) were examined to determine which analytes had results below the LRL. The LRLs for water quality analytes were assessed relative to existing British Columbia water quality guidelines (BCWQG; BCMOWLRS 2024, 2025). For analytes with results <LRL, all reported LRLs were lower than applicable BCWQG guidelines (Appendix Table B.1).[1] Overall, the achieved LRLs were appropriate for this study.

B2.2 Laboratory and Field Blanks

Method blank (MB) samples were analyzed in the ALS laboratory reports (VA24B4763, VA24B8050, VA24B8516, VA24C0557, VA24C1387, VA24C1718, VA24C2066, and VA24C2329; Appendix G). Of the 638 reported MB results, only one result for dissolved sodium (VA24C2329; Appendix G) exceeded the laboratory DQO and had detectable concentrations. However, results for these analytes were considered reliable by the laboratory, as they were greater than five-times the detected MB result. As a relatively low number of MBs exceeded the laboratory DQO (0.157%), and the MB results were not likely to impact the reliability of the results, these laboratory flags had a negligible impact on data reliability.

One field blank (VA24B8516; Appendix G) and one trip blank (VA24B8050; Appendix G) sample were submitted to ALS for water quality analyses to assess the potential for field sampling and shipping/transport contamination. Field and trip blanks were subject to the same laboratory DQOs as were used for MBs (i.e., concentrations should be <LRL). All analytes in the field and trip blank samples were below detection, indicating no discernible field sampling or shipping/transportation contamination.

B2.3 Data Precision

A total of 15 laboratory duplicate samples were used to evaluate precision within the ALS laboratory reports (VA24B4763, VA24B8050, VA24B8516, VA24C0557, VA24C1387, VA24C1718, VA24C2066, and VA24C2329; Appendix G). All 634 individual analyte results

[1] Tables only include constituents with at least one result below the LRL or where the LRL was above guidelines. This applies to all other LRL tables for this report.

Table B.1: Laboratory Reporting Limit (LRL) Evaluation for Water Quality Results Relative to BCWQG, MPMC CEMP, 2024

Constituent	Units	British Columbia Water Quality Guidelines[a]		Range of LRLs	No. Sample Results < LRL

Notes: LRL = Laboratory Reporting Limit. '-' indicates no applicable guideline exists. Only constituents with one or more result <LRL or LRLs above applicable guidelines are displayed. The total number of samples assessed (n) was 35 including 5 duplicate samples.

[a] British Columbia Water Quality Guidelines (BCWQG; BCMOWLRS 2024, 2025).

[b] Ammonia guidelines used tables in BCMOWLRS 2025, based on most conservative guideline (Temperature = 6, pH = 9).

[c] Hardness - Hardness-based guidelines calculated using the minimum hardness observed for all samples (45.6 mg/L)

met the laboratory DQO, and therefore laboratory analytical precision was considered acceptable for this study.

All measurements were within the laboratory DQO, indicating that the laboratory analytical precision can be considered excellent.

Field sampling precision looks at relative percent difference (RPD), calculated as follows:

$$RPD = \frac{|R1 - R2|}{(|R1 + R2|/2)} * 100$$

Where R1 is the value of the original ("parent") sample and R2 is the value of the duplicate sample, with the absolute difference and sum of the two samples used. RPDs cannot be calculated if both values are below the LRL. If the original and duplicate sample have the same value, then the RPD is 0%.

There are two applicable DQOs for field duplicates:

1. Each RPD comparison between the original and duplicate result should be ≤ 30%; and,
2. Within each original and duplicate pairing (i.e., each duplicate pair), fewer than 20% of the total comparisons should be above the DQO as outlined above.

Five field duplicate samples were collected to assess water quality field sampling precision (Appendix Table B.2). Several RPDs were not calculated as both analyte concentrations were below the LRL. Of the 242 RPDs that were calculated, only 13 results did not meet the DQO of 30%, including one result for each of dissolved selenium, total copper, total iron (primary analytes of interest), three results for dissolved cadmium, and one result for each of total cadmium and dissolved manganese (secondary analytes of interest; Appendix Table B.2). Of the 13 results, three RPDs were above 30% due to one result in the pair being below the LRL, where greater variability is expected. Additionally, the RPDs for these analytes were not consistently above the DQO across duplicate pairs (Appendix Table B.2). High RPDs could be a result contamination (field or laboratory; see section B2.6). Overall, as only 5.37% of all water quality duplicate comparisons did not meet the DQO, field precision and reproducibility of these samples were considered acceptable for this study.

B2.4 Data Accuracy

Data accuracy was evaluated based on results of Laboratory Control Samples (LCS) and Matrix Spike (MS) samples within the ALS laboratory reports (VA24B4763, VA24B8050, VA24B8516, VA24C0557, VA24C1387, VA24C1718, VA24C2066, and VA24C2329; Appendix G). All 645 individual LCS analyte results met the laboratory DQO. Out of 587

Value did not meet the data quality objective of≤ 30% Relative Percent Difference (RPD).

Notes: Relative Percent Difference (RPD) was calculated using the LRL if one result in a duplicate pair was below the LRL. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated. LRL = Laboratory Reporting Limit.

individual MS analyte results, only one individual MS result for dissolved silver could not be reliably calculated due to instability in the sample matrix, although the reported result was below detection and was considered reliable (VA24C1387; Appendix G). As all LCS results met the DQO and only 0.17% of MS results did not meet the DQO, the accuracy achieved by the laboratory was considered acceptable for this study.

B2.5 Hold Times

The recommended hold times were exceeded for pH (15 minute hold time) in all samples and for turbidity (three days) in 11 samples (see Appendix G). However, *in situ* pH measures were used for data interpretation and turbidity values were not included in data analysis. As such, hold time exceedances for these laboratory results had no impact on data interpretability. Additional hold time exceedances were observed for dissolved orthophosphate, nitrite, and nitrate (recommended hold times of three days [36 hour hold time]). Dissolved orthophosphate was exceeded by two days in 14 samples (see laboratory reports VA24C1387, VA24C1718, VA24C2066; Appendix G). Recommended hold times for nitrite and nitrate were each exceeded by one to two days in 16 samples (see laboratory reports (VA24C4763, VA24C1387, VA24C1718, VA24C2066; Appendix G). These hold time exceedances were a result of multiple factors, including short hold times, remote work location, and delays in the sample processing/ analysis at the receiving laboratory due to workload. Analyte results with hold time exceedances were similar to those samples without hold time exceedances in 2024 and were within the range of historic results, suggesting little if any impact of the hold time exceedances on analyte results.

B2.6 Other Concerns

Results for several analytes showed dissolved concentrations that were greater than the corresponding total concentrations in some samples. Differences were less than two-times the concentration of total analytes in most cases, except for one sample where dissolved cadmium was two times greater than the total concentration (VA24B4763; Appendix G), and one sample where dissolved selenium was one and a half times greater than the total concentration (VA24C0557; Appendix G). All results were verified by repeat analysis. A higher concentration of dissolved metals compared to total could be a result of contamination (field or laboratory).

B2.7 Data Quality Statement

Water quality data collected for the 2024 CEMP were considered acceptable for this study as characterized by good detectability, appropriate LRLs, negligible analyte concentrations in MBs, good laboratory precision and accuracy, and few hold time exceedances. One or more

results for primary analytes (dissolved selenium, total copper, total iron) and secondary analytes (dissolved cadmium, total cadmium, and dissolved manganese) did not meet the DQO in field duplicate samples. For a subset of samples, hold time exceedances occurred for orthophosphate, nitrate, and nitrite, but results were within the range of similar samples, suggesting that hold time exceedances had little, if any impact on analyte results. Therefore, the 2024 water quality data can be used with a good level of confidence for interpretation.

B3 SEDIMENT QUALITY

B3.1 Laboratory Reporting Limits

The analytical ALS laboratory reports for sediment quality (VA24C0980, VA24C2399, and VA24C2503; Appendix G) were examined to determine which analytes had one or more results below the LRL. The range of reported LRLs for these analytes were assessed relative to applicable British Columbia Working Sediment Quality Guidelines (BCWSQG; BCMOWLRS 2024, 2025; Appendix Table B.3). Total nitrogen, total sulphur, bismuth and boron, and thallium all had at least one result below the LRL. For these analytes, 5% to 21% of samples were below the LRL; however, these analytes do not have associated guidelines (i.e., all analytes with associated guidelines were detectable above the LRL; Appendix Table B.3). Therefore, the achieved LRLs were appropriate for this study.

B3.2 Laboratory Blanks

Laboratory MB samples were analyzed in the ALS laboratory reports (VA24C0980, VA24C2399, and VA24C2503; Appendix G). All 186 reported MB results met the laboratory DQO, indicating no inadvertent contamination within the laboratory.

B3.3 Data Precision

A total of 12 laboratory duplicate samples were used to evaluate precision in the ALS laboratory reports (VA24C0980, VA24C2399, and VA24C2503; Appendix G). All the 191 analyte results met the laboratory DQO for laboratory duplicates, and thus the laboratory analytical precision was considered acceptable for this study.

A total of six field duplicate samples were collected to assess sediment quality field sampling precision (Appendix Table B.4; see Section B.2.3 for explanation on RPD calculation and DQOs). Some RPDs were not calculated as both analyte concentrations were below the LRL. Of the 235 comparisons that were calculated, only eight RPDs exceeded the DQO of 30% (Appendix Table B.4). These DQO exceedances include three comparisons for particle size composition (% sand), and one comparison each of total nitrogen, antimony, mercury, tin, and zirconium. Fewer than 20% of analytes within each duplicate pair exceeded the 30% DQO. Exceedances of the DQO exceedances may be attributed to variability during the multi-element scan as well as subtle differences in the distribution of fine particulate matter (and associated analytes) amongst split samples that may exist even after homogenization in the field. As only 3.40% of all comparisons exceeded the DQO, sample precision and reproducibility were considered acceptable for this study.

Table B.3: Laboratory Reporting Limits (LRLs) for Sediment Quality Results, MPMC CEMP, 2024

Constituent	Units	Range of LRLs	No. Sample Results < LRL
Anions and Nutrients			
Nitrogen (N)-Total	%	0.0200	3 (5%)
Sulphur (S)-Total	mg/kg	500	7 (11%)
Metals, Metalloids, and Non-metals			
Bismuth	mg/kg	0.100	8 (12%)
Boron	mg/kg	5.00	14 (21%)
Thallium	mg/kg	0.0500	3 (5%)

Notes: LRL = Laboratory Reporting Limit. Only constituents with one or more results < LRL or LRLs above applicable guidelines are displayed. The total number of samples assessed (n) was 66, including six duplicate samples.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were <LRL. RPD = relative percent difference. "-" = not calculated. LRL = Laboratory Reporting Limit.

B3.4 Data Accuracy

Data accuracy for sediment quality analyses completed by ALS was evaluated based on the analysis of LCS and reference material (RM) samples. All 192 individual LCS met the laboratory DQO. Of the 177 individual RM analyte results, one individual bismuth result was marginally above the DQO (see laboratory report VA24C2399; Appendix G). As fewer than 10% of analyte results in the multi-elemental scan, the results were considered acceptable by the laboratory[2]. Overall, accuracy achieved by the laboratory was acceptable for this study.

B3.5 Hold Times

Seventeen samples exceeded the recommended hold times for total nitrogen analysis by one to three days due to a delay between sample receipt at the analytical laboratory and sample processing date (VA24C0980; Appendix G).

B3.6 Other Concerns

The measurement uncertainty for particle size analysis was higher than usual due to limited sample availability in 13 lake sediment samples (VA24C2503; Appendix G). The minimum standard sample size is 100g, which can be difficult to achieve when samples have high moisture content. High moisture content is difficult to manage in the field as decanting excess water may lead to loss of important sample material (i.e., fine sand, silt, and/or clay particles in which metals are known to accumulate). However, particle size results were similar among replicate samples and were comparable to those from previous years. As such, the effect of limited sample volume on particle size measurements was considered negligible. Future monitoring efforts will implement strategies to try and avoid the uncertainty associated with particle size analysis (e.g., collection of additional sample material if available, or alternate laboratory processing approaches.[3]

B3.7 Data Quality Statement

Sediment quality data collected for the 2024 CEMP were considered acceptable for this study as characterized by appropriate LRLs, appropriate detectability, negligible concentrations in method blank samples, excellent laboratory and field sampling precision, and excellent

[2] Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).

[3] Additional jars of sediment were collected in 2024 to provide sufficient sample volume for particle size analysis (i.e., one two jars for particle size instead of one) following similar flags in the 2023 data quality review; however, sample volume in 2024 was still limited due to high moisture content in samples. The ALS Burnaby laboratory manager proposed adjusting logistics so that that future sediment quality samples are processed at a single analytical laboratory location (i.e., ALS Saskatoon) to allow the analytical laboratory to manage sample weights more efficiently.

laboratory accuracy. Although measurement uncertainty for particle size analysis was higher in sediment samples due to low sample volumes, most particle size results were within range of historic results. Most laboratory quality control samples met the internal DQOs, and overall, the associated data can be used with a high level of confidence in the derivation of conclusions.

B4 SEDIMENT TOXICITY

Sediment toxicity testing was completed by Nautilus Environmental. During the 2024 sediment toxicity, an insufficient number of test organisms was used for the *C. dilutus* test, which resulted in a separate batch of test organisms being used between tests for MP_BOL-B2 compared to MP_POL-P2 and MP_POL-P1. Data interpretation and statistical approaches are outlined in Section 3.2.3 of the present CEMP report.

B4.1 Laboratory Control

Sediment toxicity test laboratory controls met the acceptable criteria and water quality requirements of the Environment Canada protocols (Nautilus Environmental 2024; Appendix G). Sediment toxicity data were considered of excellent quality for data interpretation.

B4.2 Reference Toxicants

The results of the reference toxicant (KCl) on *Hyallela azteca* and *Chironomus dilutus* produced toxicity endpoints that met the passing control criterion of ≥80% survival and ≥0.1 mg/amphipod weight for *H. azteca* and ≥70% survival and ≥0.6 mg/worm dry weight for *C. dilutus*. The results for the test were within the acceptable range of organism performance (mean LC_{50} within two standard deviations of historical laboratory values; Nautilus Environmental; Appendix G). Most water quality parameters remained within acceptable ranges throughout the tests except for pH for QUL-LREF1 and QUL-LREF1, which exceeded a pH of 8.0 by a small margin for most tests (Nautilus 2024; Appendix G). For *H. azteca* testing, pH ranged from 7.7 to 8.3 in the control sediment test vessels, 7.9 to 8.3 in the QUL-LNF1 test vessels, and 7.5 to 8.1 in the QUL-LREF1 test vessel. For *C. dilutus* testing, pH ranged from 7.4 to 8.2 in the control sediment test vessels. For Polley Lake and Bootjack Lake test vessels, pH ranged from 7.8 to 8.1 (POL-P1 and POL-P2) and 7.2 to 7.9 (BOL-B2; Nautilus 2024; Appendix G). For Quesnel Lake test vessels, pH ranged from 7.9 to 8.3 (QUL-PNF) and 6.9 to 7.9 (QUL-PREF1). Despite this, examination of laboratory bench sheets indicated that temperature, dissolved oxygen, conductivity, and pH were all stable over the course of the toxicity tests. Reference toxicant test results fell within the acceptable range and therefore the sensitivity of test organisms was appropriate (Nautilus 2024; Appendix G). All ammonia concentrations were at levels that are not expected to cause adverse effects to *H. azteca*.

B4.2 Overlying Water Chemistry

As part of the sediment toxicity sampling, water samples were sent from Nautilus Environmental to ALS Environmental for analysis of dissolved organic carbon (DOC), dissolved copper, and ammonia (WT2430256, Appendix G). Laboratory MB samples for DOC did not meet the DQO and had detectable concentrations. However, all DOC results were greater than five-times the detected MB result and was therefore considered reliable by the laboratory. Additionally, LRLs were adjusted for dissolved copper results due to matrix interference, but all dissolved copper results were above LRL.

B4.4 Data Quality Statement

Based on acceptability criteria, water quality requirements of the Environment Canada protocols and reference toxicant test results, data from sediment toxicity tests can be used with a good degree of confidence in the 2024 CEMP.

B5 PLANKTON COMMUNITY AND PRODUCTIVITY

B5.1 Laboratory Reporting Limits

The analytical ALS laboratory reports for phytoplankton productivity were examined to assess the LRLs for chlorophyll-a results (VA24B6518, VA24B8959, and VA24C2323; Appendix G). All individual measures of chlorophyll-a were above the LRL and, as such, no table was presented for phytoplankton productivity LRLs. The achieved LRLs were appropriate for the study.

B5.2 Laboratory Blanks

A total of five MB samples were analyzed in the ALS laboratory reports for phytoplankton productivity (VA24B6518, VA24B8959, and VA24C2323; Appendix G). All chlorophyll-a results met the laboratory DQO, indicating that no inadvertent laboratory contamination occurred.

B5.3 Data Precision

Laboratory precision was not assessed for chlorophyll-a as the entire sample must be consumed for analysis. Three field duplicate samples were collected to assess the precision of field sampling for chlorophyll-a (Appendix Table B.5; see Section B.2.3 for explanation on RPD calculation and DQOs). All RPDs met the DQO of 30%. Therefore, the field precision and reproducibility of chlorophyll-a samples were acceptable for this study.

B5.4 Data Accuracy

Chlorophyll-a accuracy was evaluated based on results of five LCS samples which all met the laboratory DQO (VA24B6518, VA24B8959, and VA24C2323; Appendix G). The accuracy achieved by the laboratory was considered acceptable for this study.

B5.5 Hold Times

Chlorophyll-a samples were field filtered and frozen before shipment to the laboratory for analysis to prolong recommended hold times[4]. The recommended hold time (28 days) for phytoplankton chlorophyll-a was exceeded in three samples by one day (see laboratory report VA24B6518; Appendix G). The hold time exceedance was due to a delay between sample receipt at the analytical laboratory and sample analysis. As only 7.14% of samples

[4] Aqueous (non-filtered) chlorophyll-a has a recommended hold time of 48 hours which was often exceeded in earlier years of sampling (e.g, Minnow 2022a).

Table B.5: Field Duplicate Results for Phytoplankton Chlorophyll-a, MPMC CEMP, 2024

Constituent	Unit	MP_POL-P2_CHLA-2_2024-07	MP_POL-P2_CHLA-2X_2024-07	RPD (%)	MP_QUL-ZOO-1_CHLA-1_2024-06	MP_QUL-ZOO-1_CHLA-1X_2024-06	RPD (%)	MP_QUL-ZOO-7_CHLA-1_2024-08	MP_QUL-ZOO-7_CHLA-1X_2024-08	RPD (%)
Chlorophyll-a	µg/L	1.24	1.09	12.9	0.796	0.885	10.6	0.652	0.788	18.9

Note: µg/L = micrograms per litre.

exceeded the recommended hold time, and results were within historic range, any impact on data interpretability there was considered negligible.

Plankton community samples were preserved at the end of each field day and were processed by the analytical laboratory within hold times (as applicable).

B5.6 Phytoplankton Density Accuracy

Phytoplankton density was re-analyzed in 10% of all samples (i.e., three samples) to evaluate sub-sampling accuracy and enumeration precision, as outlined in laboratory methods report (fp24-169, Appendix G). Since there was a high percent of agreement between the quality control samples (mean = 90.8%), the laboratory subsampling precision and reproducibility was considered acceptable for this study (Appendix Table B.6).

B5.7 Zooplankton Abundance Accuracy

Zooplankton density was re-analyzed in 10% of all samples (i.e., four samples) to evaluate sub-sampling accuracy and taxonomic consistency, outlined in the laboratory methods report (10% of all samples; fz24-169, Appendix G). Since there was a high percent of agreement between the duplicate pairs (mean = 91.6%), the laboratory subsampling precision and reproducibility was considered acceptable for this study (Appendix Table B.7).

B5.8 Data Quality Statement

Plankton community data collected for the 2024 CEMP were considered acceptable for this study as characterized by good sub-sampling accuracy. Additionally, productivity measurements (chlorophyll-a) results were characterized by appropriate LRLs, excellent detectability, negligible analyte concentrations in MBs, good laboratory precision, and good laboratory accuracy. Therefore, the associated data can be used with a good level of confidence in the derivation of conclusions.

Table B.6: Percent Agreement for Freshwater Phytoplankton Community Samples, MPMC CEMP, 2024

[a] Percent agreement calculated as: (100- [(difference in abundance between samples) / total abundance of original sample)] *100)%.

B6 ZOOPLANKTON TISSUE QUALITY

B6.1 Laboratory Reporting Limits

The analytical ALS laboratory reports for zooplankton tissue quality (VA24C2311, VA24B6519, VA24C0701; Appendix G) were examined to provide an inventory of analytes for which sample results were less than the LRL. The maximum LRLs for these analytes were assessed relative to existing guidelines, which were only available for selenium (BC interim guideline for benthic invertebrate tissue [4 mg/kg]; BCMOE 2014). Selenium LRLs were all well below the BC interim guideline. The LRLs were adjusted for several analytes across samples due to high moisture content, due to dilution during the laboratory analysis process, or due to small sample volumes[5]. As all selenium LRLs were below the available guideline for selenium (Appendix Table B.8), the achieved LRLs were appropriate for the study.

B6.2 Laboratory Blanks

Laboratory MB samples were analyzed in the ALS laboratory reports (VA24C2311, VA24B6519, VA24C0701; Appendix G). All 259 individual analyte results met the laboratory DQO, indicating no inadvertent laboratory contamination.

B6.3 Data Precision

Two laboratory duplicate samples were used to evaluate precision within the ALS laboratory report (VA24C0701, VA24C2311; Appendix G). Of the 38 individual laboratory duplicate results, two did not pass the laboratory DQO due to sample heterogeneity. This included one duplicate result each for barium and cadmium (VA24C0701; Appendix G). As only 5.26% of laboratory duplicate results exceeded the laboratory DQO, laboratory precision and reproducibility were considered acceptable for this study.

A total of three field duplicate samples were collected to assess field sampling precision and reproducibility in zooplankton tissue (Appendix Table B.9; see Section B.2.3 for explanation on RPD calculation and DQOs). Several RPDs were not calculated as both analyte concentrations were below the LRL. Replicability was poor in zooplankton tissue field duplicate samples collected in July and August, as 32.3% and 22.2% of calculable analyte comparisons exceeded the DQO of 30% (Appendix Table B.9). The RPDs for nickel and tin (both secondary analytes of interest) exceeded the DQO in both July and August measured duplicate pairs. In contract, the duplicate pair in June had excellent agreement, with only one analyte

[5] Zooplankton tissue samples can be time intensive to collect and there is sometimes a trade-off between sampling effort and amount of sample due to timing restraints. In addition, once the samples are prepared for analysis at the laboratory, sample volume might be reduced (due to drying, transfer etc.).

Table B.8: Laboratory Reporting Limits (LRLs) for Zooplankton Tissue Quality Results, MPMC CEMP, 2024

Constituent	Units	Guidelines	Range of LRLs	No. Sample Results < LRL
Metals				
Antimony	mg/kg	-	0.0100 to 0.116	1 (3%)
Beryllium	mg/kg	-	0.0100 to 0.0580	10 (32%)
Bismuth	mg/kg	-	0.0100 to 0.0580	17 (55%)
Boron	mg/kg	-	1.00 to 7.70	10 (32%)
Cesium	mg/kg	-	0.00500 to 0.0290	2 (6%)
Chromium	mg/kg	-	0.200 to 1.16	3 (10%)
Lead	mg/kg	-	0.0500 to 0.290	3 (10%)
Lithium	mg/kg	-	0.500 to 2.90	17 (55%)
Mercury	mg/kg	-	0.00500 to 0.158	6 (19%)
Molybdenum	mg/kg	-	0.0400 to 0.232	2 (6%)
Nickel	mg/kg	-	0.200 to 1.16	2 (6%)
Selenium	mg/kg	4.00	0.100 to 0.580	2 (6%)
Silver	mg/kg	-	0.00500 to 0.0290	3 (10%)
Tellurium	mg/kg	-	0.0200 to 0.116	28 (90%)
Thallium	mg/kg	-	0.00200 to 0.0154	6 (19%)
Tin	mg/kg	-	0.100 to 0.580	9 (29%)
Zirconium	mg/kg	-	0.200 to 2.00	9 (29%)

Notes: LRL = Laboratory Reporting Limit. Only constituents with one or more results < LRL or LRLs above applicable guidelines are displayed. The total number of samples assessed (n) was 31, including 3 duplicate samples.

[a] British Columbia guideline for the protection of aquatic life (for invertebrate tissue; BCMOE 2014).

Table B.9: Field Duplicate Results for Zooplankton Tissue Analyses, MPMC CEMP, 2024

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were <LRL. RPD = relative percent difference. "-"= no data/not calculated. LRL = Laboratory Reporting Limit. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight.

(antimony) that exceeded the DQO (i.e., 4.8% of comparisons; Appendix Table B.9). Differences in the agreement of field duplicate pairs are likely the result of natural variability in community composition, which may vary among seasons, and variability associated with multi-element scans. Results were confirmed by reanalysis for samples with sufficient remaining mass. These discrepancies will be taken into consideration during interpretation.

B6.4 Data Accuracy

Data accuracy was evaluated based on the results of LCS samples and RM samples (VA24C2311, VA24B6519, VA24C0701; Appendix G). The laboratory added an incorrect amount of standard in one sample lot, which resulted in elevated LCS results; however, the corresponding RM results remained within QC limits, confirming the reported results (VA24C0701; Appendix G). As such, the LCS and RM samples from laboratory report VA24C0701 were not evaluated for data accuracy. The LCS and RM samples from the remaining laboratory reports were evaluated for data accuracy, and all 218 LCS and 160 RM results met the laboratory DQO (VA24C2311, VA24B6519; Appendix G). As all viable LCS and RM results met the laboratory DQO, the accuracy achieved by the laboratory was considered acceptable for this study.

B6.5 Hold Times

Recommended hold times were met for all zooplankton tissue samples (VA24C2311, VA24B6519, VA24C0701; Appendix G).

B6.6 Other Concerns

Concentrations of several analytes, including copper, a primary analyte of interest, were elevated in one sample (MP_POL-P2_ZOOT-1_2024-06; see laboratory report VA24B6519; Appendix G) when results were compared to historic concentrations in zooplankton tissue collected at the same station and time of the year. Laboratory reanalysis confirmed the original reported data. Analyte concentrations that were above historic values could be a result of field or laboratory contamination.

B6.7 Data Quality Statement

Zooplankton tissue quality collected as part of the 2024 CEMP were considered acceptable for this study as characterized by appropriate detection limits, no detectable concentrations in MBs, and good laboratory precision. Poor field replicability will be considered during data interpretation, as samples collected in July and August both exceeded the 30% DQO for RPDs between field duplicates. Overall, zooplankton tissue quality collected as part of the

2024 CEMP can be used with a good level of confidence in the derivation of conclusions, provided that natural variability is considered.

B7 PERIPHYTON COMMUNITY AND PRODUCTIVITY

B7.1 Laboratory Reporting Limits

Periphyton productivity was assessed through collection of ash free dry mass (AFDM) and chlorophyll-a results were examined to provide an inventory of analytes that were less than the LRL (VA24C1399; Appendix G). All AFDM and chlorophyll-a results were above the LRL and, as such, no table was presented for periphyton productivity LRLs. The achieved LRLs were appropriate for the study.

B7.2 Laboratory Blanks

Four MB samples were analyzed in the ALS Laboratory Report (VA24C1399; Appendix G). All eight results for dry weight, ash weight, ash free dry weight, and chlorophyll-a met the laboratory DQO. Therefore, laboratory contamination had no impact on the results.

B7.3 Data Accuracy

Accuracy of periphyton productivity endpoints was evaluated based on results of four LCS. All eight results met the laboratory DQO (VA24C1399; Appendix G). Therefore, accuracy achieved by the laboratory in this study was considered acceptable for this study.

B7.4 Data Precision

Laboratory precision was not assessed for periphyton productivity (i.e., ash free dry mass and chlorophyll-a) as the entire sample must be consumed for analysis. No field duplicates were collected due to the high inherent natural variability. The level of replication (n=5) at each monitoring area was considered sufficient for this study.

B7.5 Hold Times

The recommended hold time (28 days) for periphyton chlorophyll-a was exceeded in three samples by one day (see laboratory report VA24C1399; Appendix G). The hold time exceedance was due to a delay between sample receipt at the analytical laboratory and sample analysis. As only 12% of samples exceeded the recommended hold time, and results were within historic range, any impact on data interpretability there was considered negligible.

Periphyton community samples were preserved at the end of each field day and were processed by the analytical laboratory within hold times (as applicable).

B7.6 Subsampling Precision

Periphyton density was re-analyzed in 10% of total samples (i.e., two samples) to evaluate precision of enumeration and taxonomic agreement, as outlined in the laboratory methods (pp24-169; Appendix G). As there was a high percent of agreement between the duplicate pairs (mean = 94.5%) the samples were considered to have good laboratory subsampling precision and reproducibility (Appendix Table B.10).

B7.7 Data Quality Statement

Periphyton productivity measurements (ash free dry weight and chlorophyll-a) results had appropriate LRLs, were of acceptable detectability, and demonstrated good laboratory precision and laboratory accuracy. Productivity measurements (ash free dry weight and chlorophyll-a) results had appropriate LRLs, were of acceptable detectability, and demonstrated good laboratory precision and laboratory accuracy. Additionally, community data collected for the 2024 CEMP were of acceptable quality as characterized by good enumeration precision. Therefore, the associated data can be used with a high level of confidence in the derivation of conclusions.

Table B.10: Percent Agreement for Freshwater Periphyton Community Samples, MPMC CEMP, 2024

Sample ID	Laboratory ID	Original Density	Quality Assurance Density	Percent Agreement[a] (%)
MP_HAC-U-PERC-2_2024-08	pp24-169-055	804,808	892,598	89.1
MP_EDC-U-PERC-2_2024-08	pp24-169-060	1,782,268	1,779,222	99.8
			Average	**94.5**

[a] Percent agreement calculated as: (100- [(difference in abundance between samples) / total abundance of original sample)] *100)%.

B8 BENTHIC INVERTEBRATE COMMUNITY

B8.1 Sorting Efficiency

The analytical laboratory reports for benthic invertebrate community composition (Appendix G) were assessed for the organism sorting efficiency relative to the laboratory's DQO (≥ 90%) in four samples (Appendix Table B.11). One of the lake benthic invertebrate samples (MP_QUL-PFF1_PON-2_2024-08; Appendix G) did not meet the laboratory DQO for sorting efficiency; however, this may be attributed to the low number of organisms recovered from the initial sort (25 organisms). Despite this, the average recovery was 95.1% and so organism sorting efficiency was considered acceptable[6].

B8.2 Subsampling Precision and Accuracy

Of the 55 benthic invertebrate community samples analyzed, 26 were subsampled. Of those 26 samples, the proportion of sample sorted ranged from 5% to 50% of the total sample material (Appendix Table B.12). Five samples (i.e., 9% of all samples) were assessed for precision and accuracy. All assessed samples met the laboratory DQO (<20%) for both precision and accuracy (Appendix Table B.13). Thus, the precision and accuracy for sub-sampling of the benthic invertebrate community samples was considered acceptable for this study.

B8.3 Taxonomic Identification Accuracy

The laboratory performed an internal audit of taxonomic identification for six samples (11% of all samples; Appendix Table B.14). The analysts reported total identification error rate (TIR) of 0%, percent difference in enumeration (PDE) of 0 to 0.288%, percent taxonomic disagreement (PTD) of 0% to 1.437%, and Bray Curtis Dissimilarity Index (BCDI, a measure of the differences in identifications between different analysts) of 0 to 0.012 (Appendix Table B.14). All TIRs were below the laboratory DQO (<5% TIR), which is based on CABIN laboratory methods (Environment Canada 2014), so the taxonomic accuracy of analyses was considered acceptable for this study.

B8.4 Data Quality Statement

Benthic community data collected for the 2024 CEMP was considered acceptable for this study as characterized by appropriate sorting efficiency for most samples, excellent subsampling

[6] The analytical laboratory stated: "when a failure of a QC [quality control] occurs, the person who failed is required to go back to all of the samples that they processed and redo [re-check] them to ensure that they are looked at a second time and QC would be passed on those samples".

Notes: TIR = Total Identification Error Rate. PDE = Percent Difference in Enumeration. PTD = Percent Taxonomic Disagreement. BCDI = Bray Curtis Dissimilarity Index to quantify differences in identifications.

[a] For error rationale and calculations, refer to Cordillera report (Appendix G).

precision and accuracy, and excellent taxonomic identification accuracy. One lake benthic community sample did not meet the internal DQO for sorting efficiency, although the lower efficiency rate may be attributed to low abundance in the sample. Overall, the associated data can be used with a high level of confidence in the derivation of conclusions.

B9 PERIPHYTON AND BENTHIC INVERTEBRATE TISSUE QUALITY

B9.1 Laboratory Reporting Limits

One analytical ALS laboratory report for benthic invertebrate and periphyton tissue quality (VA24C1418; Appendix G) was examined to provide an inventory of analytes for which sample results were less than the LRL (Appendix Table B.15). The maximum LRLs for these analytes were assessed relative to existing guidelines, which were only available for selenium (BC interim guideline for benthic invertebrate tissue [4 mg/kg]; BCMOE 2014). Selenium LRLs were all well below the BC interim guideline. As such, the achieved LRLs were appropriate for the study.

B9.2 Laboratory Blanks

A total of 20 MB samples were analyzed in the ALS laboratory report (VA24C1418; Appendix G). Out of the 380 individual results met the laboratory DQO, four results (three for manganese and one for tin) did not meet the DQO and had detectable concentrations. However, results for these analytes were considered reliable by the laboratory, as they were either greater than five-times the detected MB result (manganese results) or below LRLs (tin results). As a relatively low number of MBs exceeded the laboratory DQO (1.14%), and the MB results were not likely to impact the reliability of the results, these laboratory flags had a negligible impact on data reliability.

B9.3 Data Precision

A total of eight laboratory duplicate samples were used to evaluate precision (see laboratory report VA24C1418; Appendix G). Of the 290 laboratory duplicate results, 20 did not pass the laboratory DQO (i.e., 6.90% of all results) due to sample heterogeneity. Laboratory DQOs were not met for the primary analytes selenium and iron (one duplicate result each) and secondary analytes cadmium (two duplicate results), and cobalt, manganese, molybdenum, nickel, phosphorus, silver, titanium, uranium, vanadium and zinc (one duplicate result each). Since these analytes have been identified as strongly indicative (primary) or potentially indicative (secondary) of mine influence, consideration will be given to other quality control samples and interpretation of data. As the overall occurrence of laboratory duplicate DQO exceedances was low, laboratory precision and reproducibility in benthic invertebrate and periphyton tissue was considered acceptable for this study.

Table B.15: Evaluation of Laboratory Reporting Limits (LRLs) in Benthic Invertebrate and Periphyton Tissue Quality Results Relative to Guidelines, MPMC CEMP, 2024

Constituent	Benthic Invertebrate Tissue		Periphyton Tissue	
	Range of LRLs	No. Sample Results < LRL	Range of LRLs	No. Sample Results < LRL
Metals

Mercury	0.00100 to 0.00200	0 (0%)	0.00100 to 0.00200	1 (2%)
Nickel	0.200 to 0.400	19 (18%)	0.200 to 1.09	0 (0%)
Silver	0.00500	18 (17%)	0.00500	7 (13%)
Tellurium	0.0200 to 0.0400	102 (96%)	0.0200 to 0.109	49 (92%)
Thallium	0.00200 to 0.00400	26 (25%)	0.00200 to 0.0109	2 (4%)
Tin	0.100 to 0.200	99 (93%)	0.100 to 0.540	45 (85%)
Titanium	0.500	2 (2%)	0.500 to 0.530	0 (0%)
Uranium	0.00200 to 0.00400	1 (1%)	0.00200 to 0.0109	0 (0%)
Vanadium	0.100 to 0.200	3 (3%)	0.100 to 0.540	0 (0%)
Zirconium	0.200 to 0.400	43 (41%)	0.200 to 1.09	2 (4%)

Notes: Only analytes for which at least one sample was <LRL are displayed. All concentrations are in milligrams per kilogram dry weight (mg/kg dw). The total number of samples in 2024 was 209, which included 15 field duplicate samples.

A total of fifteen field duplicate samples were collected for benthic invertebrate and periphyton tissue (five of each composite-taxa, caddisfly, and periphyton tissue samples) to assess the precision associated with field sampling (Appendix Table B.16; VA24C1418; Appendix G). Please see Section B.2.3 for explanation on RPD calculation and DQOs. Of the 15 duplicate pairs, 13 had >20% of analytes with RPDs >30% including all composite-taxa and caddisfly duplicate sets, and four of five periphyton duplicate sets. All primary and secondary analytes had at least one RPD that exceeded the 30% RPD DQO, with iron (primary analyte), aluminum, barium, calcium, lead, strontium, and zinc (all secondary analytes except for aluminum) exceeding the DQO in over half of the duplicate sets (Appendix Table B.16). This variability is due to sample heterogeneity (e.g., taxonomic variability in composite-taxa samples or natural variability within a single taxon) rather than inconsistent field sampling methods. Reanalysis was requested for four field duplicate pairs[7] and reanalysis results confirmed low agreement (i.e., high RPDs) between parent and duplicate samples, likely due to sample heterogeneity. Field crews strived to split field samples evenly between the parent and duplicate sample containers; however, a perfect split was not always feasible. It should be noted that tissue samples were collected in replicates of eight for each tissue type (periphyton, composite-taxa, and caddisfly) to account for sampling heterogeneity (i.e., a total of 24 samples per sampling area). As a high proportion of all field duplicate analyses exceeded the DQO, these sources of variability will be considered during data interpretation.

B9.4 Data Accuracy

Data accuracy was evaluated based on results of 36 LCS samples and 24 RM samples, which yielded 380 LCS results and 280 RM results (see laboratory report VA24C1418; Appendix G). Of these, one LCS result for titanium and did not meet the DQO. The results are still considered acceptable as the LCS result for titanium exceeded the DQO by a marginal (<10%) amount, and less than 10% of analyte results in the multi-elemental scan exceeded the DQO. As the laboratory DQO was only exceeded in 0.263% of LCS results and all RM results met the laboratory DQO, accuracy achieved by the laboratory was considered acceptable for this study.

[7] There was insufficient sample volume for reanalysis of the duplicate pair VA24C1418-084 and -153 (composite-taxa benthic tissue). Reanalysis of duplicate pairs VA24C1418-096 and-150 (composite-taxa benthic tissue) and VA24C1418-048 and -147 (periphyton tissue) confirmed high variability (i.e., high RPDs) of these duplicate pairs due to sample heterogeneity. For the duplicate pair VA24C1418-132 and -155 (caddisfly tissue), reanalysis results showed better agreement between the duplicate pair but there was no justification for reporting the reanalysis results instead of the original data, therefore the original data were reported.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were <LRL. RPD = relative percent difference. "-" = not calculated. LRL = Laboratory Reporting Limit.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were <LRL. RPD = relative percent difference. "-" = not calculated. LRL = Laboratory Reporting Limit.

B9.5 Hold Times

Recommended hold times were met for all benthic invertebrate and periphyton tissue quality samples (VA24C1418; Appendix G).

B9.6 Data Quality Statement

Benthic and periphyton tissue quality data collected as part of the 2024 were considered acceptable for this study as characterized by good detectability and appropriate LRLs (below the BCMOE guideline for selenium), few detectable analyte concentrations in MBs, and acceptable laboratory accuracy and precision. Field sampling precision, as quantified by calculation of relative percent differences between parent and field duplicate sample results, was relatively low across all tissue types; however, this is likely compensated for by the number of replicate tissue samples. Interpretation of benthic invertebrate and periphyton tissue quality results from the 2024 CEMP should be approached carefully and compared relative to historic results before derivation of conclusions. Several primary and secondary analytes did not meet the DQO in laboratory and field duplicate samples, suggesting natural heterogeneity in sample; however, the study design addressed this variability by targeting eight replicates sampled for each tissue type. These sources of variability will be considered during data interpretation.

B10 FISH TISSUE QUALITY

B10.1 Laboratory Reporting Limits

The analytical ALS laboratory reports for fish tissue quality (VA24B0407, VA24C1393, VA24C9858, VA24C9929, and VA24C9932; Appendix G) were examined to provide an inventory of analytes for which the sample results were less than the LRL. The LRL range for these analytes were also assessed relative to available guidelines, which exist only for mercury (wet weight; CFIA 2015) and selenium (dry weight; BCMOE 2014). Results for several analytes were frequently below the LRL, although all results for mercury (wet weight) and selenium were above LRLs (Appendix Table B.17). All achieved LRLs were below the available guidelines and, as such, the achieved LRLs were appropriate for this study.

B10.2 Laboratory Blanks

Laboratory MB samples were analyzed in the ALS laboratory reports (VA24B0407, VA24C9858, VA24C9932, VA24C1393 and VA24C9929; Appendix G). Of the 1,138 individual MB results, only two did not meet the laboratory DQO and include one result for each of zirconium and manganese, and LRLs were raised for associated samples (see laboratory reports VA24C0407, VA24C9858; Appendix G). Only 0.18% of results did not meet the laboratory DQO, indicating minimal inadvertent laboratory contamination.

B10.3 Data Precision

A total of 30 laboratory duplicate samples were used to evaluate laboratory precision (see laboratory reports VA24B0407, VA24C9858, VA24C9932, VA24C1393 and VA24C9929; Appendix G). Of the 847 duplicate pair results, 30 did not meet the laboratory DQO due to sample heterogeneity (laboratory reports VA23B1226 and VA23B4184; Appendix G). This included four results for iron (a primary analyte), two results each for aluminum, manganese, and uranium, and one result each for barium, cadmium, chromium, copper, and strontium (all secondary analytes except for aluminum and chromium). As only 1.79% of laboratory duplicate samples exceeded the laboratory DQO, laboratory precision and reproducibility were considered acceptable for this study.

A total of 27 field duplicate samples were collected to assess field sampling precision (Appendix Table B.18), with 12 field duplicate samples collected during the spring fish tissue monitoring program and 15 field duplicate samples collected during the fall fish tissue monitoring program. Spring fish tissue samples included three of each tissue type (muscle, ovary, liver, kidney) from longnose sucker and rainbow trout captured (Polley and Bootjack Lakes), while fall samples included either three (ovary) or four (muscle, liver, kidney)

Table B.17: Evaluation of Laboratory Reporting Limits (LRL) in Fish Tissue Quality Results, MPMC CEMP, 2024

Analyte	Units	Range of LRLs	No. Sample Results < LRL
Metals			
Aluminum	mg/kg	2.00 to 6.70	124 (37%)
Antimony	mg/kg	0.0100 to 0.0270	296 (88%)
Arsenic	mg/kg	0.0200 to 0.0670	4 (1%)
Barium	mg/kg	0.0500 to 0.0670	39 (12%)
Beryllium	mg/kg	0.0100 to 0.0130	335 (99%)
Bismuth	mg/kg	0.0100 to 0.0130	315 (93%)
Boron	mg/kg	1.00 to 1.80	335 (99%)
Cadmium	mg/kg	0.00500 to 0.0130	101 (30%)
Chromium	mg/kg	0.0500 to 0.270	142 (42%)
Cobalt	mg/kg	0.0200 to 0.0270	48 (14%)
Lead	mg/kg	0.0200 to 0.0670	251 (74%)
Lithium	mg/kg	0.500 to 0.670	336 (99%)
Mercury	mg/kg	0.00500 to 0.0942	6 (2%)
Molybdenum	mg/kg	0.0200 to 0.0540	74 (22%)
Nickel	mg/kg	0.200 to 0.270	228 (67%)
Silver	mg/kg	0.00500 to 0.00670	154 (46%)
Tellurium	mg/kg	0.0200 to 0.0270	313 (93%)
Thallium	mg/kg	0.00200 to 0.00360	50 (15%)
Tin	mg/kg	0.100 to 0.130	304 (90%)
Titanium	mg/kg	0.250 to 0.890	178 (53%)
Uranium	mg/kg	0.00200 to 0.00270	134 (40%)
Vanadium	mg/kg	0.100 to 0.130	174 (51%)
Zirconium	mg/kg	0.200 to 0.400	337 (100%)

Notes: mg/kg = milligrams per kilogram dry weight. LRL = laboratory reporting limit. Only constituents for which at least one sample was <LRL are displayed. Fish tissue guidelines only exist for mercury (wet weight) and selenium (dry weight), which are not displayed in the table as all results were >LRL. The total number of samples in 2024 was 338, which included 27 field duplicate samples.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: Relative Percent Difference (RPD) was calculated using the LRL if one result in a duplicate pair was below the LRL. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated. LRL = Laboratory Reporting Limit. Duplicate samples could not be collected for whole-body tissue samples (i.e., northern pikeminnow from Quesnel Lake and coho salmon or rainbow trout from Hazeltine Creek, Frypan Creek, and Edney Creek).

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: Relative Percent Difference (RPD) was calculated using the LRL if one result in a duplicate pair was below the LRL. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated. LRL = Laboratory Reporting Limit. Duplicate samples could not be collected for whole-body tissue samples (i.e., northern pikeminnow from Quesnel Lake and coho salmon or rainbow trout from Hazeltine Creek, Frypan Creek, and Edney Creek).

of each tissue type from lake trout, peamouth chub from Quesnel Lake and rainbow trout from Quesnel River. Field duplicates could not be collected for whole-body tissue samples (i.e., coho salmon and rainbow trout from Hazeltine Creek, Frypan Creek, and Edney Creek and northern pikeminnow from Quesnel Lake) as the entire sample was required for analysis. Several RPDs were not calculated as both analyte concentrations were below the LRL (Appendix Table B.18; see Section B.2.3 for explanation on RPD calculation and DQOs). Of the 27 field duplicate pairs, 15 (i.e., 55.6% of duplicate pairs) pairs had >20% of analytes with RPDs >30%. Muscle tissue had the highest rate of DQO exceedances (85.7% of muscle tissue comparisons), and ovary tissue had the lowest average rate of DQO exceedances (20% of ovary tissue comparisons). In response to high RPDs, three field duplicate sample pairs from Quesnel Lake (VA24C9858)[8] and two field duplicate pairs from Quesnel River (VA24C9932)[9] were reanalyzed to check variability (see laboratory reports VA24C9858 and VA24C9932, respectively; Appendix G). In most or all cases, this variability was confirmed by reanalysis.[10] These relatively high rates of DQO exceedances were likely due to sample heterogeneity expected in biological tissues, as well as variability associated with multi-element scans. Tissue samples were collected in replicates of eight for each tissue type (muscle, liver, kidney, and ovary [as available]) to account for sampling heterogeneity (i.e., a total of 24 samples per sampling area). As a high proportion of all field duplicate analyses exceeded the DQO, these sources of variability will be considered during data interpretation.

B10.4 Data Accuracy

Data accuracy was evaluated based on results of RM and LCS samples (VA24B0407, VA24C9858, VA24C9932, VA24C1393 and VA24C9929). Out of 420 individual analyte results for RM samples, only three results (one for each of calcium, barium, and aluminum) did not meet the laboratory DQO (VA24C9858, VA24C9932, VA24C1393; Appendix G). This DQO exceedance occurred in multi-element scans where >10% of analytes met the laboratory DQO, which is a level deemed acceptable by the CCME. Out of the 416 individual LCS results, three did not meet the laboratory DQO, including one result each for boron, cadmium, and silver, phosphorus, and rubidium (VA24C9858; Appendix G). The DQO exceedances (as above) were due to multi-element scans where >10% of analytes met the laboratory DQO,

[8] Sample pairs VA24C9932-043 and -0114 (peamouth chub muscle), VA24C9858-071 and -119 (lake trout muscle), and VA24C9858-081 and -121 (lake trout kidney) were reanalyzed. Variability (i.e., high RPD) was confirmed in all samples except for VA24C9858-071 and -119 (lake trout muscle), for which revised results were reported.

[9] Sample pairs VA24C9932-019 and -032 (rainbow trout kidney) and VA24C9932-028 and -036 (rainbow trout ovary) were reanalyzed. The results of reanalysis confirmed variability in the metal scans (i.e., high RPDs).

[10] The ALS DQO for metals reanalysis is met if results from reanalysis are within 40 to 60% of the original results.

which is a level deemed acceptable by the CCME. As these DQO exceedances only represent 0.71 and 0.72% of all individual analyte results for RM and LCS samples respectively, laboratory accuracy was considered acceptable for this study.

B10.5 Hold Times

Recommended hold times were met for all fish tissue samples (VA24B0407, VA24C9858, VA24C9932, VA24C1393 and VA24C9929; Appendix G).

B10.6 Other Concerns

Concentrations of several analytes in 2024 were higher than historic maximum results for Quesnel River rainbow trout ovary tissue, including primary analytes selenium and iron (2.2-times and 5.7-times, respectively), and secondary analytes manganese, nickel and vanadium (2.5-times, 6.8-times, and 86-times higher, respectively) in sample MP_QUR_RB-OV-1_2024-10 (VA24C9932; Appendix G). Laboratory reanalysis did not find any obvious errors in the data nor justification to report the reanalysis results instead than the original data, therefore the original data were reported. Analyte concentrations that were above historic values could be related to observed variation in the development stage of the collected ovary tissues, or possibly a result of field or laboratory contamination.

B10.7 Data Quality Statement

Fish tissue quality data collected as part of the 2024 CEMP were of good quality as characterized by appropriate LRLs, excellent laboratory precision, no evidence of laboratory contamination, and excellent laboratory accuracy. Field sampling precision, as quantified using field duplicate samples, was relatively low (especially in muscle tissue); however, this was likely compensated for by the number of replicate fish tissue samples employed in this study. Therefore, fish tissue quality data can be used with a high level of confidence in the derivation of conclusions for the 2024 CEMP, though sources of variability in fish tissue samples will be considered during data interpretation.

B11 FISH AGING

B11.1 Data Accuracy

Analytical reports of fish age estimates from AAE Tech Services Inc. (see laboratory reports in Appendix G) were examined to evaluate data accuracy. Fish aging samples were collected from rainbow trout, longnose sucker, peamouth chub, lake trout, and northern pikeminnow (lakes) and coho salmon and rainbow trout (creeks). To determine the accuracy of age estimates, a subset (51% of all samples) of aging structures were re-assessed by a second analyst. The original and second analyst assigned a confidence index to each age estimate. Out of 64 total samples that were reassessed for quality control, 59 samples had perfect agreement between the primary age and secondary age estimates. Two aging samples from longnose sucker (pectoral fins), and one aging sample from lake trout (otolith) were all reassessed at one year younger than the original age estimate, and two aging samples from northern pikeminnow (scales) were both reassessed at one year older (see laboratory reports in Appendix G). As only five aging structures were reassessed at different ages, and the difference between original and QA/QC ages was only one year (meets internal DQO), the accuracy achieved by the laboratory in this study can be considered acceptable for this study.

B12 DATA QUALITY REVIEW SUMMARY

Data collected for the 2024 CEMP were of acceptable quality as characterized by appropriate LRLs, good detectability, negligible analyte concentration in MB samples, good laboratory precision, and good laboratory accuracy in water and sediment quality samples. Concentrations of several dissolved analytes were greater than the concentration of the corresponding total analyte for some water samples. Direct comparisons for sediment toxicity results between Polley Lake (POL-P1, POL-P2) and Bootjack Lake (BOL-B2) were limited due to laboratory error, and a weight-of-evidence approach will be used to interpret results. Field sampling precision, as measured by RPD in field duplicate pairs, was low in benthic invertebrate, periphyton, and fish tissue samples, reflecting natural variability in field samples and from multi-element scans.

Overall, data collected as part of the 2024 Mount Polley Mine CEMP can be used with a high level of confidence in the derivation of conclusions.

APPENDIX C.1
WATER QUALITY

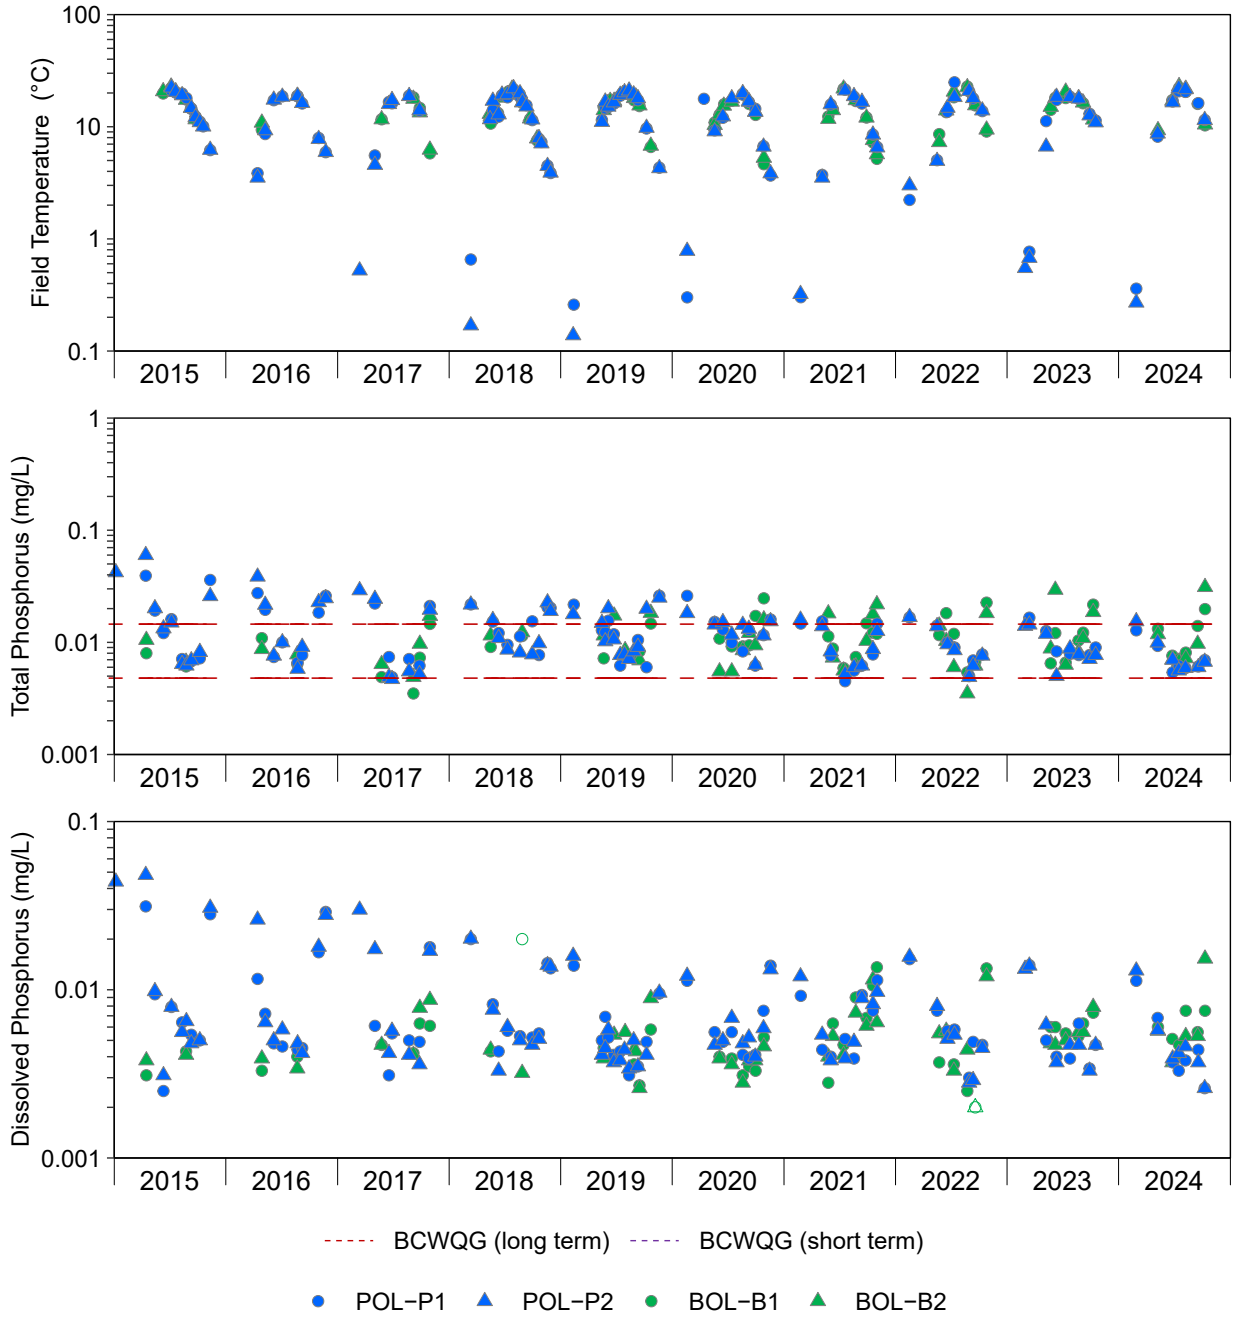

Figure C.1.1: Temperature and Nutrient Concentrations in Post−Breach Surface Water for Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B1, BOL−B2; Reference) Monitoring Stations, 2015 to 2024

Notes: BCWQG = British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025). Green represents reference stations and blue represents exposed stations. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Total phosphorus BCWQG is shown as the guideline range (0.005 to 0.015 mg/L).

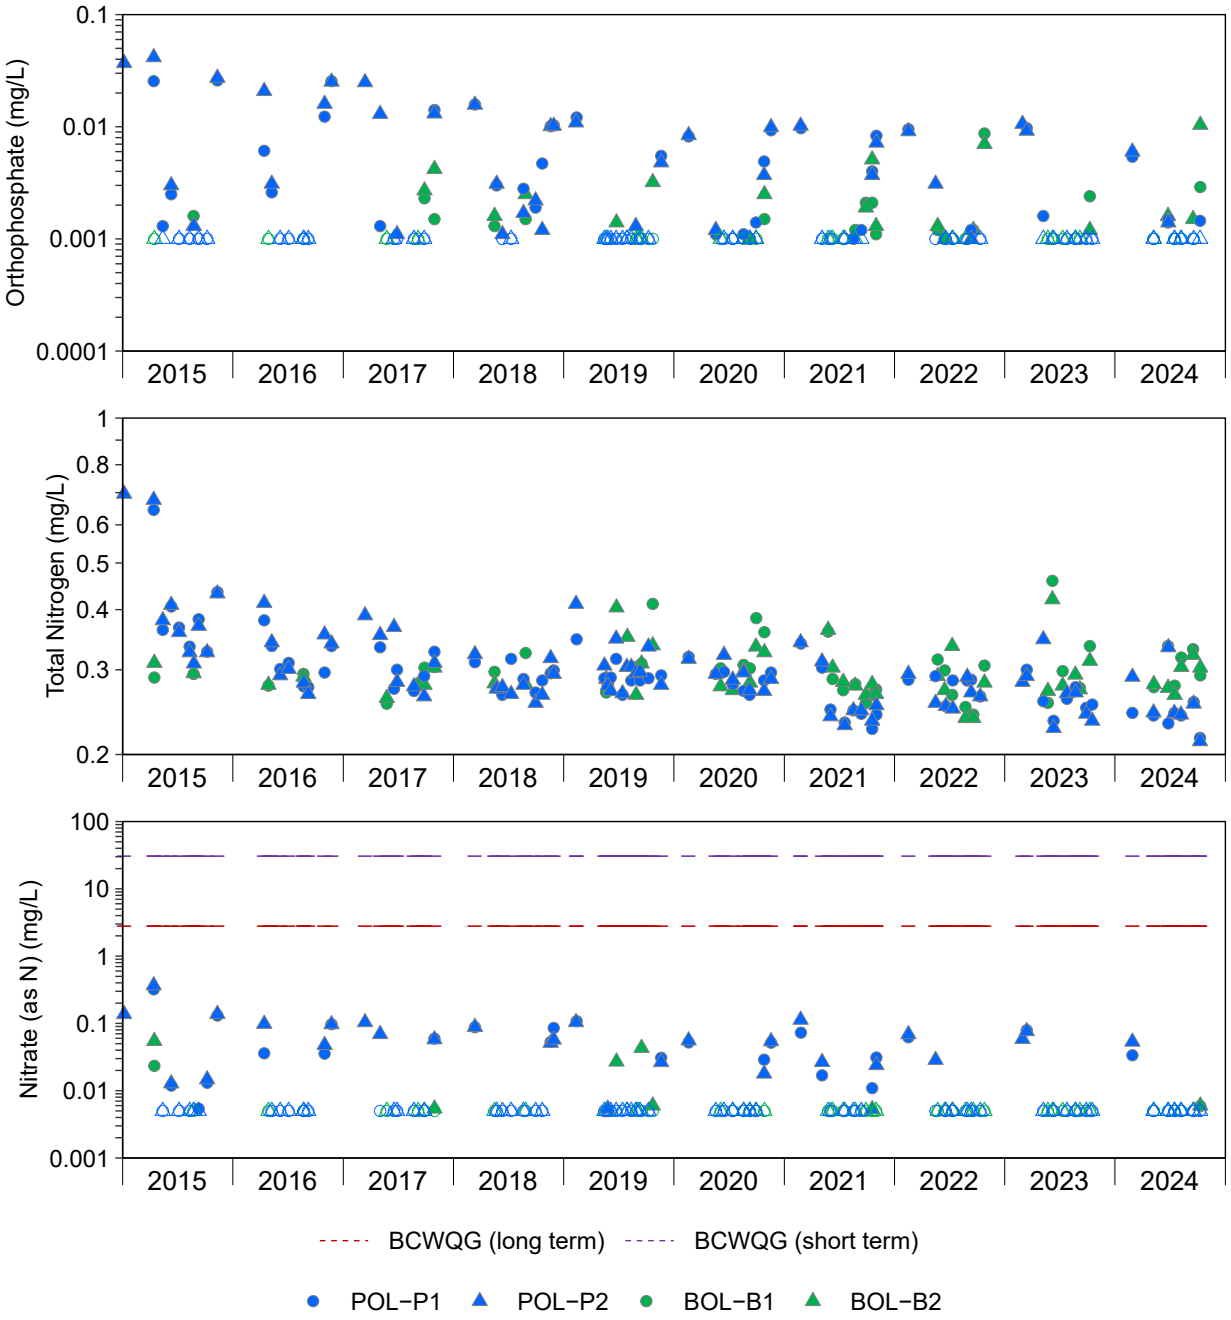

Figure C.1.1: Temperature and Nutrient Concentrations in Post−Breach Surface Water for Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B1, BOL−B2; Reference) Monitoring Stations, 2015 to 2024

Notes: BCWQG = British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025). Green represents reference stations and blue represents exposed stations. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Total phosphorus BCWQG is shown as the guideline range (0.005 to 0.015 mg/L).

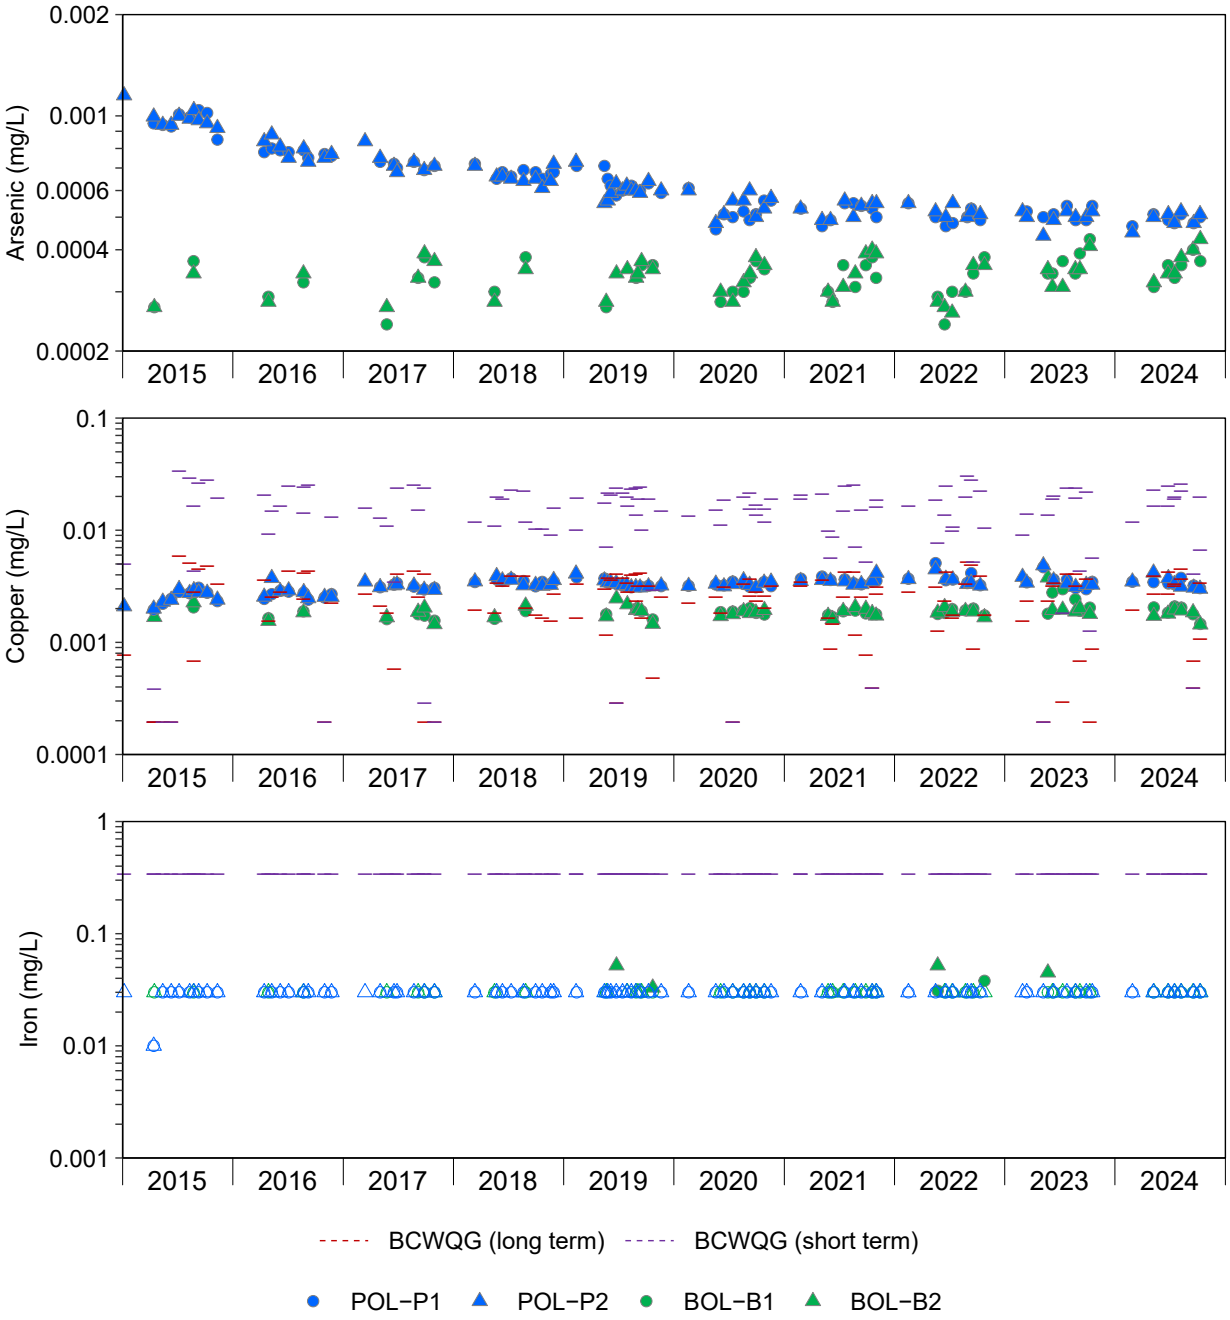

Figure C.1.2: Dissolved Aqueous Concentrations of Primary and Secondary Analytes in Post−Breach Surface Water for Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B1, BOL−B2; Reference) Monitoring Stations, 2015 to 2024

Notes: BCWQG = British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025). Green represents reference stations and blue represents exposed stations. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Values displayed for BCWQG that are condition specific (i.e., hardness dependent or based on the Biotic Ligand Model) are the most conservative (i.e., lowest) of those calculated for the multiple monitoring stations displayed. Dissolved phosphorus data are plotted in Figure C.1.1. Dissolved mercury data were not collected.

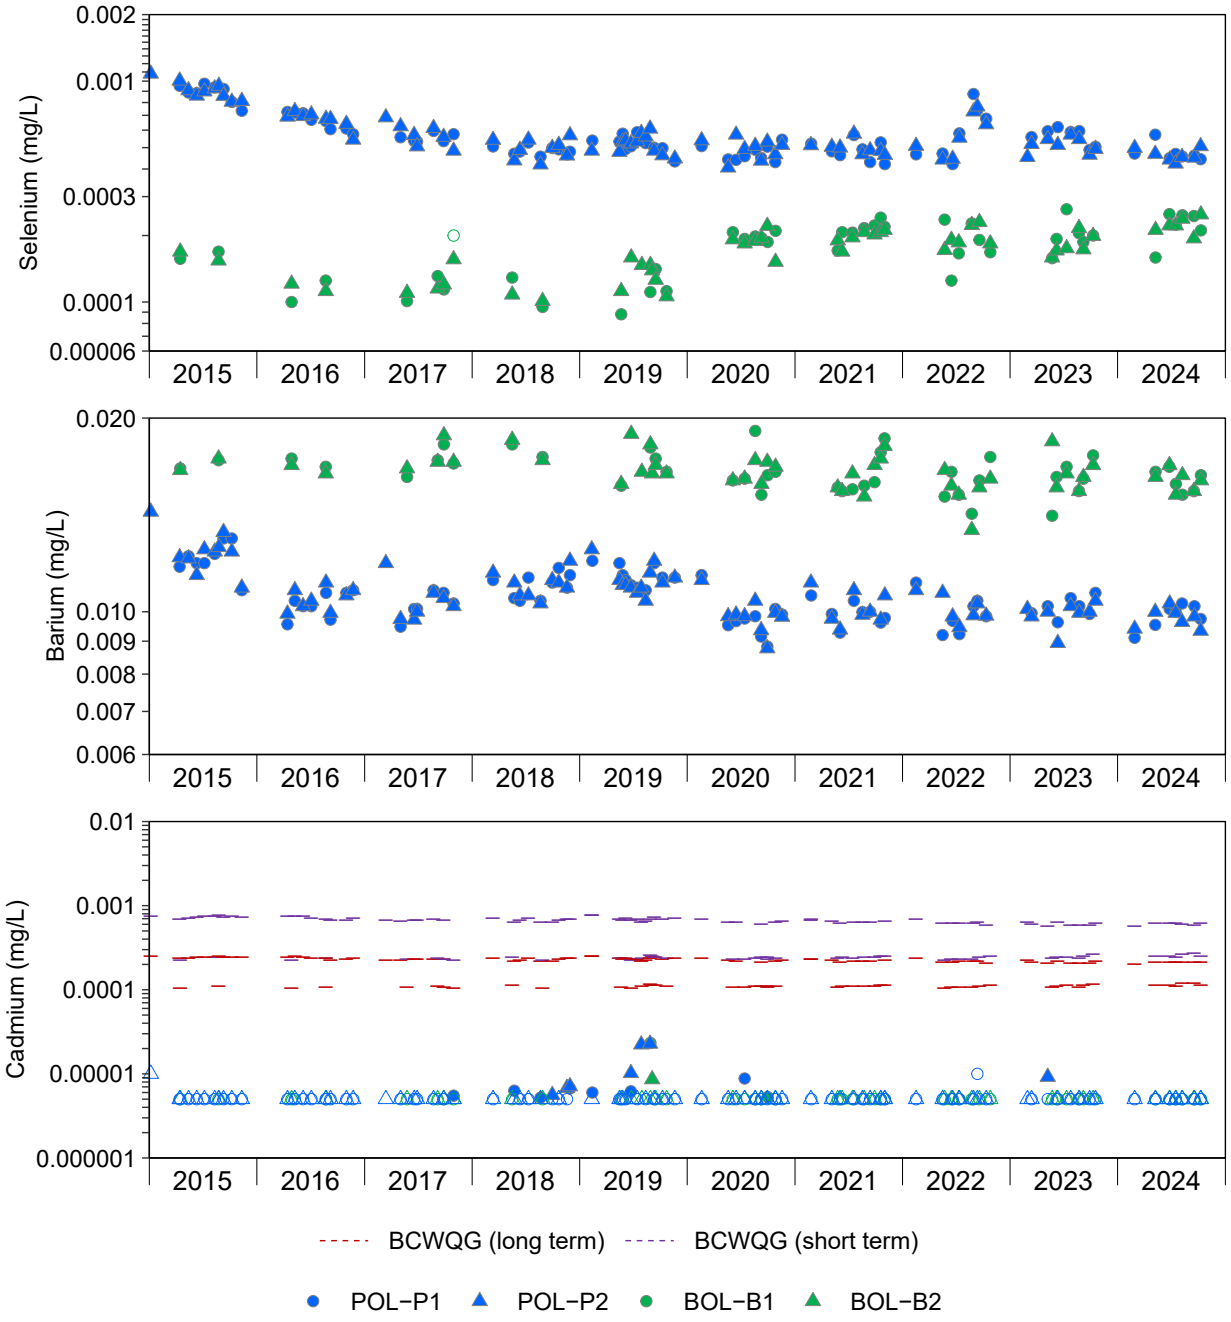

Figure C.1.2: Dissolved Aqueous Concentrations of Primary and Secondary Analytes in Post−Breach Surface Water for Polley Lake (POL−P1, POL−P2; Exposed) and Bootjack Lake (BOL−B1, BOL−B2; Reference) Monitoring Stations, 2015 to 2024

Notes: BCWQG = British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025). Green represents reference stations and blue represents exposed stations. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Values displayed for BCWQG that are condition specific (i.e., hardness dependent or based on the Biotic Ligand Model) are the most conservative (i.e., lowest) of those calculated for the multiple monitoring stations displayed. Dissolved phosphorus data are plotted in Figure C.1.1. Dissolved mercury data were not collected.

Table C.1.1: British Columbia Water Quality Guidelines for the Protection of Aquatic Life (BCMOWLRS 2024, 2025), 2024

Parameter	Units	Long-term Average	Short-term Maximum
Anions, Organics, Nutrients, and Physical Properties			
pH	pH units	6.5 - 9.0	
Temperature (*in situ*)[a]	°C	± 1	
Alkalinity ($CaCO_3$)	mg/L	> 20[b]	-
Conductivity	µS/cm	-	-
Dissolved Oxygen (*in situ*)[c]	mg/L	> 8	> 5
Dissolved Oxygen (*in situ*)[d]	mg/L	> 11	> 9
Total Suspended Solids[e]	mg/L	+ 5	+ 25
Turbidity[e]	NTU	+ 2	+ 8
Chloride	mg/L	150	600
Fluoride[f]	mg/L	-	For hardness ≤ 10 mg/L, WQG = 0.4 For hardness > 10 mg/L, WQG = [-51.73 + 92.57 × log10(hardness)]×0.01 Maximum applicable hardness = 385 mg/L
Sulphate[g]	mg/L	hardness dependent	-
Ammonia (as N)[h]	mg/L	temperature and pH dependent	temperature and pH dependent
Nitrate (as N)	mg/L	3.0	32.8
Nitrite (as N)[i]	mg/L	chloride dependent	chloride dependent
Phosphorus - Total[j]	mg/L	0.005 - 0.015	
Dissolved Organic Carbon[k]	mg/L	-	± 20%[k]
Total Metals			
Aluminum[f]	µg/L	For hardness 10 to 430 mg/L and pH 6 to 8.7 and DOC 0.08 to 12.3 mg/L, WQG = (exp([0.645 × ln(DOC)] + [2.255 × ln(hardness)] + [1.995 × pH] + [-0.284 × (ln(hardness) × pH)] -9.898))/3	-
Antimony	µg/L	74	250
Arsenic	µg/L	5	-
Barium	mg/L	1.0	
Beryllium	µg/L	0.13	-
Boron	mg/L	1.2	-
Chromium[l]	µg/L	For Cr VI, WQG = 0.0025 For Cr III, WQG = 0.0089	-
Cobalt	µg/L	4	110
Iron	mg/L	-	1
Manganese[f]	mg/L	For hardness 37 to 450 mg/L, WQG ≤ 0.004 × hardness + 0.605 Maximum applicable hardness = 450 mg/L	For hardness 25 to 259 mg/L, WQG ≤ 0.01102 × hardness + 0.54 Maximum applicable hardness = 259 mg/L
Molybdenum	mg/L	7.6	46
Selenium	µg/L	2	-
Silver[f]	mg/L	For hardness ≤ 100 mg/L, WQG = 0.00005 For hardness > 100 mg/L, WQG = 0.0015	For hardness ≤ 100 mg/L, WQG = 0.0001 For hardness > 100 mg/L, WQG = 0.003
Thallium	µg/L	0.3	-
Uranium	µg/L	7.5	16.5
Vanadium	mg/L	0.06	-
Dissolved Metals			
Cadmium[f]	mg/L	For hardness = 3.4 to 285 mg/L, WQG = {exp[0.736×ln - 4.943]} Maximum applicable hardness = 285 mg/L	For hardness = 7 to 455 mg/L, WQG = {exp[1.03×ln-5.274]} Maximum applicable hardness = 455 mg/L
Copper[m]	mg/L	Biotic Ligand Model	Biotic Ligand Model
Iron	mg/L	-	0.35
Lead[f]	µg/L	For Hardness 4.7 to 511 mg/L and Dissolved Organic Carbon 0.5 - 31.5 mg/L, WQG = {exp(0.514 [ln(DOC)] + 0.214[ln(hardness)] + 0. 4354)}/2	-
Nickel[m]	mg/L	Biotic Ligand Model	Biotic Ligand Model
Strontium	mg/L	1.25	-
Zinc[f]	µg/L	For hardness 23.4 to 399 mg/L, pH 6.5 to 8.13, and DOC 0.3 mg/L to 22.9 mg/L, WQG = (exp(0.947[ln(hardness)] − 0.815[pH] + 0.398[ln(DOC)] + 4.625))/2 Maximum applicable hardness = 399 mg/L	For hardness 13.8 to 250.5 mg/L and DOC 0.3 to 17.3 mg/L, WQG = (exp(0.833[ln(hardness)] + 0.240[ln(DOC)] + 0.526))/2 Maximum applicable hardness: 250.5 mg/L

Notes: "-" indicates no applicable guideline. BCMOWLRS = British Columbia Ministry of Water, Land and Resource Stewardship. WQG = Water Quality Guideline.

[a] Change from optimal. No guideline applied.

[b] For waterbodies with low sensitivity to acid inputs.

[c] Minimum for all life stages other than buried embryo / alevin.

[d] Minimum for buried embryo / alevin life stages.

[e] Increase relative to background; no guideline applied.

[f] For hardness-based guidelines, concurrent hardness values were used for calculating guidelines. If hardness values exceeding the maximum applicable hardness, then guidelines were determined using the maximum applicable hardness. If hardness values are lower than the minimum hardness, then guidelines were determined using the minimum hardness.

[g] 128 mg/L at hardness 0-30 mg/L; 218 mg/L at hardness 31-75 mg/L; 309 mg/L at hardness 76-180 mg/L; 429 mg/L at hardness > 250 mg/L.

[h] Used tables in BCMOWLRS 2025.

[i] When chloride < 2 mg/L, long-term = 0.02 mg/L and short-term = 0.06 mg/L; increase with increasing chloride.

[j] Aquatic Life - Lakes; minimum guideline was applied.

[k] ±20% of the background median; no guideline applied.

[l] Chromium VI is the dominant oxidation state in oxygenated environments, and so its guideline was applied.

[m] Guidelines calculated using the BLM model and calculated concurrently for each sample using the guideline lookup tables provided for dissolved copper and dissolved nickel (BCMOWLRS 2025).

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Notes: "-" indicates data not available. Standard deviation was not calculated where all results were below the laboratory reporting limit.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Table C.1.1.

[b] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table C.1.3: Supporting Overlying Water Quality Data Collected During Sediment Quality Sampling in the Quesnel Lake (QUL-LNF1; Exposed and QUL-LREF1; Reference) Shallow Monitoring Areas, 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Notes: "-" indicates data not available. Standard deviation was not calculated where all results were below the laboratory reporting limit.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Table C.1.1.

[b] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Notes: mg/kg dw = milligrams per kilogram dry weight. Sediment metal concentrations are based predominantly on bulk sediment samples. Concentrations reported in 1995 and 1996 were for the silt and clay (< 63 µm) fraction only. "-" indicates no data available.

[a] Stations were named LN (north basin) and LS (south basin) in 1989, and are approximately equivalent to stations B1 and B2 assessed in following sampling years, respectively. These are therefore displayed as B1 and B2. Concentrations reported in 1989 were for the <0.149 mm fraction only. Particle size fractions for these samples are as follows: sand (0.053 mm-2.0 mm), silt (0.002 mm-0.053 mm), clay (<0.002 mm).

[b] Particle size results are based on one composite sample and the size fractions are as follows: sand (2.0 mm - 0.065 mm), silt (0.065 mm - 0.0041 mm), clay (<0.0041 mm).

[c] Concentrations reported in October 1996 are for the silt and clay (<63 µm) fraction only. Particle size fractions for these samples are as follows: sand (2.0 mm - 0.063 mm), silt (0.063 mm - 0.0039 or 0.0038 mm), clay (<0.0039 or < 0.0038 mm).

Table C.2.2: Baseline and Pre-Breach Sediment Quality Data for Polley Lake, 1989 to 2012

Notes: mg/kg dw = milligrams per kilogram dry weight. Sediment metal concentrations are based predominantly on bulk sediment samples. Concentrations reported in 1995 and 1996 were for the silt and clay (< 63 µm) fraction only. "-" indicates no data available.

[a] Station was named L in 1989, and is approximately equivalent to station P2 assessed in following sampling years. The station is therefore displayed as P2. Concentrations reported in 1989 were for the <0.149 mm fraction only. Particle size fractions for these samples are as follows: sand (0.053 mm-2.0 mm), silt (0.002 mm-0.053 mm), clay (<0.002 mm).

[b] Particle size results for this station are based on one composite sample and the size fractions are as follows: sand (2.0 mm - 0.0705 mm), silt (0.0705 mm - 0.0041 mm), clay (<0.0041 mm).

[c] Particle size results for this station are based on one composite sample, and the size fractions are as follows: sand (2.0 mm - 0.0675 mm), silt (0.0675 mm - 0.0041 mm), clay (<0.0041 mm).

[d] Concentrations reported in October 1996 were for the silt and clay (<63µm) fraction only. Particle size fractions for these samples are as follows: sand (2.0 mm - 0.063 mm), silt (0.063 mm - 0.0040 mm or 0.0039 mm), clay (<0.0040 mm or 0.0039 mm).

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics:*** Value is > reference 95th percentile value (<5th percentile value for pH). Reference 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. All summary statistics were calculated to 3 significant figures. The reference 95th percentile value was calculated using data from 2014 to 2024.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.
Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. **Bold/Italics:** Value is > reference 95th percentile value (<5th percentile value for pH). Reference 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. All summary statistics were calculated to 3 significant figures. The reference 95th percentile value was calculated using data from 2014 to 2024.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. "-" = no current BC Working Sediment Quality Guidelines/ no data. ***Bold/ Italics*** indicates value is > pre-breach and is > reference 95th percentile value (<5th percentile value for pH).

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. The 5th percentile is reported and screened for the pH reference data. For calculation of pre-breach and reference 95th percentile values see Appendix Tables C.2.1 and C.2.3, respectively.

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Tables C.2.1).

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Table C.2.5: Sediment Quality for the Polley Lake (POL-P1, POL-P2; Exposed) Deep Monitoring Areas, 2024

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. "-" = no current BC Working Sediment Quality Guidelines/ no data. ***Bold/ Italics*** indicates value is > pre-breach and is > reference 95th percentile value (<5th percentile value for pH).

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. The 5th percentile is reported and screened for the pH reference data. For calculation of pre-breach and reference 95th percentile values see Appendix Tables C.2.2 and C.2.3, respectively.

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2021) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Table C.2.2).

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics:*** Value is > reference 95th percentile value (<5th percentile value for pH). Reference 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. All summary statistics were calculated to 3 significant figures. QUL-PREF1 was not sampled in 2017, 2021 or 2013; therefore the reference 95th percentile value was calculated using data from 2014 to 2024.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics*** : Value is > reference 95th percentile value (<5th percentile value for pH). Reference 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" indicates no guideline available or no data. All summary statistics were calculated to 3 significant figures. QUL-PREF1 was not sampled in 2017, 2021 or 2013; therefore the reference 95th percentile value was calculated using data from 2014 to 2024.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: ***Bold/ Italics*** indicates exposed value is > both reference and pre-breach (QUL-LNF; 2007) 95th percentile value (<5th percentile value for pH). Reference or pre-breach 95th percentiles that were reported as < the laboratory reporting limit were not used for screening. "-" = no current BC Working Sediment Quality Guidelines/ no data. All summary statistics were calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] The 5th percentile is reported and screened for the pH reference data. For calculation of reference and pre-breach 95th percentile values, see Appendix Tables C.2.10 and C.2.12, respectively.

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Table C.2.12).

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

APPENDIX C.3
PLANKTON COMMUNITY AND PRODUCTIVITY

Table C.3.1: Phytoplankton Community Metrics for the Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, 2019 to 2024

Notes: "-" = only one sample (replicate) collected. Cells/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

Table C.3.1: Phytoplankton Community Metrics for the Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, 2019 to 2024

Year	Area	Type	Date	Replicate	Density (cells/L)	Richness (# of Taxa)	Simpson's Diversity	Simpson's Evenness	Chlorophyll-a (µg/L)	Diatom (cells/L)	Chlorophyte (cells/L)	Chrysophyte (cells/L)	Cryptomonad (cells/L)	Cyanobacteria (cells/L)	Dinoflagellates (cells/L)

Notes: "-" = only one sample (replicate) collected. Cells/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

Notes: "-" = only one sample (replicate) collected. Cells/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

Table C.3.2: Summary Statistics for Phytoplankton Community Metrics for the Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas in July, 2019 to 2024[a]

Endpoint	Year	Area	Type	n	Mean	Standard Deviation	Minimum	Median	Maximum

Notes: Cell/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

[a] Summary statistics are displayed for replicated data collected in July 2019 to 2024. For results without replicates collected in June and August 2019 to 2024, see Appendix Table C.3.1.

Table C.3.2: Summary Statistics for Phytoplankton Community Metrics for the Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas in July, 2019 to 2024[a]

Notes: Cell/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

[a] Summary statistics are displayed for replicated data collected in July 2019 to 2024. For results without replicates collected in June and August 2019 to 2024, see Appendix Table C.3.1.

Notes: Cell/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

[a] Summary statistics are displayed for replicated data collected in July 2019 to 2024. For results without replicates collected in June and August 2019 to 2024, see Appendix Table C.3.1.

Notes: "-" = only one sample (replicate) collected. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

Notes: "-" = only one sample (replicate) collected. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

Table C.3.6: Summary Statistics for Phytoplankton Community Metrics for the Quesnel Lake (QUL-ZOO-1; Exposed and QUL-ZOO-7; Reference) Monitoring Areas in July, 2019 to 2024[a]

Endpoint	Year	Area	Type	n	Mean	Standard Deviation	Minimum	Median	Maximum

Notes: Cell/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

[a] Summary statistics are displayed for replicated data collected in July 2019 to 2024. For results without replicates collected in June and August 2019 to 2024, see Appendix Table C.3.5.

Notes: Cell/L = cells per litre. µg/L = micrograms per litre. Displayed data were collected using depth-integrated (DI) sampling methods. Sampling methods employed in 2019 included both surface (S) and DI methods. See Minnow (2019a, 2020a) for results of surface phytoplankton sampling completed in 2018 and 2019. See Minnow 2020a for a comparison of results from the S and DI sampling methodologies, and for rationale regarding the selection of DI methods for ongoing phytoplankton monitoring.

[a] Summary statistics are displayed for replicated data collected in July 2019 to 2024. For results without replicates collected in June and August 2019 to 2024, see Appendix Table C.3.5.

APPENDIX C.4
ZOOPLANKTON TISSUE QUALITY

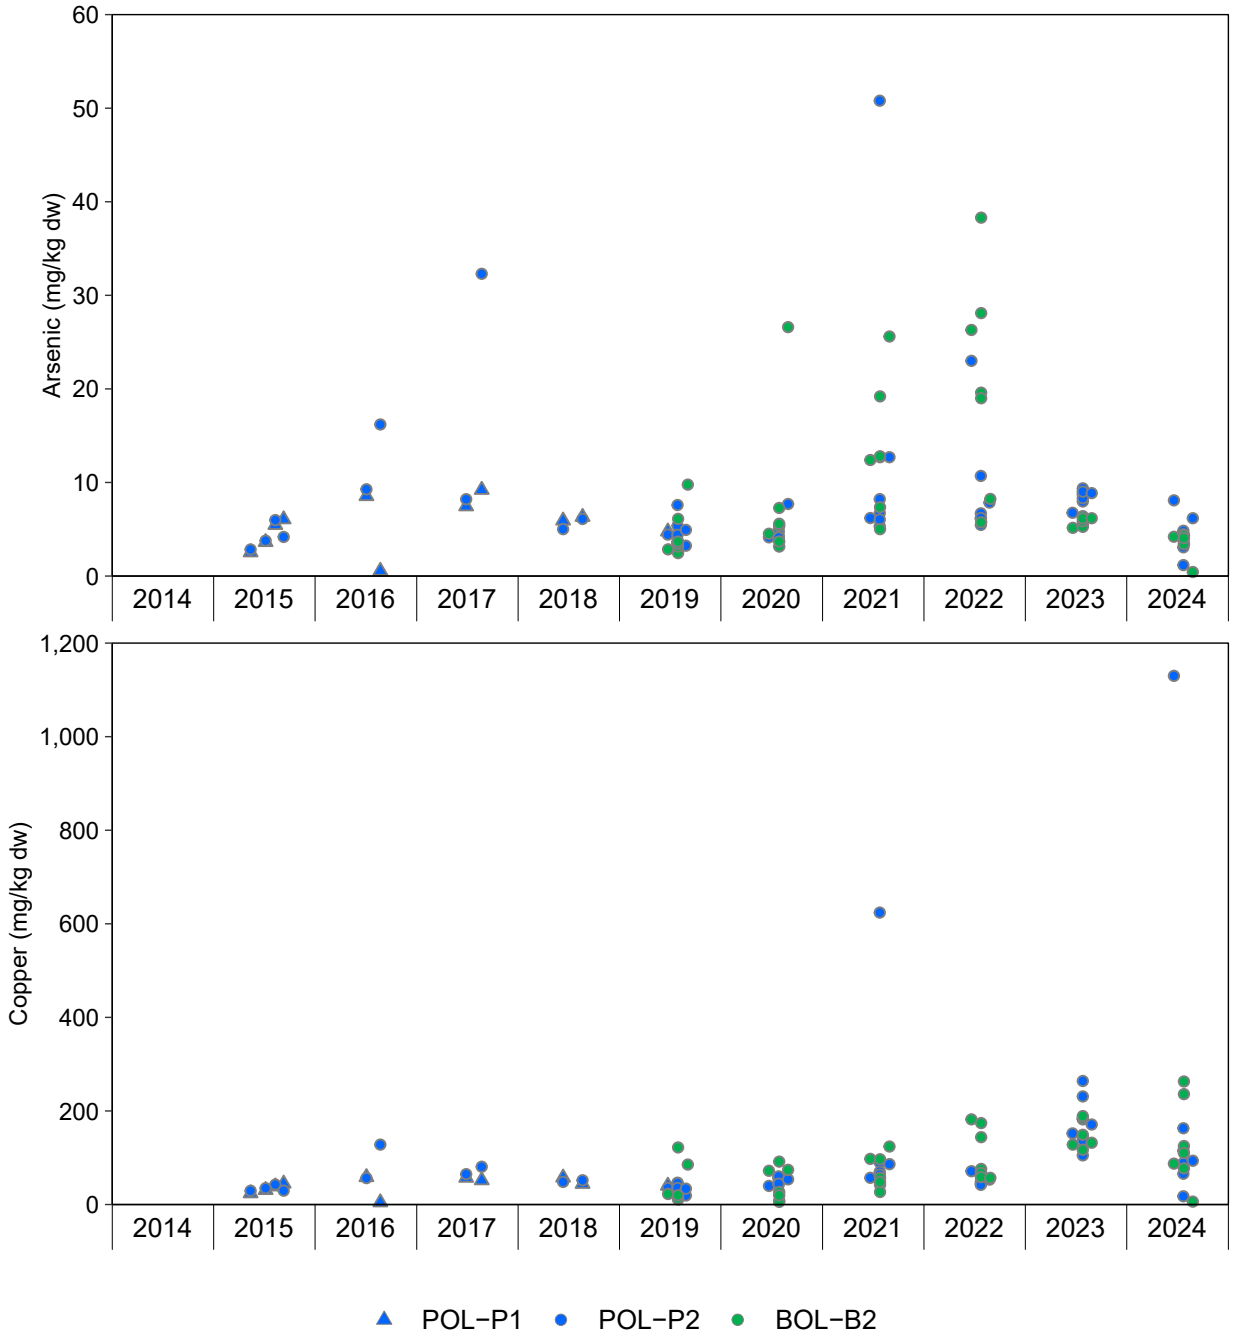

Figure C.4.1: Zooplankton Tissue Primary and Secondary Analyte Concentrations for the Polley Lake (POL-P1, POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Red horizontal line represents British Columbia interim long−term guideline for selenium in invertebrate tissue (4 mg/kg dw; BCMOE 2014). Green symbols indicate reference while blue symbols indicate exposed. Sampling at POL −P1 was discontinued after 2019.

Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Red horizontal line represents British Columbia interim long−term guideline for selenium in invertebrate tissue (4 mg/kg dw; BCMOE 2014). Green symbols indicate reference while blue symbols indicate exposed. Sampling at POL −P1 was discontinued after 2019.

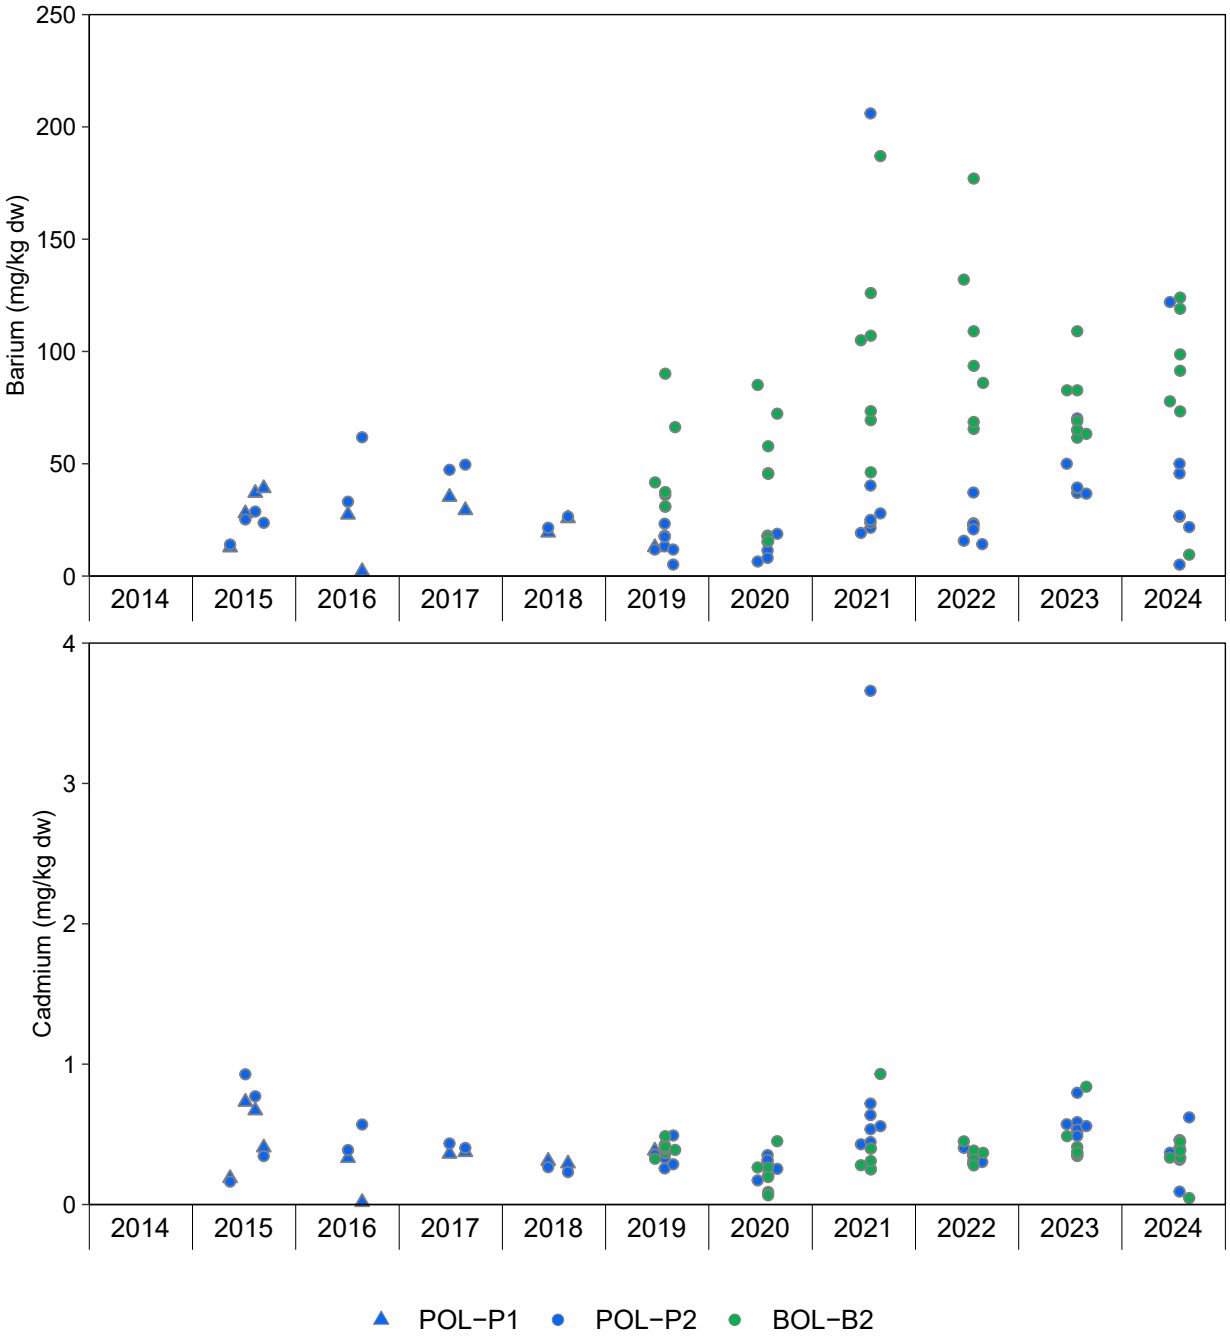

Figure C.4.1: Zooplankton Tissue Primary and Secondary Analyte Concentrations for the Polley Lake (POL-P1, POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Red horizontal line represents British Columbia interim long−term guideline for selenium in invertebrate tissue (4 mg/kg dw; BCMOE 2014). Green symbols indicate reference while blue symbols indicate exposed. Sampling at POL −P1 was discontinued after 2019.

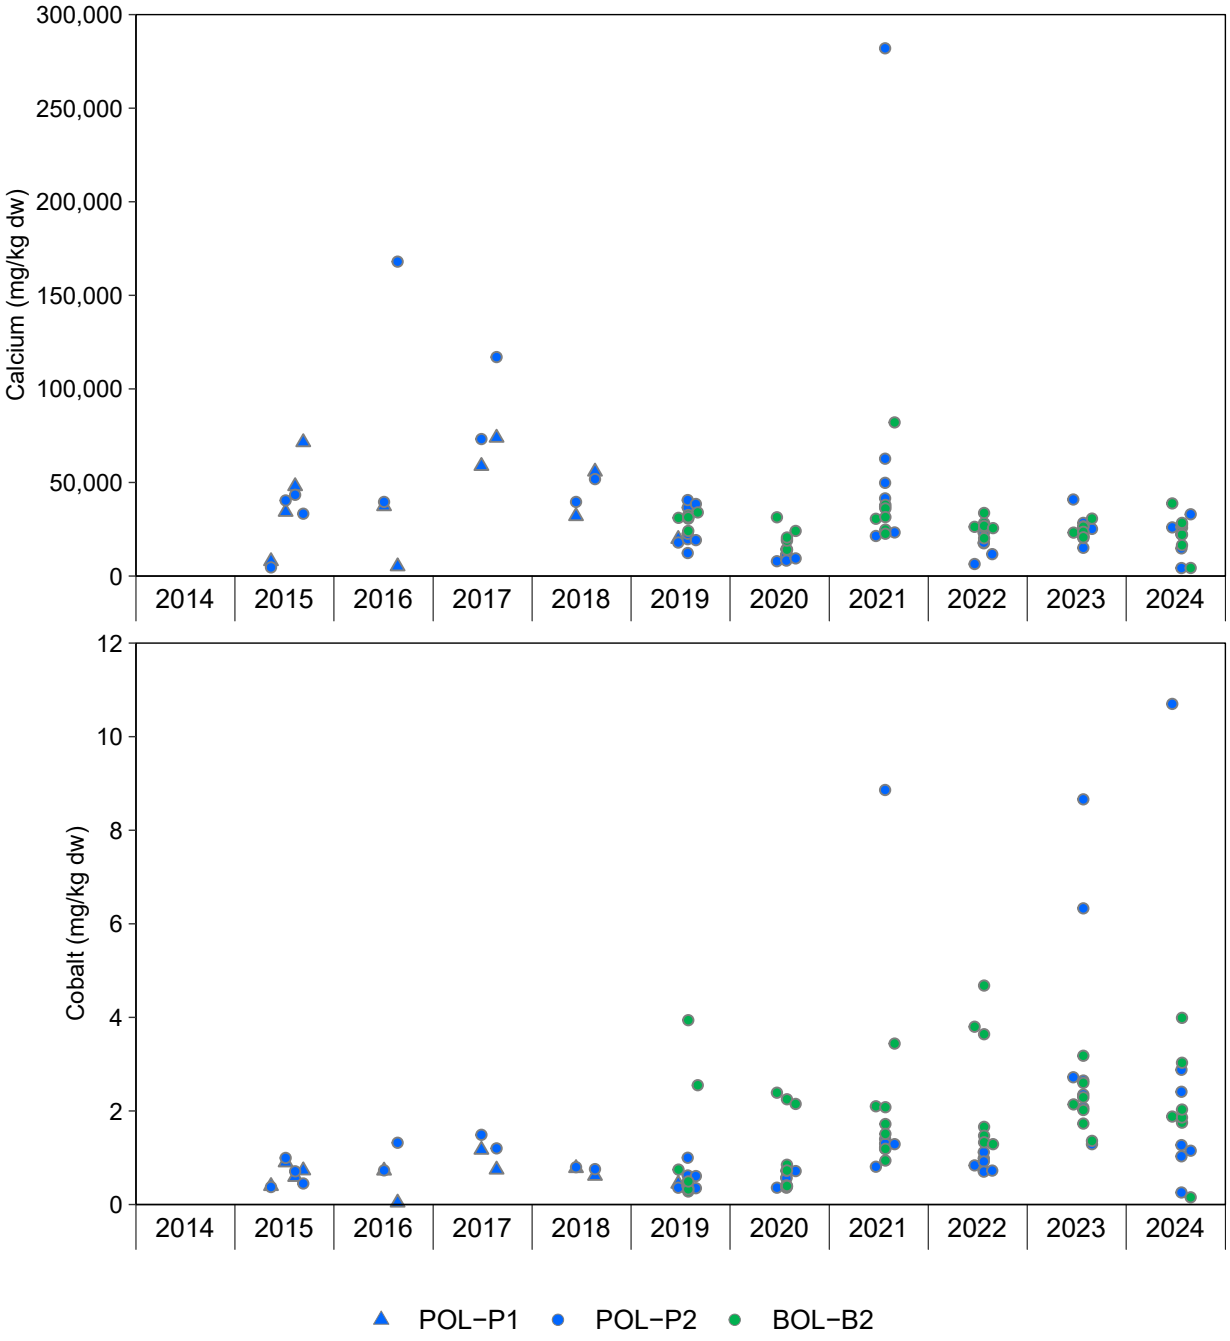

Figure C.4.1: Zooplankton Tissue Primary and Secondary Analyte Concentrations for the Polley Lake (POL-P1, POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Red horizontal line represents British Columbia interim long−term guideline for selenium in invertebrate tissue (4 mg/kg dw; BCMOE 2014). Green symbols indicate reference while blue symbols indicate exposed. Sampling at POL −P1 was discontinued after 2019.

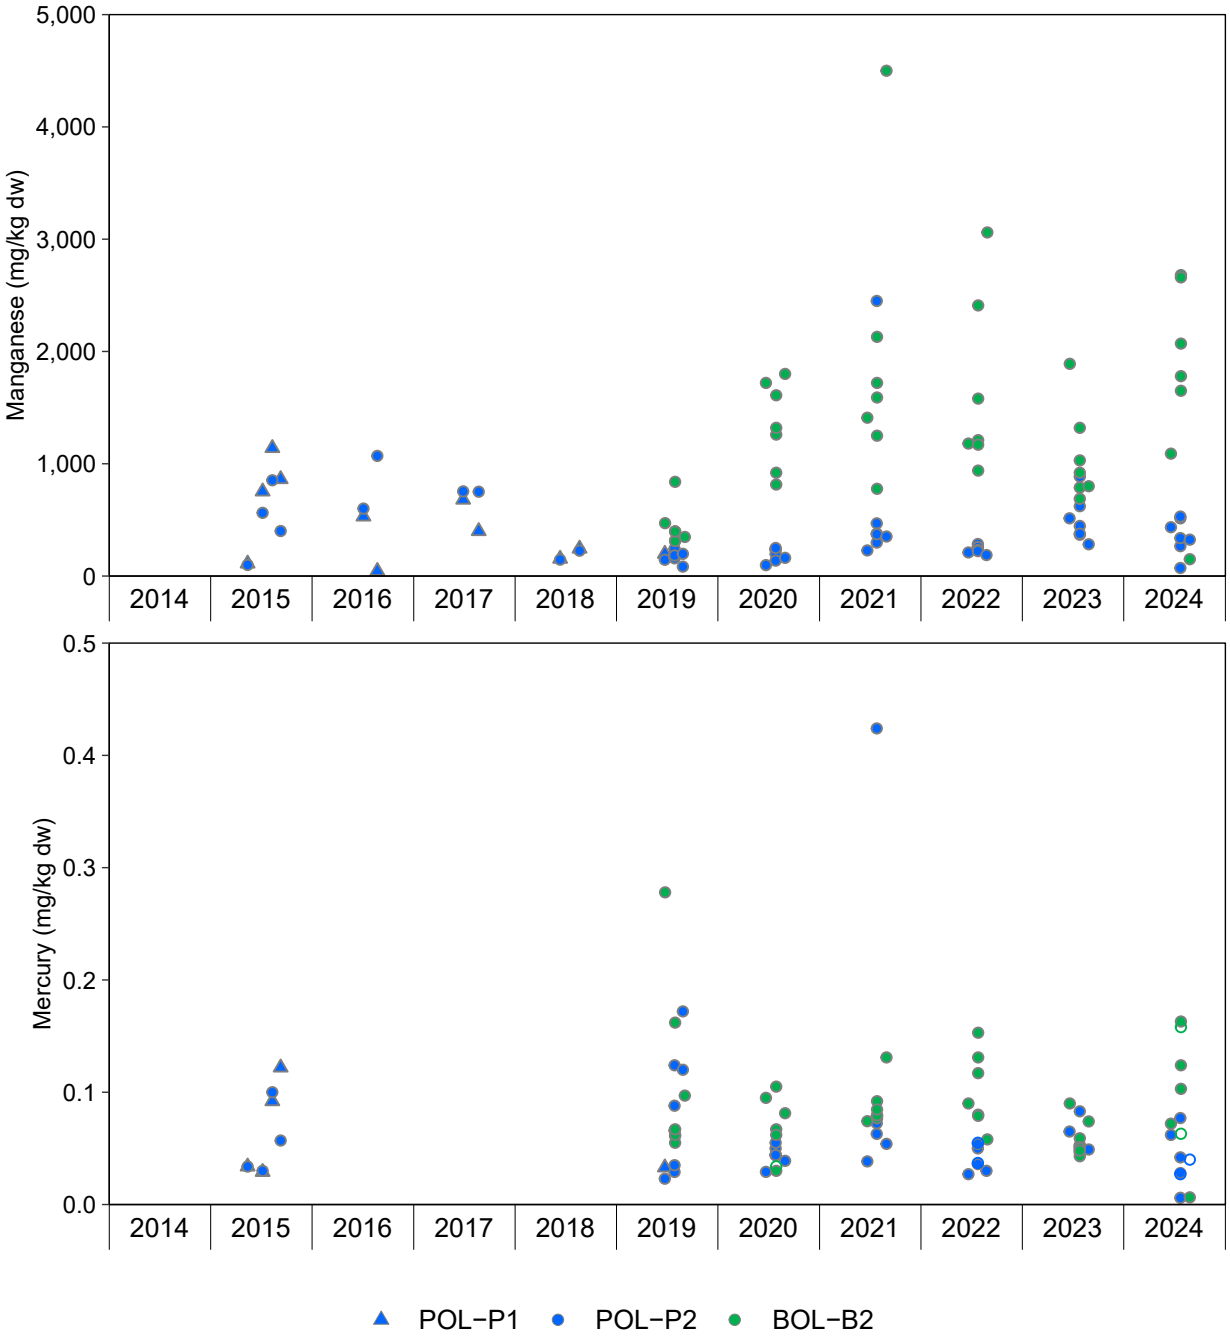

Figure C.4.1: Zooplankton Tissue Primary and Secondary Analyte Concentrations for the Polley Lake (POL-P1, POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Monitoring Areas, 2014 to 2024

Notes: mg/kg dw = milligrams per kilogram dry weight. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Red horizontal line represents British Columbia interim long−term guideline for selenium in invertebrate tissue (4 mg/kg dw; BCMOE 2014). Value exceeds the British Columbia interim guideline for selenium in invertebrate tissue (4 mg/kg dw; BCMOE 2014).

Notes: "-" = standard deviation not calculated due to insufficient detected data above the laboratory reporting limit. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. All summary statistics are reported to three significant digits for display purposes. All summary statistics were calculated using the Kaplan-Meier method. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 06]) used in the full sample identifiers.

Value exceeds the British Columbia interim guideline for selenium in invertebrate tissue (4 mg/kg dw; BCMOE 2014).

Notes: "-" = standard deviation not calculated due to insufficient detected data above the laboratory reporting limit. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. All summary statistics are reported to three significant digits for display purposes. All summary statistics were calculated using the Kaplan-Meier method. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 06]) used in the full sample identifiers.

Notes: "-" indicates no data, EPT = Ephemeroptera, Plecoptera, Trichoptera, CA = Correspondence Analysis. No organisms were present in all replicate samples from POL-P2 in 2014, therefore Simpson's Evenness, and Simpson's Diversity could not be calculated. Results from POL-P1 and POL-P2 in 2014 were excluded from CA due to insufficient taxon richness in samples (≤ 1 taxon / sample). Results displayed for post-breach richness, Simpson's Evenness, and Simpson's Diversity differ from those presented in Minnow (2022a) due to revised calculations.

Notes: "-" indicates no data, EPT = Ephemeroptera, Plecoptera, Trichoptera, CA = Correspondence Analysis. No organisms were present in all replicate samples from POL-P2 in 2014, therefore Simpson's Evenness, and Simpson's Diversity could not be calculated. Results from POL-P1 and POL-P2 in 2014 were excluded from CA due to insufficient taxon richness in samples (≤ 1 taxon / sample). Results displayed for post-breach richness, Simpson's Evenness, and Simpson's Diversity differ from those presented in Minnow (2022a) due to revised calculations.

Notes: "-" indicates no data, EPT = Ephemeroptera, Plecoptera, Trichoptera, CA = Correspondence Analysis. No organisms were present in all replicate samples from POL-P2 in 2014, therefore Simpson's Evenness, and Simpson's Diversity could not be calculated. Results from POL-P1 and POL-P2 in 2014 were excluded from CA due to insufficient taxon richness in samples (≤ 1 taxon / sample). Results displayed for post-breach richness, Simpson's Evenness, and Simpson's Diversity differ from those presented in Minnow (2022a) due to revised calculations.

Notes: " - " indicates no data, °C = degrees Celsius, mg/ L = milligrams per litre, % = percent, µS/cm = microSiemens per centimeter, TOC = Total Organic Carbon, PC Axis = Principal Components Axis, mg/kg = milligrams per kilogram (dry weight). POL-P2 did not record any benthic organisms in all replicates collected in 2014.

Table C.5.4: Benthic Invertebrate Community Metrics for the Quesnel Lake (QUL-PNF and QUL-PFF1; Exposed and QUL-PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

Year	Type	Area	Replicate	Density (#/m²)	Richness (# of Taxa)	Simpson's Evenness	Simpson's Diversity	EPT (#/m²)	Arachnida (#/m²)	Chironomidae (#/m²)	Oligochaeta (#/m²)	EPT (%)	Arachnida (%)	Chironomidae (%)	Oligochaeta (%)	CA1 (30.9%)	CA2 (16.5%)	CA3 (12.6%)

Notes: " - " indicates no data, EPT = Ephemeroptera, Plecoptera, Trichoptera, CA = Correspondence Analysis. QUL-PREF1 was not sampled in 2020, 2022, or 2023; QUL-PFF1 was not sampled in 2015, 2019, 2020, 2022, or 2023. No organisms were present in all replicate samples from QUL-PFF1-1 and QUL-PFF1-2 in 2014, therefore CA site scores could not be calculated.

Table C.5.4: Benthic Invertebrate Community Metrics for the Quesnel Lake (QUL-PNF and QUL-PFF1; Exposed and QUL-PREF1; Reference) Deep Monitoring Areas, 2014 to 2024

Notes: "-" indicates no data, °C = degrees Celsius, mg/ L = milligrams per litre, % = percent, µS/cm = microSiemens per centimeter, TOC = Total Organic Carbon, PC Axis = Principal Components Axis, mg/kg = milligrams per kilogram (dry weight). QUL-PFF1 (exposed) and QUL-PREF1 (reference) were not sampled in 2020, 2022, or 2023. % Fines represents the sum of the silt and clay fraction of sediments.

Notes: ID = identifier. UTM = Universal Transverse Mercator. NAD = North American Datum. CPUE = catch-per-unit-effort. HN = hoop net. All effort and CPUE values are displayed to three significant figures.

[a] CPUE = number of fish caught per day of fishing effort. CPUE is calculated for each fish species separately. Total CPUE for each fish species is calculated for each area as: (total number of fish caught [#]) / (total fishing effort [days]).

Notes: ID = identifier, UTM = Universal Transverse Mercator, NAD = North American Datum, CPUE = catch-per-unit-effort, HN = hoop net, ft = feet. All effort and CPUE values are displayed to three significant figures.

[a] CPUE = number of fish caught per day of fishing effort. CPUE is calculated for each fish species separately. Total CPUE for each fish species is calculated for each area as: (total number of fish caught [#]) / (total fishing effort [days]).

Notes: ID = identifier. UTM = Universal Transverse Mercator. NAD = North American Datu. CPUE = catch-per-unit-effort. YOY = Young-of-the-year.

[a] CPUE = number of fish caught per day of fishing effort. CPUE is calculated for each fish species separately. Total CPUE for each fish species is calculated for each area as: (total number of fish caught [#]) / (total fishing effort [days]).

[b] Several YOY fish were captured and could not be identified to species. These YOY fish from MP_QUL-NGC_HN-16_2024-10 were identified as subfamily Leuciscinae (i.e., peamouth chub or redside shiner). The YOY fish from other nets were too small to classify.

Table C.6.12: Hoop Net Catch Data from the Quesnel Lake near Hazeltine Creek (QUL-NHC; Exposed) and near Grain Creek (QUL-NGC; Reference) Monitoring Areas, October 2024

Area	Net ID	UTM (NAD83, Zone 10U)		Set Date	Lift Date	Set Time	Lift Time	Depth Range (m)		Effort (days)	Net Diameter (ft)	Northern Pikeminnow					Peamouth Chub					Rainbow Trout					Redside Shiner					Sockeye Salmon					Unknown YOY[b]

Notes: ID = identifier. UTM = Universal Transverse Mercator. NAD = North American Datu. CPUE = catch-per-unit-effort. YOY = Young-of-the-year.

[a] CPUE = number of fish caught per day of fishing effort. CPUE is calculated for each fish species separately. Total CPUE for each fish species is calculated for each area as: (total number of fish caught [#]) / (total fishing effort [days]).

[b] Several YOY fish were captured and could not be identified to species. These YOY fish from MP_QUL-NGC_HN-16_2024-10 were identified as subfamily Leuciscinae (i.e., peamouth chub or redside shiner). The YOY fish from other nets were too small to classify.

Notes: UTM = Universal Transverse Mercator, NAD = North American Datum, CPUE = catch-per-unit-effort, QUL = Quesnel, GN = gill net.

[a] CPUE = number of fish per m^2 per hour (# fish/[m^2 x hour]).

[b] Gill net set duration exceeded 1.5 h stipulated in the Department of Fisheries and Oceans (DFO) permit XR 145 2024 due to field crew safety concerns. DFO was notified of the situation and permitted the crew to leave nets in the water until conditions were considered safe for gill net retrieval.

Notes: UTM = Universal Transverse Mercator, NAD = North American Datum, CPUE = catch-per-unit-effort, QUL = Quesnel, GN = gill net.

[a] CPUE = number of fish per m^2 per hour (# fish/[m^2 x hour]). CPUE is calculated for each fish species separately.

[b] Gill net set duration exceeded 1.5 h stipulated in the Department of Fisheries and Oceans (DFO) permit XR 145 2024 due to field crew safety concerns. DFO was notified of the situation and permitted the crew to leave nets in the water until conditions were considered safe for gill net retrieval.

Value exceeds Se Guideline for Aquatic Life, fish muscle or whole body tissue (4 mg/kg dw; BCMOE 2014).

Value exceeds Se Guideline for Human Health, general population, high consumption (7.3 mg/kg dw; BCMOE 2014).

Value exceeds Se Guideline for Human Health, general population, moderate consumption (14.5 mg/kg dw; BCMOE 2014).

Value exceeds Hg Guideline for Human Health (0.5 mg/kg ww; CFIA 2015).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 04]) used in the full sample identifiers.

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 04]) used in the full sample identifiers.

Value exceeds Se Guideline for Aquatic Life, fish muscle or whole body tissue (4 mg/kg dw; BCMOE 2014).
Value exceeds Se Guideline for Human Health, general population, high consumption (7.3 mg/kg dw; BCMOE 2014).
Value exceeds Se Guideline for Human Health, general population, moderate consumption (14.5 mg/kg dw; BCMOE 2014).
Value exceeds Hg Guideline for Human Health (0.5 mg/kg ww; CFIA 2015).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 04]) used in the full sample identifiers.

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 04]) used in the full sample identifiers.

Value exceeds Se Guideline for Aquatic Life, fish muscle or whole body tissue (4 mg/kg dw; BCMOE 2014).
Value exceeds Se Guideline for Human Health, general population, high consumption (7.3 mg/kg dw; BCMOE 2014).
Value exceeds Se Guideline for Human Health, general population, moderate consumption (14.5 mg/kg dw; BCMOE 2014).
Value exceeds Hg Guideline for Human Health (0.5 mg/kg ww; CFIA 2015).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 04]) used in the full sample identifiers.

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 04]) used in the full sample identifiers.

Value exceeds Se Guideline for Aquatic Life, fish ovary tissue (11 mg/kg dw; BCMOE 2014).

Value exceeds Se Threshold for Effects, fish ovary tissue (20 mg/kg dw; DeForest et al 2012).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 04]) used in the full sample identifiers.

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where _YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 10]) used in the full sample identifiers.

Value exceeds Se Guideline for Aquatic Life, fish muscle or whole-body tissue (4 mg/kg dw; BCMOE 2014).

Value exceeds Se Guideline for Human Health, general population, high consumption (7.3 mg/kg dw; BCMOE 2014).

Value exceeds Se Guideline for Human Health, general population, moderate consumption (14.5 mg/kg dw; BCMOE 2014).

Value exceeds Hg Guideline for Human Health (0.5 mg/kg ww; CFIA 2015).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where _YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 10]) used in the full sample identifiers.

Value exceeds Se Guideline for Aquatic Life, fish muscle or whole-body tissue (4 mg/kg dw; BCMOE 2014).

Value exceeds Se Guideline for Human Health, general population, high consumption (7.3 mg/kg dw; BCMOE 2014).

Value exceeds Se Guideline for Human Health, general population, moderate consumption (14.5 mg/kg dw; BCMOE 2014).

Value exceeds Hg Guideline for Human Health (0.5 mg/kg ww; CFIA 2015).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where _YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 10]) used in the full sample identifiers.

Value exceeds Se Guideline for Aquatic Life, fish muscle or whole-body tissue (4 mg/kg dw; BCMOE 2014).
Value exceeds Se Guideline for Human Health, general population, high consumption (7.3 mg/kg dw; BCMOE 2014).
Value exceeds Se Guideline for Human Health, general population, moderate consumption (14.5 mg/kg dw; BCMOE 2014).
Value exceeds Hg Guideline for Human Health (0.5 mg/kg ww; CFIA 2015).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where _YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 10]) used in the full sample identifiers.

Value exceeds Se Guideline for Aquatic Life, fish ovary tissue (11 mg/kg dw; BCMOE 2014).

Value exceeds Se Threshold for Effects, fish ovary tissue (20 mg/kg dw; DeForest et al 2012).

Notes: "-" = no data available or standard deviation not calculated. mg/kg = milligrams per kilogram. dw = dry weight. ww = wet weight. LRL = laboratory reporting limit. All summary statistics were calculated using the Kaplan-Meier method and are reported to three significant digits for display purposes. Sample identifiers presented in this table are an abbreviated version of the full sample identifiers and exclude a pre-fix (MP_) and a suffix (_YYYY-MM; where _YYYY represents the year [i.e., 2024] and MM represents the month [e.g., 10]) used in the full sample identifiers.

APPENDIX D
DATA - CREEK HABITAT

APPENDIX D.1
WATER QUALITY

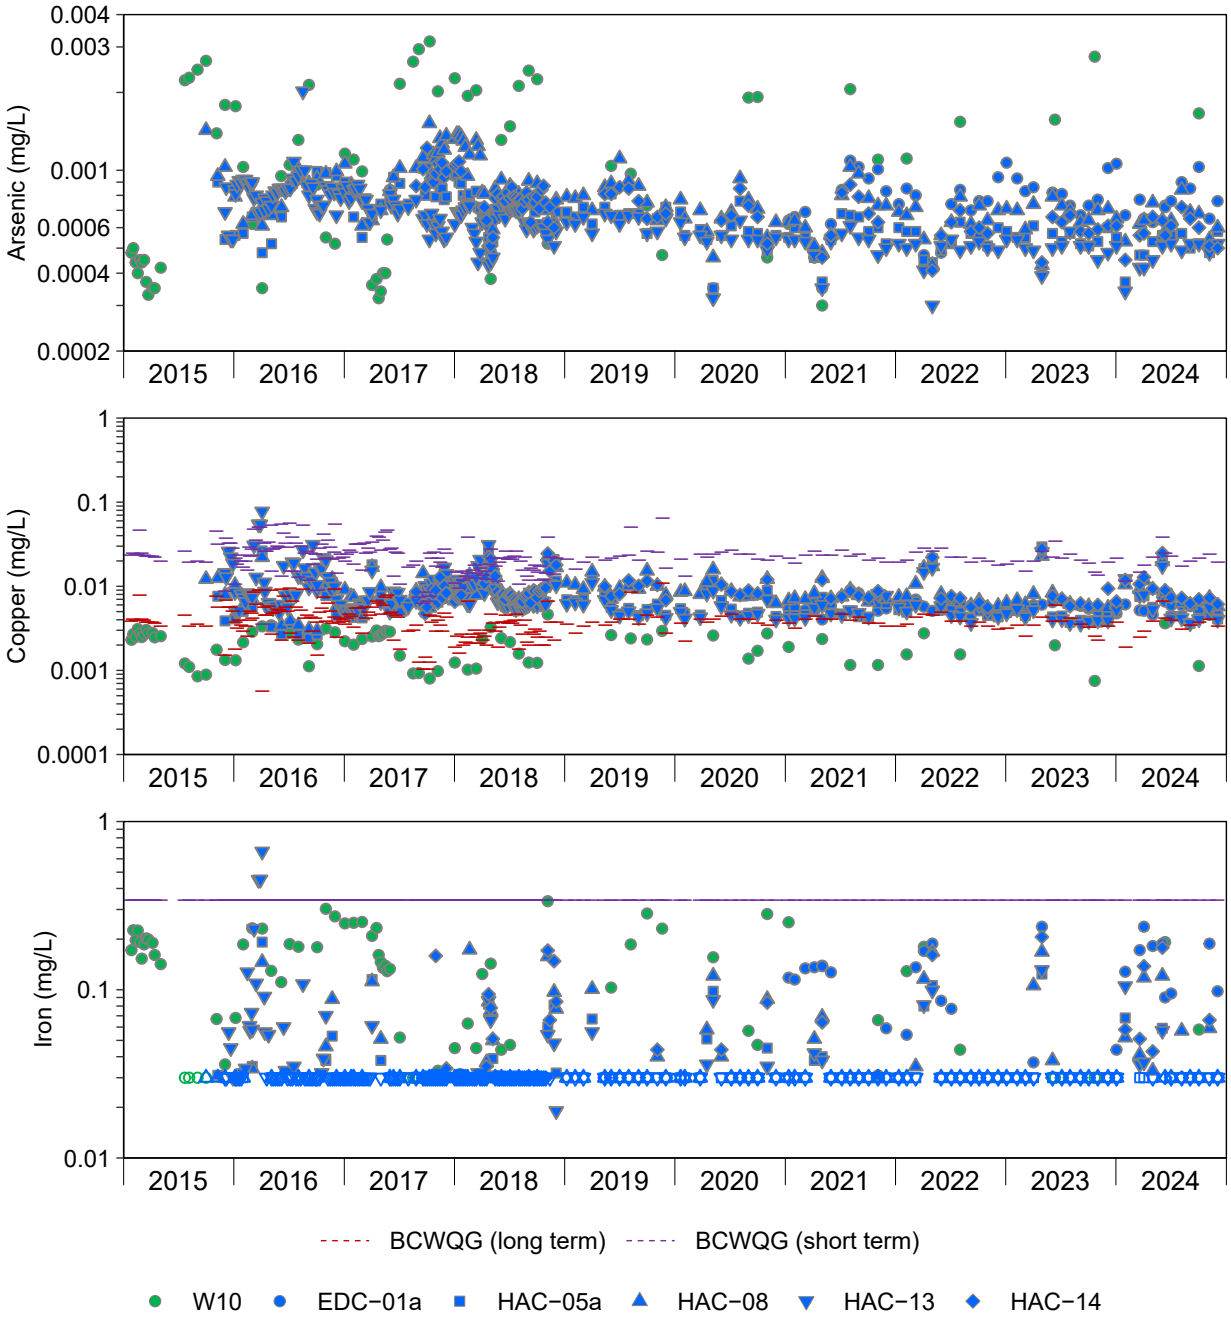

Figure D.1.1: Dissolved Aqueous Concentrations of Primary and Secondary Analytes in Surface Water Samples from Hazeltine Creek (HAC−13, HAC−05a, HAC−14, HAC−08) and Edney Creek (EDC−01a, W10), 2015 to 2024

Notes: BCWQG = British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025). Green represents reference stations and blue represents exposed stations. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Values displayed for BCWQG that are condition specific (i.e., hardness dependent or based on the Biotic Ligand Model) are the most conservative (i.e., lowest) of those calculated for the multiple monitoring stations displayed. See Appendix Tables D.1.3 to D.1.8 for tabular comparison of analyte concentrations to BCWQG for the year preceding biological sampling (September 2023 to August 2024). Dissolved mercury was not measured. Plots exclude data from EDC−01 in 2015 to 2020; EDC−01 was relocated and renamed as EDC−01a starting in 2021.

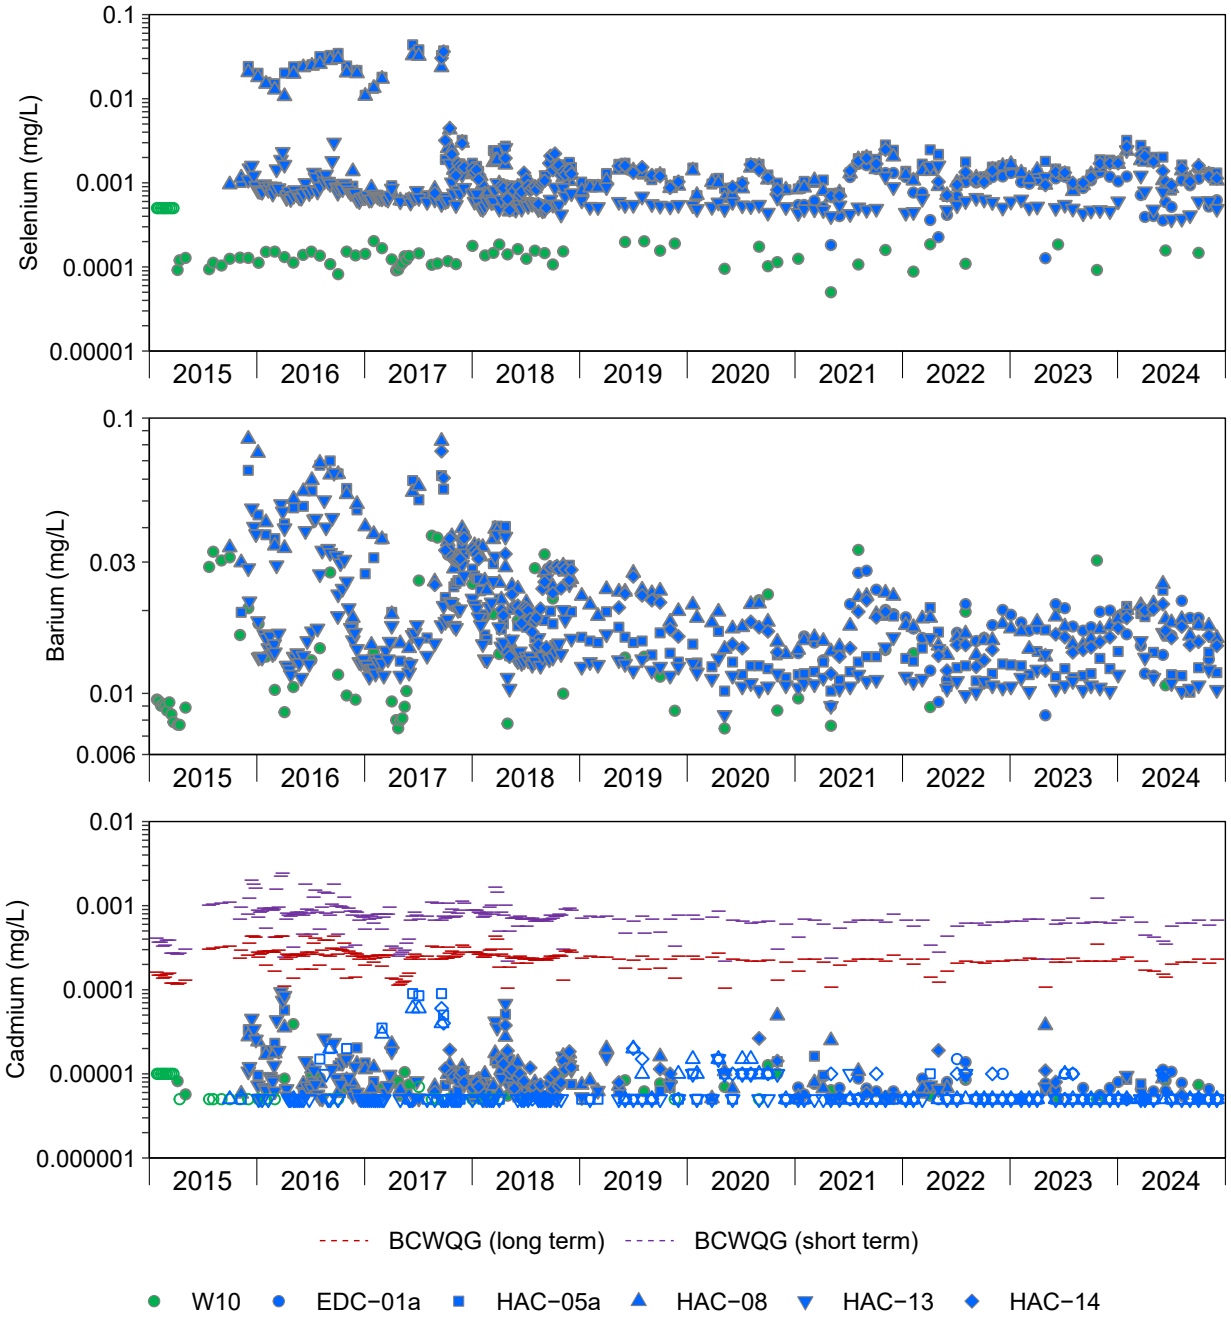

Figure D.1.1: Dissolved Aqueous Concentrations of Primary and Secondary Analytes in Surface Water Samples from Hazeltine Creek (HAC−13, HAC−05a, HAC−14, HAC−08) and Edney Creek (EDC−01a, W10), 2015 to 2024

Total mercury was not measured. Plots exclude data from EDC−01 in 2015 to 2020; EDC−01 was relocated and renamed as EDC−01a starting in 2021.

Figure D.1.3: Guideline Exceedance Factor (GEF) of Dissolved Copper in Surface Water Samples from Hazeltine Creek (HAC−13, HAC−05a, HAC−14, HAC−08) and Edney Creek (EDC−01a, W10), 2015 to 2024

Notes: GEF = Guideline Exceedance Factor. Acute and Chronic GEF's calculated from monthly averages. Green represents reference stations and blue represents exposed stations. Plots exclude data from EDC−01 in 2015 to 2020; EDC−01 was relocated and renamed as EDC−01a starting in 2021.

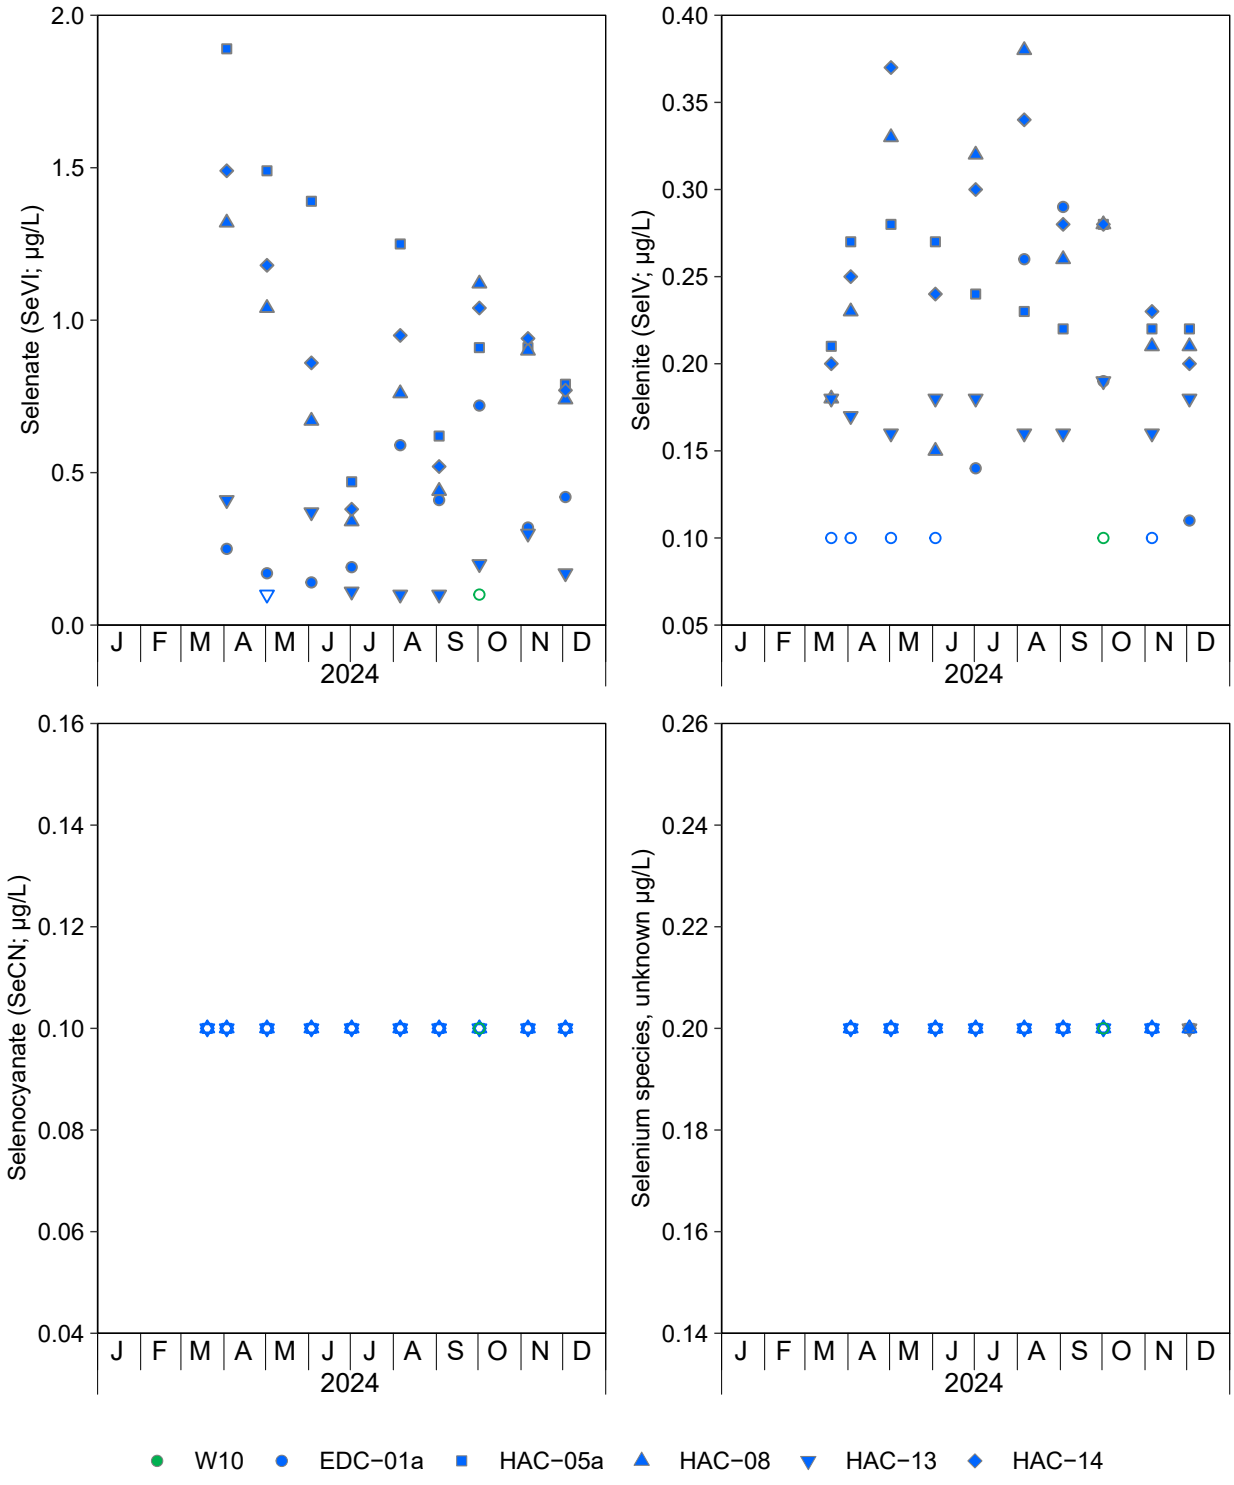

Figure D.1.4: Selenium Speciation Results from Surface Water Samples from Hazeltine Creek (HAC−13, HAC−05a, HAC−14, HAC−08) and Edney Creek (EDC−01a, W10), 2024

Notes: Green represents reference stations and blue represents exposed stations. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Selenium speciation monitoring commenced in April 2024. See Appendix Tables D.1.3 to D.1.8 for tabular comparison of analyte concentrations to BCWQG for the year preceding biological sampling (September 2023 to August 2024).

Table D.1.1: British Columbia Water Quality Guidelines for the Protection of Aquatic Life (BCMOWLRS 2024, 2025), 2024

Parameter	Units	Long-term Average	Short-term Maximum
Anions, Organics, Nutrients, and Physical Properties			
pH	pH units	6.5 - 9.0	
Temperature (*in situ*)[a]	°C	± 1	
Alkalinity ($CaCO_3$)	mg/L	> 20[b]	-
Conductivity	µS/cm	-	-
Dissolved Oxygen (*in situ*)[c]	mg/L	> 8	> 5
Dissolved Oxygen (*in situ*)[d]	mg/L	> 11	> 9
Total Suspended Solids[e]	mg/L	+ 5	+ 25
Turbidity[e]	NTU	+ 2	+ 8
Chloride	mg/L	150	600
Fluoride[f]	mg/L	-	For hardness ≤ 10 mg/L, WQG = 0.4 For hardness > 10 mg/L, WQG = [-51.73 + 92.57 × log10(hardness)]×0.01 Maximum applicable hardness = 385 mg/L
Sulphate[g]	mg/L	hardness dependent	-
Ammonia (as N)[h]	mg/L	temperature and pH dependent	temperature and pH dependent
Nitrate (as N)	mg/L	3.0	32.8
Nitrite (as N)[i]	mg/L	chloride dependent	chloride dependent
Phosphorus - Total[j]	mg/L	0.005 - 0.015	
Dissolved Organic Carbon[k]	mg/L	-	± 20%[k]
Total Metals			
Aluminum[f]	µg/L	For hardness 10 to 430 mg/L and pH 6 to 8.7 and DOC 0.08 to 12.3 mg/L, WQG = (exp([0.645 × ln(DOC)] + [2.255 × ln(hardness)] + [1.995 × pH] + [-0.284 × (ln(hardness) × pH)] -9.898))/3	-
Antimony	µg/L	74	250
Arsenic	µg/L	5	-
Barium	mg/L	1.0	
Beryllium	µg/L	0.13	-
Boron	mg/L	1.2	-
Chromium[l]	µg/L	For Cr VI, WQG = 0.0025 For Cr III, WQG = 0.0089	-
Cobalt	µg/L	4	110
Iron	mg/L	-	1
Manganese[f]	mg/L	For hardness 37 to 450 mg/L, WQG ≤ 0.004 × hardness + 0.605 Maximum applicable hardness = 450 mg/L	For hardness 25 to 259 mg/L, WQG ≤ 0.01102 × hardness + 0.54 Maximum applicable hardness = 259 mg/L
Molybdenum	mg/L	7.6	46
Selenium	µg/L	2	-
Silver[f]	mg/L	For hardness ≤ 100 mg/L, WQG = 0.00005 For hardness > 100 mg/L, WQG = 0.0015	For hardness ≤ 100 mg/L, WQG = 0.0001 For hardness > 100 mg/L, WQG = 0.003
Thallium	µg/L	0.3	-
Uranium	µg/L	7.5	16.5
Vanadium	mg/L	0.06	-
Dissolved Metals			
Cadmium[f]	mg/L	For hardness = 3.4 to 285 mg/L, WQG = {exp[0.736×ln - 4.943]} Maximum applicable hardness = 285 mg/L	For hardness = 7 to 455 mg/L, WQG = {exp[1.03×ln-5.274]} Maximum applicable hardness = 455 mg/L
Copper[m]	mg/L	Biotic Ligand Model	Biotic Ligand Model
Iron	mg/L	-	0.35
Lead[f]	µg/L	For Hardness 4.7 to 511 mg/L and Dissolved Organic Carbon 0.5 - 31.5 mg/L, WQG = {exp(0.514 [ln(DOC)] + 0.214[ln(hardness)] + 0. 4354)}/2	-
Nickel[m]	mg/L	Biotic Ligand Model	Biotic Ligand Model
Strontium	mg/L	1.25	-
Zinc[f]	µg/L	For hardness 23.4 to 399 mg/L, pH 6.5 to 8.13, and DOC 0.3 mg/L to 22.9 mg/L, WQG = (exp(0.947[ln(hardness)] − 0.815[pH] + 0.398[ln(DOC)] + 4.625))/2 Maximum applicable hardness = 399 mg/L	For hardness 13.8 to 250.5 mg/L and DOC 0.3 to 17.3 mg/L, WQG = (exp(0.833[ln(hardness)] + 0.240[ln(DOC)] + 0.526))/2 Maximum applicable hardness: 250.5 mg/L

Notes: "-" indicates no applicable guideline. BCMOWLRS = British Columbia Ministry of Water, Land and Resource Stewardship. WQG = Water Quality Guideline.

[a] Change from optimal. No guideline applied.

[b] For waterbodies with low sensitivity to acid inputs.

[c] Minimum for all life stages other than buried embryo / alevin.

[d] Minimum for buried embryo / alevin life stages.

[e] Increase relative to background; no guideline applied.

[f] For hardness-based guidelines, concurrent hardness values were used for calculating guidelines. If hardness values exceeding the maximum applicable hardness, then guidelines were determined using the maximum applicable hardness. If hardness values are lower than the minimum hardness, then guidelines were determined using the minimum hardness.

[g] 128 mg/L at hardness 0-30 mg/L; 218 mg/L at hardness 31-75 mg/L; 309 mg/L at hardness 76-180 mg/L; 429 mg/L at hardness > 250 mg/L.

[h] Used tables in BCMOWLRS 2025.

[i] When chloride < 2 mg/L, long-term = 0.02 mg/L and short-term = 0.06 mg/L; increase with increasing chloride.

[j] Aquatic Life - Lakes; minimum guideline was applied.

[k] ±20% of the background median; no guideline applied.

[l] Chromium VI is the dominant oxidation state in oxygenated environments, and so its guideline was applied.

[m] Guidelines calculated using the BLM model and calculated concurrently for each sample using the guideline lookup tables provided for dissolved copper and dissolved nickel (BCMOWLRS 2025).

Table D.1.2: Supporting Spot Water Quality Data Collected During Periphyton and Benthic Invertebrate Sampling in Hazeltine Creek, Frypan Creek, and Edney Creek, 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Notes: "-" indicates data not available. HAC-R2, EDC-REF, EDC-EXP, and HAC-R5 are alternate names used the for HAC-U, EDC-D, E1, and HAC-D sampling areas, respectively, for HRWG reporting.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.3: Surface Water Quality Data Collected Routinely at HAC-13 in Upper Hazeltine Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.3: Surface Water Quality Data Collected Routinely at HAC-13 in Upper Hazeltine Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.4: Surface Water Quality Data Collected Routinely at HAC-05a in Upper Hazeltine Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.5: Surface Water Quality Data Collected Routinely at HAC-14 in Upper Hazeltine Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.6: Surface Water Quality Data Collected Routinely at HAC-08 in Lower Hazeltine Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.6: Surface Water Quality Data Collected Routinely at HAC-08 in Lower Hazeltine Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.7: Surface Water Quality Data Collected Routinely at W10 in Lower Edney Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Table D.1.8: Surface Water Quality Data Collected Routinely at EDC-01a in Lower Edney Creek, September 2023 to August 2024

Indicates value greater than the long-term average British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Indicates value greater than the short-term maximum British Columbia Water Quality Guideline (BCMOWLRS 2024, 2025).

Percent exceedance > 0%.

Notes: "-" = data not available or no applicable guideline exists. < LRL = below laboratory reporting limit. GL = guideline. Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

[a] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOWLRS 2024, 2025) outlined in Appendix Table D.1.1.

[b] % displayed for pH indicates results falling outside the guideline range. % displayed for dissolved oxygen indicates results below the guideline.

[c] Guidelines for these parameters (Total Suspended Solids, Turbidity, Dissolved Organic Carbon) are narrative and were not evaluated.

Notes: mg/kg dw = milligrams per kilogram dry weight. Sediment metal concentrations are based predominantly on bulk sediment samples. Concentrations reported in 1995 and 1996 were for the silt and clay (< 63 µm) fraction only. Iron concentrations in sediment in 1999 were measured using both ICP-AA (Inductively Coupled Plasma Atomic Absorption) as well as ICP-MS (Inductively Coupled Plasma Mass Spectrometry for each sample collected (Beak 2000). Iron results measured using ICP-MS are displayed herein because this method is consistent with analysis methods used for post-breach monitoring (see Section 4.1.2). "-" indicates no data available.

[a] Monitoring areas WQ8, WQ8B, WQ9, and WQ10 sampled in 1995 (HKP 1996) were considered equivalent to sampling areas W8, W8A, W9, and W10 sampled in 1996 (HKP 1997a), respectively.

[b] Some unusually high sediment metal concentrations were reported for 1996 (HKP 1997a) and are suspected errors.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics*** indicates value is > reference 95th percentile value (<5th percentile value for pH). Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. "-" no data. Sediment metal concentrations are based predominantly on bulk sediment samples, concentrations reported in 1995 and 1996 were for the silt and clay (< 63 µm) fraction only. S = spring. F = fall.

[a] Some unusually high sediment metal concentrations were reported for 1996 (HKP 1997) and are suspected errors.

[b] Particle fractions for these samples are as follow: gravel (>2 mm), sand (2.0 mm - 0.050 mm), silt (0.050 mm - 0.002 mm), clay (<0.002 mm).

[c] 95th percentile includes all data except those from 1996 (HKP 1997) due to suspected errors.

Table D.2.2: Baseline and Pre-Breach Sediment Quality Data for the Upper Hazeltine Creek Monitoring Area for Calculation of Pre-Breach 95th Percentile, 1995 to 2013

Notes: mg/kg dw = milligrams per kilogram dry weight. **Bold/Italics** indicates value is > reference 95th percentile value (<5th percentile value for pH). Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. "-" no data. Sediment metal concentrations are based predominantly on bulk sediment samples, concentrations reported in 1995 and 1996 were for the silt and clay (< 63 µm) fraction only. S = spring. F = fall.

[a] Some unusually high sediment metal concentrations were reported for 1996 (HKP 1997) and are suspected errors.

[b] Particle fractions for these samples are as follow: gravel (>2 mm), sand (2.0 mm - 0.050 mm), silt (0.050 mm - 0.002 mm), clay (<0.002 mm).

[c] 95th percentile includes all data except those from 1996 (HKP 1997) due to suspected errors.

Notes: mg/kg dw = milligrams per kilogram dry weight. **Bold/Italics** indicates value is > reference 95th percentile value (<5th percentile value for pH). Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. "-" no data. Sediment metal concentrations are based predominantly on bulk sediment samples, concentrations reported in 1995 and 1996 were for the silt and clay (< 63 µm) fraction only. S = spring. F = fall.

[a] Some unusually high sediment metal concentrations were reported for 1996 (HKP 1997) and are suspected errors.

[b] Particle fractions for these samples are as follow: gravel (>2 mm), sand (2.0 mm - 0.050 mm), silt (0.050 mm - 0.002 mm), clay (<0.002 mm).

[c] 95th percentile includes all data except those from 1996 (HKP 1997) due to suspected errors.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics*** : Value is > reference 95th percentile value (<5th percentile value for pH), "-" indicates no current BC Working Sediment Quality Guidelines/ no data. The 95th percentile was calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics*** : Value is > reference 95th percentile value (<5th percentile value for pH), "-" indicates no current BC Working Sediment Quality Guidelines/ no data. The 95th percentile was calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Notes: mg/kg dw = milligrams per kilogram dry weight. ***Bold/Italics*** indicates value is > reference 95th percentile value (<5th percentile value for pH). Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. "-" no data. Sediment metal concentrations are based predominantly on bulk sediment samples, concentrations reported in 1995 and 1996 were for the silt and clay (< 63 µm) fraction only. S = spring. F = fall.

[a] Some unusually high sediment metal concentrations were reported for 1996 (HKP 1997) and are suspected errors.

[b] Particle fractions for these samples are as follow: gravel (>2 mm), sand (2.0 mm - 0.050 mm), silt (0.050 mm - 0.002 mm), clay (<0.002 mm).

[c] 95th percentile includes all data except those from 1996 (HKP 1997a) due to suspected errors.

Value is > BC Lower Working Sediment Quality Guideline.
Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. EDC-REF is the alternate name used the for EDC-D sampling area for HRWG reporting. ***Bold/Italics*** : Value is > reference 95th percentile value (<5th percentile value for pH), "-" indicates no current BC Working Sediment Quality Guidelines/ no data. The 95th percentile was calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.
Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. EDC-REF is the alternate name used the for EDC-D sampling area for HRWG reporting. ***Bold/Italics*** : Value is > reference 95th percentile value (<5th percentile value for pH), "-" indicates no current BC Working Sediment Quality Guidelines/ no data. The 95th percentile was calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] 5th percentile value for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Lower Working Sediment Quality Guideline.

Value is > BC Upper Working Sediment Quality Guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight. HAC-R2 is the alternate area identifier for HAC-U in the HRWG report. ***Bold/ Italics*** **=** value is > reference 95th percentile values (< 5th percentile value for pH). "-" indicates no current BC Working Sediment Guidelines/no data. All summary statistics were calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).

[b] Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. For calculation of pre-breach 95th percentile values see Appendix Table D.2.2. For calculation of reference 95th percentile values see Appendix Table D.2.3. Pre-breach sediment metal concentrations are based predominantly on bulk sediment rather than the fines fraction (<63 µm). The 5th percentile is reported for pH.

[c] Total Organic Carbon (TOC) and metals data are presented for the <63 µm sediment fraction for post-breach (2014 to 2024) data only. TOC and metals data presented for pre-breach results represent bulk sediment samples (see Appendix Tables D.2.2).

[d] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > BC Working Sediment Quality Guideline Effect Lower Level.
Value is > BC Working Sediment Quality Guideline Effect Upper Level.

Notes: mg/kg dw = milligrams per kilogram dry weight. HAC-R5 is the alternate name used the for HAC-D sampling area for HRWG reporting.. ***Bold/ Italics*** **=** value is > reference 95th percentile values (< 5th percentile value for pH). "-" indicates no current BC Working Sediment Guidelines/no data. All summary statistics were calculated to 3 significant figures.

[a] British Columbia Working Sediment Guidelines (BCMOWLRS 2024) and approved BC Sediment Quality Guideline for Selenium (BCMOWLRS 2025).
