Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Sub-Matrix: **Water**

Qualifiers

Qualifier	Description
B	*Method Blank exceeds ALS DQO. Associated sample results which are < Limit of Reporting or > 5 times blank level are considered reliable.*

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Water**

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

Sub-Matrix: **Water**

No. of samples analysed	: 1		

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QC Interpretive report to assist with Quality Review and Sample Receipt Notification (SRN).

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Signatories	*Position*	*Laboratory Department*
Elke Tabora		Inorganics, Calgary, Alberta
Millicent Brentnall	Laboratory Analyst	Metals, Calgary, Alberta
Sara Niroomand		Metals, Calgary, Alberta
Shirley Li		Metals, Calgary, Alberta
Vladka Stamenova	Analyst	Inorganics, Calgary, Alberta

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
mg/L	milligrams per litre

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLDS	*Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.*

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Duplicate outliers occur.
- No Laboratory Control Sample (LCS) outliers occur
- No Matrix Spike outliers occur.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- No Analysis Holding Time Outliers exist.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Matrix: **Water**

Evaluation: × = Holding time exceedance ; ✓ = Within Holding Time

Analyte Group / Container / Client Sample ID(s)	Method	Sampling Date	Extraction / Preparation				Analysis			
			Preparation Date	Holding Times Rec	Holding Times Actual	Eval	Analysis Date	Holding Times Rec	Holding Times Actual	Eval

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Water**

Evaluation: × = *QC frequency outside specification*; ✓ = *QC frequency within specification.*

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Nitrate in Water by IC (Low Level)	E235.NO3-L Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Total Organic Carbon (Non-Purgeable) by Combustion (Low Level)	E355-L Calgary - Environmental	Water	APHA 5310 B (mod)	Total Organic Carbon (Non-Purgeable), also known as NPOC (total), is a direct measurement of TOC after an acidified sample has been purged to remove inorganic carbon (IC). Analysis is by high temperature combustion with infrared detection of CO_2. NPOC does not include volatile organic species that are purged off with IC. For samples where the majority of total carbon (TC) is comprised of IC (which is common), this method is more accurate and more reliable than the TOC by subtraction method (i.e. TC minus TIC).
Total Metals in Water by CRC ICPMS	E420 Calgary - Environmental	Water	EPA 200.2/6020B (mod)	Water samples are digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Digested Dissolved Selenium in Water (Matrix Matched) by CRC ICPMS	E423BSe Calgary - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45um), digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS with matrix matching (carbon).

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Preparation for Total Organic Carbon by Combustion	EP355 Calgary - Environmental	Water		Preparation for Total Organic Carbon by Combustion
Dissolved Metals Water Digestion and Filtration	EP423 Calgary - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um) and digested with nitric and hydrochloric acids.

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Water**

					Laboratory Duplicate (DUP) Report

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Sub-Matrix: **Water**

Analyte	CAS Number	Method	LOR	Unit	Result	Qualifier
Anions and Nutrients (QCLot: 559262)

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Water**

					Laboratory Control Sample (LCS) Report				
					Spike	Recovery (%)	Recovery Limits (%)		
Analyte	CAS Number	Method	LOR	Unit	Concentration	LCS	Low	High	Qualifier
Anions and Nutrients (QCLot: 559262)

selenium, total	7782-49-2	E420	0.00005	mg/L	1 mg/L	94.8	80.0	120	----
selenium, dissolved	7782-49-2	E423BSe	0.00005	mg/L	1 mg/L	97.6	80.0	120	----

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

Sub-Matrix: **Water**

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
mg/L	milligrams per litre

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

No. of samples analysed	: 1		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Duplicate outliers occur.
- No Laboratory Control Sample (LCS) outliers occur
- No Matrix Spike outliers occur.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- No Analysis Holding Time Outliers exist.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Matrix: **Water**

Evaluation: × = Holding time exceedance ; ✓ = Within Holding Time

Analyte Group / Container / Client Sample ID(s)	Method	Sampling Date	Extraction / Preparation				Analysis

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Water**

Evaluation: × = *QC frequency outside specification*; ✓ = *QC frequency within specification.*

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Nitrate in Water by IC (Low Level)	E235.NO3-L Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Total Organic Carbon (Non-Purgeable) by Combustion (Low Level)	E355-L Calgary - Environmental	Water	APHA 5310 B (mod)	Total Organic Carbon (Non-Purgeable), also known as NPOC (total), is a direct measurement of TOC after an acidified sample has been purged to remove inorganic carbon (IC). Analysis is by high temperature combustion with infrared detection of CO_2. NPOC does not include volatile organic species that are purged off with IC. For samples where the majority of total carbon (TC) is comprised of IC (which is common), this method is more accurate and more reliable than the TOC by subtraction method (i.e. TC minus TIC).
Total Metals in Water by CRC ICPMS	E420 Calgary - Environmental	Water	EPA 200.2/6020B (mod)	Water samples are digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Dissolved Metals in Water by CRC ICPMS	E421 Calgary - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Digested Dissolved Selenium in Water (Matrix Matched) by CRC ICPMS	E423BSe Vancouver - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45um), digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS with matrix matching (carbon).

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Preparation for Total Organic Carbon by Combustion	EP355 Calgary - Environmental	Water		Preparation for Total Organic Carbon by Combustion
Dissolved Metals Water Filtration	EP421 Calgary - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um), and preserved with HNO3.
Dissolved Metals Water Digestion and Filtration	EP423 Vancouver - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um) and digested with nitric and hydrochloric acids.

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Water**

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Water**

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

Sub-Matrix: **Water**

No. of samples received	: 2		
No. of samples analysed	: 2		

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QC Interpretive report to assist with Quality Review and Sample Receipt Notification (SRN).

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Signatories	*Position*	*Laboratory Department*
Anthony Calero	Team Leader - Inorganics	Inorganics, Calgary, Alberta
Anthony Calero	Team Leader - Inorganics	Metals, Calgary, Alberta
Dwayne Bennett	Supervisor - Inorganic	Metals, Calgary, Alberta
Elke Tabora		Inorganics, Calgary, Alberta

Parker Sgarbossa	Laboratory Analyst	Inorganics, Calgary, Alberta
Ruifang Zheng	Analyst	Inorganics, Calgary, Alberta
Sara Niroomand		Inorganics, Calgary, Alberta

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
mg/L	milligrams per litre
NTU	nephelometric turbidity units

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLDS	*Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.*
RRV	*Reported result verified by repeat analysis.*

No. of samples analysed	: 2		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Duplicate outliers occur.
- No Laboratory Control Sample (LCS) outliers occur
- No Matrix Spike outliers occur.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- No Analysis Holding Time Outliers exist.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Matrix: **Water**

Evaluation: × = Holding time exceedance ; ✓ = Within Holding Time

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Water**

Evaluation: × = QC frequency outside specification; ✓ = QC frequency within specification.

Quality Control Sample Type			Count		Frequency (%)		
Analytical Methods	*Method*	*QC Lot #*	*QC*	*Regular*	*Actual*	*Expected*	*Evaluation*

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Turbidity by Nephelometry	E121 Calgary - Environmental	Water	APHA 2130 B (mod)	Turbidity is measured by the nephelometric method, by measuring the intensity of light scatter under defined conditions.
TSS by Gravimetry	E160 Calgary - Environmental	Water	APHA 2540 D (mod)	Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, following by drying of the filter at 104 ± 1°C, with gravimetric measurement of the filtered solids. Samples containing very high dissolved solid content (i.e. seawaters, brackish waters) may produce a positive bias by this method. Alternate analysis methods are available for these types of samples.
TDS by Gravimetry	E162 Calgary - Environmental	Water	APHA 2540 C (mod)	Total Dissolved Solids (TDS) are determined by filtering a sample through a glass fibre filter, with evaporation of the filtrate at 180 ± 2°C for 16 hours or to constant weight, with gravimetric measurement of the residue.
Bromide in Water by IC (Low Level)	E235.Br-L Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Chloride in Water by IC (Low Level)	E235.Cl-L Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Fluoride in Water by IC	E235.F Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrite in Water by IC (Low Level)	E235.NO2-L Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Nitrate in Water by IC (Low Level)	E235.NO3-L Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Sulfate in Water by IC (Low Level)	E235.SO4-L Calgary - Environmental	Water	EPA 300.1 (mod)	Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.
Alkalinity Species by Titration	E290 Calgary - Environmental	Water	APHA 2320 B (mod)	Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.
Ammonia by Fluorescence	E298 Calgary - Environmental	Water	Method Fialab 100, 2018	Ammonia in water is determined by automated continuous flow analysis with membrane diffusion and fluorescence detection, after reaction with OPA (ortho-phthalaldehyde). This method is approved under US EPA 40 CFR Part 136 (May 2021)

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Total Organic Carbon (Non-Purgeable) by Combustion (Low Level)	E355-L Calgary - Environmental	Water	APHA 5310 B (mod)	Total Organic Carbon (Non-Purgeable), also known as NPOC (total), is a direct measurement of TOC after an acidified sample has been purged to remove inorganic carbon (IC). Analysis is by high temperature combustion with infrared detection of CO_2. NPOC does not include volatile organic species that are purged off with IC. For samples where the majority of total carbon (TC) is comprised of IC (which is common), this method is more accurate and more reliable than the TOC by subtraction method (i.e. TC minus TIC).
Total Phosphorus by Colourimetry (0.002 mg/L)	E372-U Calgary - Environmental	Water	APHA 4500-P E (mod).	Total Phosphorus is determined colourimetrically using a discrete analyzer after heated persulfate digestion of the sample.
Total Metals in Water by CRC ICPMS	E420 Calgary - Environmental	Water	EPA 200.2/6020B (mod)	Water samples are digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Dissolved Metals in Water by CRC ICPMS	E421 Calgary - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.
Digested Dissolved Selenium in Water (Matrix Matched) by CRC ICPMS	E423BSe Calgary - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45um), digested with nitric and hydrochloric acids, and analyzed by Collision/Reaction Cell ICPMS with matrix matching (carbon).
Total Mercury in Water by CVAAS	E508 Calgary - Environmental	Water	EPA 1631E (mod)	Water samples undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS
Dissolved Mercury in Water by CVAAS	E509 Calgary - Environmental	Water	APHA 3030B/EPA 1631E (mod)	Water samples are filtered (0.45 um), preserved with HCl, then undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS.
Biochemical Oxygen Demand - 5 day	E550 Calgary - Environmental	Water	APHA 5210 B (mod)	Samples are diluted and incubated for a specified time period, after which the oxygen depletion is measured using a dissolved oxygen meter. Free chlorine is a negative interference in the BOD method; please advise ALS when free chlorine is present in samples.
Dissolved Hardness (Calculated)	EC100 Calgary - Environmental	Water	APHA 2340B	“Hardness (as $CaCO_3$), dissolved” is calculated from the sum of dissolved Calcium and Magnesium concentrations, expressed in $CaCO_3$ equivalents. “Total Hardness” refers to the sum of Calcium and Magnesium Hardness. Hardness is normally or preferentially calculated from dissolved Calcium and Magnesium concentrations, because it is a property of water due to dissolved divalent cations.
Hardness (Calculated) from Total Ca/Mg	EC100A Calgary - Environmental	Water	APHA 2340B	“Hardness (as $CaCO_3$), from total Ca/Mg” is calculated from the sum of total Calcium and Magnesium concentrations, expressed in $CaCO_3$ equivalents. “Total Hardness” refers to the sum of Calcium and Magnesium Hardness. Hardness is normally or preferentially calculated from dissolved Calcium and Magnesium concentrations, because it is a property of water due to dissolved divalent cations. Hardness from total Ca/Mg is normally comparable to Dissolved Hardness in non-turbid waters.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Preparation for Ammonia	EP298 Calgary - Environmental	Water		Sample preparation for Preserved Nutrients Water Quality Analysis.
Preparation for Total Organic Carbon by Combustion	EP355 Calgary - Environmental	Water		Preparation for Total Organic Carbon by Combustion
Digestion for Total Phosphorus in water	EP372 Calgary - Environmental	Water	APHA 4500-P E (mod).	Samples are heated with a persulfate digestion reagent.
Dissolved Metals Water Filtration	EP421 Calgary - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um), and preserved with HNO3.
Dissolved Metals Water Digestion and Filtration	EP423 Calgary - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um) and digested with nitric and hydrochloric acids.
Dissolved Mercury Water Filtration	EP509 Calgary - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um), and preserved with HCl.

QUALITY CONTROL REPORT

No. of samples analysed	: 2		

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percent Difference (RPD) and Data Quality Objectives
- Matrix Spike (MS) Report; Recovery and Data Quality Objectives
- Method Blank (MB) Report; Recovery and Data Quality Objectives
- Laboratory Control Sample (LCS) Report; Recovery and Data Quality Objectives

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Water**

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Water**

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

Sub-Matrix: **Water**

INVESTIGATION OF POTENTIAL SATURATED ROCK FILL AT WIGHT PIT – DNA SAMPLING RESULTS

1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) has retained WSP Canada Inc., (WSP) to investigate the possibility of using Wight Pit as a Saturated Rock Fill (SRF) for semi-passive water treatment at closure. Mount Polley observed that despite water of higher constituent concentrations entering Wight Pit, the water extracted from the pit had considerably lower concentrations. WSP had conducted a bench-scale trial and demonstrated that SRF technology is capable of reducing concentrations of the target analytes (selenium, nitrate, and possibly copper through sulfide precipitation) from the Site water (Golder 2021a). WSP also conducted an evaluation of the chemistry of Wight Pit waters to whether dilution could explain the observations or if there was a reduction mechanism. Based on the analysis of available data, WSP was of the opinion that something more than simple dilution was responsible for the observed parameter reduction (Golder 2021b).

Currently, the Wight Pit, which contains waste rock, is being used as a water storage facility on site and has been flooded to a considerably higher elevation than when the present sampling program and preceding chemistry evaluation were conducted (Golder 2021b). It is expected that the present use of Wight Pit will have altered the conditions from those investigated; however, these results remain useful for closure planning as the pit could be returned to its previous or other conditions. There are some 90 m of waste rock in Wight Pit so the ability to measure conditions and reactions at this depth were limited by the physical configuration. However, because it is known that certain reduction mechanisms are mediated by microbial activity, we sampled the effluent water to see if the presence of genetic material could be used to indicate the presence of these bacteria and their beneficial activity.

To confirm the microbial activity in removal of COCs, WSP collected samples from different locations on site to perform DNA analysis for the genes coding for 16S ribsomal Ribonucleic Acid (rRNA) to identify the presence of microbial species, based on their 16S rRNA genes, that could function in the removal of these COCs. The 16S subunit of ribosomes is part of the cellular “machinery” that converts genetic messages into functional components of cells. Ribosomal RNA is ubiquitously present in self-replicating systems and its sequence changes slowly with time, making this a useful molecule for detecting the relatedness of among distant species (Woese & Fox, 1977).

1.1 Background

The SRF is an emerging passive or semi-passive (if carbon source is added externally) biological treatment technology working as a fixed-film anaerobic reactor for removal of COCs. The SRF consists of a submerged waste rock bed where oxygen is consumed by microorganisms and anaerobic conditions prevail in the interstices. The waste rock media provides a biofilm growth surface for attachment and growth of bacteria.

Comparison of the predicted post-closure water quality with the proposed target limits revealed that constituents of concern (COCs) during post-closure are predicted to be selenium, nitrate and nitrite, and copper. The COCs were identified as the ones with predicted concentrations approaching or exceeding the target limits based on post-closure influent water quality models (Golder 2020a). The target limits are based on the 2020 post-closure treatment targets (Golder 2020b). The concentration of nitrate is predicted to be close to the effluent discharge limit during operations but is expected to decrease considerably below the limit after closure. Although nitrate is not a COC for post closure, nitrate reduction occurs simultaneously with Se reduction in the SRF treatment system. SRF systems are more typically viewed as systems for the removal of selenium and nitrate; however, copper is also being examined in the Mount Polley SRF investigations because copper is a current and (predicted) future COC for the site, albeit with a different removal mechanism.

The Se removal mechanism includes reduction of soluble oxidized forms of Se to particulate elemental Se by selenium-reducing bacteria (SeRB). Nitrate is removed by the process of denitrification where denitrifiers facilitate the reduction of nitrate to nitrogen gas. The nitrate reduction process is more energetically favourable to the microbial community than the Se reduction pathway, so nitrate is generally reduced prior to Se reduction. However, some nitrate reducing bacteria (NRB) can reduce Se as well. Because Cu is one of the COCs, the possibility of Cu precipitation by sulfate reducing bacteria (SRB), that transform sulfate to sulfide which then precipitates with Cu as the insoluble copper sulfide in the SRF, is investigated.

1.2 Objectives and Scope

In bioremediation of mine-influenced water, the microbial community inside the system is the core of the treatment process. The microbial community of an environmental system is often a complex consortium of different types of bacteria. To explore whether the observed reduction of COC concentrations in Wight Pit (Golder Associates Ltd. (Golder), 2021) was due to biological activity, the presence of copper-transforming bacteria, SeRB, NRB, and sulfate-reducing bacteria should be confirmed. Consequently, the microbial community composition and interactions were studied by DNA analysis of the microbial communities from different locations on Site. To achieve this objective, different steps were taken for sample collection and analysis:

- DNA samples were collected from various locations on and adjacent to the site.
- DNA samples were also collected from the bench-scale SRF leaching test being conducted on water from the Site in WSP laboratory.
- DNA extraction and sequencing was conducted by a third-party laboratory (Department of Cell & Systems Biology, University of Toronto).
- The bioinformatics analysis was done on raw sequencing data by a sub-contractor (Amplytica). The attached report (Attachment 1) was generated by Amplytica.
- Interpretation of bioinformatics data, and comparison between locations sampled and the bench-scale samples to find similarities or differences, was done by WSP.

2.0 SITE DESCRIPTION

Wight Pit is a mined area on Site that is partly filled with waste rock (Figure 1). Beginning in November of 2020, water from the NEZ sump was redirected to Wight Pit such that it infiltrates into this waste rock bed. Water extracted from Wight Pit ("effluent") was directed to the Long Ditch where it flows to the Water Treatment Plant located at the base of the Perimeter Embankment of the Tailings Storage Facility.

Figure 1: Wight Pit and Rock Back Fill

3.0 METHODS

Site locations were selected for DNA sampling to represent water quality of diverted influent from the NEZ Sump into Wight Pit, groundwater that is representative of what may be entering Wight Pit, and effluent pumped from Wight Pit. Additional samples were collected from the TSF seepage water, Cariboo Pit and from the bed of Polley Lake and a QA/QC sample to test for cross-contamination during sampling was also collected from the tap water at the Environmental Department's trailer.

The samples collected from various locations as part of this program and from the bench scale test are summarized in Table 1.

Table 1 Summary of Selected On-Site and Bench Samples For DNA Analysis

General Location Description	Sample ID in Amplytica Report	Volume of Filtered Sample (mL)	Sample Collection Date
Polly Lake	Pl	50	28 February 2022
Tailings Storage Facility Seepage	Tsf	300	28 February 2022
Wight Pit	Wp	500	1 March 2022
NEZ Seep	Nez	500	1 March 2022
Wight Pit Sump	Wps	500	1 March 2022
Kynoch Pump	Kp	500	1 March 2022
Cariboo Pit	Cp	250	2 March 2022
Environmental Trailer	Et	500	2 March 2022
Bench-scale SRF Influent	Inf	825	28 February 2022
Bench-scale SRF Effluent	Eff	165	28 February 2022

Replicate samples were taken from each location as back-up in case of sample contamination. As no contamination was observed, the replicate samples were not extracted nor sequenced. The following steps were taken for sample collection, DNA sequencing, and data analysis:

1) Samples were collected in clean 50 mL syringes. A new syringe and filter apparatus was used for each sample location.

2) Samples were filtered using a 0.22 µm cellulose filter placed in a 25 mm diameter filter holder. So that enough DNA was collected on the filter for extraction, for some Site locations with low TSS, more than 50 mL of sample was filtered. The volume of water filtered in each sample is provided in Table 1. The same volume of water was sampled for the replicate sample as well, although the replicates were not analyzed as noted above.

3) Filtering of water was continued for each sample location until the filter paper was clogged (as determined by considerable backpressure).

4) Filter papers were carefully extracted from the filter holder with decontaminated forceps, wrapped in sterile aluminum foil, and labeled properly with the site location names.

5) Samples were stored on ice or in a freezer while on site, until transferring to dry ice for shipping.

6) Samples were shipped on dry ice to Department of Cell & Systems Biology at the University of Toronto for DNA extraction and V4 16S rRNA gene sequencing (Bacteria/Archaea).

7) The bioinformatics analysis was done on raw sequencing data by Amplytica using clustering-free techniques for identifying Amplicon Sequence Variants (ASVs).

8) Information on the required data analysis was provided to Amplytica by WSP. A report summarizing the present functional genes in each sample was generated by Amplytica.

9) Interpretation of results and data analysis was done by WSP.

4.0 RESULTS

The results of the microbial taxonomy analyses are presented in the Amplytica report (Attachment 1) with details on the abundance of metabolic categories and gene abundances in each sample. Some of the noteworthy findings of the study are summarized below:

Cross-Contamination Check

Because even small amounts of DNA can be amplified through the polymerase chain reaction (PCR) process, a negative control was collected from the sink tap in Mount Polley's environmental trailer. The water at the tap is non-potable water and is not chlorinated. There were very low sequencing reads in the Environmental trailer sample (Et) meaning that the other samples (with the exception of the Tailings Storage Facility Seepage (Tsf)) contained DNA that originated from the sample and not as a result of cross-contamination through the sampling, transport, and analysis procedures used. These two samples were not further analyzed for DNA composition.

Community Diversity

- The sample collected from Polley Lake had the most unique number of identified genera which indicates that the microbial community is diverse.
- The bench-scale influent (Inf) and effluent (Eff) had the lowest number of identified genera. The fact that effluent of the bench-scale test had the lowest diversity of genera confirms that WSP was successful in selectively growing selenium and nitrate reducing bacteria in the bench-scale SRF. Selectively growing microorganisms under controlled conditions provides higher efficiency in targeted removal of COCs from the water as opposed to the high-diversity microbial community in environmental samples.

Community Relatedness Among Different Samples

- The analysis of the microbial community structure (Fig. 4 of Attachment 1) revealed that the proportion of microbial genera shared between samples Wight Pit (Wp), Wight Pit Sump (Wps), Polly Lake (Pl), and Kynoch Pump (Kp) appeared to be more similar at the genus level. Wp, Wps, Pl, and Kp also were predicted to have similar levels of nitrifying and denitrifying genes.
- Samples collected from the bench-scale effluent (Eff) was unique and quite distant from all other samples collected from the site. This could be due to the source of the inoculum used in the bench-scale tests, which came from previous bench test trials in the WSP laboratory as well as the provision of a consistent organic carbon source. Consequently, it is expected that the microbial community is different from what is seen on site locations. However, it is the function performed by the microbes that matters vis-à-vis the potential for water treatment.

Significant Identified Families

- Relative abundance of microorganisms present in each sample was analyzed in family and genus levels. The dominant families (more than 3.5% of total population) present in Pl, Wp and Wps were quite similar among all samples.

- The families that are known to be involved in selenium or nitrogen transformation which were dominant in Wp, Wps, and Pl are *Rhodocyclaceae, Comamonadaceae, Nitrosomonadaceae,* and *Gallionellaceae* from the order *Burkholderiales*. The *Rhodocyclaceae* family has been identified as a putative selenate reducer through the NarG enzyme (Baldwin et al., 2019). The *Comamonadaceae* family is in the betaproteobacteria class that has been identified as a putative reducer in nitrate and selenate bioremediation from mine influenced water (MIW) (Baldwin et al., 2019). The selenate reduction in the microorganisms of this family is possibly carried out using their nitrate reductase enzyme NarG. The *Nitrosomonadaceae* family is an ammonia oxidizing family that initiates the nitrification reaction by oxidizing ammonia to nitrite, which is subsequently oxidized by bacterial nitrite oxidizers to nitrate. These microorganisms have a major role in the nitrogen cycle in the environment and in wastewater treatment processes (Prosser et al. 2014; Atlas & Bartha, 1981). *Gallionellaceae* family can also be classified as potential participants in nitrate removal in aquatic environments. However, the pathways and the enzymes involved in the removal nitrate from groundwater have not been identified. Genetic analysis of the strains had shown that these bacteria contain genes related to nitrogen, iron and carbon metabolism which allow to grow under anoxic conditions. Although this family is involved in nitrate reduction, the study does not identify that the bacteria are capable of transforming nitrate all the way to nitrogen gas (Jakus et al. 2021).
- For the bench-scale samples, the dominant families in Eff were considerably different from the ones in Inf. The Eff contained *Rhodocyclaceae*, *Hydrogenophilacea*, *Latescribacterota*, *Desulfitobacteriaceae,* Geobacteraceae, and *Sulfurimonadacea*. Bacteria from *Desulfitobacteriaceae* family are known for their capacity to grow by anaerobic respiration using many different organic and inorganic electron acceptors such as sulfate, nitrate, nitrite, fumarate, or polysulfide. *Rhodocyclaceae* which was also dominant in multiple locations in the environmental samples, is a putative selenate reductase through NarG enzyme as described earlier.

Significant Identified Genera

- *Sulfurifustis,* which was an abundant genus in Pl, Wp, and Wps is a type of autotrophic sulfur-oxidizing bacteria belonging to the family *Acidiferrobacteraceae* in the order *Acidiferrobacterales* that are involved in sulfur oxidation and inorganic carbon fixation pathways. By contributing to the sulfur cycle, these bacteria are possibly involved in removal of copper through precipitation as a metal sulfide.
- Members of the genus *Sulfuritalea* were present in Pl, Wp, and Wps. These bacteria, from the class *Betaproteobacteria,* have been identified in activated sludge, lake water, ground water, soil, and sediment (Watanabe et al., 2016). Members of this genus are facultatively anaerobic and can reduce nitrate to nitrogen under anaerobic conditions. Under denitrifying conditions, this bacterium grows autotrophically on hydrogen, thiosulfate, and elemental sulfur, or it grows heterotrophically on various organic substrates. Members of this genus can also oxidize sulfur, thiosulfate, or hydrogen and are potentially involved in copper precipitation.
- The *Thiobacillus* genus that was abundant in Eff, Wp, and Wps can convert Se^0 to hydrogen selenide (H_2Se) under anaerobic conditions (Eswayah et al., 2016). This genus is categorized within sulfur chemolithotrophs which have been shown to be capable of oxidizing sulfide or sulfur to sulfate under aerobic condition where the final electron acceptor is O_2 (Bacon et al. 1989).

Gene Abundance Prediction

- Gene abundance prediction was done to identify the overall abundance of nitrification, denitrification, and selenate reduction genes in each sample. Gene abundance predictions indicate that selenate reduction (i.e., selenate to selenite) was present in all samples, except for the Inf (which is expected to be low in the feed water to the bench-scale reactor). The selenate reduction gene abundance predictions were slightly higher in Wp and Pl and significantly higher in Eff.
- Based on the gene abundance predictions for both Wp and Eff, although selenate reductase K17050 (Schröder et al. 1997) are predicted to be present, the abundance of nitrate reductase K15864 (Zumft 1997) and nitric oxide reductase K04561 (Heiss et al. 1989) is considerably higher; meaning that the Se reduction is potentially mainly carried out by denitrifiers.
- A list of known selenate reducing and methylating genera derived from literature was provided by WSP so that Amplytica could produce a comprehensive list for selenate reducing organisms. As a result, Wp, Eff, and Cp were found to have elevated concentrations of putative selenate reducers.

5.0 SUMMARY

Overall, the analysis of the microbial communities in the samples confirmed the presence of a diverse microbial community in all samples collected (with the exception of Et and Tsf) from different site locations and from the bench-scale SRF. The analysis of the samples collected from the site provided proof-of-concept for the biological activity in terms of selenate and nitrate reduction in Wight Pit. Several species that are potentially involved in selenium and/or nitrate removal were present in the microbial community in the Wp.

Because Cu is one of the COCs post-closure, the possibility of Cu removal through precipitation as copper sulfide was investigated. Although some sulfur/sulfide oxidizing bacteria were present in the Wp, with potential roles in the sulfur cycle, the sulfate reducing bacteria were not sufficiently present among the dominant genus or families. This could be attributed to the sequencing method or statistical tools that were used to analyze the sequencing data. To better understand the microbial community, more precise sequencing techniques such as shotgun sequencing may be an option. However, because Wight Pit is now used for water storage and lacks the general features of an SRF, such further analysis would not be possible at present, other than in the bench scale SRF reactor.

6.0 CLOSURE

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

We trust that the information provided herein is sufficient for your needs at this time. If you have any questions or need additional information, please do not hesitate to contact us.

Microbiome Functionality Report

Prepared for: WSP/ Golder Associates Inc.

Sample Overview

Golder Associates Inc. suspects their client's rock pile may possess naturally occurring Saturated Rock Fill (SRF) reactor activity. In mine remediation, operators use SRF reactors to remove excess selenium and nutrients from contaminated mine wastewaters. As part of Golder's project, ten water filter samples were collected from the field site and laboratory bench-scale tests and sent for microbiome assays. Golder sent samples to Amplytica in a blinded fashion where samples were labelled, but they provided no other sample information. Each sample is referred to in this analysis by an alphanumeric code to simplify the text and figure labels (Tab. 1).

Table 1: Sample Information

Sample Identifier	**Bioinformatics Analysis Identifier**	**Passed Quality Control**
INF-1	Inf	True
EFF-1	Eff	True
PL-1	Pl	True
TSF-1a	Tsf	False
WP1	Wp	True
KP-1	Kp	True
WPS 1	Wps	True
NEZ1	Nez	True
ET1	Et	False
CP1	Cp	True

Overview of Quality Control and Methodologies Used

DNA Sequencing and Bioinformatics Analysis

The V4 region of the 16S rRNA gene was amplified and isolated from each sample sent for microbiome assays. One or more V4 regions were amplified for each microbe in these samples. An Illumina MiSeq instrument sequenced the resulting V4 fragments. Sequencing reads were quality trimmed and quality filtered, resulting from the instrument reading each fragment's genetic sequence. Low-quality reads were removed. Later, sequencing errors were also removed from the remaining quality-filtered reads. The resulting quality-controlled reads were used to identify the samples' microbial taxa. Alpha rarefaction curves were generated for each sample. The Silva taxonomy database (Release 138.1) was used to classify the sequencing reads taxonomically, which characterized each sample's microbial taxa. Taxa represented by only two sequencing reads were removed from the overall dataset. Custom scripts were used to generate alpha rarefaction, bubble, and heatmap plots of the taxa present in samples at class, family, and genera levels. The abundance of metabolic categories and gene abundances in each sample was calculated using FAPROTAX and PICRUSt2, respectively. Custom scripts were also used to plot the FAPROTAX and PICRUSt2 output.

Samples Removed Due To Low Sequencing Reads

Although a depth of thirty thousand sequencing reads was targeted, Amplytica found some samples to have fewer reads due to a lack of extractable biomass.

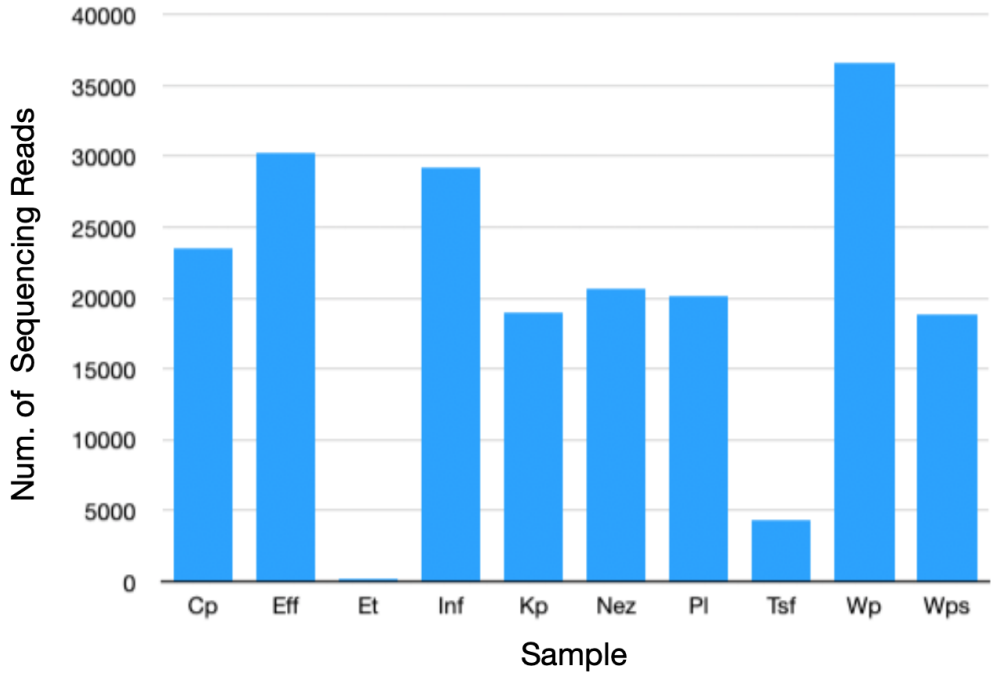

Figure 1: Number of sequencing reads acquired for each sample.

Amplytica's sequencing provider found all samples to have relatively low biomass. However, the biomass of Et and Tsf were exceptionally low, which caused very low read counts for these samples. Amplytica removed Et and Tsf from further analysis to support the analysis of the other samples and remove biases. The remaining samples were subsequently subsampled (i.e., rarefied) to twelve thousand reads to provide even coverage across samples. Amplytica's sequencing provider indicated that it might not be worthwhile to further sequence backup filters for samples like Et as they are unlikely to amplify due to their extremely low starting biomass.

Microbiome Data

Overview of Microbial Diversity

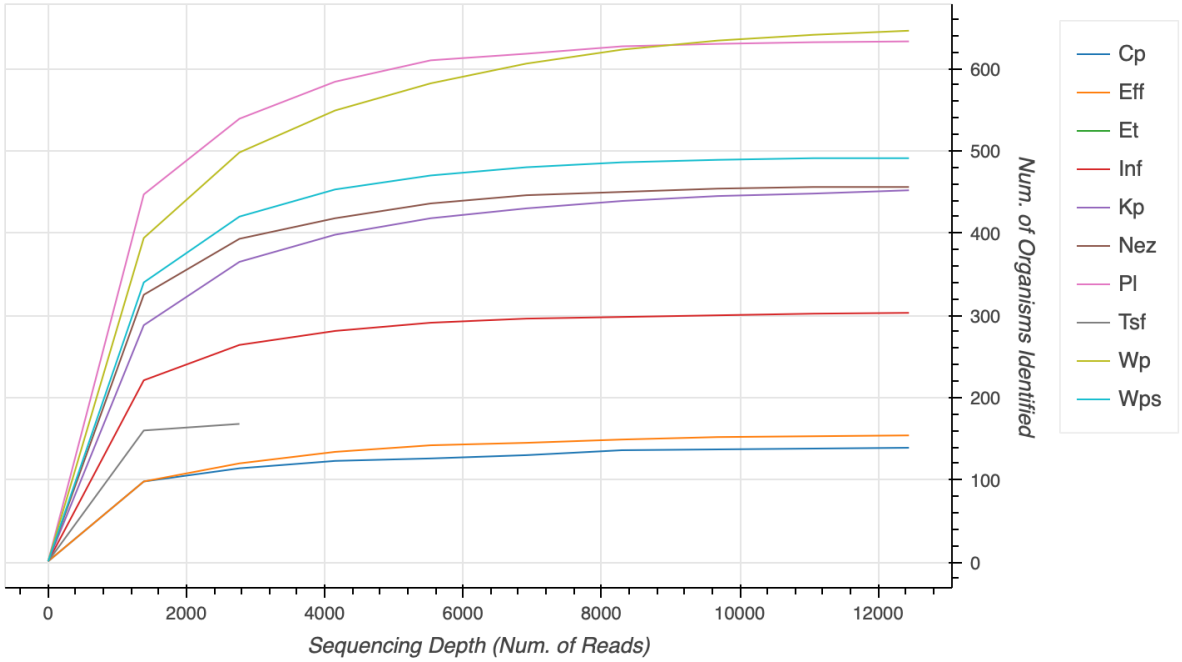

Figure 2: Alpha rarefaction curve showing the effect of sequencing depth on the number of organisms identified.

A rarefaction curve for each sample was generated (Fig. 2). For most samples, the number of organisms identified plateaued at approximately eleven thousand sequencing reads (Fig. 2). Because each sample was sequenced with at least twelve thousand reads, the plateauing indicates that most of the taxa found in each sample were identified. Sample Wp was close to plateauing but may not have plateaued by twelve thousand reads.

Samples Inf, Eff, and Cp, were shown to have lower numbers of genera than the other samples (Fig. 3). Sample Pl was shown to have substantially more unique genera when compared to other samples (Fig. 3). Sample Wp shared more genera with Wps than any other sample (Fig. 3.) Sample Wp also shared many genera with sample Kp (Fig. 3).

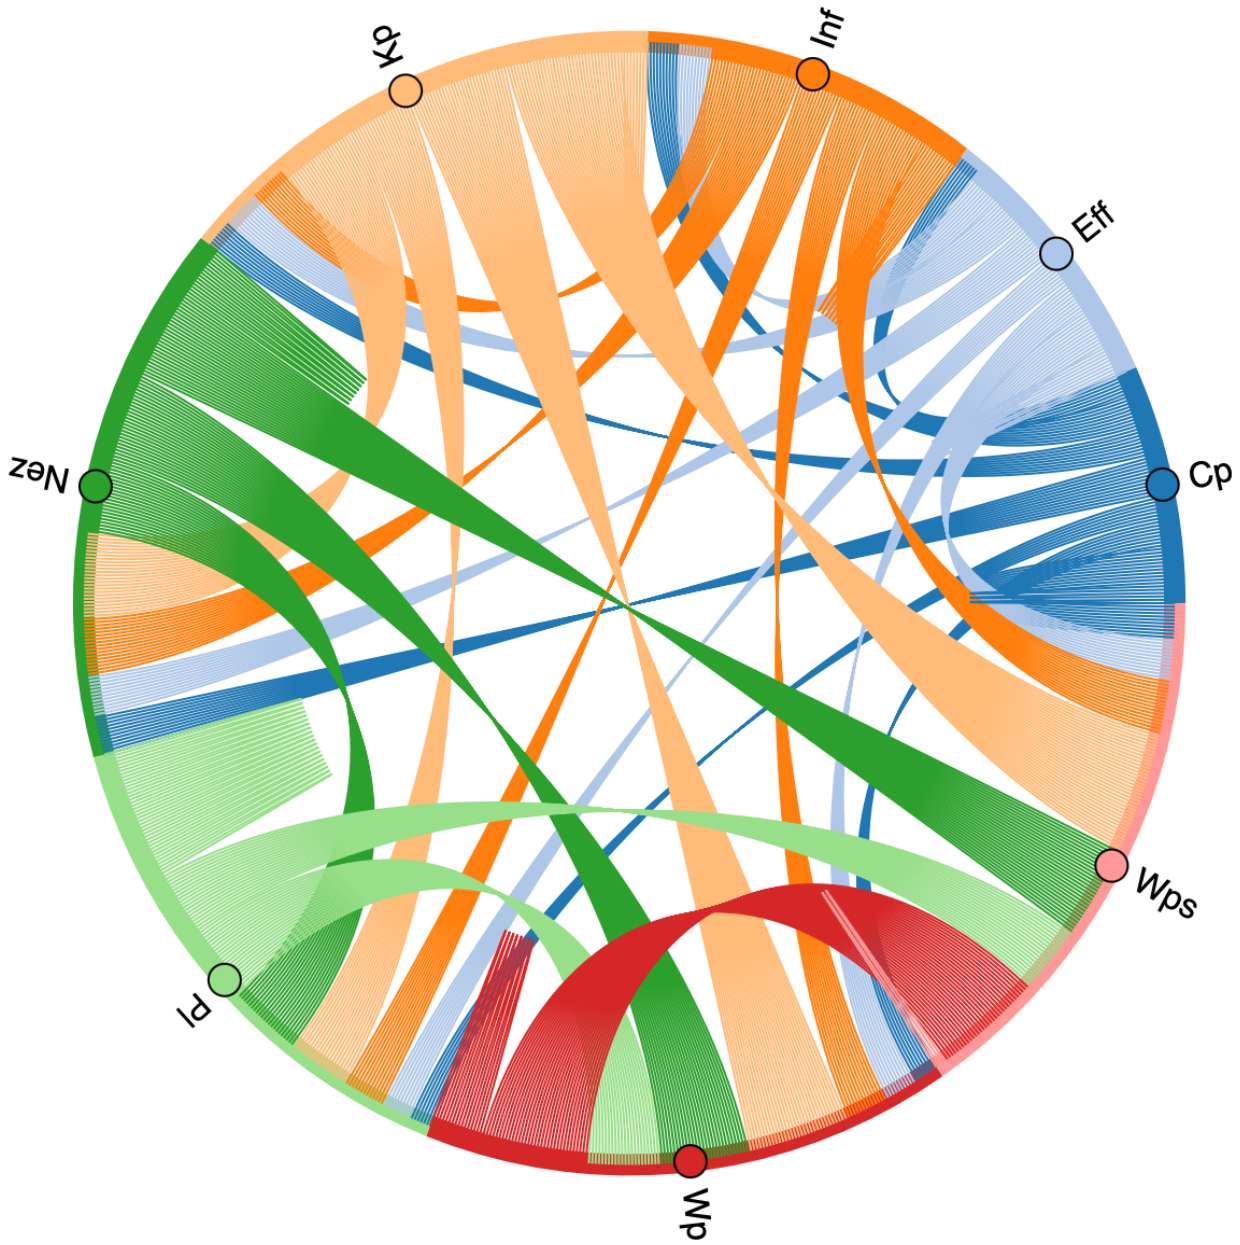

Figure 3: A chord diagram showing the proportion of microbial genera shared between or unique to individual samples. Each sample is assigned an edge fragment, and the total width of each fragment correlates with the total number of genera in its corresponding sample. The width of the arcs that cross the circle between two samples indicates the proportion of genera shared between these two samples. Arcs that fail to cross the circle indicate the proportion of genera unique to a sample.

Overview of Microbial Community Structure

At a genus level, the microbial communities of samples Eff and Cp were quite distant from the other samples and each other (Fig. 4). In contrast, the microbial communities of samples Kp, Wp, and Wps appeared to be more similar at a genus level (Fig. 4). The ordination results shown in Figure 4 correlate with the results presented in Figure 3, which show that Wp, Wps, and Kp have large numbers of overlapping genera.

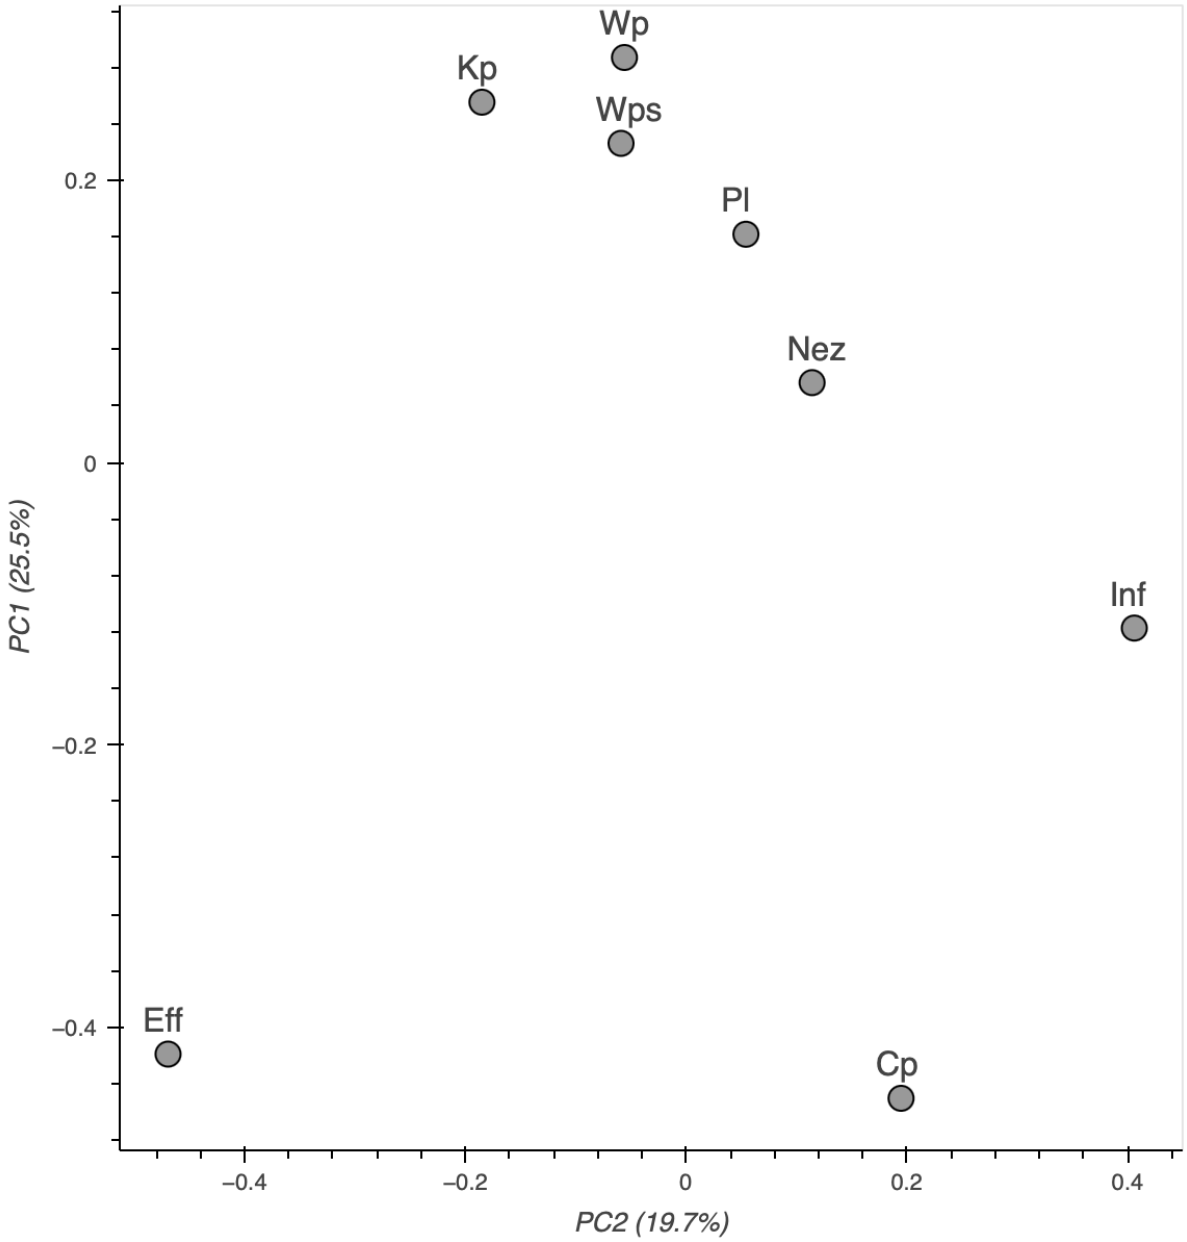

Figure 4: A Principal Coordinates Analysis (PCoA) biplot generated from genus-level prokaryotic Bray-Curtis beta diversity distances between samples. Distances were created from observations of sequencing reads being classified as belonging to a specific genus. Samples that cluster closer to each other on the biplot have similar prokaryotic communities.

Overview of Microbes Present

At a family level, the distribution of taxa appears to be patchy (Fig. 5 and Fig. 6). Sample Cp had elevated abundances of Comamonadace (>15%) and Verrucomicrobiaceae (>20%) (Fig. 5 and Fig. 6). Eff had increased abundance of Hydrogenphilaceae (>20%), Rhodocyclacaeae (>10%), Geobacteraceae (>15%), and Sulfurimonadaceae (>15%) (Fig. 5 and Fig. 6). Sample Kp had elevated levels of Rhodocyclacaeae (>20%). Samples Wp and Wps had elevated levels of Acidiferrobacteraceae (>20%) (Fig. 5 and Fig. 6). Sample Wp (~5%) and Pl (~7%) had much higher levels of KD4-96 than Wps or any other sample (Fig. 5).

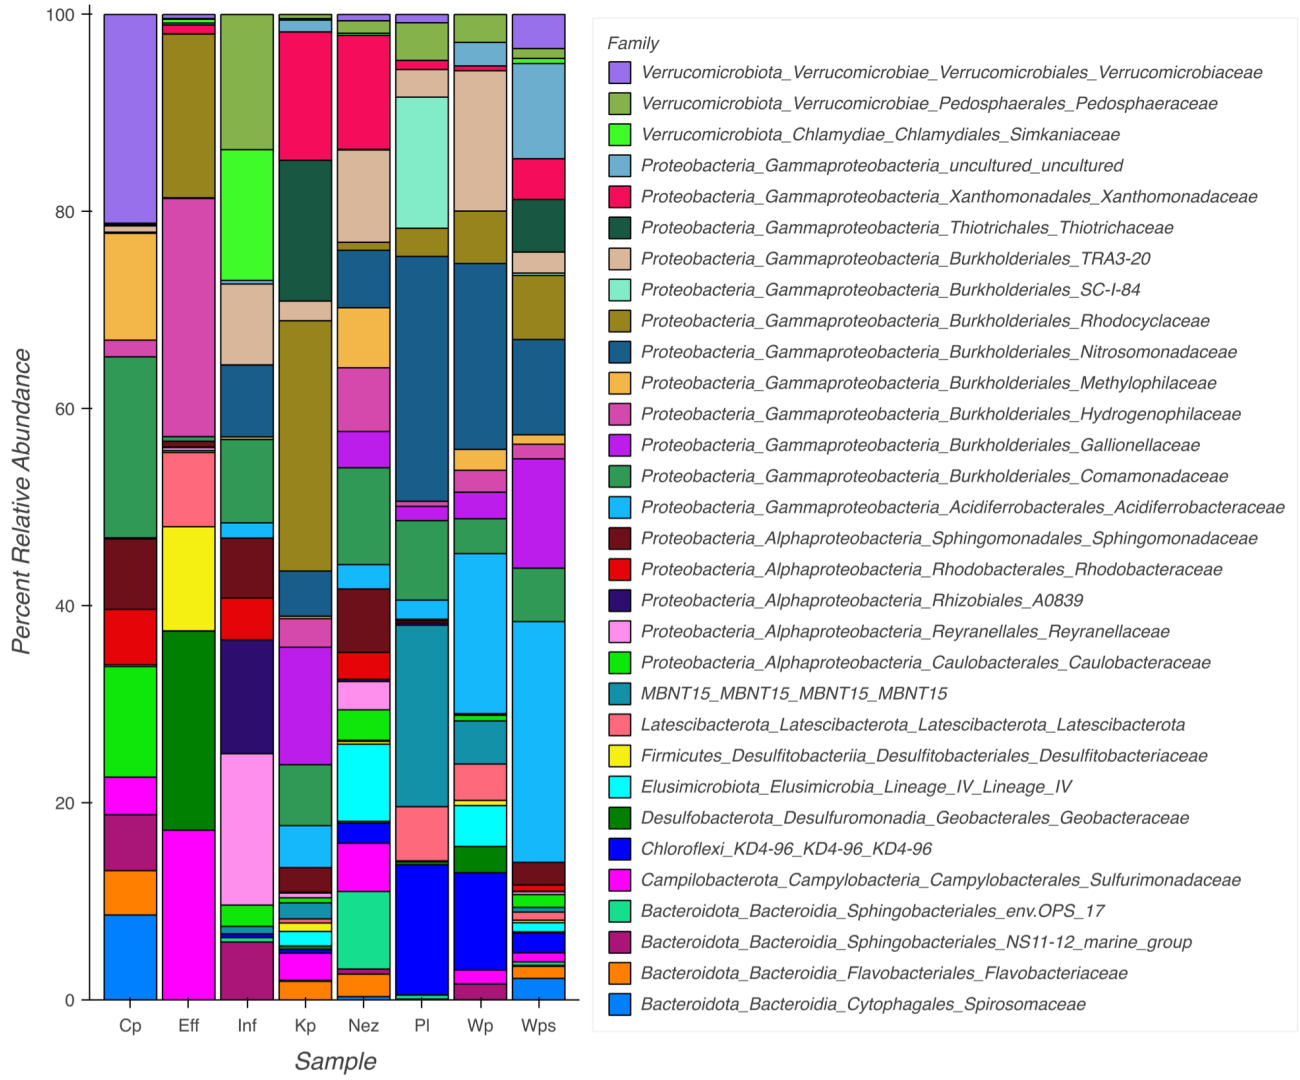

Figure 5: Relative abundance of taxonomic families in each sample with greater than 3.5% abundance.

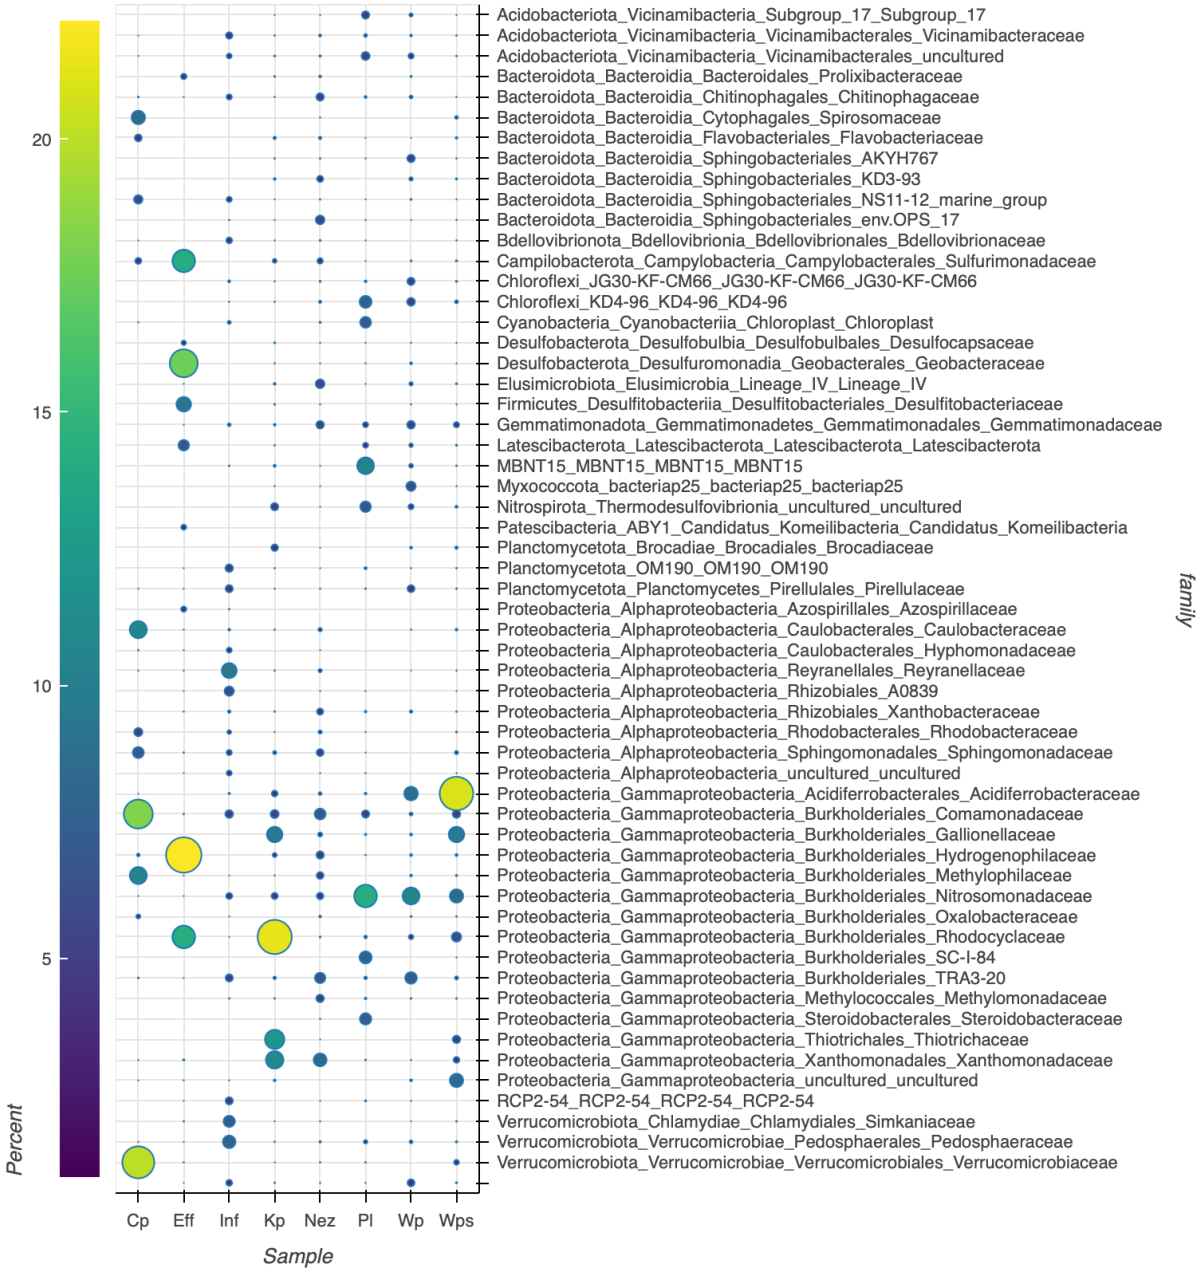

Figure 6: Relative abundance of taxonomic families in each sample with greater than 2% abundance. At the bottom of the figure, the unlabeled class represents bacteria counts that could only be classified to a kingdom level (e.g., bacteria).

At a genus level, sample Cp had high levels of *Prosthecobacter* (>20%) (Fig. 7 and Fig. 8). Kp had high levels of *Sulfuritalea* (>20%). Sample Wps and Wps had increased *Sulfurifustis* (>20%) (Fig. 7 and Fig. 8). The overall distribution of genera appears patchy (Fig. 7). Sample Wp had a much greater abundance of *GOUTA6* (> 7%) than other samples (Fig. 7).

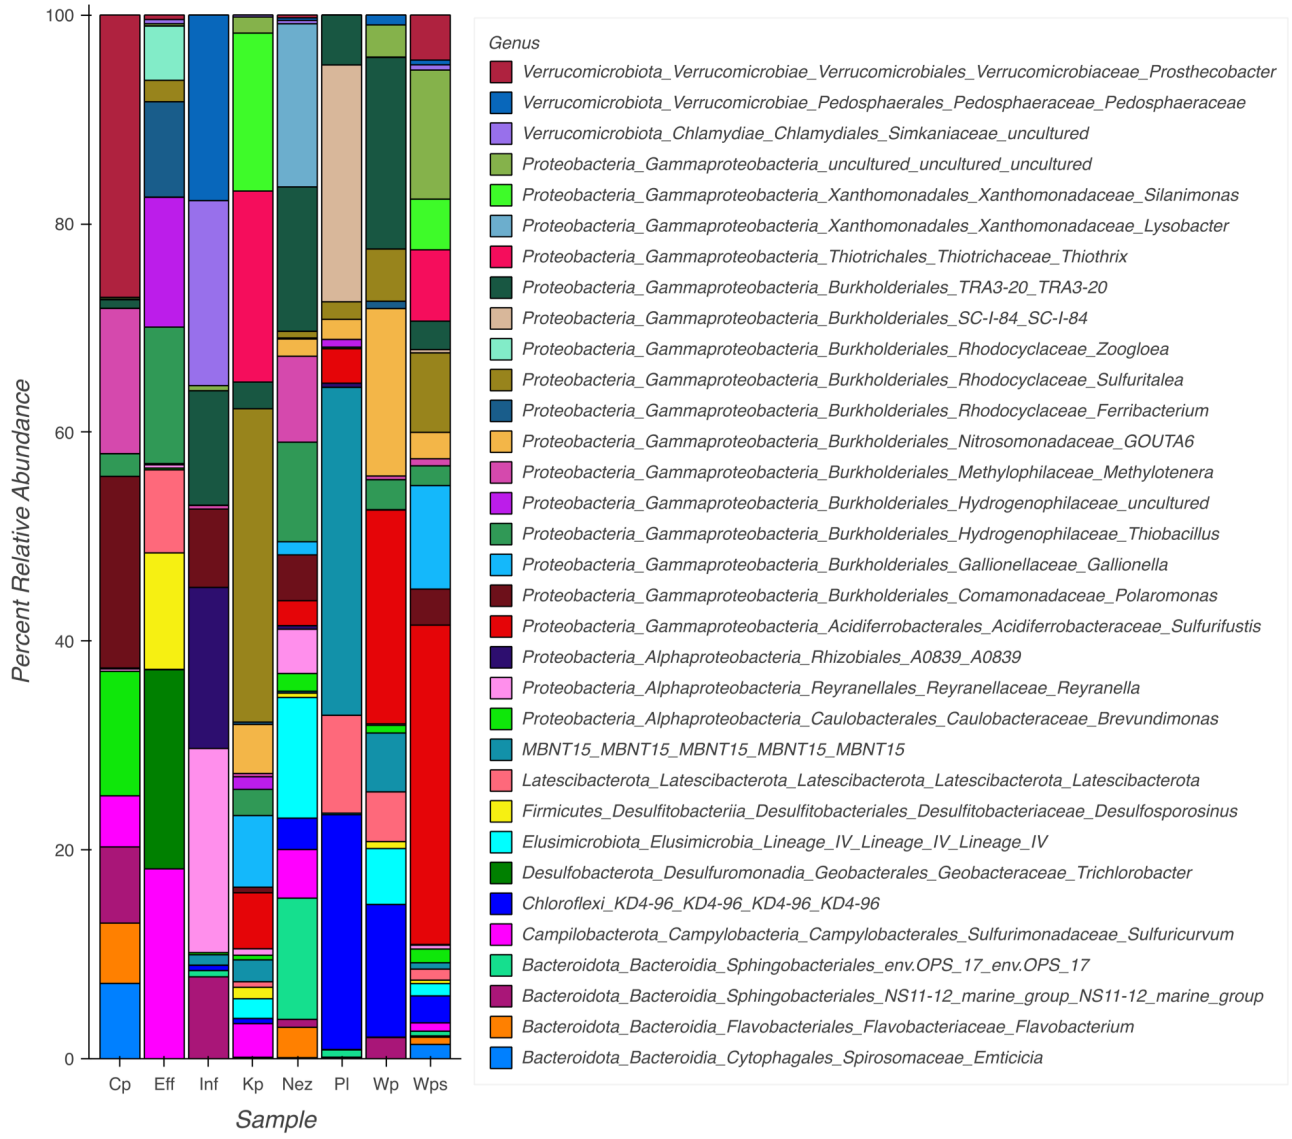

Figure 7: Relative abundance of genera with greater than 3.5% abundance.

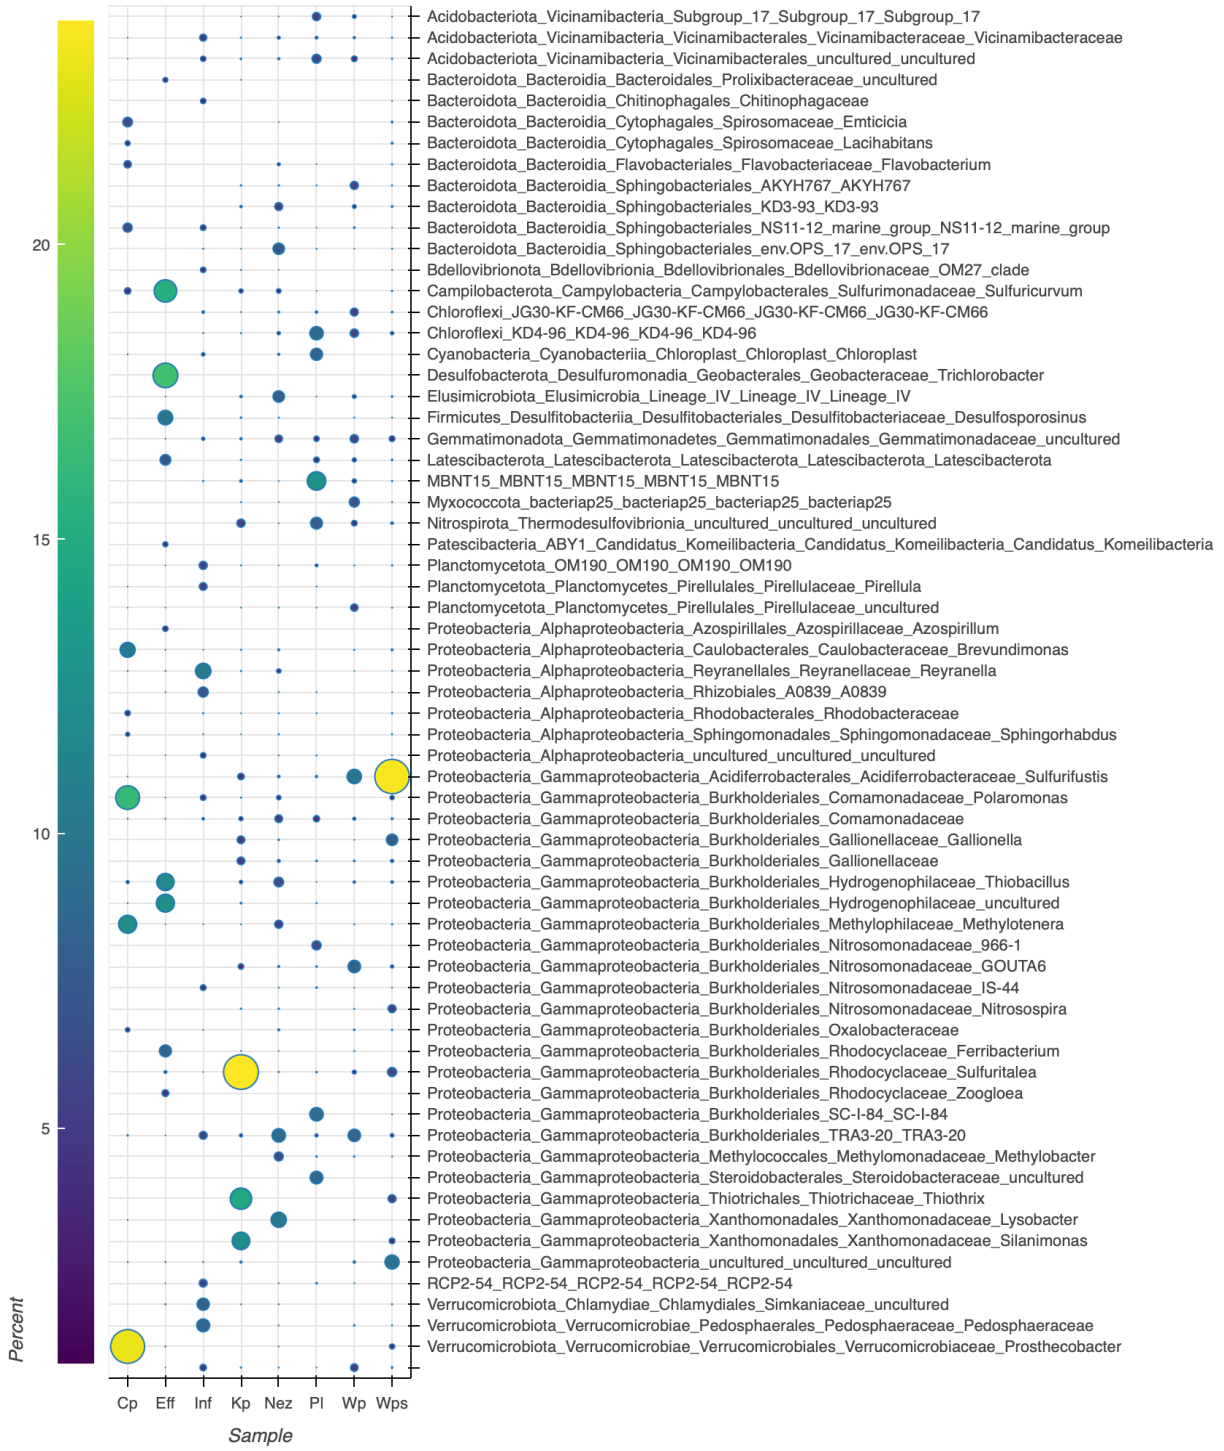

Figure 8: Relative abundance of genera with greater than 2% abundance. At the bottom of the figure, the unlabeled class represents bacteria counts that could only be classified to a kingdom level (e.g., bacteria).

Microbial Functionality Composition

Amplytica used the FAPROTAX and PICRUSt2 databases to predict the abundance of metabolic categories and SRF-relevant gene abundances in each sample. Both techniques use a taxonomy-based approach to predict the abundance of metabolic categories or gene abundances in each sample. In this approach, the taxa in each sample are categorized as having specific metabolic capabilities based on either the functions their sister organisms performed in the previous scientific literature or the genes these sister organisms possess. In some cases, these approaches can lead to miscategorization as some taxa have gained functions through horizontal gene transfer from other organisms within an environment. Also, some taxa may not be found within the databases and thus will not have any metabolic predictions.

Prediction of High-Level Metabolic Capability Using FAPROTAX

Of the highly abundant organisms found within the samples, only a subset could be categorized as carrying out a specific function (Fig. 9). *Zoogloea* was predicted to participate in nitrogen cycling, and *Thiobacillus* was predicted to be participating in sulphur cycling (Fig. 9).

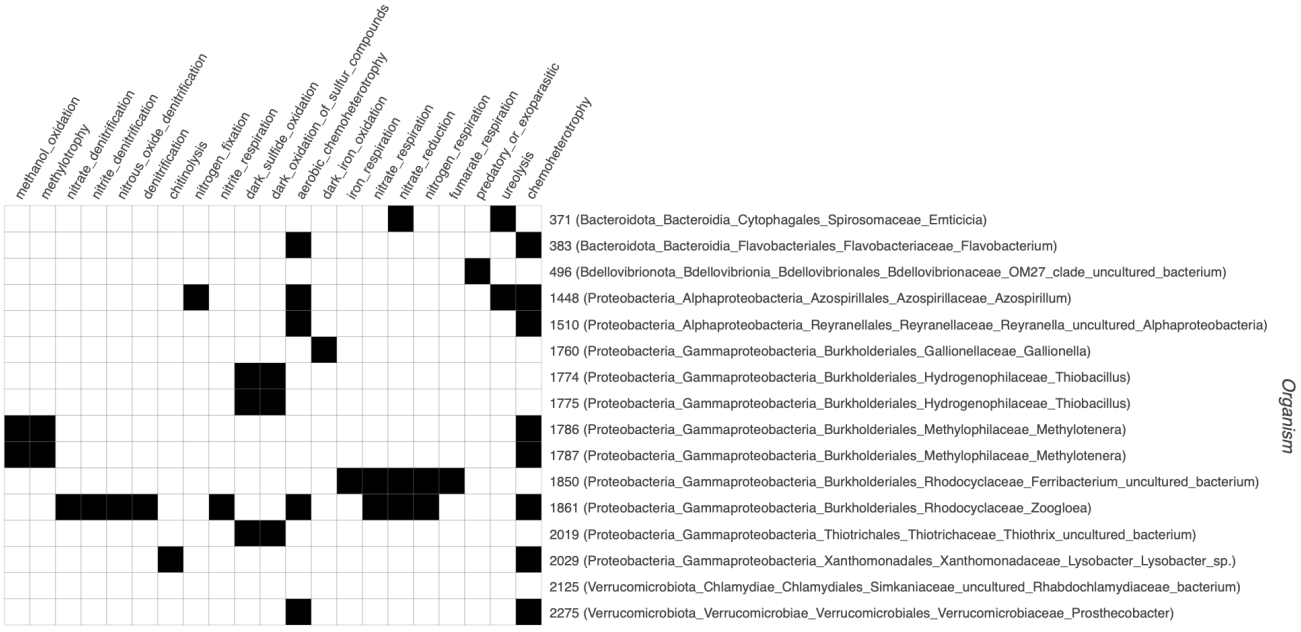

Figure 9: Metabolic capability classifications for metabolically classifiable organisms (i.e., unique sequence variants) with greater than 2% abundance.

Although FAPROTAX could only classify the metabolisms of a subset (~18%) of organisms in the samples, the data showed some trends. FAPROTAX showed that Samples Eff, Kp, and Wps were capable of sulphur oxidation (Fig. 10). Sample Eff also possesses nitrogen cycling organisms (Fig. 10). Like sample Pl, sample Wp also showed evidence of organisms capable of fermentation (Fig. 10). Sample Wp also shows a reduction in the number of organisms associated with aerobic chemoheterotrophy (Fig. 10).

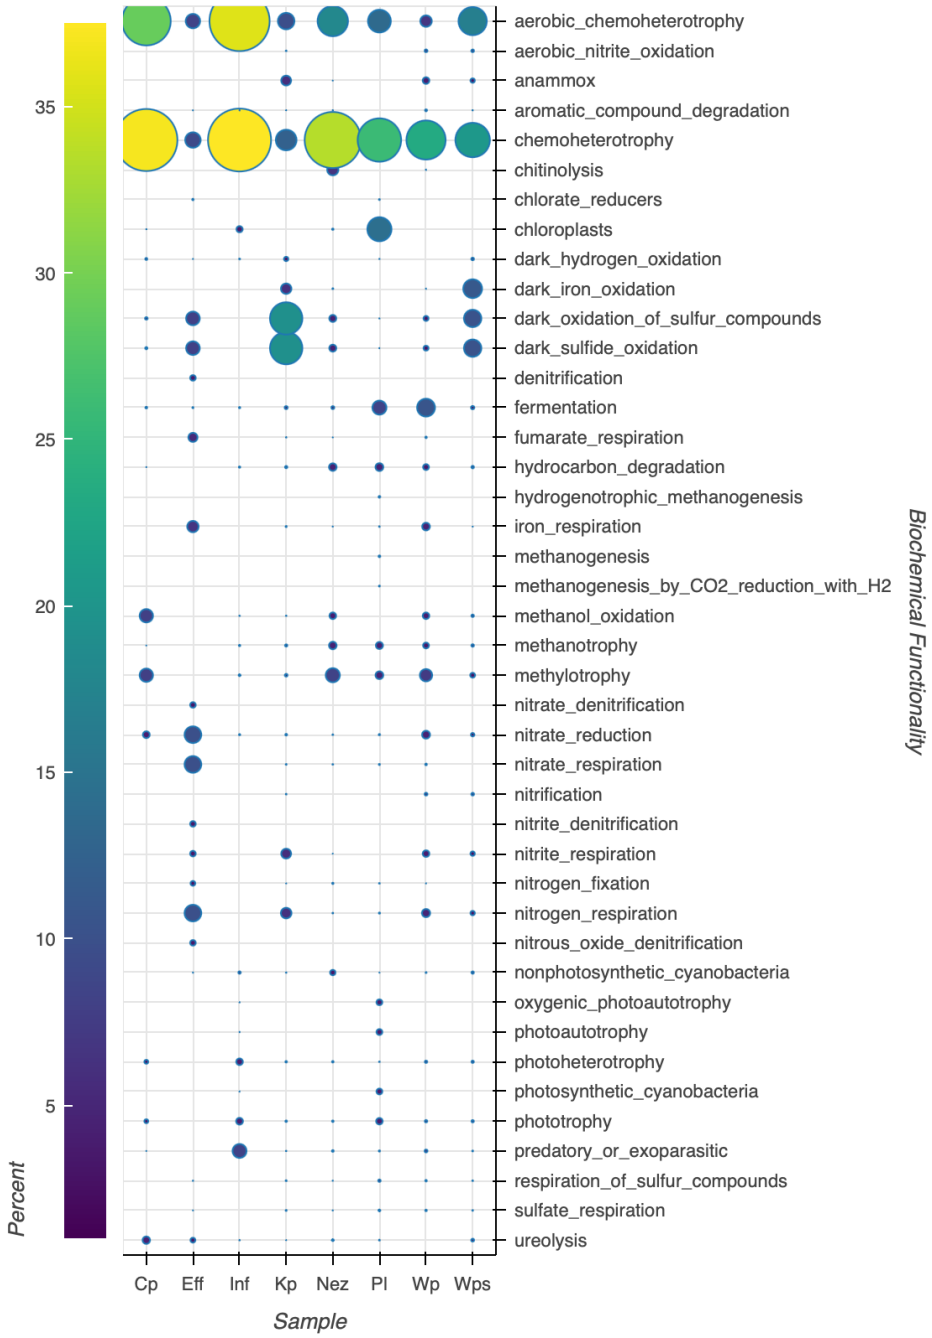

Figure 10: Percentage of total organisms predicted to carry out a metabolic category (via FAPROTAX).

Bioremediating Gene Abundance Prediction Using PICRUSt2

PICRUSt2 uses a more sophisticated mapping technique between an organism's phylogeny and its potential functions. Using phylogenetic methods, PICRUSt2 can predict functional gene abundances for each sample by combining the abundance of each taxonomic group with this group's phylogeny-based predicted genes. The tool can also predict individual taxa as possessing specific genes. PICRUSt2 can only analyze genes found in existing pathway databases like the Kyoto Encyclopedia of Genes and Genomes (KEGG) (kegg.jp).

PICRUSt2 was used to identify the overall abundance of nitrification, denitrification, and selenate reduction genes in each sample. Overall abundances of these genes are presented in Fig. 11. Due to the lack of research into the identification and isolation of selenite reduction (i.e., selenite to elemental selenium) genes (Ojeda *et al.*, 2020), no genes for selenite reduction were found in KEGG or any other pathway databases PICRUSt2 utilizes. Therefore selenite reduction genes were not presented in Figure 11. One or more genes were used to identify each nitrification and denitrification step (Fig. 11). Three types of selenate reductase genes were used to identify selenate reduction (Fig. 11).

PICRUSt2 gene abundance predictions indicate that selenate reduction (i.e., selenate to selenite) was slightly elevated in sample Pl and significantly heightened in sample Eff (Fig. 11). Almost all samples had elevated gene abundances for the third step of nitrification (i.e., nitrite to nitrate), especially sample Kp (Fig. 11). The enzyme used for the third step of nitrification can also be used for the first step of denitrification (kegg.jp/entry/R00798). Cp, Eff, and Nez were predicted to have elevated abundances of genes that carry out the second denitrification step (Fig. 11). Kp, Wp, Wps, and Pl showed similar abundances of nitrogen cycling genes. Sample Eff should have elevated predicted abundances for genes related to denitrification, whereas it lacked genes for nitrification in contrast to the other samples (Fig. 11). Sample Wp showed similar predicted gene abundances to sample Pl for nitrogen cycle genes and Kp, Nez, and Wps for selenate reduction genes (Fig. 11).

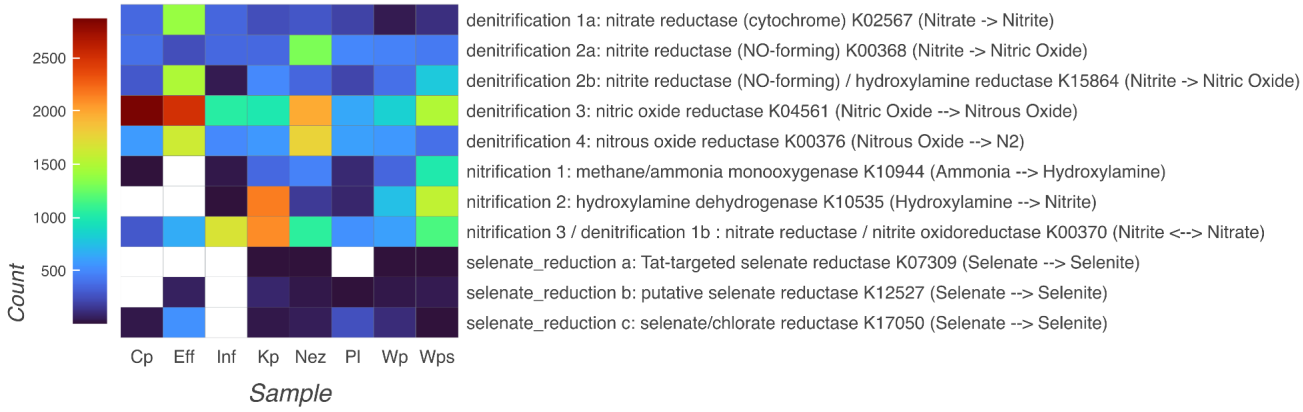

Figure 11: Normalized predicted abundances of genes related to nitrification, denitrification, and selenate reduction.

Readers should note that the gene abundances presented in Fig. 11 correspond to the abundances of organisms predicted to carry out a function. However, gene expression factors and enzyme activity can influence the throughput of a metabolic pathway *in situ*.

Predicted selenate-reducing organisms were also identified using PICRUSt2. This prediction data was combined with a list of known selenate reducing and methylating genera derived from academic literature and provided by Golder. The resulting joint dataset is presented in Fig. 12.

Samples Cp, Eff, and Wp were found to have putative selenate reducers in elevated abundance. Sample Cp had possessed genera *Brevundimonas* (~8%) and *Sulfuricurvum* (~3%) (Fig. 12). Sample Eff included the genera *Desulfosporosinus* (~8%) and *Sulfuricurvum* (~12%) (Fig. 12). *Sulfuricurvum* was also found in more than 1% abundance in Kp and Nez samples. Sample Wp only had one selenate reducer in elevated abundance, *JG30-KF-CM66* (~3%), an uncultured member of the phylum Chloroflexi whose existence was determined by shotgun metagenomic sequencing (Fig. 12) (Mehrshad *et al*., 2018). *JG30-KF-CM66* was previously identified in uranium mine waste rock piles (Mehrshad *et al*., 2018).

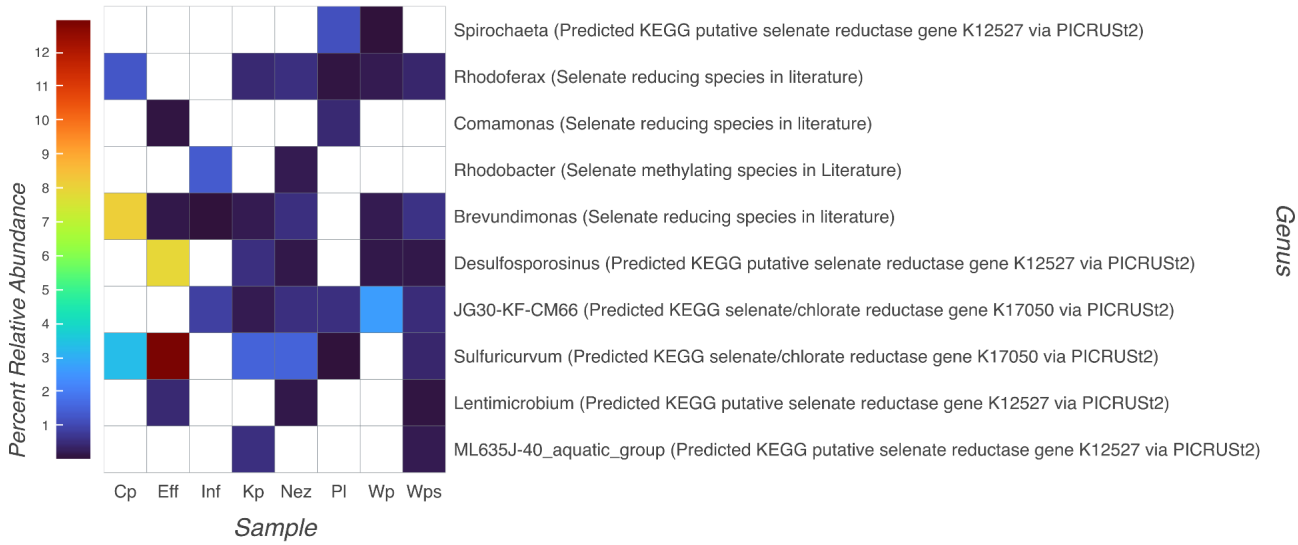

Figure 12: Abundances of genera, with greater than 0.25% abundance, predicted to be capable of selenate reduction or methylation.

One should note that the prediction of the possession of selenate reducing genes presented in Fig. 12 is based on either literature findings of members of a genus being selenate reducing or the identification of selenate reducing genes in the sequenced genomes of members of the genus. Not all organisms within a genus may be selenate reducing.

Interpretation

According to the beta diversity (i.e., diversity between samples) ordination, samples Kp, Wp, Wps, and Pl clustered together according to their microbial community composition (Fig. 4). Kp, Wp, and Wps clustered closer together than they did to Pl (Fig. 4). Kp, Wp, Wps, and Pl also were predicted to have similar levels of predicted nitrifying and denitrifying genes (Fig. 11). Sample Eff had much higher levels of predicted denitrifying genes than any other sample (Fig. 11). Due to their similar microbial and functional characteristics, Kp, Wp, Wps, and Pl likely came from similar environments.

Estimated selenate reduction gene abundance was highest in samples Eff, Pl, and Wp (Fig. 11). Cp, Eff, and Wp had elevated abundances of genera associated with selenate reduction (Fig. 12). However, the genera most likely to perform these reactions are not the same across all samples. Sample Wp had different and less selenate remediating genera than Cp or Eff (Fig. 12). Because Golder collected the samples from different environments, their selenate remediating organisms may differ due to the differences in the biogeochemical properties of the samples.

The techniques used in this analysis to determine the presence of selenate remediating organisms rely upon these organisms' phylogenetic closeness to known selenate reducers with sequenced genomes. To further prove the presence of selenate-reducing organisms, one would have to perform genome-resolved metagenomic sequencing on the samples, isolate individual genomes, taxonomically classify them, and then scan these genomes for genes encoding selenate reductases. It is possible to have selenate reducing or methylating genes on mobile genetic elements such as plasmids. Such plasmids can spread throughout microbial communities and thus result in unexpected organisms having selenate reduction or methylation capability.

1. INTRODUCTION

Mount Polley Mining Corporation (MPMC) is submitting this progress report as required by Section (s) 2.12 of *Environmental Management Act (EMA)* Permit 11678, issued on December 1, 2022. This progress report provides an update on progress on all aspects of s 2.11 under a general heading titled *Water Treatment and Discharge Program*. Progress Report #13 covers the period between July 1, 2023 and December 31, 2023, and includes relevant past work that falls under the requirements of s 2.11.

The Mount Polley mine was in care and maintenance from May 2019 through October 2021. Mining operations resumed November 2021 with the mining of Springer Phase 4, beginning with the removal of the saddle between Springer Pit and Cariboo Pit. The crusher and concentrator were refurbished, milling operations began June 2022, as did operation of the Tailings Storage Facility.

MPMC is currently mining the tailings that were deposited in the Springer Pit in 2015/2016. Ore reserves are located beneath the tailings, which are expected to provide an additional 2 years of production. MPMC is pursuing further operational permits to extend the mine life to 2032.

2. BACKGROUND

This Progress Report #13 references the newest version of *EMA* Permit 11678 (Dec 2022), which extends the effluent discharge into Quesnel Lake to June 30, 2025. A permit amendment application has been submitted through the Major Mine Office to extend the discharge to Quesnel Lake for the operating period of Mount Polley Mine.

EMA Permit 11678 (Dec 2022) includes s 2.11.2, a Numeric Performance Metric (NPM) of 0.012 mg/L total copper. The NPM value is a treatment optimization target for effluent discharge, which differs from the permit limit of 0.033 mg/L total copper.

MPMC recently filed a 5-year update to the Mine Plan and Reclamation Update 2022 (MRP) (Golder 2022g) submitted to the Ministry of Energy, Mines and Low Carbon Initiative (EMLI) in compliance with sections in *Mines Act* Permit M-200 dated December 10, 2020. Excerpts from the MRP Appendix G – Water Treatment Update are extracted to provide the update on water treatment technology development.

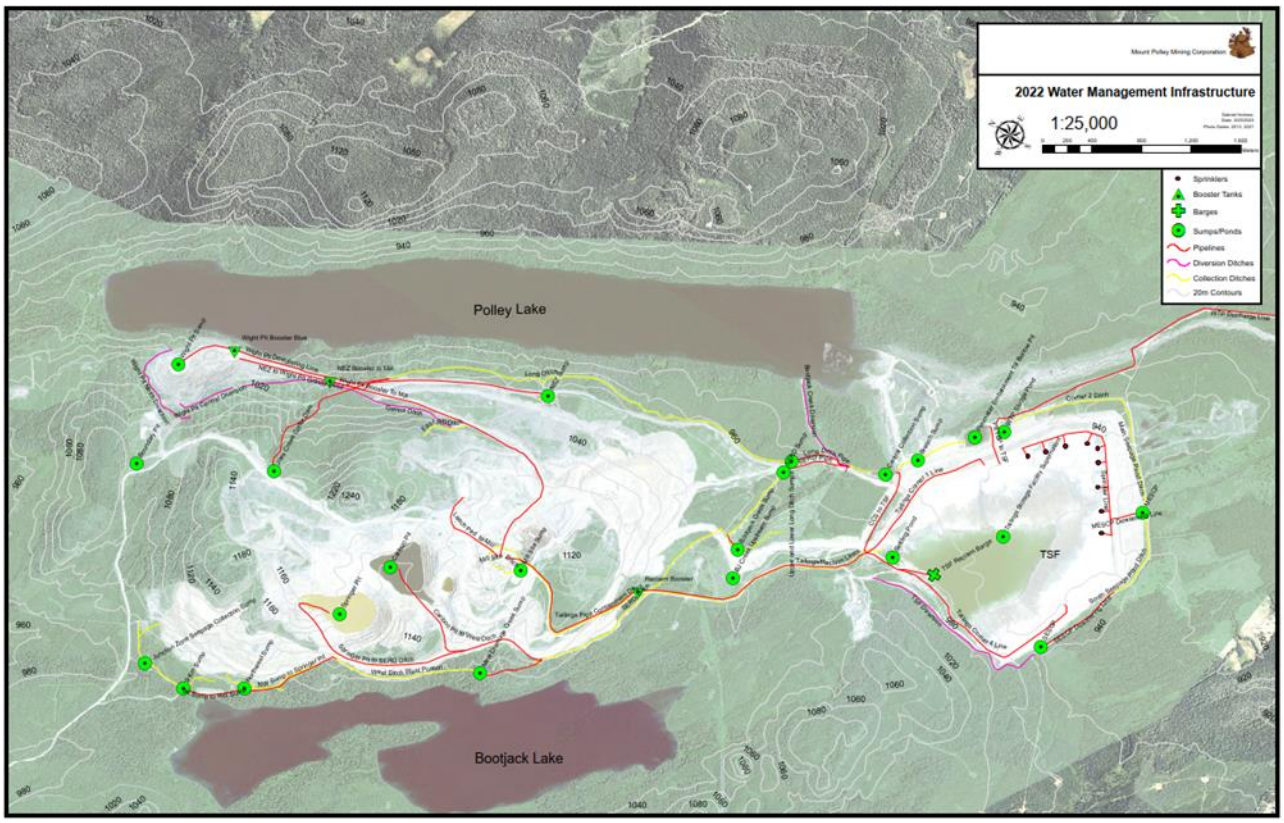

Figure 1. Water Management Infrastructure

3. WATER TREATMENT TECHNOLOGY DEVELOPMENT

Water treatment technology development is a cumulation of Best Available Technology (BAT) assessments through bench and pilot testing of treatment systems. This section of the report addresses Permit 11678 s 2.12(a) and s 2.12(b). What follows is an excerpt from the Mine Plan and Reclamation Update 2022 (MRP Appendix G) with updates of the results of BAT assessments, bench and pilot testing of treatment systems.

MPMC has been progressing and evaluating multiple technologies to support the treatment of identified constituents of concern (COCs) and to support potential decentralized treatment and discharge during closure/post-closure. Various studies have been completed since 2017 to support these efforts as an important component of closure refinement. An inventory of treatment technologies and a summary of their development is presented in Table 1.

Good engineering practice typically requires a project to follow a standardized engineering design process for the selection and progressive refinement of the final project concept. A project

progresses from a pre-concept phase for the identification of multiple treatment options, through concept, pre-feasibility, and feasibility phases to project execution. Generally, the engineering studies performed for each of these project phases are supported by test work that progresses from proof-of-concept and detailed bench-scale testing to pilot-scale and demonstration-scale test work. Some of the treatment technologies tested may not progress to the next stage of development. For example, a treatment technology may be eliminated if its treatment capacity is insufficient to treat the forecast volumes. This framework takes a staged approach, such that input assumptions, design, and cost for the total system can be refined as each stage is completed and the information that the plan relies on becomes more certain. This allows input assumptions to be less conservative as they become more accurate with accumulated knowledge. The technology development stages presented in Table 1 align with this approach. Additional details regarding this project development framework and how it aligns with the BC Ministry of Environment and Climate Change Strategy's BAT policy is provided in Golder 2020a.

This water treatment update technical memorandum assumes that the reader is familiar with the technologies in Table 1 and only provides updates on work completed by MPMC since 2017 to support the development of these technologies. Detailed descriptions of the technologies and associated process flow schematics can be found in Golder 2020a.

Table 1. Treatment Technology Inventory and Stage of Development

Technology / Stage of Development	Targeted COCs	Proof-of-Concept Bench-Scale Testing	Detailed Bench-Scale Testing	Pilot-Scale Testing	Demo-Scale Testing	Full-Scale Execution	Work Completed
Actiflo	TSS, total copper					→	Bench and full-scale testing.
Lime Treatment	Dissolved copper					→	N/A
TMT Treatment	Dissolved copper	→	→	→	→		Bench and full-scale testing. Toxicity evaluation.
Pit-Lake Treatment	Selenium, nitrate	→	→	→			Preliminary concept design and proof-of-concept bench-scale testing. Pilot-scale testing workplan.
Saturated Rock Fill (SRF)	Selenium, nitrate	→	→				Concept design, proof-of-concept bench-scale testing, detailed bench-scale testing workplan (in progress), and long-term substrate leach testing. Wight Pit SRF assessments.

Technology / Stage of Development	Targeted COCs	Proof-of-Concept Bench-Scale Testing	Detailed Bench-Scale Testing	Pilot-Scale Testing	Demo-Scale Testing	Full-Scale Execution	Work Completed
Packed Bed Reactor (PBR)	Selenium, nitrate						Concept design, proof-of-concept bench-scale testing, and detailed bench scale testing workplan (in progress).
Biochemical Reactor (BCR)	Selenium, nitrate						Concept design and proof-of-concept bench-scale testing.
Submerged Sand Reactor (SSR)	Selenium, nitrate						Screening analysis.
Constructed Wetland Treatment (CWT)	Selenium, nitrate						Concept design, bench-scale testing, and on-site pilot scale testing (by others).

3.1 Actiflo

Actiflo, the tradename of a technology supplied by Veolia, is the technology currently in use as the site's WTP and is considered the BAT for TSS removal during operations and closure/post-closure. The main targeted COC of this technology is TSS, with total copper removal also occurring via TSS removal. Polyaluminum chloride (PAC) is dosed into the influent water in the Actiflo process, which produces aluminum hydroxide precipitates that adsorb to copper complexes, thus removing copper during the solids-liquids separation step of the process. The Actiflo technology is currently implemented at full-scale on-site, as indicated in Table 1.

Concept design, bench-scale, and full-scale testing have been completed for the Actiflo technology, including assessment and optimization of PAC and various chelating agent dosages (including TMT) to assist copper removal (Golder 2016b, Golder 2017a, Golder 2018a, Golder 2019a, Golder 2019b, Golder 2020b).

Actiflo treatment is currently operating as the core component of the treatment system during operations and is currently assumed as the core component of treatment during closure/post-closure. In Q4 2023, the WTP was shut down from September 21 to October 29, 2023 and October 31 to December 31, 2023 due to limited water availability on site. The WTP will resume operations in early 2024 in preparation for freshet melts in spring 2024.

3.1.1 Flocculant Management Plan

Per Permit s 2.10, a Flocculant Management Plan (FMP) was prepared and outlines the methods for the settling of solids at the WTP using coagulant, flocculant and ballast, while preventing potential detrimental effects in the receiving environment. The FMP also outlines the procedures and equipment used for storage and dosing of the settling aids, including monitoring of the influent and effluent water quality (Golder 2023a). This document, provided by Golder, was appended to

the 2022 Annual Environmental Report and submitted to ENV in March 2023.

3.2 Lime Treatment

Active treatment with lime is currently in use at the site, where existing process plant infrastructure is used to raise contact water pH, resulting in the precipitation of metal hydroxides, particularly dissolved copper. The main targeted COC of this technology is dissolved copper. Lime treatment is currently implemented on-site, as indicated in Table 1, and used as a pre-treatment step of the Actiflo water treatment system to target dissolved copper removal. Use of this technology is well known to industry and technology development to support this has not been required.

Lime treatment, when required, is currently a component of the water treatment system during operations.

3.3 TMT Treatment

TMT is a chelating agent that aids with dissolved copper precipitation that allows copper treatment through TSS removal. The main targeted COC of this technology is dissolved copper.

Bench-scale test work completed showed that TMT is able to effectively precipitate dissolved copper (Golder 2016b, Golder 2017a, Golder 2018a) and the full-scale trials completed showed that the existing Actiflo treatment system was able to remove the copper bound with TMT to below the permit limit (Golder 2019a, Golder 2019b, Golder 2020b). Full-scale trials also showed that copper removal to lower concentrations (total copper < 0.012 mg/L) was challenging for Actiflo with TMT treatment, not due to limitations in dissolved copper precipitation but due to limitations in TSS removal. TMT was effective in precipitating dissolved copper, but the Actiflo system was not effective in subsequently removing the precipitate to result in low effluent copper concentrations. The toxicity of TMT has also been evaluated and showed that its use would not result in an acutely lethal effluent (Golder 2018b).

TMT treatment is still being considered for full-scale implementation.

3.4 Pit-Lake Treatment

Pit-lake treatment targeting COCs of selenium and nitrate is an in-situ technology that requires nutrient and carbon source dosing to create conditions for biological treatment within the pit-lake.

A conceptual assessment of full-scale pit-lake selenium treatment was completed (Golder 2017b) and the technology was deemed a cost-effective approach to managing selenium and was recommended for further bench and pilot-scale testing. Proof-of-concept bench-scale testing for pit-lake selenium treatment was also completed and showed effective removal of selenium and nitrate, with further pilot-scale testing recommended (Golder 2019c). A pilot-scale study for pit-lake treatment was designed for Cariboo Pit (Golder 2020c), but the pit is being dewatered to support future mining activities and this work has not yet been completed.

Pit-lake treatment targeting selenium and nitrate is still being considered for full-scale implementation and is currently assumed as part of the treatment system during closure/post-closure if required.

3.5 Saturated Rock Fill (SRF)

SRF treatment is a fixed-film anaerobic system targeting the treatment of selenium and nitrate and ideally utilizes a mined-out open pit as a bioreactor operated in a horizontal flow configuration.

A concept study for SRF treatment was completed (Golder 2020d) and SRF was recommended for further bench-scale and pilot-scale testing. Proof-of-concept bench-scale testing for SRF was also completed (Golder 2021), which showed effective removal of selenium and nitrate, but also indicated metal leaching. Detailed bench-scale testing and waste rock SRF substrate metal leach testing was recommended following completion of the proof-of-concept work.

Bench-scale leach testing using anticipated SRF substrate waste rock from site was completed (Golder 2022d – draft RevA, Golder 2023d), which monitored leached metals over a long-term test period of 52 weeks. A high-level summary of findings is below and the full report is included in Appendix A:

- The bench-scale SRF reactor used was very effective in removing total and dissolved selenium and nitrate.
- The use of mine waste rock as reactor media for SRF introduces the risk of leaching or release of metals into the SRF effluent. For this treatment technology to be implemented at full-scale as a viable option, the effects of metal leaching should be understood at specific reducing conditions that are required for SRF to achieve effective removal of selenium and nitrate.
- Metal leaching varies over time and differs between metals and must be considered during the start-up phase of SRF implementation (and may lead to additional required polishing treatment steps downstream of the SRF).
- SRF technology can provide copper removal during closure.

Detailed bench-scale testing for SRF has been proposed for 2024 and a test plan has been submitted in draft to MPMC (Golder 2022e – draft RevA). Additional details regarding potential timing of this work are further discussed in Section 4.

Geotechnical and geochemical substrate characterization for SRF media waste rock is currently ongoing with the geotechnical component anticipated for completion in 2023. WSP has completed geotechnical laboratory testing of the SRF substrate and the analytical results were used in a geotechnical settlement assessment of a waste rock SRF bed to estimate porosity that will inform SRF hydraulic retention time and sizing. This geotechnical assessment will be produced in draft before the close of 2023. The geochemical component of this characterization will be conducted by MPMC's geochemical consultant SRK, anticipated for completion in 2024.

SRF treatment is still being evaluated for full-scale implementation and is currently considered a technology option for semi-passive treatment of selenium and nitrate during closure/post-closure if required.

3.5.1 DNA Analysis

Additionally, to investigate if the observed reduction in contaminants of concern in Wight Pit is

facilitated by microbial activity, Golder sampled the effluent water of Wight Pit from the bench scale SRF to determine if the presence of genetic material could be used to indicate the presence of these bacteria and any favorable activity (Golder, 2023b). Microbial community composition and interactions were also studied using DNA analysis of the microbial communities from various locations on site. The analysis of samples collected from the site provided proof-of-concept for the biological activity in terms of selenate and nitrate reduction in Wight Pit as several species that are potentially involved in selenium and/or nitrate removal were present in the microbial community in the pit (Golder, 2023b). Copper removal through precipitation as copper sulfide was also investigated and it was determined that although some sulfur/sulfide reducing bacteria were present, the sulfate reducing bacteria were not sufficient. The full report was appended to Progress Report #12.

3.5.2 waterStrider Testing

MPMC sent Wight Pit water samples to waterStrider Treatment Inc. (waterStrider) in November 2023 where testing targeting the removal of dissolved cadmium, total copper, total zinc and total sulphate concentrations was performed. Reductions in the targeted contaminants of concern were observed, and further testing is being considered.

3.5.3 Water Chemistry Review

MPMC has retained SRK to review the water chemistry in the Wight Pit to help determine the mechanisms for the degradation of the pit water, particularly the concentrations of dissolved cadmium, total copper, total zinc and total sulphate. At the time of this report's submission, the review was being conducted. Results will be discussed in a subsequent Progress Report.

3.6 Packed Bed Reactor (PBR)

PBR treatment is another fixed-film anaerobic system targeting the treatment of selenium and nitrate. PBR treatment differs from SRF treatment through the use of a vertical flow (top to bottom) reactor.

Proof-of-concept bench-scale testing was completed (Golder 2019d) and PBR treatment was shown to be effective in reducing selenium and nitrate. Further detailed bench-scale and pilot-scale testing was recommended following completion of the initial testing. Detailed bench-scale testing for PBR has been proposed and a test plan has been submitted in draft to MPMC (Golder 2022f – draft RevA). PBR detailed bench scale testing has been postponed while focus is placed on immediate permit application priorities regarding the extension of the life-of-mine plan. Water balance, water quality and hydrogeological modelling as well as surface water infrastructure design are currently being completed to support permitting.

PBR treatment is still being evaluated for full-scale implementation and is currently considered a technology option for semi-passive distributed treatment of selenium and nitrate during closure/post-closure if required.

3.7 Biochemical Reactor (BCR)

BCR treatment is another fixed-film anaerobic treatment technology that consists of a lined pond filled with a submerged organic substrate media mix. The main targeted COCs of this technology

are selenium and nitrate. BCR treatment is passive and does not involve continuous dosing of a carbon source to the media bed.

Proof-of-concept bench-scale testing was completed (Golder 2019d) and BCR treatment was shown to be effective in reducing selenium and nitrate, but redox sensitive metals were present in the BCR effluent.

Upon review of the BCR technology in comparison to other passive and semi-passive technologies, MPMC decided to not proceed with further development of this technology (MPMC 2021) for the following reasons:

- Limited lifespan of BCR passive treatment systems based on the availability of a carbon source that is encapsulated in the system during construction – this needs to be replaced periodically at significant cost.
- Emission of elevated levels of biochemical oxygen demand (BOD) from the system during commissioning and start-up of operation that exceed standards for discharge to the environment.
- Persistent emission of phosphorus from the BCR during operation that will likely exceed plausible standards for discharge to the environment.

BCR treatment is no longer being developed as a passive treatment technology option during closure/post-closure.

3.8 Submerged Sand Reactor (SSR)

SSR is similar to other anaerobic reactor technologies, with the use of the existing tailings as media for the bioreactor. The main targeted COCs of this technology are selenium and nitrate.

A concept study was completed for SSR (Golder 2020d), as well as proof-of-concept bench-scale testing (Golder 2019d). Use of MPMC tailings as SSR bioreactor media or use of the site's TSF as an in-situ SSR was not recommended for further investigation. Bench-scale testing resulting in metal release in the reactor effluent when using site tailings as the reactor media. The concept study also concluded that further investigation of SSR was not warranted, based on a review of literature, an evaluation of historical water quality monitoring data, and an evaluation of the feasibility of utilizing the TSF from a hydrogeological and permitting perspective.

SSR treatment is no longer being developed as a treatment technology option during closure/post-closure.

3.9 Constructed Wetland Treatment (CWT)

MPMC retained Ensero Solutions Inc. (Ensero), formerly known as Contango Strategies Ltd., to conduct a detailed assessment and evaluation of the feasibility of a CWT system for passive/semi-passive treatment during closure/post-closure. The main targeted COCs of this technology are selenium and nitrate.

Pilot-scale design, sizing, and testing for CWT was completed by Ensero (Ensero 2020), and the technology demonstrated promising results for treatment of targeted COCs; however other passive/semi-passive technologies have indicated improved treatment capability in comparison.

MPMC may choose to proceed with demonstration-scale on-site testing of CWT once the pilot-scale results have been fully understood and if the performance of competing technologies (SRF and others) indicates an advantage for CWT.

CWT is still being evaluated for full-scale implementation and is currently considered a technology option for passive/semi-passive and distributed treatment of selenium and nitrate during closure/post-closure if required.

4. ANTICIPATED FUTURE WORK

The existing and assumed water treatment systems for operations, closure, and post-closure have been outlined in this memorandum; however, changes may still be implemented during all phases of the mine as knowledge and needs evolve. The water treatment system for closure/post-closure will continue to develop in more detail as MPMC better understands technology capabilities and refines their final approach to water treatment for the closure period.

Table 1 provides a summary of the development stage of the treatment technologies implemented or being considered for operations, closure, and post-closure. Future work is anticipated for any technology still under consideration that has not achieved full-scale implementation. The following items describe the priority treatment work anticipated over approximately the next three years, but do not exhaustively describe all potential remaining work for technologies still under consideration:

- Pit-lake treatment is currently assumed as a component of the closure/post-closure treatment system. Pilot-scale pit-lake work was anticipated for Cariboo Pit, but recent mine operational changes have resulted in the draining of both Springer and Cariboo pits and pit-lake treatment trials are no longer feasible at these locations. Operational changes have also resulted in Wight Pit being used for site storage, resulting in fluctuating water levels not suitable for a pit-lake treatment trial. The previous pilot-scale study designed for Cariboo Pit (Golder 2020c) could be redesigned for Wight Pit for when operational conditions in the future are deemed appropriate, further advancing the development of this technology.
- Two options exist as the BAT for treatment during closure/post-closure: distributed passive/semi-passive treatment systems, and pit-lake treatment followed by the centralized Actiflo plant. WSP has proposed to undertake a treatment option life cycle cost comparison study between the two options, informed by the knowledge gained during recent technology development, to assess pros/cons and capital and operating costs between the options and inform future treatment program development decisions.
    - WSP initiated the treatment option life cycle cost comparison study in Q2 2023, has compiled treatment cost inputs for the study, and has undertaken water balance and water quality modeling during closure/post-closure to be used in the study. The study is still underway and the draft report anticipated to be completed

in Q1 2024.

- SRF and PBR detailed bench scale testing have been proposed to MPMC and this work is expected for completion in the near future to continue the development of these technologies.
    - SRF and PBR detailed bench scale testing have been postponed while focus is placed on immediate permit application priorities regarding the extension of the life-of-mine plan. Water balance, water quality and hydrogeological modelling as well as surface water infrastructure design are currently being completed to support permitting. It is also recommended that the results of the closure treatment life cycle cost comparison study be first interpreted before commencing the detailed bench testing for SRF or PBR, as results may indicate technologies preferences.

5. NUMERIC PERFORMANCE METRIC

5.1 Measurement of the Numeric Performance Metric

A Numeric Performance Metric for total copper has been specified in *EMA* Permit 11678 (Dec 2022), [s 2.11.2], expressed as follows:

a. *"Numeric Performance Metric" (NPM) means a measurable value that quantifies the outcome or result of water treatment and the ability of the treatment to remove specified chemical constituent(s). It forms the basis for a numeric comparison of untreated water, to water that has been treated by the treatment system.*

b. *The permittee must operate and optimize the design and performance of the WTP to target achievement of any prescribed NPM. The stated NPM target value represents WTP operation that achieves annual average effluent quality that is at or below any specified NPM. Assessment of the attainment of NPM values must be reported in an annual optimization update progress report appended to the annual report required in section 4.2. If the effluent qualify does not achieve an NPM value specified by the director, the permittee must identify and propose response actions to bring the effluent quality toward meeting the target value in the annual optimization update progress report. Response action may include treatment plant optimization and/or source control and/or water management improvements, and a schedule for implementing the response action must be included in the annual optimization update progress report.*

The following NPM is established:

Total copper 12 µg/L

c. *"Annual average effluent quality" means the effluent concentration of total copper*

based on a 52-week rolling average, using the average of the 52 grab samples at HAD-3 when the WTP is discharging.

Progress reporting on the implementation of response action(s) for attainment of the NPM target value is a condition of Permit 11678 (Dec 2022) [s 2.12(c)]. Water quality samples of the Water Treatment Plant effluent identified as HAD-3 are taken weekly when the WTP is operating for analysis by a certified laboratory.

A graphical presentation of the weekly total copper concentrations (mg/L) of the Water Treatment Plant (WTP) effluent (HAD-3) discharge to Quesnel Lake is shown:

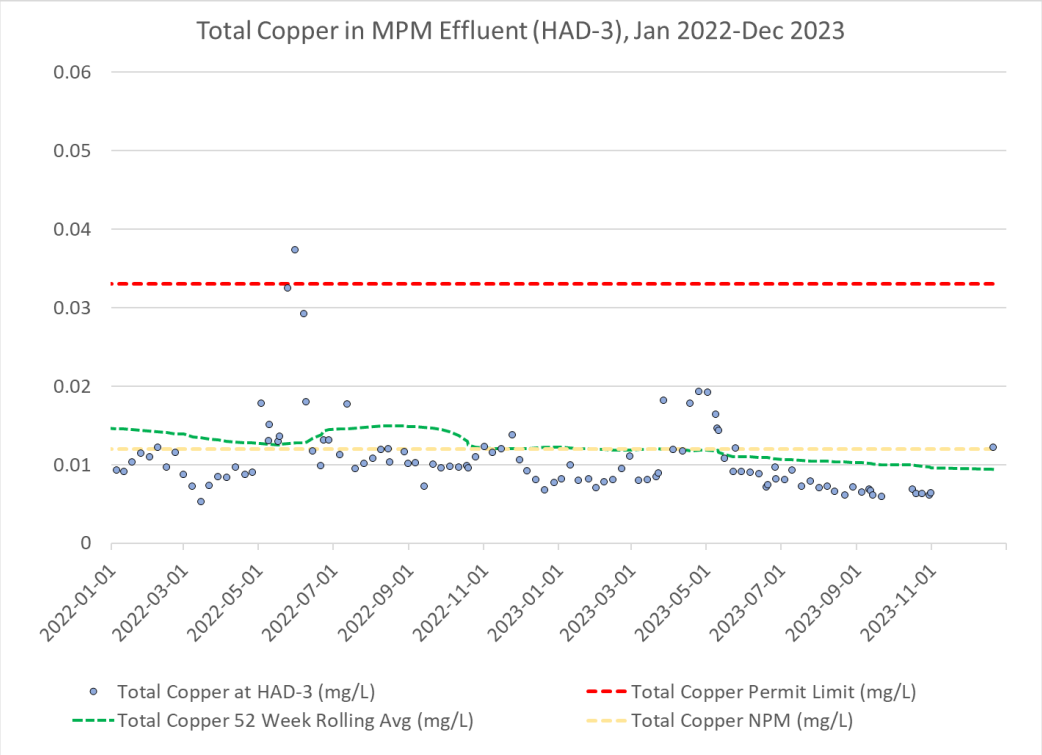

Figure 2. WTP effluent (HAD-3) total copper concentrations relative to the NPM (dashed yellow line), NPM annual average (dashed green line) and Permit 11678 end-of-pipe limit (dashed red line)

The NPM annual average of total copper is based on a 52-week rolling average, calculated using the average of 52 grab samples collected at HAD-3 when the WTP is discharging [s 2.11.2(c)].

In 2023, the NPM target has been achieved in all but one of the 52 WTP samples. In 2022, WTP samples achieved the NPM target approximately 69% of the time, in 38/55 samples. This represents an improvement over 2021 when the NPM was achieved 43% of the time, which is an improvement over 2020, when the NPM was achieved 23% of the time. The NPM annual average of total copper was 0.01217 mg/L as of December 13, 2022 and has continuously decreased to 0.00937 mg/L as of December 21, 2023 (The WTP was shut down on October 31, 2023 due to limited water availability for discharge on site, was restarted in recirculation mode on December 21, 2023 for a sample to be collected before it was shut down again, and remains down at the time of this report's submission. The December 21, 2023 sample is the last collected in 2023).

The year-over-year improvement in reaching the NPM target is a result of improved WTP optimization with the addition of a second Actiflo WTP, and the establishment of pre-treatment processes developed as part of a water treatment train preceding the WTP; in-situ pit lake treatment, pre-treatment with sodium hydrosulphide and improved source control.

The operational response actions in achieving the NPM in 2023 are detailed in later sections of this Progress Report #13.

6. WATER TREATMENT PROGRESS (JULY – DECEMBER 2023)

The site has experienced a year-over-year reduction of water stored on site, from 7.01 Mm^3 on December 28, 2021 to 5.83 Mm^3 on December 27, 2022, to 3.30 Mm^3 on December 27, 2023, a net reduction of 3.71 Mm^3. The return to milling operations in June 2022 and resulting tailings deposition into the tailings storage facility consumes free water into the void spaces of the tailings.

The volume of water treated shows a year-over-year increase in treatment capacity from 6.7 million cubic meters in 2021 to 7.0 million cubic meters in 2022. However, in 2023, there was a reduction in treatment volume. From January to October 31, 2023, 4.4 million cubic meters of water have been treated. This reduction in the volume of water treated in 2023 was due to reduced water storage on site coupled with limited precipitation in the area. The current volume of water stored on site is 3.30 Mm^3.

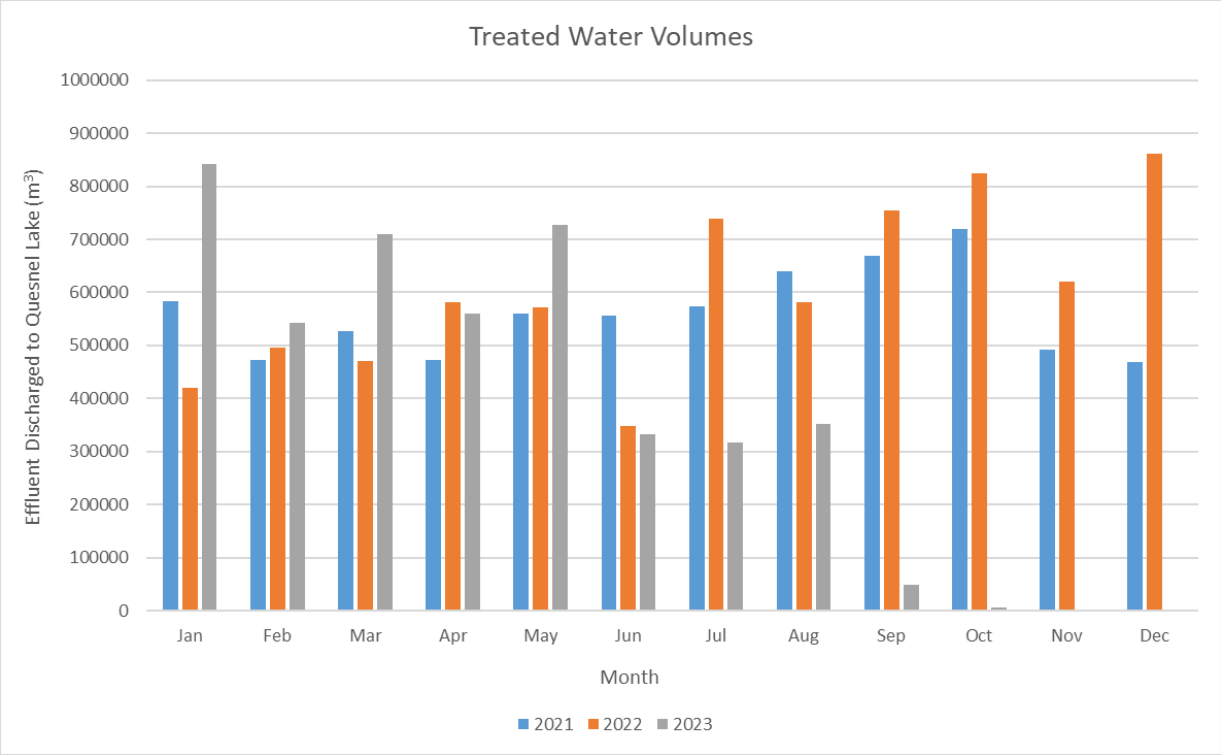

Figure 3. Treated Water Discharged over 2021, 2022 and 2023

6.1 Mobile Water Treatment Plant Installation

MPMC commissioned an interim rental Veolia Actiflo mobile water treatment plant (MWTP) to

increase discharge throughput and assist with management of onsite water inventory, Commissioning of the MWTP began on March 16, 2022, by Veolia automation and process technicians and was completed on April 1, 2022. The MWTP began discharging to Quesnel Lake on April 9, 2022, after approval was granted by BC-ENV and was decommissioned on May 10, 2023 once the Mount Polley mine water balance reached a more manageable level. The HAD-3 sample results from April 12, 2022 to May 9, 2023 represent the combined effluent from both plants. To properly represent end-of-pipe conditions, the sample port was located downstream from the wye where effluent from both plants was mixed. Sample results from May 10, 2023 onward represent effluent from the permanent WTP only.

The MWTP assisted with the optimization of water treatment plant operations by allowing for higher throughput than the permanent WTP alone, with an increased retention time to allow for more complete particle settling, resulting in lower total suspended solids (TSS). Because the NPM limit is in terms of total copper, a reduction in TSS is likely to be associated with lower copper and therefore a higher probability of NPM attainment.

6.2 Pit Lake Treatment

The Cariboo, Springer and Wight Pits have a combined 1.89 Mm^3 of stored water. The site has excess water stored in the pits currently. It is MPMC's objective to continue dewatering the site in 2024 so that mining can occur in the Springer and Cariboo Pits. A temporary mobile water treatment plant was commissioned in Q2 2022 to increase treatment capacity and was decommissioned in Q2 2023.

6.2.1 Cariboo Pit

The Cariboo Pit contains approximately 0.22 Mm^3 of stored water. The concentration of total copper and selenium have over time fallen below the *EMA* Permit 11678 limits of s 1.2.4, Column 2 of Table 1 for the Treatment Plant Outlet. In 2021, MPMC implemented a 'pit profiling' water column monitoring program to record changes in water chemistry at various water depths over time through seasonal temperature changes, lake turnover and ice cover. This data set is provided in Figure 4, supplemented by samples from E8, the regulatory site for Cariboo Pit which is analogous with surface water.

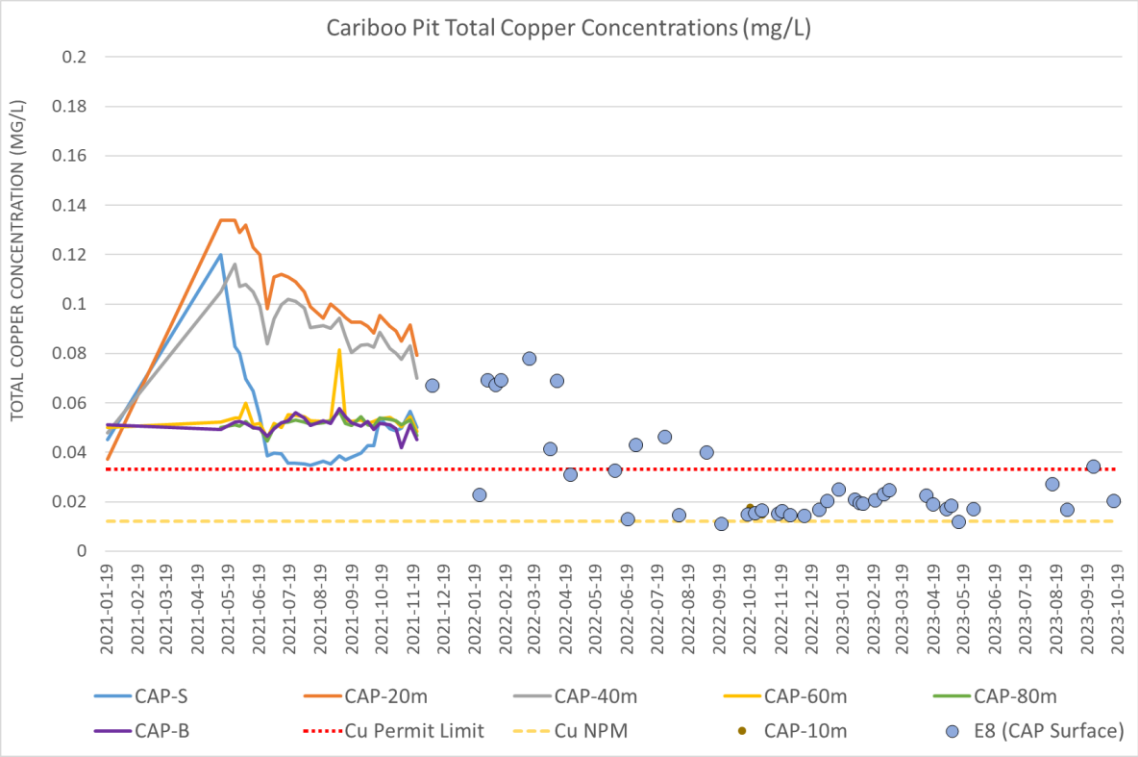

Figure 4. Cariboo Pit total copper concentration at 20 m depth increments 2021-Present.

Copper concentrations in the Cariboo Pit trended downward in 2022, with a dramatic reduction of copper observed between January and May 2022. Historically, the highest copper concentrations have been found at the 20 and 40 m depths, while surface water and water from below 60 m depth contained less copper. In the profile taken May 11, 2022, the Pit Lake was mixed at all depths, with a uniform total copper concentration of approximately 0.017 mg/L. Thus far in 2023, copper concentrations have been relatively constant with copper concentrations ranging from 0.012 mg/L to 0.0343 mg/L.

In-situ treatment processes contribute to this trend. In-situ treatments utilized in 2022 and 2023 include the settling of solids and in 2022 only, dosage with sodium hydrosulfide (NaHS) to sequester copper. More on sodium hydrosulfide treatment can be found in Section 6.3.

6.2.2 Springer Pit

Springer Pit is effectively dewatered to allow mining activities to proceed. During the ice-free season of 2021, passive treatment through settling has contributed to a reduction of total copper to less than the *EMA* Permit 11678 limits. The supernatant water meeting this threshold was removed and treated as a permit requirement through the water treatment plant.

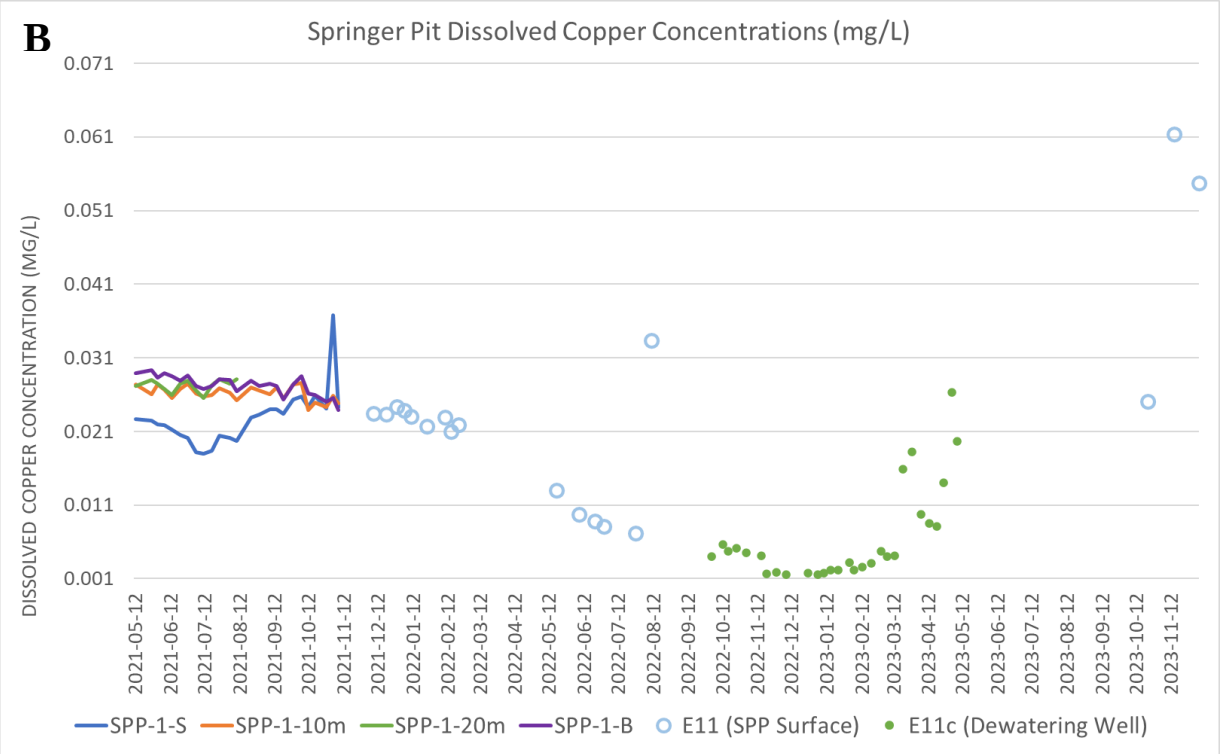

Figure 5. Springer Pit total (A) and dissolved (B) copper concentrations 2021-2023. The divergent trends in total and dissolved values may be a result of copper sequestration in sediment.

The last total copper and selenium concentrations in the Cariboo and Springer pits are shown in Table 2. Note that due to dewatering and 2023 mining activities, it is no longer practicable to profile the Springer or Cariboo pits at depth. The Springer Pit water is represented by the regulatory site E11, corresponding with Springer Pit sump water. Profiling the Cariboo Pit at depth intervals ceased in November 2022 due to winter conditions followed by dewatering of the pit to facilitate mining; therefore, the last profile of the Cariboo Pit was collected on November 1, 2022. The Cariboo Pit water is represented by the regulatory site E8, corresponding with Cariboo Pit surface water.

Table 2. Water parameters of interest as of October 16, 2023 in the Cariboo Pit and December 7, 2023 in the Springer Pit

Cariboo Pit					
Surface (E8)	<1.0	8.05	0.0202	0.0172	0.0474
Springer Pit					
Sump Surface Water (E11)	4.0	7.82	0.0713	0.0547	0.0393

6.2.3 Wight Pit

Wight Pit contains approximately 1.67 Mm^3 of stored water, sourced primarily from the dewatering of Cariboo Pit earlier in 2022. Investigations are underway to understand passive water treatment which is believed to have occurred in the Wight Pit. Golder was retained to study evidence of a naturally occurring biological reaction reducing nitrate, selenium and copper. A recent technical memorandum, entitled "Mount Polley Mine: Investigation of Potential Saturated Rock Fill at Wight Pit" was included with Progress Report #9 in December 2021 (Golder 2021b). In summary, Golder used multivariate analysis of water chemistry to investigate whether water quality improvement was due to dilution by infiltrating groundwater and found this was not the case (Figure 6). Treatment of the target analytes is occurring due to another process than dilution or displacement.

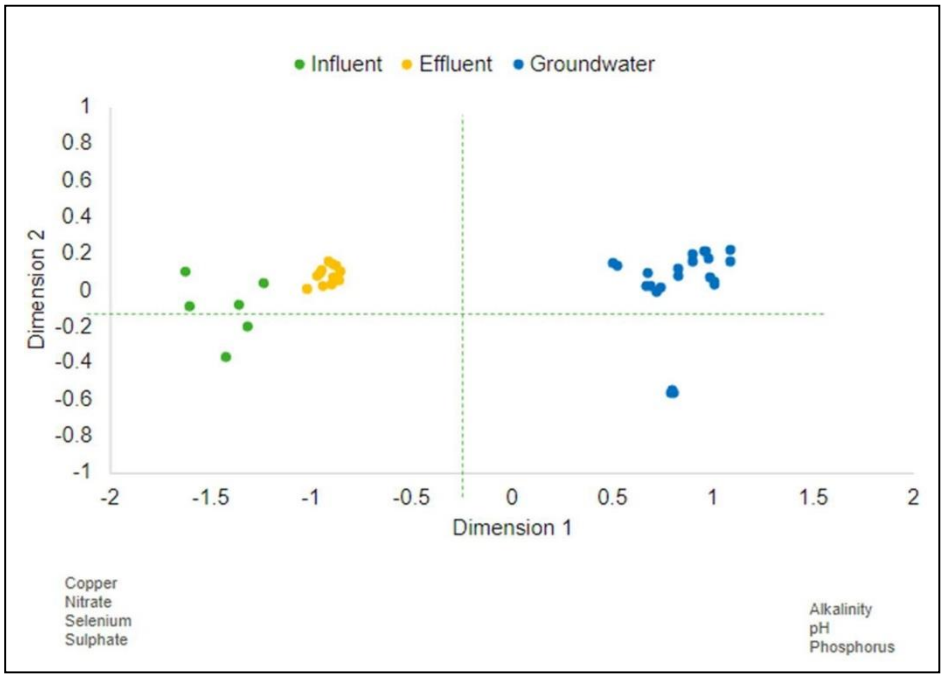

Figure 6. Visualization of Golder's Wight Pit multivariate analysis. Influent, effluent, and groundwater are dissimilar, which indicates a process other than source mixing

Work in the Wight Pit is most recently being expanded to include DNA analysis. Samples were collected from Wight Pit, the TSF, other water storage areas on-site in the winter of 2021-2022, and Golder's bench-scale reactor in the laboratory. Third party laboratory DNA analysis of the sampling was completed and results indicated the presence of several species that are potentially involved in selenium and/or nitrate removal in the pit. Copper removal through precipitation as copper sulfide was also investigated and it was determined that although some sulfur/sulfide reducing bacteria were present, the sulfate reducing bacteria were not sufficient. In addition, Wight Pit water samples were sent to waterStrider for testing targeting the removal of dissolved cadmium, total copper, total zinc and sulphate in Q4 2023. Reductions in the targeted contaminants of concern were observed, and further testing is being considered. SRK has been retained to review

the water chemistry in the Wight Pit to help determine the mechanisms for the degradation of the pit water, particularly in the aforementioned contaminants of concern. At the time of this report's submission the review was underway. Results will be reported in a subsequent Progress Report This, combined with the bench-scale investigation of SRF processes, discussed earlier in this report, will expand on the possibility of passive treatment in the Wight Pit.

6.3 Sodium Hydrosulphide Treatment for Copper

MPMC investigated the use of sodium hydrosulfide (NaHS) as an agent to reduce copper concentrations in water by precipitation of metal sulphides. NaHS is a water-soluble chemical used in the MPMC concentrator as a flotation activator for copper-oxide mineral processing. In the context of water treatment, it can be added to water with high concentrations of dissolved copper. Ionic minerals, including copper, will interact to form insoluble metal sulfides which can be removed from the water by settling, and therefore sequestered.

This process has been demonstrated to be effective at removing copper in bench and pilot-scale trials by MPMC personnel. A series of demonstration-scale trials were conducted in 2021 with favorable results indicating that NaHS could be a worthwhile component of the MPMC water treatment train. NaHS was used to treat water in the Cariboo Pit, Heap Leach Pad (HLP) leachate, and Tailings Storage Facility supernatant. A technical memorandum (Sterling 2021) summarizing these results was submitted with Progress Report #9 in December 2021. The positive results are attributable to NaHS dosage in conjunction with settling and clarification.

A further trial was held between January 24 and March 2, 2022, in which TSF water and HLP leachate were pumped to the Tailings Box in the mill and dosed with 10-100 ml/min of NaHS, then monitored while being pumped back to the TSF. This was designed to inform further NaHS treatment options for water sourced from other areas of the mine. These dosages appear to have been successful (Figure 7), with results from February 16 to March 2, 2022 showing a marked decrease in dissolved copper in mill discharge relative to TSF water.

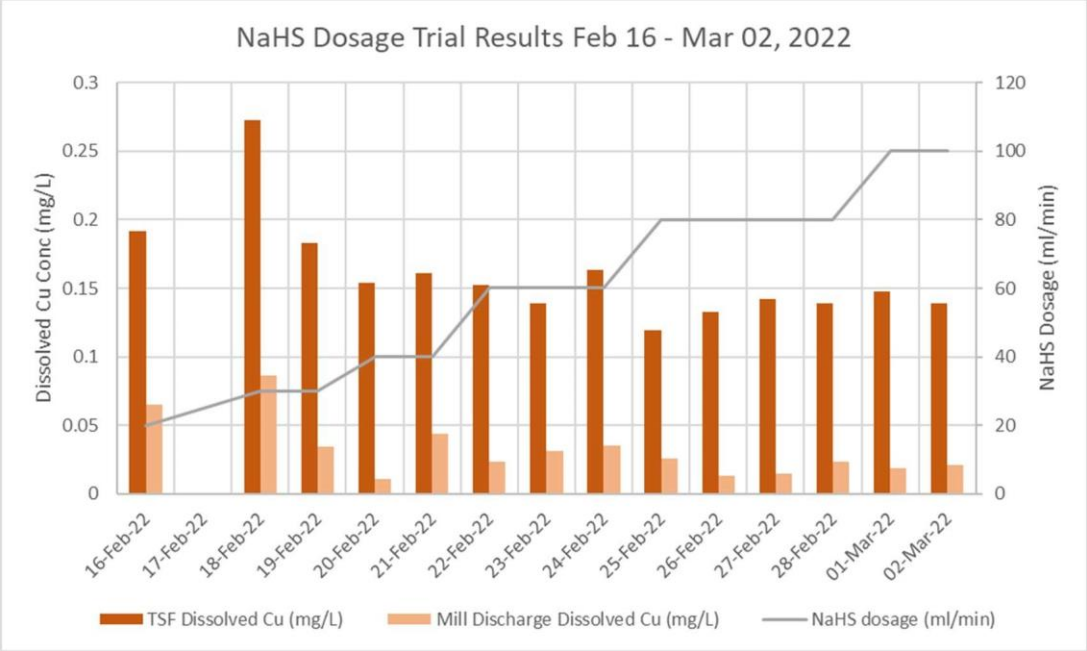

Figure 7. NaHS Dosage Trial Results Feb 16 – Mar 02, 2022. Dissolved Cu in Mill discharge water is lower than TSF source water. Dosages up to 80 ml/min appear to increase treatment efficacy.

The NaHS addition system was installed in the plant concentrator in 1997 during initial construction to assist with flotation of oxide copper minerals. The NaHS system remains in service for this purpose and can be used for future water treatment as required.

6.4 Grafta™ Treatment for Total Copper, Selenium and Other Metals

The newest treatment program being pursued by MPMC is the use of GRAFTA™ technology to remove elevated metal constituents from Northeast Zone (NEZ) seepage water. Water from the NEZ seeps have elevated concentrations of total copper and selenium, and as such NEZ seepage water has to be managed effectively on the mine site. Currently, NEZ seepage water is being pumped to the mill building for use in mineral processing or, in the event of a power outage onsite, transported to the Wight Pit where passive in pit treatment occurs.

GRAFTA™ is a nanotechnology-based adsorbent with several variations that are engineered to remove metals and organic compounds from water. GRAFTA Nanotech Inc. carried out GRAFTA™ lab-scale column adsorption test work at their laboratory in Toronto, ONT, using samples of NEZ seepage water that were shipped from the mine. The samples were used to test GRAFTA™ (fine and coarse) using a single column GRAFTA™ filter or chain of multiple GRAFTA™ filters, with which the influent (NEZ seepage water) was permeated through at a retention time of approximately 45 minutes (on average). The pH of the influent water was acidified in select tests to increase selenium removal. Functionalized GRAFTA™, that is GRAFTA™ with various reducing agents (GRAFTA™-F100 and GRAFTA™-F200), were also applied to select column tests to aid in metal reduction.

A high-level summary of findings is provided below:

- Upon testing different variations of GRAFTA™, it was concluded that the functionalized GRAFTA™-F200 was the most effective in removing both selenium and copper consistently to non-detectable levels. This was achieved through average hydraulic retentions times of approximately 45 minutes.
- Estimating the design parameters is recommended to be ensured through a larger-scale pilot to be implemented at the site and monitored for a longer period of time.
- It is estimated that the longevity of GRAFTA™-F200 should be significantly longer than what was experienced in the lab-scale tests. For an approximate 500 m^3/d flow rate of the contaminated water (i.e., NEZ seepage water), approximately 17 to 18 tons of GRAFTA™-F200 is estimated to be required which would be expected to remain active (until saturation of the adsorption sites) for several weeks to potentially months.
- Improvement in longevity at a lower retention time corresponding to lower GRAFTA™-F200 may also be possible which can be verified through onsite performance evaluation.

The findings in the technical memorandum (GRAFTA 2022) are subject to a confidentially agreement and are under review by MPMC. No further work is planned.

7. SOURCE CONTROL OPTIMIZATION STUDIES

Source control optimization is required to be performed at Mount Polley under *EMA* Permit 11678 (Dec 2022) [s 2.11.3]:

> *The permittee must undertake ongoing maintenance and surveillance of on-site water management systems and activities undertaken to increase source control of any potential contaminants of concern.*
>
> *(a) The permittee must undertake source control optimization yearly.*

MPMC undertakes ongoing maintenance, monitoring and improvements of water management systems and source control measures across the Mount Polley Mine site. This is a well-established part of operations at the Mine. MPMC's progress is described in the following sections.

7.1 Monitoring & Management Plans

Source control optimization is driven through ongoing collection and analysis of water quality and flow data per the Comprehensive Environmental Monitoring Plan (CEMP). Data is interpretated weekly to assess changing conditions and inform pre-treatment requirement, source control and discharge options. Pumping and conveyance systems are arranged to be flexible and stored volumes are managed to ensure water treatment capacity is utilized.

The environmental effects of the discharge to Quesnel Lake are monitored under the CEMP and governed by the Metal and Diamond Mining Effluent Regulations of Environment and Climate Change Canada.

Monitoring and management plans contribute to this effort, recent updates are listed;

- Comprehensive Environmental Monitoring Plan (2019) (CEMP) (MPMC 2019)
- Annual Discharge Plan
- Sediment and Erosion Control Management Plan (Jul 2023)
- ML/ARD Management Procedure Manual (Oct 2023) (MPMC 2023)
- Water Management Plan (Nov 2020) (Golder 2020a)
- Water Balance Model (Golder 2022a)
- Water Quality Model (Golder 2022b)
- Flocculant Management Plan (Golder, 2023a)
- Erosion and Sediment Control Plan Review Report (Mar 2023) (Golder, 2023c)

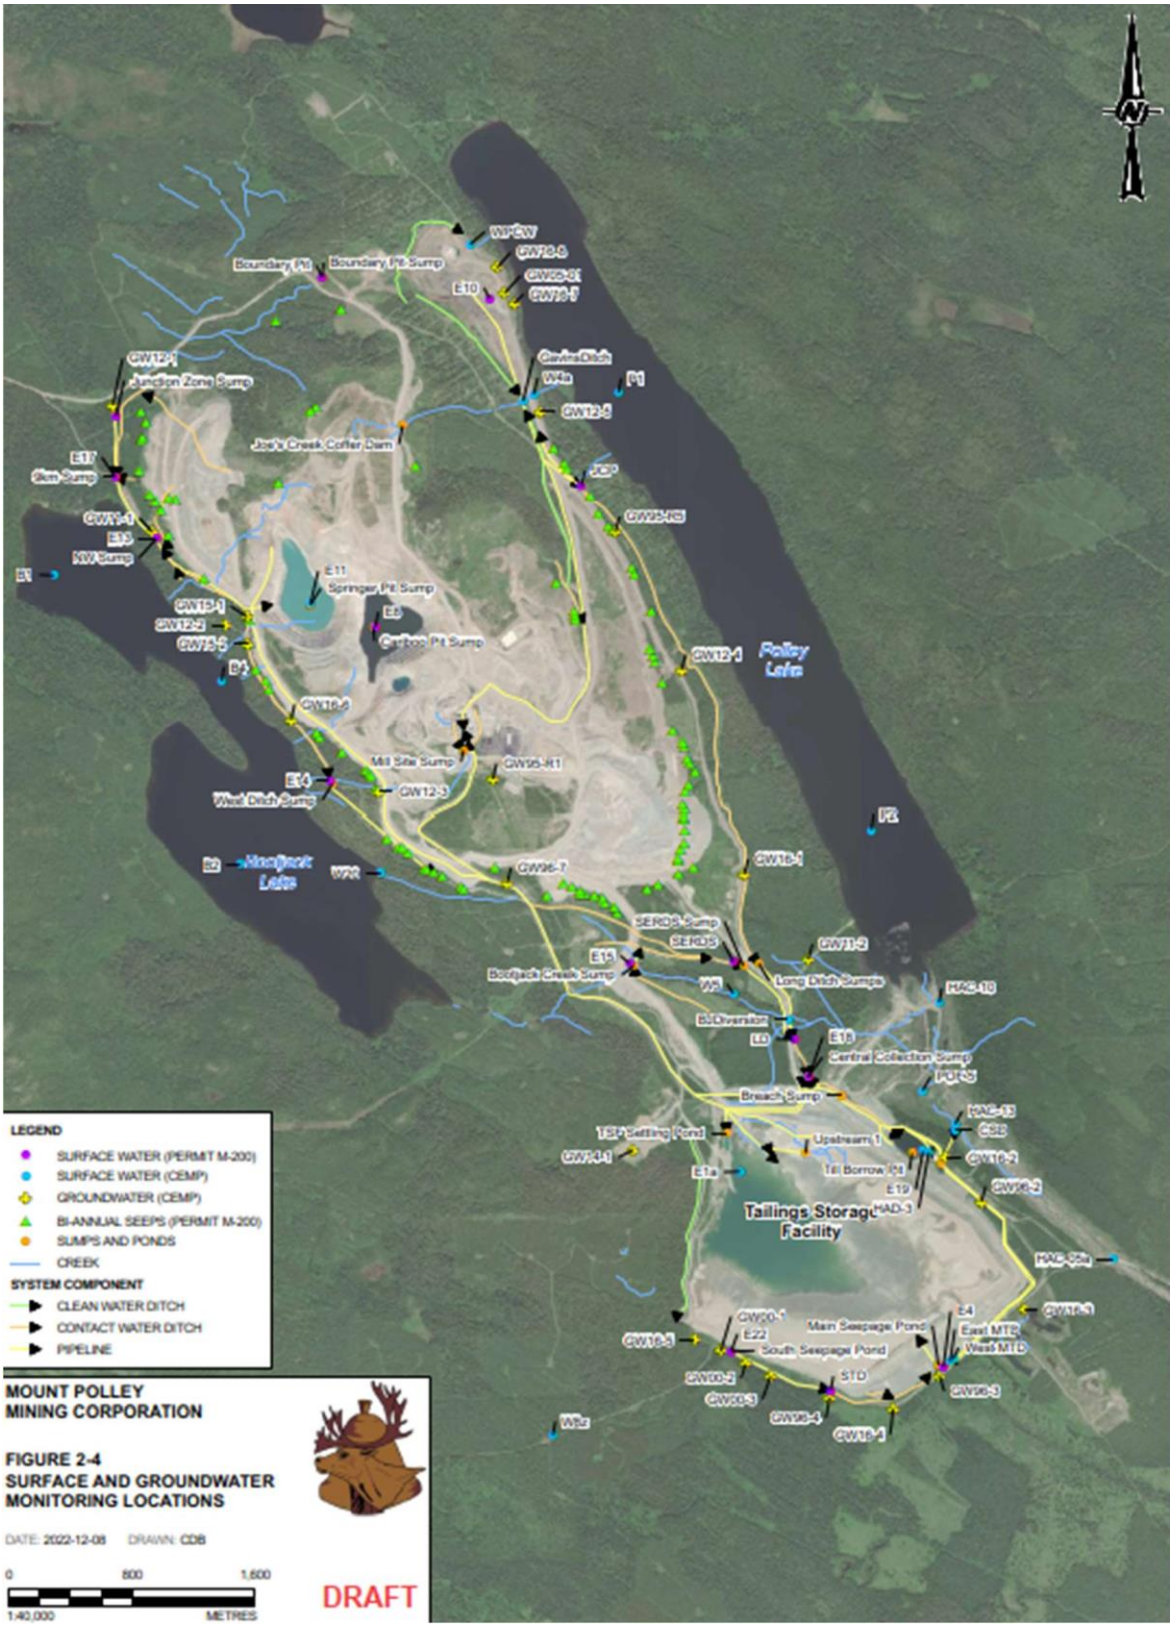

Figure 6. CEMP Monitoring Locations

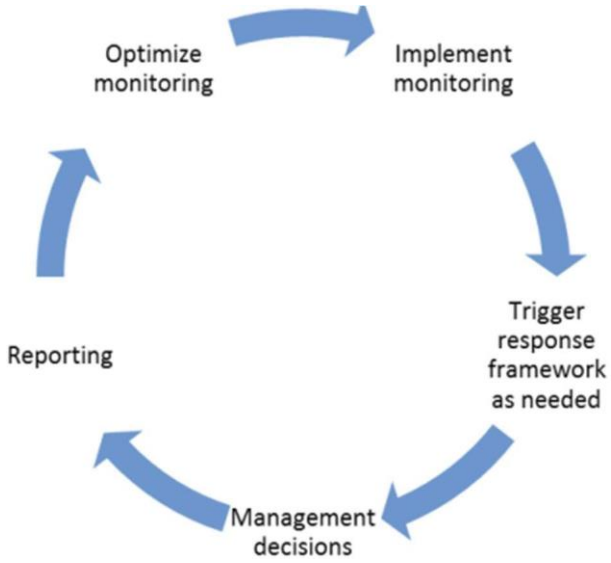
EMA Permit 11678 (Dec 2022) [s 2.12(d)] requires reporting on source control optimization. Recent interpretative reports influencing treatment options and source control decisions;

- Phase 2 Environmental Effects Monitoring Program Interpretative Report (Minnow 2019)
- 2022 Annual Environmental Report for the Mount Polley Mine. BC Ministry of Environment and Climate Change Strategy. Mount Polley Mining Corporation.

Monitoring for a specific year will be verified in monitoring work plans following the adaptive management framework.



7.2 Booster Station Overflow Alarm System

The TSF Booster Station overflow valve is used to manage supernatant water in the TSF and achieve Engineer of Record specifications for water storage and beach width by sending water from the TSF to the WTP influent pond. Although this system is essential for safe management of the TSF, its use has the potential to overwhelm the water treatment capacity of the plant, and it has been associated with copper exceedances in the past, most recently on May 31, 2022.

A full investigation report was prepared which shed light on the May 2022 permit exceedance and the possible role of the TSF booster station during that event. One planned remedial action was to install an alarm which will alert mine managers and operators when the booster station valve is open, to limit the extent of release. The booster sump water levels and high-level alarm system is monitored by the Control Room operator in the concentrator building. The plant supervisor travels the reclaim and tailings pipeline system once per shift during operations.

7.3 Heap Leach Pad Decommissioning

The experimental lined Heap Leach Pad (HLP) and excessed stockpiled elemental sulfur was identified as a source of acid rock drainage in a report; An Investigation into Determining the

Source of Elevated Metal Concentrations in Seepage at the Mount Polley Mine (Litke 2019). The acidity has been neutralized by reaction with carbonate and silicate minerals in the waste rock, but it resulted in depressed pHs and occasional breakthrough of acidic waters to waste rock seeps. The removal of the elemental sulfur pile seems to have arrested the downward trend in pH and upward trend in copper. (SRK 2022a)

A plan was developed to decommission the infrastructure, drain down and treat the leachate by NaHS addition and dispose the excess sulfur and HLP construction materials in the Tailings Storage Facility.

The decommissioning plan (Sterling 2022) was submitted to the Ministry of Energy, Mines and Low Carbon Innovation (EMLI) in April 2022. The disposal option for each material type was chosen based on geochemical characterization by qualified professionals at SRK Consulting. EMLI commented on the plan in a letter on October 13, 2022. MPMC responded to comments on May 12, 2023 after a meeting with EMLI on May 4, 2023. The decommissioning plan will be finalized once the comment period is completed.

Currently the elemental sulfur has been relocated to the HLP and contained above the HDPE liner. Precipitation on the HLP contributes to leachate production which in managed by intermittent pumping to the concentrator for NaHS treatment and discharge to the TSF. The Northeast Zone seeps at the toe of the Rock Disposal Site is collected and pumped to the concentrator for use as process water.

7.4 Review of Geochemical Source Terms

To support water quality prediction and waste management planning, Mount Polley operates kinetic tests on waste rock and tailings. This work is undertaken by SRK Consulting, with the most recent result from this test reported in a March 22, 2022 memo (SRK 2022a).

While not directly relating to water treatment, this work provides information on site water chemistry and is helpful to understand and predict water quality arising from contact water and rock dump seepage.

In 2022, the Mine Site's geochemical source terms were reviewed by SRK, as a basis for extending MPMC's *EMA* Permit 11678 permitted discharge period. SRK found that no update to the source terms was required (SRK 2022a). The SRK memo indicated that seepage from RDSs has been mostly stable for key parameters over the monitoring period, except for localized influences from sulphuric acid water likely originating from the Test Heap Leach. (Golder 2022g)

7.5 Erosion and Sediment Control Plan Review and Update

In accordance with Permit 11678 s 2.6.2, MPMC's Erosion and Sediment Control Plan (ESCP) was reviewed and an ESCP Review Report provided. Modifications recommended in the review report were applied to MPMC's ESCP. The ESCP Review Report provided by Golder was appended to the 2022 Annual Environmental Report submitted in March 2023. The updated ESCP was submitted on July 31, 2023.

8. REVIEW OF DISCHARGE ALTERNATIVES

EMA Permit 11678 (Dec 2022) s 2.11.4 requests the permittee to review discharge alternatives to Quesnel Lake:

> *The permittee must review discharge alternatives for direct discharge of treated mine water on and around the mine site including considering the following mine phases: operations, care and maintenance, closure, and post-closure.*
>
> *The review of discharge alternatives must include consideration of:*
>
> *(a) Passive and semi-passive water treatment options for distributed discharges across the mine site informed by the Water Management Plan dated November 27, 2020, and most recent Reclamation and Closure Plan for the site,*
>
> *(b) Physical (geomorphological and hydrological), chemical and biological characteristics of potential receiving environments, and*
>
> *(c) The capacity of the proposed discharge locations to receive the additional discharges of treated water and meet applicable environmental benchmarks.*
>
> *(d)* This section of Progress Report #13 addresses *EMA* Permit 11678 (Dec 2022) s 2.12 I*(e) summary and discussion of proposed alternative discharge locations that have the capacity to receive the treated water and changes from the previous progress reports,*

The Mine Plan and Reclamation Program Update 2022 (MRP) (Golder 2022g) s 5.2.4 addresses subjects related to water treatment, water balance and water quality for the periods of operations, closure, and post-closure. Further context is provided in MRP Appendices G, H & I.

The MRP s 5.2.4 discusses the approach to alternative discharge locations;

Currently, one objective for the active and post-closure phases of the Mine Site's life cycle is the development and implementation of a decentralized passive/semi-passive water treatment system. Given that the Mine Site was developed on a watershed divide, it is desired that such a system returns water to its respective pre-development watersheds – an objective consistent with the Environmental Assessment and input from local communities and First Nations. Ultimately, this decentralized system will be achieved using passive/semi-passive technologies developed through bench scale and pilot testing. The status of current research towards this end is discussed in Section 4.4. (*this report Section 3*).

While a distributed system is desired for active and post-closure, there are several challenges that will need to be overcome. For instance, the ability of the receiving environment to accommodate the post-closure flows needs to be carefully assessed. Given that runoff from disturbed areas is

higher than runoff from forested areas (the pre-mine case), the flow volumes during early post-closure may be too great to be accommodated without damaging the existing receiving environment and their associated habitats. Further, water quality receiving environment targets are likely to become more stringent, given the lower assimilative capacity of these receiving environment. Although distributed passive/semi-passive treatment and discharge is a desired closure outcome, these technologies have not yet been fully developed to full scale and face permitting uncertainty. The assumed treatment configuration for active and post-closure is pit lake pre-treatment followed by centralized Actiflo treatment (one the closure BAT options identified (Golder 2016c). Figure 5 1 and Figure 5 2 provide the current models for active closure and post-closure water management. Appendix H and Appendix I provide discussion on predicted water balance, water management, and water quality at closure. Figure 5 3 shows the anticipated catchments for the post-closure environment.

End of Excerpt from the MRP (Golder 2022g)

9. CONCLUSION

Environmentally responsible water management, treatment, and discharge are priorities at Mount Polley Mine. Effluent treatment, and interrelated monitoring and optimization activities, conform with the requirements of Permit 11678, including Sections 2.11 and 2.12. MPMC is actively pursuing the following water treatment or discharge optimization technologies: Actiflo optimization, lime treatment, pit lake treatment, saturated rock fill (SRF), packed bed reactor (PBR), constructed wetland treatment (CWT), and source control improvements.

Attainment of the NPM is becoming more prevalent over time, with 98% of WTP samples collected in 2023 below this threshold. Discharge total copper measured 0.00937 mg/L over a 52-week rolling average to December 21, 2023. This represents superior discharge performance relative to previous 6- month update periods.

As MPMC restarts and builds capacity, treatment actions are being continuously improved. The decommissioning of the Heap Leach Pad with BC-EMLI approval following a staged approach is being planned. Mount Polley strives for continual improvement and adaptive management, in collaboration with technical experts, local communities, First Nations, and regulators.

1.0 INTRODUCTION

1.1 PURPOSE AND SCOPE

DWB Consulting Services Ltd. (DWB) was retained by Mount Polley Mining Corporation (MPMC) to survey and monitor invasive plant presence within stockpiled soil, as well as to prepare this summary report to advise on the inventory, prevention, management, and monitoring of invasive plants at the Mount Polley Mine. This plan was prepared with input from Professional Biologists and Agrologists.

1.2 PROJECT DESCRIPTION

The development of this report included visual surveys conducted in combination with routine assessments of progressive reclamation sites and annual soil stockpile inspections. Invasive plant species present, and their distribution and density are documented and compiled with revegetation results.

Information provided in this report includes:

- Surveying and mapping of infestation locations, with a focus on reclamation areas and soil stockpiles;
- Identification of invasive plant species present;
- Assessment of the degree of invasive plant growth, distribution, and density present at infestation sites;
- Assessment of success of any prevention and control measures that were previously implemented;
- Recommendations for any prevention and control measures that should be implemented; and
- Recommendations for when the next inventory should be conducted.

1.3 PROJECT LOCATION

Mount Polley is located approximately 57 km (geodesic distance) northeast of Williams Lake, BC, as shown in Figure 1. From Williams Lake, the mine site is accessed by driving south on Highway 97 North and turning north just before 150 Mile House onto the Horsefly Likely Road, then driving for 4.5 km before turning west onto Likely Road. After travelling Likely Road for 64.6 km, turn south onto the Morehead-Bootjack Forest Service Road (FSR) for 14 km. Mount Polley is located at the end of the Morehead-Bootjack FSR at UTM 10 U 592897 5822603.

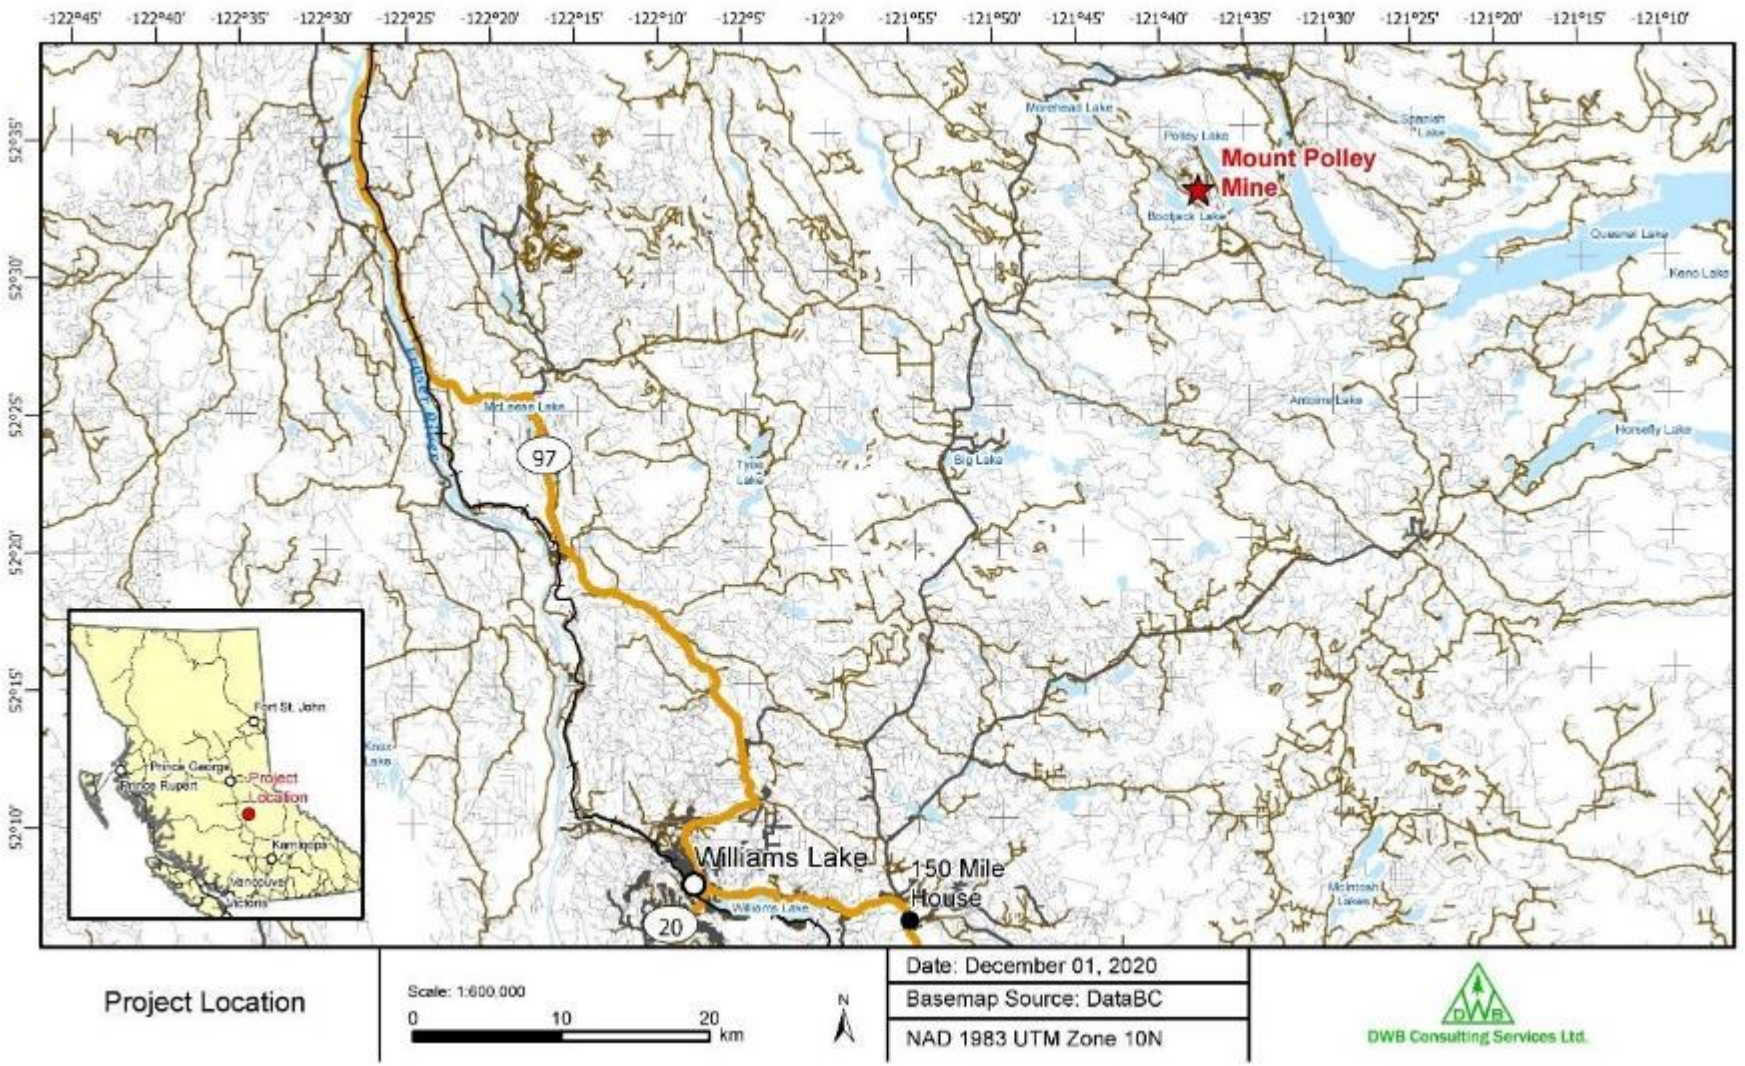

Figure 1. Location of Mount Polley Mine in relation to Williams Lake, BC.

1.4 Regulatory and Permitting Context

The following legislation, guidelines, management plans and governing agencies provide additional support regarding the management of invasive plant species:

- *BC Mines Act* (Province of British Columbia 1996) & *Health, Safety and Reclamation Code for Mines in British Columbia* (Ministry of Energy and Mines 2022); Requires that land reclamation at the end-of-use must be reclaimed at an equal or greater-than-average land capability that was present prior to mining. In addition, construction of an IPMP is required for both acts under the Vegetation Management Plan (Section 7.13 & Section 10.7.7 of the Health, Safety and Reclamation Code),
- *Weed Control Act* (Province of British Columbia 1996); Administered by the BC Ministry of Agriculture, this act requires all land occupiers of public or private lands to control designated noxious plants to prevent introduction or spread to unaffected areas,
- BC *Integrated Pest Management Act* (Environment Canada 2003); Regulates the sale and use of herbicides to control invasive plants,
- *Forest and Range Practices Act* (Province of British Columbia 2002); Requires that forestry activities should reduce establishment and spread of invasive plants,
- *Seeds Act* (Government of Canada 1985); Requires that seed sold, imported, and exported in Canada is free of prohibited noxious weeds and ensures standards of purity are met,
- *The Invasive Alien Plant Program Reference Guide* (BC MOFR 2010)*;* A resource manual for all agencies and partners involved in invasive plant management in BC; and
- *Cariboo Chilcotin Coast Invasive Plant Committee (CCCIPC)/Cariboo Regional District*; Provides information regarding important regional invasive plants and methods to mitigate the introduction and spread of invasive plants (CCCIPC 2017; May, 2023).

1.5 Project Schedule

An inventory of invasive plants was completed at the mine from July 25 to July 28, 2023. Survey timing coincided when the majority of plant species were flowering (summer), as species identification is significantly aided by the presence of inflorescence.

2.0 ENVIRONMENTAL SETTING

2.1 Vegetation

Mount Polley Mine falls within the Interior Cedar Hemlock (ICH) biogeoclimatic (BEC) zone in the moist cool (mk3) variant. Ecosystems within mk3 variant are characterized by forest cover dominated by western redcedar (*Thuja plicata*), interior Douglas-fir (*Pseudotsuga menziesii var. glauca*) and lodgepole pine (*Pinus contorta var. latifolia*). Young forests within this variant are often dominated by interior Douglas-fir and/or lodgepole pine and other seral tree species that may be present including trembling aspen (*Populus tremuloides*) and paper birch (*Betula papyrifera*). Common shrubs in the forest understorey include black huckleberry (*Vaccinium membranaceum*), black gooseberry (*Ribes lacustre*), devils club (*Oplopanax horridus*), falsebox (*Pachistima myrsinites*) and oval-leaved blueberry (*Vaccinium ovalifolium*). Examples of common herbs include rose twistedstalk (*Streptopus lanceolatus*), bunchberry (*Cornus canadensis*), oak fern (*Gymnocarpium dryopteris*), three-leaved foamflower (*Tiarella trifoliata*) and twinflower (*Linnaea borealis*; Steen and Coupe, 1997).

3.0 INVASIVE PLANT INVENTORY

3.1 METHODS

An inventory of invasive plant species was completed of the mine stockpiles from July 25-28, 2023. Prior to commencing field surveys, a desktop review was conducted to pre-determine areas of high potential for invasive plants, such as high-traffic areas, road right-of-way's, disturbed areas, and areas with poor vegetation cover; the desktop review included government websites and background documents from MPMC. Field maps were created utilizing the desktop review and highlighting areas with high potential for invasives (i.e., road right of ways, high-traffic areas). The desktop assessment also included review of existing IMC documents related to previous invasive plant survey and management activities and correspondence with the Invasive Plant Management Coordinator of the Cariboo Regional District for updated information regarding the CCCIPC Priority Plant lists (May, 2023).

As per the recommendations of the *Invasive Alien Plants Pest Management Plan (IAPP) for Provincial Public (Crown) Lands in the Southern Interior of British Columbia* (MOF, 2022) information recorded during surveys included the UTM coordinates (northing, easting and zone), location, date, species, estimated size of the infestation in hectares, distribution, density, photos, and any pertinent site characters or additional information such as soil type or proximity to a riparian area. It is recommended that invasive plant survey and inventory information be documented using the *IAPP Site & Invasive Plant Survey Record* (Appendix A) and submitted into IAPP to add to the Cariboo Chilcotin Coast Invasive Plant Committee (CCCIPC) inventory information. A comprehensive list of priority species created by the CCCIPC for 2020 within the Cariboo Chilcotin Region is included in Table 1 (CCCIPC, 2017).

Table 1 Comprehensive list of priority invasive plants targeted by the Central Chilcotin Coast Invasive Plant Committee (CCCIPC) in 2020 for treatment in the Central Cariboo Invasive Plant Management Area (CCCIPC, 2017). New invaders (newly established species, current limited distribution, or at borders. Management objective is elimination); Containment (well-established species in the Cariboo Chilcotin region, but have no yet infested all potential habitats. New sites will be managed to contain them and prevent further spread); Established (common and widespread species that occupy most or all potential habitats. Widespread control of these species is not currently possible); Biological Control (well-established species in the Cariboo Chilcotin region, for which effective biocontrol agents exist).

COMMON NAME	SCIENTIFIC NAME	Priority Ranking
Baby's-breath	*Gypsophila paniculata*	New Invader
Black henbane	*Hyoscyamus niger*	New Invader
Blueweed	*Echium vulgare*	New Invader
Burdock	*Arctium spp*	Established
Canada thistle	*Cirsium arvense*	Established
Caraway	*Carum carvi*	New Invader
Common tansy	*Tanacetum vulgare*	Containment
Dalmatian toadflax	*Linaria dalmatica*	Biological Control
Diffuse knapweed	*Centaurea diffusa*	Containment
Field scabious	*Knautia arvensis*	New Invader
Flowering rush	*Butomus umbellatus*	New Invader
Himalayan balsam	*Impatiens glandulifera*	New Invader

Common Name	Scientific Name	Priority Ranking
Hoary alyssum	*Berteroa incana*	New Invader
Hoary cress	*Cardaria draba*	New Invader
Hound's-tongue	*Cynoglossum officinale*	New Invader
Knotweed spp	*Polygonum* spps.	New Invader
Leafy spurge	*Euphorbia esula*	New Invader
Marsh plume thistle	*Cirsium palustre*	New Invader
Meadow knapweed	*Centaurea debeauxii*	New Invader
Mountain bluet	*Centaurea montana*	New Invader
Nodding thistle	*Carduus nutans*	Biological Control
Orange hawkweed	*Hieracium aurantiacum*	Established
Oxeye daisy	*Leucanthemum vulgare*	Established
Perennial pepperweed	*Lepidium latifolium*	New Invader
Plumeless thistle	*Carduus acanthoides*	New Invader
Purple loosestrife	*Lythrum salicaria*	New Invader
Russian knapweed	*Acroptilon repens*	New Invader
Scentless chamomile	*Matricaria perforata*	Established
Spotted knapweed	*Centaurea biebersteinii*	Containment
St. John's wort	*Hypericum perforatum*	Containment
Sulphur cinquefoil	*Potentilla recta*	Containment
Tansy ragwort	*Senecio jacobaea*	New Invader
Yellow flag iris	*Iris pseudachorus*	New Invader
Yellow hawkweed	*Hieracium* spp	Established
Wild chervil	*Anthriscus sylvestris*	New Invader
Wild parsnip	*Heracleum maximum*	New Invader

3.2 Results

The desktop review revealed historical presence of orange hawkweed on the site (Government of BC, 2024) and that Mount Polley mine lies inside an orange hawkweed, yellow hawkweed, and spotted knapweed (*Centaurea biebersteinii*) containment area (CCCIPC, 2017). Containment areas are management approaches to prevent existing established plant populations from spreading into new areas.

Previous field surveys conducted in 2017 surveyed 95 polygons (432.0 ha) and identified onsite presence of priority species Canada thistle, oxeye daisy, orange hawkweed, and scentless chamomile and lower priority species bull thistle, yellow hawkweed and shepherd's-purse (Spectrum, 2017). Extensive herbicide treatment of invasive species identified in 2017 was conducted in 2018 (Holmes, 2023). In addition, some incidental hand pulling and mechanical treatments have been conducted onsite (Holmes, 2023).

Field survey results in 2023 determined presence of species with CCCIPC Priority Ranking "Established" including Canada thistle, orange and yellow hawkweed, oxeye daisy, and scentless chamomile. Established species, as per the CCCIPC Strategic Plan, are defined as common and widespread species that occupy most or all potential habitats and widespread control is currently not possible (CCCIPC, 2017). Other

invasives not listed within the CCCIPC priority list included bull thistle (*Cirsium vulgare*), Western goat's-beard (*Tragopogon dubius*), mullein (*Verbascum thapsis*), and sow thistle (*Sonchus* spps; also designated as provincially noxious) within the soil stockpile polygons. Table 2 summarizes the results of the survey, photo documentation is provided in Appendix B, and a detailed summary of the inventory results is provided in Appendix C.

Table 2. Invasive plants identified at the Mount Polley Mine from July 25 to 28, 2023 including Priority Ranking within the Central Cariboo Sub-Region of the Cariboo Chilcotin Coast Invasive Plant Committee (CCCIPC) Priority Plant List, stockpiles infested by species and total number, and area of species infestation by species and total in hectares (ha). Invasive plants were categorized New Invader, Containment, Established, Biological Control or Not Listed, as listed by the CCCIPC (CCCIPC, 2017; May, 2023).

Priority Ranking the Central Cariboo Sub-Region of the CCCIPC	Invasive Plant Species	Scientific Name	Number of Soil Stockpiles Infested	Total Area of Infestation (Ha)
New Invader	-	-	-	-
Containment	-	-	-	-
Established	Canada thistle[1]	*Cirsium arvense*	26	33.1
	Orange hawkweed[2]	*Hieracium aurantiacum*	19	24.8
	Oxeye daisy[1]	*Leucanthemum vulgare*	66	81.2
	Yellow hawkweed	*Hieracium* spp	49	65.9
	Scentless chamomile[1]	*Matricaria perforata*	8	10.0
Biological Control	-	-	-	-
Not listed	Bull thistle	*Cirsium vulare*	50	63.0
	Mullein	*Verbascum thapus*	27	34.2
	Sow thistle[1]	*Sonchus* spps.	21	26.5
	Western goat's beard	*Tragopogon dubius*	48	60.6
Total number of polygons infested			66 stockpiles, Target Area 16 & 17, Junction Zone Seepage Sump Road, North Bail Dump and several access roads.	
Total Area of infestation (ha)			399.3	

[1]These species are also listed as provincially noxious in British Columbia (Province of British Columbia, 1996).

[2]These species are also listed as regionally noxious in the Cariboo region in British Columbia (Province of British Columbia, 1996).

Appendix D provides maps that show the locations of the invasive species found on the mine site.

4.0 INVASIVE PLANT MANAGEMENT PLAN

4.1 PREVENTION

Preventing the introduction of invasive plants, as well as quickly responding to an initial spread, is the most effective way to manage invasive plants. These actions will reduce treatment cost and ensure unmanageable outbreaks do not occur during post-mining activities. Preventative measures include identifying potential sources of invasive plant spread. Table 3 summarizes invasive plant sources, potential vectors, and whether control methods are possible.

Table 3. Potential vectors, sources and possible control of invasive plant spread with remediation activities at the Mount Polley Mine site.

VECTORS	SOURCE	CONTROL METHODS POSSIBLE
Human-mediated	People – footwear, clothing	Y
	Vehicles & equipment – moving onto and off of site	Y
	Permanent forest canopy openings	Y
VECTORS	**SOURCE**	**CONTROL METHODS POSSIBLE**
Reclamation Activities	Movement of soil	Y
	Use of seed mixture or soil contaminated with invasive plants	Y
Animals	Wildlife	N
Natural	Wind	Y
	Rhizome or seed spread	Y

Preventative measures to reduce potential spread of invasive plants include:

- Minimizing disturbance,
- Prompt ground seeding of disturbed areas (right-of-way's, powerline access, inactive sections of mill, storage and equipment yards, etc.) with a rapidly establishing seed mixture to prevent soil erosion and establishment of invasive plants,
- Use only tested and approved seed mixtures that have a Certificate of Analysis,
- Retain natural vegetation in ditches, right-of-way's, powerlines, storage, and equipment areas,
- Soil should not be moved into an area of existing invasive plants,
- Monitor for presence of invasive plants in soil that has been moved and stored,
- Ensure that footwear, clothing, equipment, vehicles, and undercarriages are mud and debris free prior to entering and leaving site as they may contain invasive plants. This includes socks, pant legs and cruise vest,
- Prevent human, equipment and vehicle access through known areas of invasive plant infestation,
- Educate personnel on ways to reduce invasive plant spread and invasive plant identification.

4.2 Treatment

Control and monitoring measures for invasive plant species found on the site will be determined by consulting the appropriate authorities. If treatment of invasive plants is required, timing windows that incorporate the invasive plant will be established that include consideration of the invasive plant species, site conditions, and infestation size.

Treatment of invasive plants may include chemical, mechanical or biological control methods.

4.1.1 Chemical Treatment

Chemical treatments include fertilizers and herbicides. Fertilizer can aid native plant species in competing with invasive plants and increase their competitiveness. Herbicides are useful as a last resort but should be used only if all other options have failed.

If herbicide use is required, selection and application of approved herbicide will be performed in compliance with BC's *Integrated Pest Management Act* (Environment Canada 2003). In order to reduce negative impacts on the environment, chemical spot-treatment will be used instead of broadcast spraying. It is recommended that application information be documented using the BC Ministry of Forests, Lands and Natural Resource Operations *Invasive Plant Chemical and Mechanical Treatment Record* (Appendix E) and submitted into the IAPP (BC MOFR 2010).

In addition, herbicides will not be used under the following conditions:

- Invasive plants are within a Pesticide Free Zone (PFZ), such as near a water source or well,
- Invasive plants are within coarse textured soils that would reduce effectiveness of herbicide,
- Invasive plant treatment is occurring under inappropriate weather conditions (e.g., persistent precipitation, wind >8 km/hr, temperature >28°C,
- Residual herbicides may not be used within 10 m of water source and 30 m from well,
- Non-residual herbicides may not be used within 1 m of water source or well,
- Residual herbicides may not be used within a gravel pit,
- Residual herbicides with the active ingredient 24-D may not be used on areas that fall within Ministry of Transportation and Infrastructure (MOTI) jurisdiction.

4.1.2 Spills & Safety Data Sheets

During the chemical treatment of invasive plants, there is a potential for an inadvertent release of chemical herbicide. It is necessary to provide spill response kits which include the basic contents of a chemical spill kit.

MPMC will ensure that, for all chemical substances used on site, a copy of the Safety Data Sheets (SDS) is made available on site in a clearly marked binder. These sheets will identify: product information, hazardous ingredients, physical data, fire and explosion hazard, reactivity data, toxicological properties, preventative measures, first aid measures, and preparation information as required by the Workers' Compensation Board of BC. In the event of a spill or leak, the Safety Data Sheets will be consulted to determine if there are any potential risks for health and environment related to the product.

4.1.3 Spill Investigation / Spill Report Form

If the spill is a reportable emergency, an investigation report and spill report form must be completed and forwarded to the Emergency Management BC (1-800-663-3456) within 24 hours of the incident occurring. The company responsible for the spill must prepare the investigation and spill report.

4.1.4 Mechanical Treatment

In areas where invasive plants have low distribution/density, mechanical treatment methods are often used because the treatment is simple, effective, and eliminates the potential negative effects of chemical treatment.

Mechanical treatment techniques are frequently utilized in targeted areas of an invasive plant infestation where the use of herbicide is not permitted or feasible. This is particularly relevant near riparian habitats or other environmentally delicate features. Some of examples of mechanical treatment methods include:

- Hand-pulling
- Digging/Excavating
- Cutting
- Mowing
- Mulching
- Controlled Burning (Flaming, Tiger Torch)
- Cultivation/Tilling
- Dead-heading
- Cover/Smother
- Salt water/Vinegar

However, mechanical treatment options can be limited by:

- Safety issues: burning can jeopardize the well-being of employee and have detrimental effects on the environment.
- Timing windows: mowing needs to be considered prior seed dispersal taking place.
- Cost: mechanical treatment may be labour intensive; follow-up treatments may be required throughout the growing season and can be required for a consecutive 3-5 years to ensure effective treatment.
- Effectiveness: mowing is not effective on smaller invasive plant species; digging/deadheading/mowing is not effective on species that grow from adventitious root buds or rhizomes, such as hawkweed species (*Hieracium* spp.).

If mechanical treatment does occur, appropriate disposal of all plant material and propagules is required. This includes placing invasive plants into dark plastic bags and bringing bags to a landfill that has a designated area for invasive plant species. Invasive plant species must not be composted. It is recommended that mechanical treatment of invasive plants is documented using the *Invasive Plant Chemical and Mechanical Treatment Record* and submitted into the IAPP (BC MOFR 2010).

4.1.5 Biological Control

Typically used to address invasive plants, biological control agents include fungi, viruses, nematodes, and insects that lower plant density and seed production. Biological control agents are helpful, but they must be used carefully to prevent off-target damage to adjacent habitats and non-target vegetation. Any use of biological controls is recommended to be documented using the *Biological Control Agent Release and Monitoring Record* (Appendix F) and submitted into the IAPP.

4.3 MONITORING

In order to ensure that management strategies are being implemented and that any alterations to existing infestations of invasive plant species are documented, monitoring protocols are required. Inspections will be conducted by trained personnel in invasive plant species identification that are familiar with the CCCIPC's current targeted species within the Chilcotin Cariboo IPMA.

In order to provide any propagules sufficient time to resume growth and assess the efficacy of the treatment, post-treatment monitoring should take place no later than two weeks following the treatment.

Information including the date, species, UTM coordinates, location description, estimation of distribution and density, distance to sensitive areas, soil texture, previous treatment method, and the efficacy of the treatment method on the population of invasive plants, will be gathered if invasive plant species are discovered during monitoring. Up to five years after treatment, frequent monitoring and further treatment may be necessary, depending on the type of treatment used and its success rate.

If monitoring indicates that a previous mitigation strategy was ineffective, further mitigation techniques will be investigated. Chemical therapy, for example, can be taken into consideration as an alternative if mechanical treatment appears to be unsuccessful. It is recommended that monitoring records be documented using the *Chemical and Mechanical Treatment Monitoring Record* (Appendix G)*, Biological Treatment Monitoring Record* and/or the *Photoplot Record for Biological Control Method* and submitted into the IAPP to add to the CCCIPC's inventory information.

5.0 IMPLENTATION

5.1 Training and Available Resources

A pre-work orientation with all individuals who will be involved in any fieldwork to manage invasive plant species will be held on site at the beginning of the project and as applicable prior to the commencement of each phase (e.g., prior to truck access). These meetings will have the following components:

- A review of this IPMP to ensure that all parties involved understand the objectives of the plan, and what environmental protection measures are to be used; and
- A review of additional mitigation measures outlined by regulatory agencies. Copies of relevant approval documents will be kept on site and it is important that all persons understand these regulatory requirements.

Any new contractors or employees arriving at the work site after the initial meeting will be briefed in subsequent meetings on an as needed basis by the site supervisor or Environmental Monitor (EM).

5.2 Site Access Management

As the Morehead-Bootjack FSR is an existing road system, there is 2WD access to the site along the existing roadway. Any equipment on site should be free from leaks, fluid, fuel/sediment buildup and invasive plant species. During access, the following best management practices apply:

- Minimize disturbance while accessing the site.
- Removal of invasive plants from personnel, vehicles and equipment before entering and leaving site.

In order to adequately ensure all personnel and equipment are free of invasive plants when entering and leaving the site, inspections should be conducted for invasive plants parts/seeds on clothing, tools, equipment/vehicles and undercarriages of vehicles.

It should be noted that areas free of invasive plants on the mine site should be protected from areas on site where invasive plants are present. As such, procedures for inspecting equipment and clothing should apply not only to when entering and leaving the mine site, but also when entering and leaving areas in the mine where invasive plant infestations occur. Emphasis should be placed on inspections of equipment and

clothing when entering or leaving infested areas identified on the Invasive Plant Infestation Maps in Appendix D.

5.3 Invasive Plant Treatment Recommendations

The invasive plant species found at Mount Polley are all considered Established under the Central Cariboo Priority Ranks of the CCCIPC; Canada thistle, orange hawkweed, oxeye daisy, and scentless chamomile are also considered provincially or regionally noxious (Province of British Columbia, 1996). The *Weed Control Act* (1996) requires control of noxious plants to prevent the introduction and spread to unaffected areas. Table 4 provides recommendations for treatment of invasive plants present on site.

Table 4. Recommendations of treatment types for Canada thistle, oxeye daisy, yellow hawkweed, orange hawkweed, and scentless chamomile on the Mount Polley Mine site.

Species	Recommended Treatment Type
Canada thistle	**Chemical & Containment Areas:** The Canada thistle found onsite had high distribution, density, and total area covered. Mechanical treatment of these large infestations would be impractical. Biological control for Canada thistle exists but is not recommended. Targeted chemical treatment at high-use areas and areas where seed susceptibility is high (e.g. road right-of-way's, areas around buildings, infestation with susceptible area downwind) combined with creation of containment polygons around low-use areas (e.g., deactivated road right-of-way's) would be a feasible treatment and management plan.
Hawkweed species (Orange and Yellow)	**Chemical & Containment Areas:** The hawkweed species found onsite had high distribution, density, and total area covered. Mechanical treatment of these species is not recommended as hawkweed has indeterminate growth (i.e., can grow from any plant part left in the soil). No biological control exists for hawkweed. Targeted chemical treatment at high-use areas and areas where seed susceptibility is high (e.g. road right-of-way's, areas around buildings, infestation with susceptible area downwind) combined with creation of containment polygons around low-use areas (e.g., deactivated road right-of-way's) would be a feasible treatment and management plan.
Oxeye daisy	**Chemical & Containment Areas:** The oxeye daisy identified onsite had areas with high distribution and density and large areas of infestation. Mechanical treatment of these large infestations would be impractical. Currently there is no biological control for oxeye daisy. Targeted chemical treatment at high-use areas and areas where seed susceptibility is high (e.g. road right-of-way's, areas around buildings, infestation with susceptible area downwind) combined with creation of containment polygons around low-use areas (e.g., deactivated road right-of-way's) would be a feasible treatment and management plan.
Scentless chamomile	**Chemical, Mechanical & Containment Areas:** The scentless chamomile identified onsite had areas with moderate distribution

Species	Recommended Treatment Type
	and density and moderate areas of infestation. Mechanical treatments for scentless chamomile identified with low density, distribution, and area, is recommended, especially in high-use areas and areas where seed susceptibility is high. Biological control for scentless chamomile exists but is not recommended as efficacy is not certain. Targeted chemical treatment in high-use areas and areas where seed susceptibility is high (e.g. road right-of-way's, areas around buildings, infestation with susceptible area downwind) combined with creation of containment polygons around low-use areas (e.g., deactivated road right-of-way's) is recommended for scentless chamomile.

A novel approach to mechanical treatment onsite could also include a tilling approach that comprises of ripping the top layer of stockpiled soil, containing invasive plant presence, and placing it underneath the remainder of the stockpiled soil followed by heavy seed application. This novel approach would require monitoring by a qualified professional in invasive plants to increase effectiveness. Treatment of invasive plants should be implemented in early summer to avoid seed heads reaching maturity and spreading more individuals.

6.0 DISTRIBUTION OF THE IPMP

Each member of the project team and the client will receive a copy of the IPMP. A pre-project meeting is required to further go over site specific details. Additional copies of the finalized plan will be available on site, and every team member will understand the strategy and how it operates.

APPENDIX B

Site Photographs (July 25 to 28, 2023)

Photo 1. Stockpile 2: Oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), bull thistle (*Cirsium vulgare*), yellow hawkweed (*Hieracium* spps), orange hawkweed (*Hieracium aurantiacum*), and Canada thistle (*Cirsium arvense*) present. July 28th 2023.

Photo 2. Stockpile 3: Bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), yellow hawkweed (*Hieracium pratense*), Mullein (*Verbascum thapsis*), and Western goat's-beard (*Tragopogon dubius*) present. July 26, 2023.

Photo 3. Stockpile 4: Oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), bull thistle (*Cirsium vulgare*), and yellow hawkweed (*Hieracium* spps) all present. July 26th 2023.

Photo 4. Stockpile 5: Western goat's-beard (*Tragopogon dubius*), bull thistle (*Cirsium vulgare*), and Canada thistle (*Cirsium arvense*) present. July 25th 2023.

Photo 5. Stockpile 6: Oxeye daisy (*Leucanthemum vulgare*), orange hawkweed (*Hieracium aurantiacum*), Western goat's-beard (*Tragopogon dubius*), bull thistle (*Cirsium vulgare*), and Canada thistle (*Cirsium arvense*) present. July 26th 2023.

Photo 6. Stockpile 7: Oxeye daisy (*Leucanthemum vulgare*), scentless chamomile (*Matricaria perforate*), Western goat's-beard (*Tragopogon dubius*), sow thistle (*Sonchus* spps), and Mullein (*Verbascum thapsis*) all present. July 25th 2023.

Photo 7. Stockpile 8: Oxeye daisy (*Leucanthemum vulgare*), scentless chamomile (*Matricaria perforate*), Western goat's-beard (*Tragopogon dubius*), Mullein (*Verbascum thapsis*), bull thistle (*Cirsium vulgare*), and yellow hawkweed (*Hieracium* spps) present. July 25th 2023.

Photo 8. Stockpile 10: Oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), and yellow hawkweed (*Hieracium* spps) present. July 25th 2023.

Photo 9. Stockpile 12: Western goat's-beard (*Tragopogon dubius*), orange hawkweed (*Hieracium aurantiacum*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*)**,** Canada thistle (*Cirsium arvense*)**,** and yellow hawkweed (*Hieracium* spps) present. July 26th 2023.

Photo 10. Stockpile 13: Oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*)**,** Canada thistle (*Cirsium arvense*)**,** and Western goat's-beard (*Tragopogon dubius*) present. July 26th

Photo 11. Stockpile 14: Oxeye daisy (*Leucanthemum vulgare*), orange hawkweed (*Hieracium aurantiacum*), yellow hawkweed (*Hieracium* spps), Western goat's-beard (*Tragopogon dubius*), Mullein **(***Verbascum thapsis*), scentless chamomile **(***Matricaria perforate*), sow thistle (*Sonchus* spps)**,** and bull thistle (*Cirsium vulgare*) present. July 25th 2023.

Photo 12. Stockpile 15: Bull thistle (*Cirsium vulgare*)**,** Canada thistle (*Cirsium arvense*)**,** yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), scentless chamomile **(***Matricaria perforate*), and Mullein **(***Verbascum thapsis*) present. July 25th 2023.

Photo 13. Stockpile 16: Bull thistle (*Cirsium vulgare*)**,** Canada thistle (*Cirsium arvense*)**,** yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), Mullein **(***Verbascum thapsis*), and sow thistle (*Sonchus* spps) present. July 27th 2023.

Photo 14. Stockpile 17: Bull thistle (*Cirsium vulgare*)**,** Canada thistle (*Cirsium arvense*)**,** yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), Mullein **(***Verbascum thapsis*), and sow thistle (*Sonchus* spps), and orange hawkweed (*Hieracium aurantiacum*) present. July 27th 2023.

Photo 15. Stockpile 18: Bull thistle (*Cirsium vulgare*)**,** Canada thistle (*Cirsium arvense*)**,** yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), and orange hawkweed (*Hieracium aurantiacum*) present. July 25th 2023.

Photo 16. Stockpile 19: Canada thistle (*Cirsium arvense*)**,** yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), and Western goat's-beard (*Tragopogon dubius*). July 25th 2023.

Photo 17. Stockpile 20: Bull thistle (*Cirsium vulgare*)**,** orange hawkweed (*Hieracium aurantiacum*)**,** yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), and Western goat's-beard (*Tragopogon dubius*) present. July 25th 2023.

Photo 18. Stockpile 21: Yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), and Mullein **(***Verbascum thapsis*) present. July 25th 2023.

Photo 19. Stockpile 22: Yellow hawkweed (*Hieracium* spps), oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), sow thistle (*Sonchus* spps), Canada thistle (*Cirsium arvense*)**,** and bull thistle (*Cirsium vulgare*) present. July 27th 2023.

Photo 20. Stockpile 23: Canada thistle (*Cirsium arvense*)**,** Western goat's-beard (*Tragopogon dubius*), oxeye daisy (*Leucanthemum vulgare*), and sow thistle (*Sonchus* spps) present. July 27th 2023.

Photo 21. Stockpile 24: Oxeye daisy (*Leucanthemum vulgare*), Canada thistle (*Cirsium arvense*), bull thistle (*Cirsium vulgare*), scentless chamomile **(***Matricaria perforate*), Western goat's-beard (*Tragopogon dubius*), sow thistle (*Sonchus* spps), yellow hawkweed (*Hieracium* spps), and orange hawkweed (*Hieracium aurantiacum*) present. July 28th 2023.

Photo 22. Stockpile 25: Oxeye daisy (*Leucanthemum vulgare*), Western goat's-beard (*Tragopogon dubius*), yellow hawkweed (*Hieracium* spps), Canada thistle (*Cirsium arvense*), and Mullein **(***Verbascum thapsis*) present. July 25th 2023.

Photo 23. Stockpile 28: Canada thistle (*Cirsium arvense*), bull thistle (*Cirsium vulgare*), Western goat's-beard (*Tragopogon dubius*), sow thistle (*Sonchus* spps), orange hawkweed (*Hieracium aurantiacum*), and oxeye daisy (*Leucanthemum vulgare*) present. July 26th 2023.

Photo 24. Stockpile 30: Mullein **(***Verbascum thapsis*), Western goat's-beard (*Tragopogon dubius*), Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), and sow thistle (*Sonchus* spps) present. July 26th 2023.

Photo 25. Stockpile 31: Western goat's-beard (*Tragopogon dubius*), Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), and bull thistle (*Cirsium vulgare*). July 25th 2023.

Photo 26. Stockpile 32: Western goat's-beard (*Tragopogon dubius*), Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), and bull thistle (*Cirsium vulgare*). July 26th 2023.

Photo 27. Stockpile 33: Western goat's-beard (*Tragopogon dubius*), oxeye daisy (*Leucanthemum vulgare*), and yellow hawkweed (*Hieracium* spps) present. July 26th 2023.

Photo 28. Stockpile 34: Canada thistle (*Cirsium arvense*), bull thistle (*Cirsium vulgare*), oxeye daisy (*Leucanthemum vulgare*), yellow hawkweed (*Hieracium* spps), Western goat's-beard (*Tragopogon dubius*), and orange hawkweed (*Hieracium aurantiacum*) present. July 27th 2023.

Photo 29. Stockpile 35: No invasive plants observed, stockpile buried with rock. July 26th 2023.

Photo 30. Stockpile 36: Oxeye daisy (*Leucanthemum vulgare*), yellow hawkweed (*Hieracium* spps), and Canada thistle (*Cirsium arvense*). July 26th 2023.

Photo 31. Stockpile 38: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), yellow hawkweed (*Hieracium* spps), Western goat's-beard (*Tragopogon dubius*), orange hawkweed (*Hieracium aurantiacum*), bull thistle (*Cirsium vulgare*), and Mullein **(***Verbascum thapsis*) present. July 27th 2023.

Photo 32. Stockpile 39: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), and yellow hawkweed (*Hieracium* spps) present. July 26th 2023.

Photo 33. Stockpile 40: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), sow thistle (*Sonchus* spps), bull thistle (*Cirsium vulgare*), and yellow hawkweed (*Hieracium* spps) present. July 27th 2023.

Photo 34. Stockpile 41: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), yellow hawkweed (*Hieracium* spps), Western goat's-beard (*Tragopogon dubius*), and bull thistle (*Cirsium vulgare*) present. July 27th 2023.

Photo 35. Stockpile 42: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), and Western goat's-beard (*Tragopogon dubius*) present. July 26th 2023.

Photo 36. Stockpile 44: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), yellow hawkweed (*Hieracium* spps), and orange hawkweed (*Hieracium aurantiacum*) present. July 27th 2023.

Photo 38. Stockpile 46: Oxeye daisy (*Leucanthemum vulgare*), and Mullein **(***Verbascum thapsis*) present. July 26th 2023.

Photo 39. Stockpile 49: Oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), yellow hawkweed (*Hieracium* spps), and sow thistle (*Sonchus* spps) present. July 27th 2023.

Photo 40. Stockpile 50: Mullein **(***Verbascum thapsis*), Western goat's-beard (*Tragopogon dubius*), sow thistle (*Sonchus* spps), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), and Canada thistle (*Cirsium arvense*) present. July 26th 2023.

Photo 41. Stockpile 52: No invasive plants observed, stockpile buried with rock. July 26th 2023.

Photo 42. Stockpile 53: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), Western goat's-beard (*Tragopogon dubius*), and scentless chamomile **(***Matricaria perforate*) present. July 25th 2023.

Photo 43. Stockpile 54: No invasive plants observed, stockpile buried with rock. July 28th 2023

Photo 44. Stockpile 55: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), Mullein **(***Verbascum thapsis*), and yellow hawkweed (*Hieracium* spps) present. July 25th 2023.

Photo 45. Stockpile 56: Oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), Mullein **(***Verbascum thapsis*), yellow hawkweed (*Hieracium* spps), and Western goat's-beard (*Tragopogon dubius*) present. July 26th 2023.

Photo 46. Stockpile 57: : Oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), yellow hawkweed (*Hieracium* spps), and Western goat's-beard (*Tragopogon dubius*) present. July 26th 2023.

Photo 47. Stockpile 59: Oxeye daisy (*Leucanthemum vulgare*), and yellow hawkweed (*Hieracium* spps) present. July 26th 2023.

Photo 48. Stockpile 61: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), and Western goat's-beard (*Tragopogon dubius*) present. July 26th 2023.

Photo 49. Stockpile 62: Oxeye daisy (*Leucanthemum vulgare*), yellow hawkweed (*Hieracium* spps), sow thistle (*Sonchus* spps) present. July 27th 2023.

Photo 50. Stockpile 63: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), yellow hawkweed (*Hieracium* spps), Western goat's-beard (*Tragopogon dubius*), and orange hawkweed (*Hieracium aurantiacum*) present. July 26th 2023.

Photo 51. Stockpile 64: Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), yellow hawkweed (*Hieracium* spps), orange hawkweed (*Hieracium aurantiacum*), sow thistle (*Sonchus* spps), and Mullein **(***Verbascum thapsis*) present. July 27th 2023.

Photo 52. Stockpile 65: : Canada thistle (*Cirsium arvense*), oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), yellow hawkweed (*Hieracium* spps), and Mullein **(***Verbascum thapsis*) present. July 27th 2023.

Photo 53. Stockpile 66: Oxeye daisy (*Leucanthemum vulgare*), bull thistle (*Cirsium vulgare*), and yellow hawkweed (*Hieracium* spps) present. July 25th 2023.

APPENDIX C

Results of Inventory of Invasive Plants

Table 5. Invasive Plants identified at Mount Polley Min between July 25-28, 2023 including polygon name, survey date, species code, approximately area of infestation (ha), distribution, density and comments. Species found include oxeye daisy (OD), orange hawkweed (OH), Canada thistle (CT), scentless chamomile (SH), bull thistle (BT), mullein (MU), sow thistle (SO), and Western goat's beard (WG).

Polygon Name	Survey Date	Species Code	Approximate Area of Infestation (ha)	Distribution	Density	Comments
Junction zone seepage sump road	2023-07-25	OD	1.24	8	4	All along road.
Junction zone seepage sump road	2023-07-25	OH	1.24	3	2	All along road.
Junction zone seepage sump road	2023-07-25	BT	1.24	4	2	All along road.
Junction zone seepage sump road	2023-07-25	CT	1.24	6	4	All along road.
North Bail Dump	2023-07-24	CT	1.87	5	2	Patches of CT throughout the polygon.
road to stockpile 10	2023-07-25	OD	6.33	8	4	All along road.
road to stockpile 10	2023-07-25	OH	6.33	4	2	All along road.
road to stockpile 10	2023-07-25	YH	6.33	4	2	All along road.
road to stockpile 10	2023-07-25	BT	6.33	2	1	All along road.
road to stockpile 10	2023-07-25	WG	6.33	2	1	All along road.
stockpile 0	2023-07-26	CT	0.001	3	4	CT in meadow on southeast side of polygon.
stockpile 0	2023-07-26	OD	2.78	7	3	Throughout polygon.
stockpile 0	2023-07-26	BT	2.78	4	2	BT at road entrance
stockpile 0	2023-07-26	WG	2.78	6	4	WG at road entrance and southeast side of polygon.
stockpile 0	2023-07-26	YH	2.78	6	4	YH within disturbed gravel area
stockpile 1	2023-07-26	OD	2.45	7	4	Throughout polygon.
stockpile 1	2023-07-26	CT	2.45	6	4	Patchy along entire length of road, some individuals sporadic throughout.
stockpile 1	2023-07-26	BT	2.45	6	3	Patchy along entire road.

Polygon Name	Survey Date	Species Code	Approximate Area of Infestation (ha)	Distribution	Density	Comments
stockpile 1	2023-07-26	SO	2.45	2	1	Throughout polygon.
stockpile 1	2023-07-26	WG	2.45	4	2	Throughout polygon.
stockpile 1	2023-07-26	YH	2.45	3	3	
stockpile 1	2023-07-26	SH	2.45	6	3	Patchy along entire length of road.
stockpile 1	2023-07-26	MU	2.45	3	3	One patch at southeast end.
stockpile 10	2023-07-25	OD	0.52	8	4	
stockpile 10	2023-07-25	CT	0.52	8	4	
stockpile 10	2023-07-25	BT	0.52	2	1	
stockpile 10	2023-07-25	YH	0.52	7	2	Along road.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Notes: Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) Hardness, dissolved organic carbon, and pH dependent copper guidelines selected from the BC ENV look up table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

Notes

Values are taken from the approved guidelines unless otherwise noted.

W = working guideline; M = interim guideline, Min = Minimum concentration requirement based on life stage.

Guidelines based on toxicity modifying factors are presented based on the mean baseline values (hardness of 54 mg/L, pH of 7.8, DOC 2.2 mg/L, temperature of 7 oC, and chloride of 0.50 mg/L) in Quesnel Lake, considered representative of average conditions in the receiving environment.

Shaded values indicates concentrations exceed the most conservative guideline of each maximum and chronic WQG for ecological receptors.

a) hardness, dissolved organic carbon, and pH dependent copper guideline selected from BC ENV copper guideline lookup table.

- = no guideline or no data; BC WQGs = British Columbia water quality guidelines; $CaCO_3$ = calcium carbonate; FDA = field duplicate available; FD = field duplicate; mg/L = milligrams per litre; QA/QC = quality assurance/quality control.

YOY – Young-of-the-Year
WSQG – Working Sediment Quality Guidelines
WTP – Water Treatment Plant
WW – wet weight

1 INTRODUCTION

1.1 Site Description and Background

Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals, owns and operates the Mount Polley copper-gold mine (Mount Polley) located approximately 9 kilometers southwest of Likely, British Columbia (BC) and 56 km (100 km by road) northeast of Williams Lake, BC (Figure 1.1). Infrastructure at the Mount Polley Mine site includes open pits, an underground mine, a crusher, a mill and office spaces, a Tailings Storage Facility (TSF), a Water Treatment Plant (WTP), waste rock disposal areas, collection and settling ponds, a surface water collection system, haul roads, access roads, and storage facilities (Figure 1.2). The total lease area associated with the mine is 18,892 hectares (ha).

Mount Polley began operating in 1997 and operated from 1997 to 2001, when it entered into care and maintenance. The discovery of new ore reserves at the site and improved commodity prices prompted MPMC to reopen the mine in 2005 (MPMC 2009). Mount Polley continued operating until August 4, 2014, when a foundation failure at the perimeter embankment of the TSF resulted in a breach (Ministry of Energy and Mines 2015; Province of British Columbia 2015). The TSF perimeter embankment breach ("the breach") resulted in the release of approximately 25 million cubic meters of water, tailings slurry, and dam construction material into nearby Polley Lake, Hazeltine Creek, and Quesnel Lake (Figure 1.1).

MPMC ceased operations immediately after the breach to focus on impact assessment, cleanup, and remediation. Restricted operations were permitted to commence on August 5, 2015. During restricted operations, all tailings were placed under water in the Springer Pit (Figure 1.2). Approval for discharge of treated mine effluent to Quesnel Lake was granted under the *Environmental Management Act* (EMA*)* on November 29, 2015, and MPMC initiated discharge of treated effluent to Quesnel Lake on December 1, 2015 (Figure 1.2). Restrictions on operations were lifted on June 23, 2016, and the mine began operating at full capacity on June 27, 2016 (MPMC 2017). On January 7, 2019, MPMC announced that Mount Polley Mine operations would be suspended in May 2019 due to declining copper prices. MPMC was placed under care and maintenance on May 31, 2019 and remained so until September 2021 when MPMC initiated a transition back to active operations. Full active operations at MPMC have currently resumed, with the resumption of active pit mining operations in November 2021, and the resumption of milling and copper concentrate production in summer 2022. Discharge of treated effluent to Quesnel Lake has been ongoing since 2015 (including during care and maintenance) and is currently permitted to June 30, 2025.

1.2 Regulatory Environment

Mount Polley is required to comply with Permit 11678, which was first issued under the British Columbia EMA on May 30, 1997. Conditions of the permit include criteria for effluent quality and non-lethality, water quality monitoring, and biological monitoring. Permit 11678 was amended on November 7, 2012, to allow for effluent discharge from the TSF to Hazeltine Creek, which began on April 10, 2014. Discharges were halted in response to the August 4, 2014, breach.

Following extensive clean-up and remediation efforts, the British Columbia Ministry of Environment and Climate Change Strategy (BCMOECCS; i.e., ENV) issued an amendment to Permit 11678 on November 29, 2015, which allowed MPMC to discharge treated effluent into Quesnel Lake via Hazeltine Creek as part of a short-term water management strategy. Permit 11678 was amended again on April 7, 2017, allowing for the use of a pipeline to convey treated water from the WTP to diffusers in Quesnel Lake (see Figure 1.2). Permit 11678 was most recently amended on December 1, 2022, and included an update to the permitted date for the direct discharge of treated effluent to Quesnel Lake via the pipeline and diffusers, which is now allowed under Permit 11678 until June 30, 2025.

Section 3.2 of the amended Permit 11678 requires MPMC to develop and implement a Comprehensive Environmental Monitoring Plan (CEMP) for the Mount Polley Mine site and surrounding receiving environment that combines pre-existing monitoring programs into an integrated plan:

> *3.2.1 "The Permittee must continue to develop, submit, and implement an ongoing Comprehensive Environmental Monitoring Plan to evaluate the effects of mining-related activities on the physical, chemical, and biological characteristics of Hazeltine Creek, Edney Creek, Bootjack Lake, Morehead Creek, Polley Lake, Quesnel Lake, Quesnel River, and associated riparian and upland areas."*
>
> *3.2.4 "The CEMP must meet all the following requirements:*
>
> *(a) Consolidate and integrate all of the monitoring programs that are being conducted in the vicinity of the mine site and include, at minimum, surface water (quality and quantity), groundwater (characterization and interactions with surface water), sediments, soils, periphyton, phytoplankton, benthic invertebrates, zooplankton, fish, floodplain and upland vegetation, and wildlife.*
>
> *(b) At a minimum address a three-year time span.*

(c) At a minimum include all sampling sites, frequency of sampling, variables to be analyzed, method detection limits, sampling methods, sample analysis methods, and data analysis methods.

(d) The updated CEMP must be approved by the Director"

In accordance with this requirement, the CEMP (MPMC 2019) covers the 2018 to 2020 period and was developed based on an approved updated Terms of Reference (TOR) provided by ENV. The 2019 CEMP (MPMC 2019) was submitted to ENV on October 31, 2019, and was approved by ENV on February 10, 2021, subject to additional monitoring requirements (BCMOECCS 2021c). Monitoring in 2022 was completed in accordance with the approved CEMP (MPMC 2019) and the additional CEMP requirements (outlined in BCMOECCS 2021c), although the CEMP covers the 2018 to 2020 period. Based on the requirements of Permit 11678, an updated CEMP will be submitted by March 31, 2023.

The CEMP is an integrated monitoring plan that has been developed to capture in one document a number of independent and interdependent monitoring programs, including: site monitoring, water discharge monitoring, Metal and Diamond Mining Effluent Regulations (MDMER) monitoring, and breach response monitoring, and monitoring following completion of remediation efforts. The CEMP has been developed through an extensive consultative process that encompasses several permitting and other regulatory processes. This integrated monitoring plan offers the additional benefit of facilitating more efficient monitoring plan review by regulatory agencies, First Nations, and stakeholders.

1.3 Scope of this Report

This report covers a subset of the CEMP. It includes monitoring of the aquatic receiving environment adjacent to, and downstream of the Mount Polley Mine in 2022. Where relevant, data collected prior to 2022 (as far back as baseline data collected in 1995) are used in data interpretation in reference to the previous reports that provided the raw data.

This report specifically includes lakes, creeks, and rivers with the potential to have been influenced by the Mount Polley Mine through effluent discharge, the breach, or general mine operations, including Polley Lake, Bootjack Lake, Hazeltine Creek, Edney Creek, Quesnel Lake, and the Quesnel River (Figure 1.1). Additional areas were also evaluated as references for the potentially affected areas to facilitate interpretation of potential effects (as outlined in the Study Design Overview; Section 2). This report is focused on sediment quality, periphyton, plankton, benthic invertebrates, and fish. However, additional supporting data (e.g., physical habitat characteristics, water quality) are used in the interpretation of the key monitoring components.

1.4 Monitoring Objectives

The overarching objective of the monitoring undertaken under the CEMP is to support the evaluation of the potential for effects of mine-related activities on the physical, chemical, and biological characteristics of the environment surrounding the Mount Polley Mine (i.e., the receiving environment). Monitoring under the CEMP is completed to:

1. Evaluate if pollution[1] is occurring in the receiving environment as a result of the existing water discharge or mine-related activities;
2. Evaluate the environmental impacts of the August 2014 TSF embankment breach, to inform the remediation plan, as well as to evaluate the effects of mitigation measures that are implemented as part of the remediation strategy; and
3. Inform management decisions, including reclamation and closure.

General objectives of the CEMP elements reported herein (i.e., sediment quality, periphyton, plankton, benthic invertebrates, and fish) are to:

1. Evaluate the influence of mine activities on the receiving environments in comparison to baseline/pre-breach and/or reference conditions;
2. Determine potential implications to aquatic life; and
3. Provide data to support exposure assessment as part of Ecological Risk Assessment (ERA) and Human Health Risk Assessment (HHRA).

Specific questions being addressed under these objectives are:

1. Are there differences in conditions at exposed areas relative to baseline/pre-breach and/or reference conditions?
2. If yes, are the differences mine-related?
3. Does the weight-of-evidence indicate that the usefulness of the aquatic environment is impaired?

Specific objectives associated with the CEMP elements herein are provided in Table 1.1.

[1] Pollution as defined in the BC EMA (S.1(1)) means "*…the presence in the environment of substances or contaminants that substantially alter or impair the usefulness of the environment*".

Table 1.1: Objectives of Specific Mount Polley CEMP Monitoring Components Covered in this Report

Component	Objectives	Sub-Components
Sediment	1. Evaluate the influence of mine activities on depositional receiving environments (e.g., Polley Lake, Quesnel Lake, and limited locations in Hazeltine Creek) in comparison to baseline and/or reference conditions; 2. Determine potential implications to aquatic life (e.g., relative to available sediment quality guidelines); 3. Provide supporting information for benthic invertebrate community monitoring; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Sediment Quality 2. Sediment Toxicity
Periphyton[b]	1. Evaluate the influence of mine activities on erosional receiving environments (e.g., Hazeltine Creek and Edney Creek) in comparison to baseline and/or reference conditions; 2. Serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (benthic invertebrates and fish); 3. Provide supporting information for the assessment of benthic invertebrate tissue quality, benthic invertebrate community condition, and fish habitat productivity; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Productivity 2. Community Composition 3. Tissue Quality
Plankton	1. Evaluate the influence of mine activities on lake environments (Polley Lake and Quesnel Lake) in comparison to baseline and/or reference conditions; 2. Serve as supporting information for the determination of potential effects to aquatic life at higher trophic levels (fish); 3. Provide supporting information for the assessment of fish habitat productivity and fish tissue quality; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Phytoplankton Productivity 2. Phytoplankton Community Composition 3. Zooplankton Productivity 4. Zooplankton Community Composition 5. Zooplankton Tissue Quality
Benthic Invertebrates	1. Evaluate the influence of mine activities on receiving environments (e.g., Hazeltine Creek, Edney Creek, and Quesnel Lake) in comparison to baseline and/or reference conditions; 2. Determine potential implications to aquatic life (e.g., through assessment of benthic invertebrate community and productivity endpoints, and comparison of benthic tissue quality results to available guidelines); 3. Provide supporting information for the assessment of potential effects to higher trophic levels (e.g., fish); and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Productivity[b] 2. Community Composition 3. Tissue Quality[b]
Fish	1. Evaluate the influence of mine activities on receiving environments (e.g., Hazeltine Creek, Edney Creek, Polley Lake, Quesnel Lake, and Quesnel River) in comparison to baseline and/or reference conditions; 2. Determine potential implications to aquatic ecosystem health and human health (e.g., relative to available fish tissue quality guidelines); 3. Document fish habitat utilization in creek and lake areas that were physically impacted by the TSF breach (most notably Hazeltine Creek and lower Edney Creek), thereby documenting the effectiveness of fish habitat rehabilitation efforts; and 4. Provide data to support exposure assessment as part of ERA and HHRA[a].	1. Fish Habitat and Usage[b] 2. Community Composition 3. Fish Health 4. Tissue Quality

[a] Ecological Risk Assessment and Human Health Risk Assessment.
[b] Denotes a component or sub-component that only applies to creeks.

1.5 Report Organization

This report is presented in eight sections, the first of which is this introduction (Section 1). Section 2 provides an overview of the approach and study design for the CEMP elements reported herein (i.e., sediment quality, periphyton, plankton, benthic invertebrates, and fish). Section 3 provides the methods used for data collection, treatment, and interpretation applicable to lake habitat. Section 4 provides the same for creek habitat. Sections 5 and 6 provide the results, assessment, and interpretation of data collected in lake habitat and creek habitat, respectively. Section 7 provides an integrated summary of key findings and recommendations. All references cited throughout the report are provided in Section 8.

2 STUDY DESIGN OVERVIEW

2.1 Conceptual Overview

The overall study design for the MPMC CEMP, including rationale for the design, is provided in the approved 2019 CEMP study design document (MPMC 2019). That document provides an overview of the mine site and its surrounding environment, an overview of environmental management on the mine site, and a detailed description of every component of the CEMP. The latter includes the monitoring objective, a summary of historic findings, a study design overview and rationale, and methodology associated with quality assurance / quality control (QA/QC), sample collection, laboratory analyses, data quality review (DQR), data handling, data interpretation, and reporting (MPMC 2019).

This report covers a subset of MPMC's CEMP – it is specifically focused on sediment and aquatic biological monitoring under the CEMP (i.e., sediment, periphyton, plankton, benthic invertebrate, and fish components of the CEMP). Briefly, sediment and aquatic biological monitoring under the CEMP was developed in consideration of:

- Pathways of potential effects (MPMC 2019);
- Accepted biological monitoring tools and measurement endpoints sensitive to mine-related influences (Table 2.1; MPMC 2019);
- The availability of baseline and/or pre-breach data (MPMC 2019);
- The findings of previous studies (MPMC 2019);
- Statistical considerations for comparisons of exposed-area data to reference, baseline, and/or over time (MPMC 2019);
- Needs of the ERA and HHRA (Golder 2017b,d); and
- Consultation (MPMC 2019).

Key pathways of potential effects to the aquatic environment include diffuse influences of the mine footprint and mining operations, the direct influence of the breach on Polley Lake, Hazeltine Creek, Edney Creek, and Quesnel Lake, and the direct discharge of treated mine water to Quesnel Lake. Sediment and aquatic biological monitoring endpoints used under the CEMP include chemical tools that address key questions and biological monitoring endpoints that are typically recognized as being the most sensitive to metals and to the potential influence of mine operations in general (Table 2.1; ESG 1999, Environment Canada 2012b; British Columbia Ministry of Environment [BCMOE] 2013, 2016; Arche et al. 2016; Simpson and Batley 2016). Baseline and/or pre-breach data are available for lakes and creeks immediately adjacent to

Table 2.1: Mount Polley CEMP Sediment and Aquatic Biological Monitoring Components and Measurement Endpoints, 2022[a]

Monitoring Component	Habitat Type	Sub-Component	Measurement Endpoints
Sediment	Lake and Creek[b]	Sediment Texture	moisture particle size distribution total organic carbon
		Sediment Quality	metals (CRC-ICP-MS scan[d]) total nitrogen total sulphur mercury
		Sediment Toxicity	14-day test of *Hyalella azteca* survival and growth (static)
Periphyton	Creek	Productivity	chlorophyll-a biomass (ash free dry mass)
		Community Composition	density (organisms/surface area) taxon richness[e] diatom taxon richness Simpson's index of diversity Simpson's index of evenness density and proportions of major taxon groups
		Tissue Quality	moisture metals (CRC-ICP-MS scan[d]) mercury
Phytoplankton	Lake	Productivity	chlorophyll-a
		Community Composition	density (organisms/volume) taxon richness[e] Simpson's index of diversity Simpson's index of evenness density and proportions of major taxon groups
Zooplankton	Lake	Productivity	biomass
		Community Composition	density (organisms/volume) taxon richness[e] Simpson's index of diversity Simpson's index of evenness density and proportions of major taxon groups
		Tissue Quality	moisture metals (CRC-ICP-MS scan[d]) mercury
Benthic Invertebrates	Lake and Creek	Productivity[c]	biomass
		Community Composition	density (organisms/surface area) taxon richness[e] Simpson's index of diversity Simpson's index of evenness density and proportions of major taxon groups Correspondence analysis[f]
		Tissue Quality	moisture metals (CRC-ICP-MS scan[d]) mercury
Fish	Lake and Creek	Habitat[g]	water depth and velocity wetted and bankfull width substrate characteristics riparian vegetation and canopy cover instream cover
		Habitat Usage[g]	repeated observation counts fish collection counts and catch-per-unit-effort[h]
		Catchability	fish collection counts and catch-per-unit-effort[h]
		Population Health	size-at-age condition size-frequency distribution
		Tissue Quality	moisture metals (CRC-ICP-MS scan[d]) mercury

[a] A number of additional supporting measures were collected to assist in the interpretation of results associated with the core measurement endpoints displayed.

[b] Due to the predominantly erosional habitat of the creek habitats assessed, measurement endpoints for sediment collected from these creek habitats were limited to the sub-components texture and chemistry.

[c] Benthic invertebrate biomass as a measure of secondary productivity was limited to creek habitats only.

[d] Metal scans by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) or Collision Reaction Cell ICP-MS (CRC-ICP-MS). "Metals" includes non-metallic parameters, such as phosphorus, which are common in CRC-ICP-MS analysis packages.

[e] Taxa reported at the lowest practicable level of taxonomy.

[f] Correspondence analysis was employed in cases where differences in community composition were not evident based on the evaluation of the density and proportions of major taxon groups.

[g] Fish habitat and fish habitat usage were monitored in creek habitats only.

[h] Fish collection and catch-per-unit-effort using a variety of techniques: minnow trapping and backpack electrofishing in creek habitats; minnow trapping, hoop netting, and gill netting in lake habitats; angling in Quesnel Lake and Quesnel River.

the mine (Polley Lake, Hazeltine Creek, Edney Creek, Bootjack Lake, and Quesnel Lake). To the extent possible, monitoring is designed to make the best use of baseline and/or pre-breach data in interpretation. Findings of previous studies (reviewed in the CEMP; MPMC 2019) also informed the study design, with the design focused on areas of greatest potential impact and on addressing key questions of effect or of recovery.

The assessment of potential mine-related effects is predicated on the detection of differences between exposed areas and baseline, pre-breach, or reference areas, or over time. Therefore, the study design was driven by considering statistical requirements (e.g., the number of reference areas and replication within each exposed and reference area) to support sufficiently powerful comparisons among areas and over time (replication level is typically n=5 to n=8). The design was also developed in consideration of data needs to support future iterations of ERA and HHRA.

2.2 Lake Habitat

Monitoring of lake habitat in the vicinity of the Mount Polley Mine in 2022 focused on two lakes: Polley Lake, which is located to the immediate east of the mine and Quesnel Lake, which is located further to the east of Polley Lake and approximately 3.7 kilometers from the mine at its nearest point (Figure 2.1). As indicated above, Polley Lake may be influenced by mining operations, and was also influenced by the breach in August 2014. Quesnel Lake was influenced by the breach in August 2014 (via Hazeltine Creek) and is currently also influenced by the direct discharge of treated mine water to Quesnel Lake (as of January 8, 2018[2]; Figure 2.1). Bootjack Lake serves as reference for Polley Lake, and unexposed/unimpacted areas within Quesnel Lake serve as references for exposed/impacted areas of the lake (Figures 1.2 and 2.1).

CEMP monitoring in lakes is outlined in detail in the CEMP study design document (MPMC 2019), including detailed description of each monitoring component and associated rationale for the study design and for the selected measurement endpoints. This section provides a general overview of the sediment and aquatic biological monitoring of lakes completed in 2022 (see Figure 2.1, Table 2.2). Briefly, CEMP monitoring of lakes in 2022 included the following components: sediment quality, sediment toxicity, phytoplankton productivity and community, zooplankton productivity and community, zooplankton tissue quality, benthic invertebrate community, fish community/population, and fish tissue quality. Not all monitoring components were completed at every area/station (Figure 2.1, Table 2.2). Detailed descriptions of monitoring conducted in lake habitats in 2022 are provided in Section 3.

[2] Discharge of treated mine water to Quesnel Lake via Hazeltine Creek was initiated on December 1, 2015. Direct discharge to Quesnel Lake (via a pipe) was initiated on January 8, 2018.

[a] Detailed descriptions of each monitoring element and associated rationale based on historical findings are provided in the CEMP (MPMC 2019); detailed methods are provided in Section 3 of this report.

[b] Fish tissue quality monitoring includes multiple species (rainbow trout and longnose sucker in Polley and Bootjack Lakes; lake trout, northern pikeminnow, and peamouth chub in Quesnel Lake; rainbow trout in Quesnel River).

2.3 Creek Habitat

Monitoring of creek habitat in the vicinity of the Mount Polley Mine in 2022 focused on two creeks: Hazeltine Creek, which flows from Polley Lake to Quesnel Lake, and Edney Creek which conflows with Hazeltine Creek before entering Quesnel Lake (Figure 2.2). Hazeltine Creek is influenced by mining operations, was impacted by the breach in August 2014, and has conveyed Mount Polley mine water over two periods (April 11 to August 4, 2014, and November 29, 2015 to September 30, 2017). The lower 775 m of Edney Creek was also impacted by the breach. Remediation efforts of Hazeltine Creek and lower Edney Creek following the breach were initiated in 2014. Edney Creek con-flowed with Hazeltine prior to the breach, but remediation efforts separated the two creeks (Edney Creek near Quesnel Lake flowed adjacent to Hazeltine Creek) from 2014 until September 2020 when the creeks were rejoined. Two creeks (Edney Creek upstream of the impacted area and Frypan Creek) serve as references for Hazeltine Creek and the impacted area of Edney Creek (Figure 2.2).

CEMP monitoring in creeks is outlined in detail in the CEMP study design document (MPMC 2019), including detailed description of each monitoring component and associated rationale for the study design and for the selected measurement endpoints. This section provides a general overview of the sediment and aquatic biological monitoring of creeks completed in 2022 (see Figure 2.2, Table 2.3). Briefly, CEMP monitoring of creeks in 2022 included the following components: sediment quality, periphyton community and productivity, benthic invertebrate community and productivity, periphyton and benthic invertebrate tissue quality, and fish habitat usage and community. Not all components were completed at every area/station (Figure 2.2, Table 2.3). Although fish habitat characterization and fish usage monitoring (for spawning and rearing purposes) in upper and lower Hazeltine Creek and lower Edney Creek is part of the CEMP (Table 2.3), this monitoring focuses on a set of objectives identified and reviewed by the Habitat Remediation Working Group[3] (HRWG). As such, results of this monitoring in 2022, and prior years, are summarized in a separate report (Minnow 2023). Detailed descriptions of monitoring conducted in creek habits in 2022 are provided in Section 4.

2.4 Interpretive Approach

The interpretation of sediment and aquatic biological data collected under the CEMP (i.e., data reported herein) is based on a number of key interpretive tools. The approach to data

[3] The HRWG was established at the request of Fisheries and Oceans Canada (DFO; April 9, 2015), in response to regulatory requirements set out in Section 38(6) of the *Fisheries Act*. Members of the working group include: DFO, British Columbia Ministry of Environment (BCMOE), British Columbia Ministry of Forest Lands and Natural Resource Operations and Rural Development (FLNRORD), Soda Creek Indian Band, Williams Lake Indian Band, and Mount Polley Mining Company.

[a] Detailed descriptions of each monitoring element and associated rationale based on historical findings are provided in the CEMP (MPMC 2019); detailed methods are provided in Section 4 of this report.

[b] Fish habitat assessment, fish habitat usage and community monitoring documented fish habitat conditions, and the usage of fish habitat by any / all fish species.

interpretation is outlined in the CEMP (MPMC 2019) and detailed methods are provided in Sections 3 and 4 of this document. Briefly, chemical data collected at potentially impacted areas are evaluated in comparison to environmental quality guidelines (as available), and based on statistical comparison to reference, to baseline and/or pre-breach, and over time (replication [n] is 5 to 8).

Presentation of chemical data incorporates results for all analytes reported by the laboratory; however, detailed analyses and discussion are focused on "primary" and "secondary" analytes (Table 2.4).[4] Primary and secondary analytes are constituents that have been identified in previous monitoring as being indicative of a mine influence on the receiving environment. Specifically, primary analytes are those that were previously identified as strongly indicative of a mine influence for most monitoring components and for which environmental quality guidelines are available. Secondary analytes are those that were previously identified as potentially indicative of a mine influence in only a subset of monitoring components. Evaluation of primary and secondary analytes was completed for all chemical data in the present report (i.e., water, sediment, and tissue quality data). To focus the interpretation of primary and secondary analyte results, discussion was limited to those analytes for which temporal differences (at the exposed areas) and/or spatial differences (between the exposed and reference or baseline/pre-breach areas) were reported. Biological data for potentially impacted areas are evaluated based on the measurement endpoints presented in Table 2.1 and are based on statistical comparison to reference, to baseline and/or pre-breach, and over time (replication [n] is typically 5).

Relationships between chemical and physical features (e.g., sediment chemistry and particle size distribution) and relationships between biological measurement endpoints and chemistry (e.g., benthic invertebrate community taxon richness and water or sediment chemistry) are evaluated using correlation or regression analysis to enhance understanding of potential cause. Although it is recognized that a significant correlation does not indicate cause, it can be useful in identifying potential cause and/or in distinguishing among different potential causes (e.g., Suter 2015). Lastly, data interpretation includes a step to bring the sediment and aquatic biological data together to identify consistencies (or inconsistencies) in the findings and to assist in the derivation of conclusions in consideration of all lines of evidence and relationships among them.

[4] Primary and secondary analytes are analytes that were classified as POIs (parameters of interest) and IPs (indicator parameters) for monitoring components in previous evaluations (see Minnow 2019a for details).

3 METHODS – LAKE HABITAT

3.1 Sediment Quality

Sediment was collected from shallow areas of Polley Lake (POL-S), Bootjack Lake (BOL-S), and Quesnel Lake (QUL-LNF1[5] and QUL-LREF1) in 2022 to support 14-day *Hyalella* Azteca toxicity testing (Figures 3.1 and 3.2, Tables 3.1 and 3.2). This sampling was completed in accordance with the requirements for shallow sediment monitoring outlined in the CEMP approval conditions dated February 10, 2021 (BCMOECCS 2021c; Section 1.2). Sediment was collected from the deep near-field area of Quesnel Lake (QUL-PNF), but not reference (QUL-PREF1)[6], to support benthic invertebrate community monitoring in this area (see Section 3.5).

Sample collection and analysis methods for 2022 are described herein and are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Tables 3.1 and 3.2.

3.1.1 Sample Collection

Sediment samples were collected from Polley Lake (and the associated reference, Bootjack Lake) and Quesnel Lake between August 24 and August 27, 2022 (Appendix Table A.1.1). Five replicate stations were sampled to represent each monitoring area (Tables 3.1 and 3.2). Samples were collected using a stainless-steel Petite Ponar for the analysis of total organic carbon (TOC), total sulphur, total nitrogen, particle size, and metal concentrations. Sampling was conducted in accordance with technical guidance outlined in the British Columbia Field Sampling Manual (BCMOE 2013) and in federal Technical Guidance Manual for (Environment Canada 2012b) and was also consistent with previous years of monitoring (Minnow 2020a, 2022a; Table 3.1).

At each sampling station, samples were collected using a stainless-steel Petite Ponar as follows. The Petite Ponar used is a 6” x 6” (15.24 cm x 15.24 cm) grab sampler with jaws that can be held open by shear-pressure on a spring-loaded pin which is released when the sampler is lowered to the substrate and the shear-pressure on the pin is eliminated. The collection of each grab sample was initiated by carefully lowering the ponar to the sediment surface.

[5] Due to changing water levels in Quesnel Lake, the shallow near-field area (QUL-LNF1) was moved in 2019 to a deeper and continually submerged location nearby (see Minnow 2020a for details). Samples collected in 2020 to 2022 were also from this deeper monitoring location, consistent with 2019 monitoring locations.

[6] Evaluation of benthic invertebrate community recovery at the deep near-field area (QUL-PNF) in 2022 could be addressed without comparison to the deep reference area (QUL-PREF1). See Section 3.5 for details.

		Exposed	QUL-LNF1 (QUL in 2007)	5	5	3		-	5	5	5	5

Notes: "-" = not applicable. Sediment Quality analyses included: metals and Total Organic Carbon (TOC) in < 63 µm fraction, moisture, particle size, pH, total nitrogen, and total sulphur for sampling completed between 2014 and 2022.

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored in 2022 are displayed, as well as historical data for these areas.

Care was taken to control the rate at which the ponar was lowered to allow appropriate sediment penetration and to minimize sediment disturbance. Once the ponar was lowered to the sediment surface, surficial sediment was collected by pulling upwards on the sampler so that the jaws of the ponar closed, capturing the surficial sediment. The ponar was then carefully retrieved to surface, the sediment grab was placed into a plastic tote, and observed for completeness and unusual characteristics. If the sample was deemed acceptable (i.e., the sampler was full to each end and was representative of surface sediment), material to a depth of 3 cm was transferred to a second tote using a stainless-steel spoon, and the remaining sediment was discarded. This procedure was repeated at each station for a minimum of five successful grabs. At that point, the composite material within the tote was homogenized using a stainless-steel spoon and transferred into two 250 mL glass sampling jars labeled with the project number, sample location, and collection date. All sampling equipment was rinsed between stations using site water. At the deep near-field area of Quesnel Lake (QUL-PNF; Figure 3.2, Table 3.2), the ponar sampler was retrieved with the assistance of a commercial line hauler (Ace Line Hauler Brutus Plus 40).

Duplicate (split) sediment samples were collected at a target frequency of 10% for QA/QC purposes. Immediately after collection, samples were stored in a cooler with ice packs until they were placed in a refrigerator at the field laboratory, where they were held until shipment (on ice) to the analytical laboratory.

Supporting measures were collected at each sampling station to support data interpretation (Appendix Tables A.1.1, A.1.2; see Section 3.8.1 for details).

3.1.2 Laboratory Analysis

Laboratory analysis of sediment quality samples from lake habitats was completed by ALS Environmental in Burnaby BC, a laboratory that is accredited by the Canadian Association for Laboratory Accreditation (CALA). Upon receipt of the sample shipment(s), ALS Environmental measured temperature in each cooler to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique sample identification code. A sample receipt notification (SRN) was then sent to MPMC and Minnow for verification.

Laboratory analysis included moisture content, pH, particle size distribution, TOC, total nitrogen, total sulphur, and total metal concentrations for all samples. Analysis methods for all parameters were consistent with previous post-breach sampling years (Tables 3.1 and 3.2). Analyses except for moisture, pH, total nitrogen, total sulphur, and particle size distribution were completed on the silt/clay fraction (<63 µm diameter) in accordance with recommendations (BCMOE 2016) and consistent with previous methods (2014 to 2021; Tables 3.1 and 3.2). Analysis of pH was completed by electrode; particle size analysis was completed by sieve and pipette; TOC was completed by combustion and titration (total carbon minus total inorganic carbon); and total

nitrogen and total sulphur were completed by combustion. Analysis of metals was based on the BC Strong Acid Leachable Metals digestion (SALM; BCMOE 2016), with total metals analysis completed by Collision Reaction Cell Inductively Coupled Plasma – Mass Spectrometry (CRC-ICP-MS; United States Environmental Protection Agency [USEPA] Method 6020B; USEPA 2014]), and mercury analysis completed by Cold Vapour Atomic Absorption Spectrophotometry (CVAAS; USEPA Methods EPA 200.2/1631; USEPA 1994, 2001).

QA/QC sampling completed by the laboratory included method blanks (MBs), laboratory replicates, and laboratory accuracy measures (i.e., laboratory control samples, and/or internal reference materials). Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow in Adobe Acrobat Portable Document Format (PDF) and Microsoft Excel files (Appendix G).

3.1.3 Data Analysis

3.1.3.1 Data Screening and Analytes of Interest

Upon receipt of the initial analytical data, a DQR was completed, including an examination of data completeness, laboratory reporting limits (LRLs) achieved, laboratory precision, laboratory accuracy, and field precision (Appendix B). Following completion of the DQR, raw data were summarized by area by calculating mean, median, standard deviation (SD), minimum, and maximum. Summary statistics were calculated using the Kaplan-Meier (K-M) method as described in Section 3.8.3.1.

Data were evaluated in comparison to British Columbia Working Sediment Quality Guidelines for the protection of aquatic life (BCMOECCS 2021a) and the British Columbia Approved Water Quality Guideline for selenium in sediment (BCMOECCS 2021b), collectively termed Working Sediment Quality Guidelines (WSQG) in this report. WSQGs are numerical criteria that are protective of sediment-dwelling organisms based on long-term exposure. Most WSQGs have been adopted from the Canadian Council of Ministers of the Environment (CCME; CCME 1999) or from Ontario (OMOE 1993) and have two levels – a Lower WSQG and an Upper WSQG. The Lower WSQG is intended to represent a concentration that will protect aquatic life from adverse effects of a toxic substance in most situations. The Upper WSQG is intended to represent a concentration that, if exceeded, will likely cause severe effects on aquatic life (BCMOECCS 2021a). However, WSQGs (even the Upper WSQGs) are often naturally exceeded in mineralized areas. In addition, WSQGs were developed based on co-occurring bulk surficial sediment data and biological effect data (CCME 1995). Bulk sediment chemistry can differ substantially from the <63 µm fraction. This discrepancy between measurement

(<63 µm fraction) and exposure (to bulk sediment to which WSQGs are most applicable) should be considered in interpretation, as "caution should be used in interpreting the biological significance of chemical concentrations in sediments for different types based on these guidelines" (CCME 1995).

Sediment quality data from exposed areas were also evaluated relative to 1) "reference data" and 2) "pre-breach data". Reference data included all post-breach data (2014 to 2022) from reference areas that were sampled in 2022. Reference and pre-breach data were compiled separately and used to calculate reference and pre-breach 95th percentile screening values, respectively. Reference 95th percentile screening values were calculated from each post-breach reference dataset (i.e., separately for Bootjack Lake shallow [BOL-S] and Quesnel Lake shallow [QUL-LREF1] and deep [QUL-PREF1][7] reference areas). Pre-breach 95th percentile screening values were calculated from each available pre-breach dataset (i.e., Quesnel Lake shallow area QUL-LNF1 [2007]). Once calculated, the 95th percentile reference and pre-breach screening values were compared, and the highest value for each analyte was then used to screen the associated exposed data. If pre-breach data were not available, as is the case for the shallow areas of Polley Lake and the deep monitoring areas of Quesnel Lake, only the 95th percentile reference values were used. The reference and pre-breach data used in the calculation of the 95th percentiles and used in data screening are presented in Appendix C.

All analytes (including primary and secondary analytes) were screened against WSQG and reference/pre-breach 95th percentile values. Analytes at exposed areas with mean concentrations that exceeded all the following criteria were termed "Analytes of Interest": 1) the WSQG, 2) the associated reference 95th percentile value, and 3) the associated pre-breach 95th percentile value (if available). Analytes of Interest were determined separately for each monitoring area (i.e., separately for shallow area of Polley Lake, and deep and shallow areas of Quesnel Lake). Concentrations of the Analytes of Interest, along with TOC, were the focus of more detailed interpretation which included graphical plots, formal statistical contrasts of temporal changes, and spatial differences in concentrations, and examination of relationships to physical and chemical sediment variables.

3.1.3.2 Statistical Analyses

Statistical analyses of Analyte of Interest and TOC concentrations in lake sediments were conducted using post-breach data (i.e., 2014 to 2022) to answer the following questions:

[7] The deep reference area of Quesnel Lake (QUL-PREF1) was not sampled in 2022 (see above), therefore reference 95th percentile values for this area were calculated using post-breach data from previous years (2014 to 2021; data previously presented in Minnow 2022a).

1. Have mean analyte concentrations at the exposed area changed relative to the reference area?[8]
2. Are there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?
3. Have mean analyte concentrations at the exposed area changed over time since the breach?

To answer these questions, data were grouped into three categories for separate tabular and graphical presentation and statistical analyses:

1. Shallow Polley Lake (POL-S; exposed) compared to a shallow reference area (Bootjack Lake; BOL-S).
2. Deep exposed area of Quesnel Lake (QUL-PNF) compared to an un-impacted deep reference area (QUL-PREF1)[9].
3. Shallow exposed area of Quesnel Lake (QUL-LNF1) compared to an un-impacted shallow reference area (QUL-LREF1).

Questions 1 and 2 were answered by conducting a two-way Analysis of Variance (ANOVA) assessing the exposed:reference ratios of results, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA included all data with paired exposed and reference results (i.e., excluded QUL-PNF data from 2020 and 2022 which did not have corresponding reference results). Except for TOC, the data used in the two-way ANOVA model were $\log_{10}$ transformed. As such, differences between the exposed and reference areas were multiplicative when testing the significance of the interaction between *Area* and *Year* (i.e., if the concentration in the reference area decreases by 50%, then the null hypothesis would be that the concentration in the exposed area also decreases by 50%). Few data points were below the LRL but were replaced with the highest LRL when present. If the *Area*×*Year* interaction term was significant ($\alpha = 0.05$), then the ratios of the concentrations from the exposed area to the reference area differed among years. In this case, pairwise contrasts among years were completed to compare the relative difference in means (in $\log_{10}$ units) between areas among years. The hypotheses tested were:

$$H_0: \left(\mu_{\text{Exposed}} - \mu_{\text{Reference}}\right)_i = \left(\mu_{\text{Exposed}} - \mu_{\text{Reference}}\right)_j \text{ for all years i, j, i} \neq \text{j}$$

[8] i.e., has the ratio of concentrations (exposed:reference) changed over time?

[9] Although the deep reference area of Quesnel Lake (QUL-PREF1) was not sampled in 2022, results from this area (2014 to 2021; Minnow 2022a) were included in tabular and graphical presentation and in statistical analyses to provide additional context for the interpretation of temporal changes at the deep near-field area (QUL-PNF) from 2014 to 2022.

The contrasts were completed for all pairwise comparisons among years, where paired exposed and reference data were available. The analysis for metals assumed data were $\log_{10}$ distributed so the hypothesis of testing differences between means is equivalent to testing the ratios of exposed to reference concentrations on the untransformed scale because of the following property of logarithms:

$$log\left(x_{\text{Exposed}}\right) - log\left(x_{\text{Exposed}}\right) = log\left(\frac{x_{\text{Exposed}}}{x_{\text{Reference}}}\right).$$

Comparisons of TOC were conducted on untransformed data and thus significant interactions tested for absolute rather than relative differences between reference and exposed areas. The results of the multiple comparisons among years were displayed by assigning letters (e.g., A, B, C) to each year. Letters were assigned such that the year with the highest ratio (or absolute difference for TOC) of exposed:reference was assigned the letter "A" and years that do not differ significantly (α = 0.05) share a letter. When the *Area*×*Year* interaction term was not significant (α = 0.05), the differences between areas were consistent among years and no exposed:reference relative contrasts were conducted.

Temporal changes in the ratio of exposed:reference (or absolute difference for TOC) were quantified by calculating a Magnitude of Difference (MOD), which is the difference between the value for the exposed area and the predicted value for the exposed area, assuming the same ratio (i.e., exposed:reference) from the baseline year (the first year the data were collected). This MOD was expressed as a percent change as:

$$MOD = \frac{10\text{^}\bar{x}_{Exposed\ Observed} - 10\text{^}\bar{x}_{\text{Exposed }Predicted}}{10\text{^}\bar{x}_{\text{Exposed }Predicted}} \times 100\%$$

where $\bar{x}_{Exposed\ Observed}$ is the mean for the exposed area (in $\log_{10}$ units) for the given year and $\bar{x}_{\text{Exposed }Predicted}$ is the predicted mean (log units), assuming the relative difference between the exposed area and reference area did not change from the baseline year (i.e., $\bar{x}_{\text{Exposed }Predicted} = \bar{x}_{\text{Reference}} + \left(\bar{x}_{\text{Exposed B}aseline} - \bar{x}_{\text{Reference B}aseline}\right)$). The MODs for TOC did not need to be back-transformed but were calculated using the same formula otherwise.

Question 3 was answered using the results of the same two-way ANOVA used to answer Question 1 but considered exposed and reference data independently (rather than assessing the exposed:reference ratio as outlined for Questions 1 and 2). These analyses included unpaired exposed and reference data that were not assessed as part of the analyses addressing in Questions 1 and 2 (i.e., QUL-PNF results from 2020 and 2022). When the interaction term of this two-way ANOVA was significant, spatial and temporal *post hoc* contrasts were conducted to test for differences among years for each area and between reference and exposed areas in

each year. The MOD between the exposed and reference areas for significant spatial comparisons was calculated in each year as:

$$MOD = \frac{10\text{^}\bar{x}_{Exposed} - 10\text{^}\bar{x}_{\text{Reference}}}{10\text{^}\bar{x}_{\text{Reference}}} \times 100\%$$

where $\bar{x}_{Exposed}$ and $\bar{x}_{Reference}$ are the exposed and reference area means (in log units), respectively. The MOD for temporal differences from the base year were similarly calculated as:

$$MOD = \frac{10\text{^}\bar{x}_{Yeari} - 10^{\bar{x}}{}_{\text{Base year}}}{10\text{^}\bar{x}_{\text{Base year}}} \times 100\%$$

where $\bar{x}_{Yeari}$ and $\bar{x}_{Baseyear}$ are the means for the selected year and base year of monitoring (in log units), respectively. For both MOD calculations, the means for TOC were not back-transformed because the model used untransformed data. When the interaction term was not significant, the differences between exposed and reference areas were consistent over time and a spatial MOD (i.e., between areas) was calculated for all years combined if the *Area* term was significant, and temporal contrasts and MODs were conducted for the pooled areas (i.e., combined reference and exposed).

Analytes of Interest and TOC concentrations were plotted to support the two-way ANOVA results. Where relevant, these plots included comparison of post-breach data (i.e., those data included in the analyses) to WSQG and reference/pre-breach 95th percentile values. Pre-breach data were also included in a sub-set of the plots for context.

Relationships between the Analytes of Interest concentrations and sediment physical (i.e., particle size) and chemical variables (TOC, total nitrogen, and total sulfur content) were evaluated using Spearman correlation analysis. Correlation analyses were conducted separately for each of the three data groupings outlined above (1: shallow Polley Lake and Bootjack Lake areas; 2: deep Quesnel Lake areas; 3: shallow Quesnel Lake areas) using all available post-breach data (i.e., 2014 to 2022) to evaluate these relationships over time. For both deep and shallow monitoring areas, differing relationships were apparent for the exposed areas relative to reference. As such, correlations were run separately for two groups of data: 1) the paired exposed and reference areas combined (i.e., POL-S and BOL-S; QUL-PNF and QUL-PREF1, and QUL-LNF1 and QUL-LREF1); 2) exposed areas only (i.e., POL-S, QUL-PNF, QUL-LNF1 independently and separate from reference). Metal concentrations were measured in the <63 µm fraction of sediment (see Section 3.1.2), therefore relationships between Analyte of Interest concentrations and particle size were completed for this fraction of sediment only, with clay content used in correlations calculated as (% clay)/(% silt and clay). Following the derivation

of correlation coefficients, a Bonferroni-type correction (i.e., α = 0.05 divided by the total number of independent variables) was applied to minimize the risk of declaring false positive correlations since at least 5% of derived correlations would be expected to occur by chance alone at an uncorrected α of 0.05. Any significant correlations found at the Bonferroni-adjusted α were further investigated using scatter plots.

Sediment quality data were analysed using Principal Component Analysis (PCA) as a means of summarizing the data for use in correlation analyses to assess potential physical and/or chemical causes of differences in benthic invertebrate community condition (see Section 3.5.3.2). PCA is a multivariate statistical ordination technique that can be used to reduce many variables (in this case 34 analytes for sediment quality) and to assist in the identification of patterns in datasets. PCA was completed using data from the deep exposed area of Quesnel Lake (QUL-PNF) collected from 2014 to 2022. Prior to running PCA, analytes for which more than 25% of the data were below the LRL, or analytes for which an incomplete dataset existed were excluded from the data matrix. All concentration data were transformed using a $\log_{10}$-transformation and principal component axes were then generated. Subsequently, the correlation between each parameter and the first two principal components (PCs) were tested using a Pearson's correlation coefficient and plotted to identify analytes that best explained similarities and differences in sediment chemistry among stations.

All sediment statistical analyses and plots were completed using R (R Core Team 2022).

3.2 Sediment Toxicity

Toxicity testing was completed in 2022 using sediments from shallow areas of Polley Lake, Bootjack Lake, and Quesnel Lake to satisfy Condition 9 of the CEMP approval issued by ENV (BCMOECCS 2021c) which specified the following:

> *"The 14-day sediment toxicity test on H. azteca must be conducted every three years (i.e., next in 2022) using sediment of shallow habitat from Polley Lake unless MPMC can clearly show that copper concentrations in all Polley Lake shallow sediment samples are below the 95th percentile of the copper concentrations in the Bootjack Lake reference area shallow sediment samples. H. azteca toxicity testing using sediment from shallow areas of Quesnel Lake must be continued as stated in the March 14, 2019 approval letter. "No effect to H. azteca" in that letter shall mean "no unacceptable response" relative to the reference area, as defined on page 37 of "Mount Polley Comprehensive Environmental Monitoring Program 2019 – Sediment and Aquatic Life".*

In accordance with this CEMP condition (BCMOECCS 2021c), 14-day toxicity testing using *H. azteca* (an epi-benthic amphipod) was completed in 2022 using shallow

breach-impacted sediments from Polley Lake (POL-S; with shallow Bootjack Lake sediments serving as reference [BOL-S]) and from Quesnel Lake (QUL-LNF1; with shallow un-impacted sediments from Quesnel Lake serving as reference [QUL-LREF1]; Figures 3.1 and 3.2, Table 3.3).

Sample collection and analysis methods for 2022 are described herein are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years refer to the references listed in Table 3.3.

3.2.1 Sample Collection

Sediment samples for toxicity testing using *H. azteca* in 2022 were collected from shallow areas of Polley Lake (POL-S), Bootjack Lake (BOL-S), and Quesnel Lake (QUL-LNF1, QUL-LREF1; Figures 3.1 and 3.2, Table 3.3) as described in Section 3.1.1. Sediments were collected at a total of five replicate stations per area, with the field replicates serving as replicates in the laboratory. Sediment samples for toxicity testing were shipped to Nautilus Environmental (Nautilus) in Burnaby BC following the methods used for sediment quality samples, described in Section 3.1.1.

3.2.2 Laboratory Analysis

Upon receipt, Nautilus opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and confirmed sample receipt with MPMC and Minnow. Static water toxicity testing of *H. azteca* is outlined in detail in Nautilus (2022; Appendix G) and was conducted according to procedures described in the Biological Test Method for the 14-day survival and growth test using *H. azteca* (Environment Canada 2017). Briefly, for the 14-day test of *H. azteca*, Nautilus set up five field-replicate test vessels per area (i.e., with each replicate representing a sampling station). A laboratory control (beach sand in accordance with the biological test method) was also set up with five laboratory replicates.

In the toxicity test laboratory, several supporting measurements were collected within the toxicity test vessels as described by Nautilus (2022; Appendix G). Briefly, this included meter measurements of overlying water (temperature, dissolved oxygen, conductivity, and pH) and the collection of overlying water for analysis of ammonia and dissolved copper by ALS Environmental (Burnaby, BC). Collection of overlying water samples for analysis of dissolved copper was completed at test termination (Nautilus 2022; Appendix G).

Table 3.3: Overview of Sediment Toxicity Monitoring in Lake Habitats in the Vicinity of the Mount Polley Mine, 2014 to 2022 [a]

Waterbody		Area Type	Area Code	2014 (Minnow 2015a)		2016 (Minnow 2017d)		2019 (Minnow 2020a)	2020 (Minnow 2021a)	2021 (Minnow 2022a)	2022
				Chironomus dilutus	*Hyalella azteca*	*Chironomus dilutus*	*Hyalella azteca*	*Hyalella azteca*	*Hyalella azteca*	*Hyalella azteca*	*Hyalella azteca*
				10-day survival and growth	14-day survival and growth	10-day survival and growth	14-day survival and growth	14-day survival and growth	14-day survival and growth	14-day survival and growth	14-day survival and growth
Bootjack Lake	Shallow	Reference	BOL-S	-	-	-	-	5	-	-	5
Polley Lake		Exposed	POL-S	-	-	-	-	5	-	-	5
Quesnel Lake	Shallow	Reference	QUL-LREF1	5 (5)	5 (5)	5	5	5	5	5[b]	5
		Near-field	QUL-LNF1	5 (5)	5 (5)	5	5	5	5	5[b]	5

Notes: "-" = not applicable/ not tested.

[a] Values indicate the number of stations sampled per area. Values in brackets, e.g., (x), indicate the number of replicates per station. If no value in brackets is given, the number of replicates was one per station. Only sampling areas that were monitored between in 2022 are displayed, as well as historical data for these areas.

[b] 14-day survival and growth tests were completed using two methodologies in 2021 as part of an investigation: 1) the standard static exposure methods that have been employed in all prior years; and 2) static-renewal exposure methods that differ from methods used in prior years. See Minnow 2022a for details.

3.2.3 Data Analysis

Statistical analyses for the tests were performed by Nautilus using CETIS software (Tidepool Scientific Software 2021) and included contrasts of the exposed area against laboratory controls and the matched reference area. Statistical contrasts were completed following guidance provided by Environment Canada (2005) and involved the use of an ANOVA with Dunnett's test for quantitative data that met parametric test assumptions. When nonparametric techniques were required, the data were analyzed using the Steel Many-one rank sum test. For quantile data, the Fisher Exact/Bonferroni Holm test was performed. Significant differences were determined at a significance level $\alpha = 0.05$.

Sediment toxicity test results were interpreted based on a combination of statistical contrasts and effect size by comparing exposed area results relative to both the laboratory control and reference area results. For this evaluation, results were grouped into two categories for separate tabular and graphical presentation, statistical analyses, and interpretation:

1. Shallow Polley Lake area (POL-S; exposed) compared to a shallow reference area (Bootjack Lake; BOL-S), tested using *H. azteca*.
2. Shallow exposed area of Quesnel Lake (QUL-LNF1) compared to an un-impacted shallow reference area (QUL-LREF1), tested using *H. azteca*.

Comparisons for each test endpoint were evaluated using a stepwise procedure similar to that of the Southern California Coastal Water Research Project (SCCWRP) California Sediment Quality Objectives (CASQO; Bay et al. 2014):

1. Mean responses (percent survival and growth [dry weight per surviving organism]) were expressed as a percentage of the mean laboratory control result and the mean field reference result.
2. Results of the statistical contrasts of mean responses in tests of impacted sediment against the laboratory control and the field reference sediment were compiled (i.e., the impacted area was identified as significantly different or not significantly different from the mean laboratory control result and the mean field reference result).
3. Results were categorized as follows:
    a. No unacceptable response was identified as a mean response within 20% of the mean laboratory control result and the mean field reference result (i.e., survival or growth were ≥80% of the control and field reference);
    b. Low to moderate response was identified as a mean response of between 20% and 50% of the mean laboratory control result and the mean field reference result (i.e., survival or growth were 50% to 80% of the control and field reference);

c. High (large) response was identified as a mean response of >50% of mean laboratory control result and the mean field reference result (i.e., survival or growth were <50% of the control and field reference);

1. Results that were in the low to moderate response category were subject to a further categorization step:

   a. If the “low to moderate” response did not differ statistically from the laboratory control and the field reference, it was categorized as a low response;
   b. If the “low to moderate” response differed statistically from the laboratory control and the field reference, it was categorized as a moderate response.

2. Where comparisons to mean laboratory control result and the mean field reference result did not fall into the same response category, the result was discussed relative to both the control and the field reference.

Application of a 20% reduction in survival relative to the field reference to define acceptability is consistent with thresholds used elsewhere (e.g., Suter et al. 1995; BCMELP 1998; Government of Canada 2010; Mebane 2010; Nautilus and Zajdlik 2011; Bay et al. 2014). The 20% threshold is the same as the acceptability threshold for laboratory control survival identified in the test method (i.e., a test is considered acceptable if fewer than 20% of organisms in the laboratory control die; Environment Canada 2017).

Toxicity test results were evaluated relative to *in situ* water quality measures *(*field and laboratory) and relative to results of other components of the CEMP. Control normalized survival and growth results (i.e., presented as a percentage of the average laboratory control result) were plotted over time for each exposed and corresponding reference monitoring area. Relationships between control normalized survival and growth results and supporting chemical and physical variables (i.e., sediment TOC and copper concetrations and overlying water dissolved copper concentrations [field and laboratory]) were evaluated using a simple linear regression model. Data were explored for outliers based on studentized residuals of the linear regression; data points with values > 3 were considered outliers. When outliers were identified, correlations were run with and without outliers included in the data and results of both analyses presented.

The regression analysis included all avaliable data for each monitoring area (2014 to 2022 for shallow Quesnel Lake areas, and 2019 and 2022 for shallow Polley Lake and refererence) and relationships were plotted along with the line of best fit. Statistically significant regressions were identified using an α of 0.05. All analyses were conducted using R (R Core Team 2022).

3.3 Plankton Community and Productivity

Plankton community and productivity monitoring in 2022 was completed at an exposed area in Polley Lake (POL-P2) with Bootjack Lake (BOL-B2) serving as a reference, and exposed (QUL-ZOO-1) and reference (QUL-ZOO-7) areas of Quesnel Lake (Figure 3.3, Tables 3.4 and 3.5; Appendix Table A.1.3). Monitoring was completed in June, July, and August, with each sampling event occurring at least 30 days apart. Single (n = 1) phytoplankton and zooplankton samples were collected in June and August at each monitoring area, and five replicate (n = 5) samples were collected in July at each monitoring area (Tables 3.4 and 3.5), in accordance with the CEMP (MPMC 2019). As outlined in the CEMP (MPMC 2019), the frequency of plankton community and productivity sampling is annual, and monitoring at these areas was last completed in 2021 (Minnow 2022a). It should be noted that phytoplankton productivity has been evaluated solely based on chlorophyll-a concentrations since (including 2022; see Minnow 2021a for details).

Sample collection and analysis methods for 2022 are described herein. For details pertaining to prior sampling years, refer to the references listed in Tables 3.4 and 3.5.[10]

3.3.1 Sample Collection

3.3.1.1 Phytoplankton

Phytoplankton sampling was completed in June (n=1 per area), July (n=5 per area), and August (n=1 per area) 2022 and included the collection of community composition and productivity (chlorophyll-a) samples (Table 3.4; Appendix Table A.1.3).

Phytoplankton samples were collected using a depth-integrated tube water sampler that is weighted at the bottom. The depth-integrated sampler (length ~13 m) enables collection of water and phytoplankton throughout the photic zone (the upper layer of the water column receiving light penetration). Depth-integrated samples were collected using nearly the full length of the tube whenever station depth is greater than 12 m, or only a portion of the tube in areas < 12 m deep (Appendix Table A.1.3) to prevent collection of sediment or water from the sediment-water interface. To collect one sample, the weighted end of the plastic tubing was lowered to the required sampling depth, the hose was crimped, and the depth-integrated sampler was pulled to the surface with the hose remaining crimped the entire time.

[10] Minnow has completed interpretive reporting for plankton community and productivity monitoring data collected since 2018 (Minnow 2019a, 2020a, 2021a, 2022a) and has completed monitoring implementation since 2019 after providing monitoring program design modifications (Minnow 2019c) at the request of MPMC. A complete description of historic plankton sampling activities was included in Minnow (2019a) and the modified monitoring program design was included in the approved CEMP (MPMC 2019).

Notes: "-" = not applicable. Data from 2014 to 2018 were provided in electronic form to Minnow from the Mount Polley Mine database.

[a] Values indicate the number of samples collected per area per year or month. Only sampling areas that were monitored in 2022 are displayed, as well as historical data for these areas.

[b] Analysis of zooplankton samples from Quesnel Lake was performed using two mesh sizes (50 µm and 150 µm) to facilitate comparison to historical samples collected using 150 µm mesh size. See (Minnow 2020a) for details.

The weighted end was then placed into a clean plastic pail and the crimped end was released allowing the water to flow into the clean bucket.

Upon retrieval of the depth-integrated sample into the clean bucket, *in situ* water measurements were immediately taken with a YSI EXO™ (see Section 3.8.1). Phytoplankton and water samples were then taken by decanting water from the bucket into appropriate sample bottle(s), and samples were preserved and stored as follows. Samples for phytoplankton community composition were decanted into an opaque 250 mL plastic bottle and then preserved using Lugol's solution, which was added using an eyedropper until the sample colour was like that of weak tea, mixed thoroughly and stored in a cool dark environment prior to shipment to the laboratory for analysis. Samples for chlorophyll-a were decanted into an opaque 250 mL plastic bottle and supporting water samples were decanted into pre-cleaned routine water quality sample bottles and preserved as required. Routine water quality samples were kept on ice in the field and refrigerated until being shipped (on ice) to the analytical laboratory. Duplicate (split) routine water quality and chlorophyll-a samples were collected at a target frequency of 10% for QA/QC purposes Appendix Table A.1.3.

Water collected for phytoplankton chlorophyll-a was kept cool until same-day filtration as follows.[11] A measured volume of sample was decanted into the vacuum filter apparatus and filtered through 0.45 µm pore diameter Whatman mixed cellulose ester (MCE) filter paper. The filter paper (containing sample) was then placed into a labeled opaque centrifuge tube and frozen until shipment (on ice) to the analytical laboratory. All filter apparatus equipment was rinsed with distilled water between each sample.

Supporting *in situ* water quality depth profiles were recorded at every area (n=1) and Secchi depth was measured at every station (n=1 per area in June and August, n=5 per area in July; Appendix Table A.1.3; see Section 3.8.1 for description of supporting measures collection).

3.3.1.2 Zooplankton

Zooplankton sampling was carried out concurrently with phytoplankton sampling in June (n=1 per area), July (n=5 per area), and August (n=1 per area) 2022 and included collection of samples for assessment of community composition and productivity (Table 3.5; Appendix Table A.1.3).

Samples were collected using a using a 30 cm diameter, 90 cm long, zooplankton haul net with a 0.5 m diameter mouth opening and 50 µm Nitex mesh. Zooplankton community samples were

[11] Chlorophyll-a samples collected during the August sampling event could not be field-filtered due to a sampling supply shortage. These samples refrigerated until shipment on ice to the analytical laboratory where they were filtered prior to analysis.

collected by lowering the zooplankton haul net to ~2 m above the lake bottom, then retrieving the net vertically through the water column at a rate of ~0.5 m/sec. (a single vertical haul). Each zooplankton sample consisted of a single vertical haul.[12] Haul depths differed among lakes based on lake depth (~2 m less than bottom depth), with hauls beginning at a 33 m depth in Quesnel Lake, at ~26 m in Polley Lake, and at ~16 m in Bootjack Lake (Appendix Table A.1.3).

Upon retrieval, material on the inside of the net was rinsed into the cod end by lifting the net in and out of the water without submerging the mouth of the net. Sample material was then rinsed from the cod end of the net into a 250 mL plastic bottle using a squeeze bottle filled with filtered water. Samples were then preserved with buffered formalin solution to a nominal concentration of 4%. Preserved samples were stored in a dark, cool place prior to shipment to the laboratory for taxonomic analysis.

Supporting measures collected included those outlined above for phytoplankton sample collection (Section 3.3.1.1; Appendix Table A.1.3; see Section 3.8.1 for description of supporting measures collection).

3.3.2 Laboratory Analysis

3.3.2.1 Phytoplankton

3.3.2.1.1 Community

Phytoplankton samples were sent to Biologica Environmental Services Ltd. (Victoria, BC) for taxonomic identification and enumeration. Upon arrival, samples were examined, and additional Lugol's preservative was added (if required) to ensure adequate preservation. An inventory form was created and verified with the Chain of Custody (COC) to ensure that all

[12] The CEMP approval amendment letter from ENV (dated July 15, 2019; BCMOECCS 2019b) stipulated that zooplankton samples must be collected using a modified horizontal tow method; which is a condition that applies to all zooplankton sample collection. This was not the intent of the plankton program recommendations provided by Minnow (dated May 28, 2019; Minnow 2019c) which included the use of different plankton tow methods for the collection of: 1) zooplankton productivity and community samples, and 2) zooplankton tissue chemistry samples. Minnow maintains that zooplankton productivity and community samples should be collected using a vertical tow method only (consistent with the recommendations provided by Minnow in May 2019; Minnow 2019c). A modified horizontal tow method was not recommended for the collection of zooplankton community samples for two reasons. Firstly, zooplankton samples for community analysis have previously been collected by a single vertical tow. Changing the collection method for this sample type to a modified horizontal tow would limit comparability with previously collected data. Secondly, it is difficult to ensure that the sampling net ascends through the water column at a constant speed when conducting a horizontal tow. Since zooplankton community composition differs through the water column, variability in the amount of time that the net samples a given depth during a horizontal tow could influence the community results. Use of a vertical tow method eliminates this consideration entirely. Following consultation with MPMC regarding the above rationale and the best methodological approach to implement, Minnow collected zooplankton community and productivity samples using a vertical haul methodology between 2019 and 2022. For a comparison of zooplankton community and productivity samples collected using both vertical and modified horizontal haul methodologies, see Minnow (2020a).

samples were accounted for, and each sample had the appropriate number of jars as indicated on the COC.

For processing, plankton community samples were first thoroughly mixed by shaking the sample container and sub-samples (50 to 100 mL), then were dispensed into Utermöhl settling chambers and allowed to settle for 36 to 48 hours, depending on sub-sample volume. Sub-samples were then systematically scanned using a Zeiss Axio Vert A.1 inverted phase contrast microscope at 400x magnification. All algal cells were counted in a series of randomly located field of view (FOV) until a minimum of 300 algal units were identified and enumerated. Algal units represent single cells of all algal groups, as well as colonies or filaments of blue-green algae. Given that blue-green algal colonies and filaments may contain hundreds of cells, enumerating units (rather than individual cells) allows for a more equal representation of algal groups. The mean number of cells per unit (1 for single cells, >1 for all other algal forms) were estimated for all taxa and used to calculate total densities. Only "viable" cells (those that appeared to be alive at the time of collection) were identified and enumerated. *Chrysophyte loricas*, cellulose cups formed by some chrysophyte species, were also counted (USEPA 2010).

Phytoplankton were identified to genus, where possible, following the most up-to-date taxonomic references and collaborations with international and local algal taxonomic experts. Species-level identifications were only given to identifiable taxa for which there are reliable taxonomic references available that encompass the species-level morphological diversity in North America. This approach ensures long-term consistency of data sets and is in accordance with the trend in algal taxonomic practice to be more conservative with delineation of species. Species-level identifications for some taxa are problematic due to widespread phenotypic plasticity that can artificially inflate species richness (Wehr et al. 2015). When applicable, the terms "cf." (*confertim*, possibly for species) and "sp.1", "sp. 2", etc. (a single undetermined species) were employed to distinguish between different species in the same genus.

Taxa were grouped according to their major ecological groupings (e.g., Diatoms, Cyanobacteria, etc.). Data were reported as density (cells per liter) for each taxon, for each ecological grouping, and as total density at each station. Laboratory QA/QC included evaluation of sub-sampling accuracy on at least 10% of samples. Data were provided to MPMC and Minnow as a Microsoft Excel spreadsheet along with a methods and QA/QC report as an Adobe Acrobat PDF file (Appendix G).

3.3.2.1.2 Productivity

Phytoplankton chlorophyll-a analysis was completed by ALS Environmental (Burnaby, BC). Upon receipt, ALS Environmental measured the internal temperature of shipping coolers to verify

the integrity of samples, logged each sample, and assigned each sample a unique identification code. A sample receipt confirmation was then sent to Minnow and MPMC. Samples were laboratory filtered if required (i.e., for samples collected in August; see Section 3.3.1.1) prior to analysis of chlorophyll-a followed procedures adapted from USEPA Method 445.0 (USEPA 1997) Chlorophyll-a concentrations were determined by routine acetone extraction followed by fluorescence detection using a non-acidification procedure, a method that is not subject to interferences from chlorophyll-b.

Laboratory QA/QC included reagent blanks and laboratory accuracy measures (i.e., laboratory control samples). Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G).

3.3.2.2 Zooplankton

3.3.2.2.1 Community

Zooplankton community samples were sent to Biologica Environmental Services Ltd. (Victoria, BC) for taxonomic analysis. The sample receipt procedure was as described above for phytoplankton (Section 3.3.2.1.1). Samples were transferred from their formalin solution into 70% ethanol and assigned a unique identification number.

The zooplankton community samples were processed through a 45 µm screen and analyzed in two fractions as follows:

1. A “coarse” fraction comprised of Cladocera, adult Copepoda, and copepodids, in which a minimum count of 200 organisms was obtained; and
2. A “fine” or “micro” fraction, in which Copepod Nauplii and Rotifera were identified and enumerated. Processing of the micro fraction was completed to either a 100-count or a minimum of three sub-samples.

The coarse fraction was analyzed in a Bogorov tray through a stereo microscope at 10-40x magnification and the micro fraction was analyzed using a 1-mL Sedgewick-Rafter counting chamber. Sub-sampling for all fractions was performed using Hensen-Stempel pipettes. Generally, subsamples were 1/10th of total sample volume for the coarse fraction and 1/100th for the micro fraction. Organisms were identified by taxonomic experts to the lowest practicable taxonomic level (LPL)[13] using a compound microscope (100–400x magnification),

[13] The term “Lowest Practical Level” is commonly used to describe the level of resolution for taxonomic identification (often relating to benthic invertebrate taxonomy; e.g., Environment Canada 2012b). However, the term “Lowest Practicable Level" (e.g. Carter and Resh 2001; Bailey et al. 2001) has been used throughout this report because it is a

appropriate dissection tools, and standard taxonomic references. Crustacean zooplankton were identified to species wherever possible, although this was not possible for immature copepods that lack differentiating features required for identification beyond order (e.g., Calanoida, Cyclopoida, or Harpacticoida). For Copepoda, the stage of development was recorded as Nauplii or copepodite stages I-V as was the sex for mature individuals (copepod stage VI). Rotifera were identified to the genus level. All identifications were performed using taxonomic references and collaborations with external experts, where necessary.

Laboratory QA/QC included evaluation of sub-sampling accuracy on at least 10% of samples. Data were provided to Minnow as a Microsoft Excel spreadsheet (Appendix G).

3.3.2.2.2 Productivity

Zooplankton productivity was evaluated as biomass values derived from biovolume estimates based on cell measurements performed by Biologica Environmental Services Ltd. Biomass calculations were performed for the seven most dominant zooplankton taxa by measuring at least five to 10 specimens of each taxon and applying length/weight regression formulae (USEPA 2003). Biomass estimates were presented as total wet weight (ww) and dry weight (dw) values derived from per-sample abundances. Data were provided to Minnow as a Microsoft Excel spreadsheet (Appendix G).

3.3.3 Data Analysis

3.3.3.1 Phytoplankton

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, formulae checks, and evaluation of percent agreement of laboratory sub-sampling accuracy samples (see Appendix B).

3.3.3.1.1 Community Metrics

Phytoplankton community data were evaluated in terms of total density (cells/L), taxon richness (# of taxa), Simpson's Diversity and Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012b), and the relative density (%) and cell densities of major ecological groups (cells/L). These endpoints were calculated at the LPL of taxonomy. Phytoplankton community results at the LPL taxonomy level can contain a mixture of taxonomic levels (e.g., species, family, order, and phylum), which can affect the calculation of metrics such as taxon richness and Simpson's Diversity and Evenness. To address this issue, a series of decision criteria were applied to the data to reassign taxon abundance across levels of

more accurate description of the taxonomic decision (the term "practicable" implies the level of identification that is attainable).

taxa, while conserving the relative abundances within the higher taxon levels (see Appendix E.2 text for details). For the calculation of relative densities (%) of major phytoplankton groups, taxa were grouped as Diatoms, green algae (Chlorophytes), blue-green algae (Cyanobacteria), golden algae (Chrysophytes and Cryptomonads), Dinoflagellates, and Euglenophytes, and the densities and relative densities of all groups were determined for each sample. Phytoplankton productivity was evaluated using chlorophyll-a concentrations (µg/L).

Phytoplankton community and productivity metrics were calculated for each monitoring area in each year and were summarized by area and year using the following statistics: sample size, mean, median, minimum, maximum, and SD (where replicate data were available).

3.3.3.1.2 Statistical Analyses

Statistical analyses of phytoplankton community and productivity data were conducted to answer the following questions:

1. Are there differences in phytoplankton community and productivity between the exposed and reference areas in 2022?
2. Has the phytoplankton community and productivity of exposed areas changed among years (2019 to 2022) relative to changes at reference areas over this time?

To answer these questions, data were grouped into two categories for the separate calculation of community metrics, tabular and graphical presentation, and statistical analyses:

1. Polley Lake (POL-P2) compared to reference (Bootjack Lake; BOL-B2).
2. Quesnel Lake exposed area (QUL-ZOO-1) compared to an un-impacted reference (QUL-ZOO-7).

Phytoplankton data cannot be pooled across different sampling events due to high variability among seasons. As such, statistical analyses focused on replicate samples (n=5) collected in July, as per the CEMP (MPMC 2019). Results of single samples collected in June and August were interpreted without the use of formal statistical contrasts.

Statistical comparisons of data from July 2019 to 2022 were conducted as two--way ANOVAs with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year*. If the *Area*×*Year* interaction term was significant, all pairwise contrasts were evaluated. If the interaction term was not significant but the *Area* term was significant, pairwise contrasts were conducted between areas pooling years; if the *Year* term was significant, pairwise contrasts were conducted between years pooling areas. Pairwise contrasts were evaluated using Sidak correction to account for multiple comparisons. Regardless of which overall ANOVA terms were significant, Magnitudes of Difference (MOD) were calculated based on Measures of

Central Tendency (MCT) of individual samples described below. The results of the multiple comparisons were displayed by assigning letters (e.g., A, B, C) to each unique combination of year and method.

Prior to analysis, the assumptions of normality and homogeneity of variances were tested on the residuals of the two-way ANOVA model using the Shapiro-Wilk test and Levene's test based on median values, respectively using α=0.05. Data were transformed as necessary to satisfy assumptions of normality and homogeneity of variance (log_{10}, $log_{10}(X+1)$ when zeros were present in the data). In instances where the residuals of the ANOVA model did not meet the assumptions of normality and homogeneity of variances, the analysis was conducted on ranks (equivalent to a non-parametric test).

MOD between the exposed area and reference area was calculated as:

$$MOD = \frac{MCT_{Exposed} - MCT_{Reference}}{SD_{Pooled}}$$

MOD between years was calculated as:

$$MOD_{Year} = \frac{MCT_{Year} - MCT_{Baseline\ Year}}{SD_{Pooled}}$$

where MCT is the Measure of Central Tendency (mean for untransformed data and geometric mean for log_{10}-transformed data) and the SD is the pooled standard deviation from the ANOVA model. The effect size calculations were conducted on the transformed scale when the data were transformed for analysis. When the analysis was done on the rank--transformed scale, the observed effect size was estimated using median values instead of means, and the Median Absolute Deviation (MAD) instead of SD:

$$MAD = median(|x_i - median(dataset)|)$$

where x_i is each observation in the dataset and $|f(x)|$ is the absolute value of $f(x)$.

All statistical comparisons were conducted using R (R Core Team 2022). Statistically significant differences in phytoplankton community between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were further identified as potentially ecologically meaningful in both statistical analyses results and in data interpretation (Environment Canada 2012b[14]).

[14] Environment Canada (2012b) identifies a critical effect size (CES) of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community. This criterion has been applied here to the interpretation of phytoplankton community.

Total phytoplankton density (cells/L), taxon richness, and chlorophyll-a concentrations were plotted as time-series figures comparing sampling areas over time (including all seasonal data from baseline, where applicable, to present). Proportional densities (%) and densities of major phytoplankton groups were plotted from 2019 to 2022 as stacked bar charts. Phytoplankton community metrics from July 2019 to 2022 only were also plotted to support the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2022). Historic phytoplankton proportional density data had low comparability with 2019 to 2022 data due to changes in taxonomist and were therefore excluded from plots (see Minnow 2019a for details regarding the previous taxonomist and data limitations that affect comparability).

3.3.3.2 Zooplankton

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, formulae checks, and evaluation of percent agreement of laboratory sub-sampling accuracy samples (see Appendix B).

3.3.3.2.1 Community Metrics

Zooplankton community data were evaluated in terms of total density (# of organisms/L), taxon richness (# of taxa), Simpson's Diversity and Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012b), and the relative abundance (%) and organism densities (# of organisms/L) of major ecological groups. Zooplankton endpoints were calculated at the LPL of taxonomy. Zooplankton community results at the LPL taxonomy level can contain a mixture of taxonomic levels, which can affect the calculation of metrics such as taxon richness and Simpson's Diversity and Evenness. To address this issue, a series of decision criteria were applied to the data to reassign taxon abundance across levels of taxa, while conserving the relative abundances within the higher taxon levels (see Appendix E.2 text for details). Zooplankton data were converted from per-sample abundance values to volumetric density values (# of organisms/L) by dividing total densities by the volume of water through which the net passed (see Appendix E.2 text for details). For the calculation of relative abundance (%) of major zooplankton groups, taxa were grouped as Calanoida, Cyclopoida, Cladocera, and Rotifera, with Copepoda Nauplii (the earliest juvenile stage of Copepoda) left as their own grouping. Zooplankton productivity was evaluated using dry weight biomass (mg/L).

Zooplankton community and productivity metrics were calculated for each monitoring area in each year and were summarized by area and year using the following statistics: sample size, mean, median, minimum, maximum, and SD (where replicate data were available).

3.3.3.2.2 Statistical Analyses

Zooplankton community data were evaluated to answer the following questions:

1. Are there differences in zooplankton community and productivity between exposed and reference areas in 2022?
2. Has the zooplankton community and productivity of exposed areas changed among years (2019 and 2022) relative to changes at reference areas over this time?

To answer these questions, data were grouped into two categories for the separate calculation of community metrics, tabular and graphical presentation, and statistical analyses:

1. Polley Lake (POL-P2) compared to reference (Bootjack Lake; BOL-B2).
2. Quesnel Lake exposed area (QUL-ZOO-1) compared to an unimpacted reference (QUL-ZOO-7).

Methods for replicate analysis, data pooling, statistical analyses, presentation of historic data, and current limitations of data for temporal statistical analyses of zooplankton data are the same as those outlined for phytoplankton in Section 3.3.3.1.2, with the one exception that dry weight biomass served as the measure of productivity in both statistical analyses and plots.

3.4 Zooplankton Tissue Quality

Zooplankton tissue quality monitoring in 2022 was completed at an exposed area in Polley Lake (POL-P2) with Bootjack Lake (BOL-B2) serving as a reference, and an exposed (QUL-ZOO-1) and a reference (QUL-ZOO-7) area of Quesnel Lake (Figure 3.3, Table 3.6; Appendix Table A.1.3). Monitoring was completed in June, July, and August, with each sampling event occurring at least 30 days apart (Appendix Table A.1.3). Single (n=1) zooplankton tissue quality samples were collected in June and August at each monitoring area and five replicate (n = 5) samples were collected in July at each monitoring area (Table 3.6), in accordance with the CEMP (MPMC 2019). As outlined in the CEMP (MPMC 2019), the frequency of zooplankton tissue quality sampling is annual, and monitoring at these areas was last completed in 2021 (Minnow 2022a).

Sample collection and analysis methods for 2022 are described herein. For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Table 3.6.[15]

[15] Minnow has completed interpretive reporting for plankton community and productivity monitoring data collected since 2018 (Minnow 2019a, 2020a, 2021a, 2022a) and has completed monitoring implementation since 2019 after providing monitoring program design modifications (Minnow 2019c) at the request of MPMC. A complete description of historic plankton sampling activities was included in Minnow (2019a) and the modified monitoring program design was included in the approved CEMP (MPMC 2019).

Table 3.6: Overview of Zooplankton Tissue Chemistry Monitoring in Lake Habitats in the Vicinity of the Mount Polley Mine, 2014 to 2022[a]

Waterbody		Area Type	Area Code	2014[b] (Golder 2017a)	2015[c] (Golder 2017a)	2016[c] (Golder 2017a)	2017[c] (Golder 2017a)	2018[c] (Minnow 2019a)	2019[d] (Minnow 2020a)	2020[d] (Minnow 2021a)	2021[d] (Minnow 2022a)	2022[d]
				September to December	May to September	Early and Late Season	Early and Late Season	Early and Late Season	June to August	June to August	June to August	June to August
Polley Lake	South Basin	Exposed	POL-P2	-	4	2	2	2	3	3	3	3
Bootjack Lake		Reference	BOL-B2	-	-	-	-	-	3	3	3	3
Quesnel Lake	Central West Arm	Exposed	QUL-ZOO-1 (ZP 2, 4, 6, 9, 12, 15, 18, 21)	8	5	2	2	2	3	3	3	3
	Near Cariboo Island	Reference	QUL-ZOO-7 (ZP 8, 11, 14, 17, 20)	5	5	2	2	2	3	3	3	3

Notes: "-" = not sampled, "ZP" = zooplankton. In 2014, QUL-ZOO-1 and QUL-ZOO-7 were reported as ZP stations. Data from 2014 to 2018 were provided in electronic form to Minnow from the Mount Polley Mine database.

[a] Values indicate the number of samples collected per area per year. Only sampling areas that were monitored in 2022 are displayed, as well as historical data for these areas.

[b] Values represent the number of single samples that were collected over the four month period.

[c] Values represent the number of months for which single samples were collected.

[d] Values represent the number of months for which samples were collected. Single samples were collected in June and August; five replicate samples were collected in July.

3.4.1 Sample Collection

Zooplankton tissue quality samples were collected in June (n =1 per area), July (n = 5 per area), and August (n=1 per area; Appendix Table A.1.3), 2022, using methods largely consistent with the CEMP (MPMC 2019). [16]

Zooplankton tissue samples were collected using a 30 cm diameter, 90 cm long, zooplankton haul net with a 0.5 m diameter mouth opening and 50 µm Nitex mesh. Sampling in Polley Lake (POL-P2) and Bootjack Lake (BOL-B2) was completed using the vertical haul method described in Section 3.3.1.2, with a maximum start depth of approximately 22 to 26 m in Polley Lake and 10 to 16 m in Bootjack Lake (Appendix Table A.1.3). Vertical hauls were completed until a sufficient sample weight was obtained (minimum 1.5 g wet weight).

Zooplankton tissue quality samples were collected from Quesnel Lake (QUL-ZOO-1 and QUL-ZOO-7) by completing a single modified horizontal haul at each area[17]. Each horizontal haul was completed by lowering the net to a start depth of 33 m and then towing the net through the water column for a set time (e.g., 4 to 10 minutes; Appendix Table A.1.3) while slowly retrieving the net to the surface.

Upon retrieval of each vertical or horizontal haul, the plankton net was rinsed towards the cod end to concentrate the sample. Excess water was decanted through the mesh of the cod end or the net, and the remaining sample was transferred into a pre-labelled plastic scintillation vial using a scoopula. Duplicate (split) sediment samples were collected at a target frequency of 10% for QA/QC purposes. Immediately after collection, samples were stored in a cooler with ice packs until being frozen prior to shipment (on ice) to the analytical laboratory.

Supporting measures included one vertical depth profile of *in situ* water quality measures and one supporting depth-integrated water quality sample collected from each area during each

[16] Zooplankton tissue quality samples were historically collected using multiple vertical hauls until a sufficient sample weight was obtained. Due to the low productivity in Quesnel Lake, this process was labour-intensive for Quesnel Lake. Therefore, Minnow recommended substitution of the vertical tow method for a modified horizontal tow method in Quesnel Lake to decrease the time required to collect sufficient sample material. Minnow recommended the continuation of vertical haul methods in Polley Lake (Minnow 2019c). The modified horizontal tow method for the collection of zooplankton tissue quality samples from Quesnel Lake was incorporated into the CEMP approval amendment letter from ENV (dated July 15, 2019; BCMOECCS 2019b). However, the letter stipulated that all zooplankton samples must be collected using the modified horizontal tow method. This methodology was only recommended for use in Quesnel Lake (not Polley or Bootjack Lakes) and specifically for zooplankton tissue quality sample collection for the reasons outlined above (Minnow 2019c). Minnow maintains that the use of a vertical tow method for the collection of zooplankton tissue quality samples is suitable for Polley and Bootjack lakes and has implemented this methodology in 2019 to 2022. The haul method used (vertical or horizontal) does not affect the characteristics of the resulting zooplankton tissue quality sample; only the time associated with sample collection.

[17] Modified horizontal tow methods were consistent with those approved by ENV (as part of the plankton program amendments in July 2019) and incorporated into the CEMP (MPMC 2019).

sampling event (see Section 3.3.1.1 for depth-integrated sample collection methods). See Section 3.8.1 for a description of supporting measures collection.

3.4.2 Laboratory Analysis

Laboratory analysis of zooplankton tissue quality samples was completed by ALS Environmental in Burnaby BC. Upon receipt of the sample shipment(s), ALS Environmental measured temperature in each cooler to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique sample identification code. A SRN was then sent to MPMC and Minnow for verification.

Laboratory analysis of zooplankton tissue quality samples included metals by CRC-ICP-MS (USEPA Method 6020B; USEPA 2014), mercury by CVAAS (USEPA Methods EPA 200.2/1631E; USEPA 1994, 2001), and moisture content. Laboratory QA/QC included MB samples, laboratory duplicates, and laboratory accuracy measures (i.e., laboratory control samples and/or internal reference materials). Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow (Appendix G).

3.4.3 Data Analysis

Upon receipt of the initial analytical data, a DQR was completed, including an examination of data completeness, LRLs achieved, laboratory precision, laboratory accuracy, and field precision (Appendix B).

Data analysis of zooplankton tissue quality results focused on replicate samples (n=5) collected in July of each year (2019 to 2022). Results of single (n=1) samples collected from 2014 to 2019 were interpreted without the use of formal statistical contrasts. Zooplankton tissue quality data from each sampling event in 2022 (June, July, and August) were screened against the British Columbia selenium guideline for the protection of aquatic life (for invertebrate tissue) of 4 milligrams per kilogram dry weight (mg/kg dw; BCMOE 2014). Replicated zooplankton tissue quality data (i.e., collected in July) were summarized by area by calculating sample size, mean, SD, minimum, median, and maximum. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1.

Statistical analyses of metal concentrations in zooplankton tissues were conducted using replicated data (i.e., data from July 2019 to 2022) to answer the following questions:

1. Have mean analyte concentrations at the exposed area changed relative to the reference area?[18]

[18] I.e., has the ratio of concentrations (exposed:reference) changed over time?

2. Are there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?

To answer these questions, data were grouped into two categories for separate tabular and graphical presentation and statistical analyses:

1. Polley Lake (POL-P2; exposed) compared to Bootjack Lake (BOL-B2; reference).
2. Quesnel Lake exposed area (QUL-ZOO-1) compared to an un-impacted reference (QUL-ZOO-7).

Question 1 was answered by conducting a two-way ANOVA assessing the exposed:reference ratios of results, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA model was conducted assuming data were log distributed, and thus differences between the exposed and reference areas were multiplicative when testing the significance of the interaction between *Area* and *Year* (i.e., if the concentration in the reference area decreases by 50%, then the null hypothesis would be that the concentration in the exposed area also decreases by 50%). Due to the prevalence of analyte results which were below the LRL, the two-way ANOVA was completed with Maximum Likelihood Estimation (MLE) using a censored regression, assuming a lognormal distribution. If the *Area*×*Year* interaction term was significant (α = 0.05), then the ratios of the concentrations from the exposed area to the reference area differed among years. In this case, pairwise contrasts among years were completed to compare the relative difference in means (in log-units) between areas among years. To address question 1 the hypotheses tested were:

$$H_0: \left(\mu_{\text{Exposed}} - \mu_{\text{Reference}}\right)_i = \left(\mu_{\text{Exposed}} - \mu_{\text{Reference}}\right)_j \text{ for all years i, j, i} \neq \text{j}$$

The contrasts were completed for all pairwise comparisons among years. The analysis assumed data were log distributed so the hypothesis of testing differences between means is equivalent to testing the ratios of exposed to reference concentrations on the untransformed scale because of the following property of logarithms:

$$log\left(x_{\text{Exposed}}\right) - log\left(x_{\text{Exposed}}\right) = log\left(\frac{x_{\text{Exposed}}}{x_{\text{Reference}}}\right).$$

The results of the multiple comparisons among years were displayed by assigning letters (e.g., A, B, C) to each year. Letters were assigned such that the year with the highest ratio of exposed:reference was assigned the letter “A” and years that do not differ significantly (α = 0.05) share a letter. When the *Area*×*Year* interaction term was not significant (α = 0.05), the differences between areas were consistent among years and no relative contrasts were conducted.

Temporal changes in the ratio of exposed:reference were quantified by calculating a MOD, which is the difference between the value for the exposed area and the predicted value for the exposed area, assuming the same ratio (i.e., exposed:reference) from the baseline year (the first year the data were collected). This MOD was expressed as a percent change as:

$$MOD = \frac{exp\hat{}\bar{x}_{Exposed\ Observed} - exp\hat{}\bar{x}_{\text{Exposed }Predicted}}{exp\hat{}\bar{x}_{\text{Exposed }Predicted}} \times 100\%$$

where $\bar{x}_{Exposed\ Observed}$ is the mean for the exposed area (in log units) for the given year and $\bar{x}_{\text{Exposed }Predicted}$ is the predicted mean (log units), assuming the relative difference between the exposed area and reference area did not change from the baseline year (i.e., $\bar{x}_{\text{Exposed }Predicted} = \bar{x}_{\text{Reference}} + \left(\bar{x}_{\text{Exposed B}aseline} - \bar{x}_{\text{Reference B}aseline}\right)$).

Question 2 was answered using the results of the two-way ANOVA. When the *Area*×*Year* interaction term was significant (α = 0.05), contrasts were conducted for each year to compare the exposed and reference areas. When the *Area*×*Year* interaction term was not significant, (i.e., the difference between areas did not depend on year) the area comparison was assessed using the *Area* term of the two-way ANOVA. The MOD between the exposed area and reference area was calculated in each year as:

$$MOD = \frac{exp\hat{}\bar{x}_{Exposed} - exp\hat{}\bar{x}_{\text{Reference}}}{exp\hat{}\bar{x}_{\text{Reference}}} \times 100\%$$

where $\bar{x}_{Exposed}$ and $\bar{x}_{Reference}$ are the exposed and reference area means (in log units), respectively. When the interaction term was not significant the MOD between reference and exposed areas was calculated across all years combined.

Statistical comparisons were completed for all available analytes; however, data interpretation focused on primary and secondary analytes (see Table 2.4). Plots of data from July 2019 to 2022 that support the two-way ANOVA were presented for primary and secondary analytes that: 1) had a significant *Area* × *Time* interaction in the analyses; and 2) lacked a significant *Area* × *Time* interaction in the analyses but had a positive MOD (i.e., exposed concentrations were significantly higher than reference and the difference did not depend on year). Concentrations of primary and secondary analytes from all seasons from 2014 to 2022 were also plotted to allow qualitative comparison among seasons and qualitative temporal comparison of results. Years with more than 50% of the data reported below the LRL for any given year were excluded from the analysis. All statistical comparisons and plots were completed using R (R Core Team 2022).

Routine water quality monitoring data collected by MPMC staff between 2015[19] and 2022 in Polley Lake, Bootjack Lake, and Quesnel Lake were used to aid in tissue quality interpretation and to evaluate how water quality has changed following the breach. The evaluation included water quality data collected at the surface of the north and south basin of Polley Lake (POL-P1 and POL-P2, respectively), and from stations QUL-18 (exposed), QUL-2a (exposed), and QUL-120a (reference) of Quesnel Lake (Figure 3.3). Post-breach trends (2015 to 2022) of total and dissolved concentrations of primary and secondary analytes (Table 2.4) were evaluated at these routinely monitored stations using a seasonal Kendall test (as described in Section 3.8.3.4) and were also graphically compared to approved and working British Columbia Water Quality Guidelines (BCWQG; refer to Sections 3.8.3.2 and 3.8.3.3 for details). Results of depth-integrated water quality samples collected concurrently with the zooplankton tissue samples in 2022 were also compared to BCWQG (for details, refer to Section 3.8.3.2).

3.5 Benthic Invertebrate Community

Benthic invertebrate community monitoring was completed at the deep near-field area of Quesnel Lake in 2022 (QUL-PNF; approximately 100 meters depth; Figure 3.2, Table 3.7). Benthic invertebrate community monitoring of lake habitats last completed in 2021 (Minnow 2022a) to fulfill the requirements of the CEMP, and monitoring of these areas in 2022 was not a CEMP requirement (MPMC 2019). Monitoring was completed at QUL-PNF in 2022 with the objective of continuing the ongoing monitored natural recovery of the benthic invertebrate community in this area. This objective could be achieved by making temporal comparisons within the deep near-field area; therefore, a deep reference area was not sampled in 2022 (similar to the monitoring approach used in 2020; Minnow 2021a). As the benthic invertebrate community at the deep near-field area recovers to a condition more similar to the reference area (particularly in terms of organism density), the comparison reference condition will be more important for the monitoring the natural recovery of this area.

Sample collection and analysis methods for 2022 are described herein are consistent with those outlined in the CEMP (MPMC 2019). For details pertaining to prior sampling years, refer to the references listed in Table 3.7.

[19] Routine water quality data prior to 2015 are available for Polley Lake, Bootjack Lake, and Quesnel Lake but were excluded from plots and statistical analyses to distinguish between short-term effects from potential long-term effects of the breach on water quality trends analysis in these waterbodies. The exclusion of data prior to January 2015 was based on the rationale explained in Minnow (2019a). Briefly, laboratory turbidity data resulting from the suspension of fine particulate matter immediately after the breach were used to qualitatively identify a “breach” period (i.e., a period characterized by short-term effects on water quality). By late 2014, laboratory turbidity had decreased to values more similar to pre- breach. Based on these results, the 'breach” period was defined as beginning on August 4, 2014, and ending in December 2014. Therefore, use of data starting in January 2015 should be effective in excluding short-term breach effects on water quality.

Table 3.7: Overview of Benthic Invertebrate Community Monitoring in Lake Habitats in the Vicinity of the Mount Polley Mine, 2014 to 2022[a]

Program Component	Waterbody	Area Code	Post-Breach							
			2014 (Minnow 2015a)	2015 (Minnow 2016a)	2016 (Minnow 2017a)	2018 (Minnow 2019a)	2019 (Minnow 2020a)	2020 (Minnow 2021a)	2021 (Minnow 2022a)	2022
Breach-Related Monitoring	Quesnel Lake	QUL-PNF	5	5						

Notes: Displayed monitoring efforts used the following sampling methodology: petite-ponar grab sampler, 5-grab composite, 250 µm sieve, LPL (Lowest Practicable Level) taxonomy.

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored in 2022 are displayed, as well as historical data for these areas.

3.5.1 Sample Collection

Benthic invertebrate community samples were collected on August 26 and 27, 2022, from five replicate stations within the deep near-field monitoring area of Quesnel Lake (QUL-PNF; Figure 3.2, Table 3.7). The level of replication (n = 5 per area) provides adequate statistical power to detect differences of ± two SDs at α and β of 0.10. One sample was collected at each replicate station. To ensure that the sample was representative of the station, each single sample was a composite of five sub-samples (grabs; 0.116 m^2 of bottom area in total; Appendix Table A.1.1).

Samples were collected using a Petite Ponar grab sampler according to methods consistent with provincial and federal guidance (i.e., BCMOE 2013; Environment Canada 2012b) and with previous monitoring (see Table 3.7). Samples were retrieved from each station using the ponar sampling methods described in Section 3.1.1 for the deep near-field area of Quesnel Lake. Upon retrieval, grab samples were closely examined to verify that only high quality, comparable samples were retained. Each grab was placed into a tub to evaluate whether the grab was complete (i.e., that the grab captured the surface material and was full to each edge), to evaluate the depth to which the grab penetrated, and to verify consistency in terms of particle size, organic matter, and the presence or absence of plants or algae. Incomplete or unusual grabs were discarded. Acceptable grab samples were rinsed from the Ponar into a plastic tub to ensure the complete removal of all material from the grab sampler. This grab sampling method was repeated until five acceptable grabs were collected at a given station.

At each replicate station, the composite sample of five grabs was placed into a 250 µm mesh sieve bag and sieved free of all material less than 250 µm in diameter. After sieving, the retained material (sample) was carefully transferred to internally and externally labelled 1 L wide mouth plastic jars using a wash bottle. The transfer was completed while working over a plastic tub to avoid any potential loss of organisms. Any organisms that fell into the tub or adhered to the sieve bag were removed and added to the sample. Each sample was then preserved with buffered formalin solution to achieve a nominal concentration of 10% and stored at room temperature until shipment to the laboratory.

Supporting measures were collected at each sampling station, including *in situ* water measures, Secchi depth, and supporting sediment measures (sediment quality; see Section 3.1). Refer to Section 3.8.1 for additional details about supporting measures.

3.5.2 Laboratory Analysis

Taxonomic identification of the benthic invertebrate community samples was completed by Cordillera Consulting (lead taxonomist Scott Finlayson), in Summerland BC, using standard

methods that incorporate QA/QC measures (e.g., Environment Canada 2012b, 2014). Taxonomists at Cordillera have achieved Level 2 certification by the Taxonomic Certification Program of the Society for Freshwater Science (formerly the North American Benthological Society), including certification for Group 1 (general Arthropods East/West), 2 (Ephemeroptera, Plecoptera and Trichoptera [EPT] East/West), 3 (Chironomidae East/West), and 4 (Oligochaeta) benthic organisms. Organisms were identified to the LPL[20] (typically genus or species) using up-to-date taxonomic keys.

Upon arrival, each benthic sample was logged into proprietary software, followed by a preservation check and the addition of Rose Bengal dye. Sample processing was initiated with sample washing, including elutriation to remove sand and gravel. The remaining organic material was then examined to estimate the total number of invertebrates and preserved in 70% ethanol. If the estimated number of invertebrates was greater than 600 individuals and the sample was fine and non-clumping, a subsample was taken using a Marchant Box (Marchant 1989) as described by Environment Canada (2014). All samples were sieved and processed in the laboratory using the same mesh size as used in during field collections (250 µm).

Samples (or sub-samples) were sorted using a gridded Petri dish under a low power stereo microscope into family/order while maintaining counts (counts excluded Porifera, Nemata, Platyhelminthes, Ostracoda, Copepoda, Cladocera, and any terrestrial drop-ins). When specimens were broken, only heads were counted towards the total, and larval and pupal exuviae were not counted. All samples were processed to a minimum 300 organism count. If the 300th organism was found part way through counting a cell, the entire cell was completed, and if 300 organisms had not been reached by the 50th cell of the Marchant Box, then the entire sample was sorted. All sorted organisms were stored in 80% ethanol by family/order in separate labeled vials and debris was preserved and labeled separately.

Insects were identified to the genus/species level and non-insects were identified to a minimum of family level (and to the genus/species level where possible). Identification was completed by experienced, certified taxonomists using standard keys. Taxonomists made comparisons to an externally verified reference collection, and to Standard Taxonomic Effort lists compiled by the Canadian Aquatic Biomonitoring Network (CABIN), Southwest Association of Freshwater Invertebrate Taxonomists (SAFIT), and Pacific Northwest Aquatic Monitoring Partnership (PNAMP) to ensure accuracy. Following identification, newly identified representative specimens of each taxon were placed in separate vials to update an ongoing reference collection.

[20] The term “Lowest Practical Level” is commonly used to describe the level of resolution for benthic invertebrate taxonomic identification (e.g., Environment Canada 2012b). However, the term “Lowest Practicable Level" (e.g., Carter and Resh 2001; Bailey et al. 2001) has been used throughout this report to more accurately described the taxonomic effort.

Laboratory QA/QC included an assessment of sub-sampling error, sorting efficiency, and taxonomic quality control on at least 10% of the samples (Environment Canada 2012b, 2014). Data were entered into proprietary software (INSTAR1), which was also used to calculate benthic invertebrate community metrics and to generate the taxonomic report. Data were provided to Minnow as a Microsoft Excel spreadsheet along with a methods and QA/QC report as an Adobe Acrobat PDF file (Appendix G).

3.5.3 Data Analysis

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, organism sorting efficiency, subsampling precision and accuracy, and taxonomic identification error (see Appendix B). Following completion of the DQR, benthic invertebrate community results were analyzed as described below.

3.5.3.1 Metrics

Benthic invertebrate community condition was evaluated using metrics of organism density, taxon richness, Simpson's Diversity and Evenness, and the density and relative density of dominant taxa groups. These endpoints were calculated at the LPL of taxonomy. Benthic invertebrate community results at the LPL taxonomy level can contain a mixture of taxonomic levels (e.g., species, family, order, and class), which can affect the calculation of metrics such as taxon richness and Simpson's diversity. To address this issue, a decision key was applied to the benthic invertebrate data to reassign taxon abundance across levels of taxa, while conserving the relative abundances within the higher taxon levels (see Appendix E.4 text and Appendix Figure E.4.1 for details). Several taxa were excluded from total organism counts by the laboratory (see Section 3.5.2) prior to application of the decision key and endpoint calculation. Rare members of the benthic invertebrate community for which the level of identification was insufficient to determine whether the individual was a member of the aquatic or terrestrial community were also excluded.

Following taxa exclusions, application of the decision key, and the collapsing of taxonomic data to maintain consistency among years, the metrics outlined above were calculated for all years included in the evaluation (2014 to 2022; Table 3.7): organism density (organisms per m^2), taxon richness, Simpson's Diversity and Evenness (calculated as in Smith and Wilson 1996; Environment Canada 2012b). The densities and relative densities (%) of the most abundant taxa were also calculated. Dominant/indicator taxon groups were defined as those groups representing more than 5% of total organism abundance within each set of data, or any taxon groups considered to be important indicators of environmental stress. The benthic invertebrate

community metrics were calculated and summarized for each year using the following statistics: sample size, mean, median, minimum, maximum, and SD.

Correspondence Analysis (CA) was used to further examine benthic invertebrate community structure across all sampling years (2014 to 2022) at the deep near-field and reference areas of Quesnel Lake. CA is a multivariate ordination method that is used to reduce complex multivariate data into a smaller number of independent variables (Gauch 1982; Pielou 1984). The analysis extracts theoretical values (CA axis scores) that capture the variation in the abundance of benthic taxa. The CA produces axis scores for each deep station (near-field and reference[21]) in each year as the sum of a weighted average of $ln_{(x+1)}$-transformed species densities (#/m^2). Taxa scores are also produced as the sum of weighted averages of their densities across stations and years. The structure of the data can then be depicted in scatter plots of one CA axis against another, showing both taxa and station scores. Taxa that tend to co-occur plot together and those that rarely co-occur plot farther apart. Similarly, years at the deep near-field and reference areas that share many taxa plot closer to one another, while those with few in common plot further apart. Thus, CA can be used to describe which benthic invertebrate taxa best accounts for observed differences in the overall benthic invertebrate community between years and/or stations. The CA analysis was conducted at the LPL of taxonomic organization using $ln_{(x+1)}$-transformed density data. CA is sensitive to the presence of rare taxa (Legendre and Legendre 1983; Poos and Jackson 2012). Taxa occurring in fewer than 1% of samples or those that made up less than 1% of the total abundance of Quesnel Lake dataset were excluded from the analysis (Dolédec and Chessel 1991). The ordination was conducted using the cca() function in the vegan package (Oksanen et al. 2020) of R statistical software (R Core Team 2022). Results of the CA were summarized by sampling station and year. Taxa with the highest magnitude weights on the CA axes were identified and used in interpretation of the separation of stations on the CA axes.

3.5.3.2 Statistical Analyses

Statistical analyses of benthic invertebrate community data were conducted using post-breach data from the deep near-field (QUL-PNF; 2014 to 2022; Table 3.7) and un-impacted reference

[21] Although the deep reference area of Quesnel Lake (QUL-PREF1) was not sampled in 2022, results from this area (2014 to 2021; Minnow 2022a) were included in the CA to provide additional context for the interpretation of temporal changes at the deep near-field area (QUL-PNF) from 2014 to 2022.

(QUL-PREF1; 2014 to 2021; Minnow 2022a)[22] areas of Quesnel Lake to answer the following question:

> Has the benthic invertebrate community at the deep near-field area of Quesnel Lake changed among years since the TSF breach?

To answer this question, statistical analyses were completed following the two-way ANOVA methods outlined in Section 3.3.3.1.2 using post-breach results from the deep near-field and reference Quesnel Lake areas for the calculation of community metrics, tabular and graphical presentation, and statistical analyses.

Interpretation of benthic invertebrate community metrics was enhanced by inspection of raw data and taxonomic proportions to detect patterns of ecologically relevant spatial and temporal differences. Ecological and habitat requirements of benthic invertebrates, as outlined in standard references (Clarke 1981; Edmunds et al. 1976; Weiderholm 1983; Wiggins 1996; Vieira et al. 2006; Merritt et al. 2008) were also used in data interpretation. All statistical comparisons were conducted using R (R Core Team 2022). Statistically significant differences in benthic invertebrate community between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were identified as potentially ecologically meaningful in statistical analyses results and in data interpretation (Environment Canada 2012b[23]). Densities and relative densities (%) of major benthic invertebrate groups were plotted as stacked bar charts. Benthic invertebrate community metrics were plotted to support the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2022).

Potential relationships between benthic invertebrate community metrics and physical and chemical conditions of the monitoring areas were explored using correlation analysis as part of causal assessment. Correlation analyses were completed using available data from the deep near-field (2014 to 2022) and reference (2014 to 2021) areas of Quesnel Lake. Although correlation is not causation (e.g., Suter 2015; Pearl et al. 2016), it is a fundamental tool applied for exploring data and generating evidence of causation (Suter 2015). Benthic invertebrate community metrics (including CA axis scores) were compared to environmental variables including physical measures (station depth), *in situ* water quality measures (temperature, dissolved oxygen, pH, and specific conductance),

[22] Although the deep reference area of Quesnel Lake (QUL-PREF1) was not sampled in 2022, results from this area (2014 to 2021; Minnow 2022a) were included in the statistical analyses to provide additional context for the interpretation of temporal changes at the deep near-field area (QUL-PNF) from 2014 to 2022.

[23] Environment Canada (2012b) identifies a CES of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community.

physical/chemical sediment measures (% fines and TOC content), sediment Analyte of Interest concentrations (see Section 3.1.3.1 for details), and sediment chemistry Principal Component Analysis [PCA] axis scores (see Section 3.1.3.2 for details). Following derivation of correlation coefficients using Spearman's Rank correlation, a Bonferroni-type correction (i.e., α [0.05] divided by the total number of independent variables) was applied to minimize the risk of declaring false positive correlations.

Statistically significant correlations found at the Bonferroni-adjusted p-value were further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were leveraged by outlying points (or groups of points). The effects of leverage were carefully considered because any differences in benthic community attributes observed at the exposed areas relative to reference, or temporal differences at the exposed area, might be correlated with breach-related differences in water or sediment quality regardless of cause. Leverage is a particularly important consideration in cases where substantially impacted areas are compared to unimpacted reference areas, because physical, chemical, and biological features may all be impacted and relationships among them may not actually indicate a cause other than "they were all impacted". Statistically significant correlations, coupled with careful examination of scatterplots, were used to identify the factors that most contribute to temporal and spatial variability in benthic invertebrate community endpoints. These factors were then considered considering known physical and chemical influences on benthic invertebrate communities (e.g., limitation due to low nutrient availability, toxicity by exposure to high metal concentrations).

3.6 Fish Catchability, Usage, and Population Health

3.6.1 Overview

Fish population monitoring in Polley Lake was completed in 2022, in accordance with the CEMP (MPMC 2019), to continue to document population structure and abundance, provide an estimate of young-of-the-year (YOY) survival in Polley Lake, and to assess the success of remediation efforts in Hazeltine Creek. As outlined in the CEMP (MPMC 2019), the frequency of fish population monitoring in Polley Lake is annual, and monitoring was last completed in 2021 (Minnow 2022a). A brief background and summary of historic findings of this monitoring is provided below.

Historically, the majority of Polley Lake rainbow trout (*Oncorhynchus mykiss*) recruitment was supported by spawning and rearing in Hazeltine Creek and lower Bootjack Creek, downstream of Polley Lake (Bruce and Slaney 1991). Following the breach, both Hazeltine Creek and Bootjack Creek were inaccessible to Polley Lake fish and spawning and juvenile rearing habitat for the

Polley Lake rainbow trout population was limited to Frypan Creek and a few unnamed intermittent tributaries around the lake (Figure 3.4). However, production of rainbow trout fry from these creeks was insufficient to sustain the historic rainbow trout population within Polley Lake (Minnow 2018d).

Post-breach monitoring in Polley Lake was initiated in 2014 to assess the impact of the breach and monitor the health of fish populations (particularly rainbow trout and longnose sucker [*Catostomus catostomus*]) over time. Notably, age- and size-frequency distributions for rainbow trout caught in 2016 indicated that far fewer age-1 and age-2 individuals were captured than in 2014 (Minnow 2017d) and an absence and near absence of age-1, age-2, and age-3 fish was reported in 2017 and 2018, respectively (Minnow 2018d, Minnow 2019a). This is indicative of limited recruitment associated with Hazeltine Creek being inaccessible for spawning and rearing from 2014 to 2017.

After remediation efforts in Hazeltine Creek were completed in the fall of 2017, fish from Polley Lake were allowed access to upper Hazeltine Creek (HAC-R1 and HAC-U) on April 26, 2018, and subsequently to the entire length of Hazeltine Creek on October 7, 2020.[24] Following re-establishment of access to upper Hazeltine Creek, rainbow trout catch-per-unit-effort (CPUE) in spring of 2019 was higher than in 2018 and 2017 but substantially lower than in 2016. Rainbow trout CPUE in the spring subsequently decreased from 2019 to 2021, consistent with loss of recruitment and natural mortality of older fish since the breach. However, CPUE in the fall, when fishing is randomized in Polley Lake, was higher from 2019 to 2021 than in 2016 and 2018 with the highest CPUE documented in 2021 (Minnow 2022a). More smaller rainbow trout were caught from 2019 to 2021 than in 2016 and 2018 and based on predicted length-at-age from a linear model, many of these individuals likely represented YOY to age-2, indicating successful recruitment of rainbow trout to Polley Lake and overwintering survival. In 2021, the length frequency distribution indicated a relatively diverse range of size classes (including YOY to age-4 or 5), further suggesting successful rainbow trout survival and recruitment from 2018 to 2021 (Minnow 2022b). In particular, more age-4 rainbow trout (which are from the 2018 cohort)

[24] High water levels associated with the spring freshet in May 2020 caused flooding that enabled adult rainbow trout to bypass the fish fence located at the downstream extent of HAC-U and access the creek downstream (Minnow 2021b). In response, MPMC extended monitoring to include Reach 3 of Hazeltine Creek (HAC-R3) in the 2020 Hazeltine Creek Monitoring Program (Minnow 2021b). On July 4, 2020, the fish fence at the downstream extent of HAC-U was moved to lower Hazeltine Creek (in the vicinity of HAC-D). On October 7, 2020, the fish fence in lower Hazeltine Creek was removed (following completion of remediation works in this area), and fish were allowed access to the entire length of Hazeltine Creek. The entirety of Hazeltine Creek remained accessible to fish from October 2020 until present, except for a brief period (July to August 2021) when lower Hazeltine Creek was inaccessible during the completion of final instream remediation works in this area (Minnow 2022b).

were captured in 2021 compared to 2020 and 2019 and were anticipated to spawn for the first time in 2022. Rainbow trout older than age-5 were absent in 2021 but this was expected as all spawners that were present in 2018 will likely have reached the end of their life expectancy with little replacement by recruits from 2014 to 2017 when Hazeltine Creek was inaccessible.

Sampling methodologies for fish surveys completed in 2022 are described herein are consistent with those outlined in the CEMP (MPMC 2019). The methodologies associated with historic monitoring to assess fish population structure and abundance in Polley Lake are described elsewhere (MPMC 2019; Minnow 2019a).

Two fish surveys were completed in 2022: spring sampling was completed in May (May 26 to 30, 2022; Appendix Table C.6.1) in Polley Lake with Bootjack Lake serving as reference, and fall sampling was completed in September (September 21 to 26, 2022; Appendix Table C.6.2) in Polley Lake. The monitoring completed in spring 2022 served two purposes: 1) to provide data for the evaluation of fish population structure and abundance in Polley Lake; and 2) to provide data for the evaluation of fish tissue quality in Polley Lake compared to reference (Bootjack Lake; see Section 3.7).

Fish sampling described herein was conducted under British Columbia Ministry of Forest, Lands and Natural Resource Operations and Rural Development (FLNRORD) fish Permit WL22-714043.

3.6.2 Spring Survey

The spring survey was initiated shortly after ice-out in Polley and Bootjack lakes and when water temperatures approached 5°C (i.e., May 13, 2022) in Polley Lake (and a similar date in Bootjack Lake). Ice cover, water temperature, and fish “homing” to natal streams (e.g., Hazeltine Creek or Bootjack Creek which is currently diverted directly into the south-west end of Polley Lake; Figure 3.4) were closely monitored by mine staff to support the timing of program commencement and initial fish aggregation in Hazeltine Creek was observed on May 3, 2022.

Spring fishing was conducted using five hoop net sets in Polley Lake and four in Bootjack Lake (0.75 m diameter, 3.8 cm stretched mesh; Appendix Table C.6.1). Hoop nets were set for one to three nights; key spawning areas such as Hazeltine Creek and Bootjack Creek (for Polley Lake) and small tributary streams of Bootjack Lake were targeted to capture individuals that were ready to spawn (Figure 3.4).

For each hoop net set, the level of sampling effort was recorded (i.e., set duration), along with supporting Global Positioning System (GPS) coordinates (Appendix Table C.6.1). Supporting measures also included vertical depth profiles of *in situ* water quality measures at the

two deep basins of each lake (Polley and Bootjack Lakes; see Section 3.8.1 for details). Captured fish were identified and enumerated to characterize the fish community. Species and catch totals were recorded on field sheets.

3.6.3 Fall Survey

Fall fishing was conducted in Polley Lake using seven hoop nets (four 0.6 m diameter nets [2 cm stretched mesh] and three 0.75 m diameter nets [3.8 cm stretched mesh]). The seven hoop nets were each set overnight at randomized locations in Polley Lake for five nights (Appendix Table C.6.2). The randomized net set locations were selected by separating Polley Lake into 28 fish sampling areas (Figure 3.5) and using a random number table to select the sampling area where any given net would be set in the lake on a given day. Set locations were determined *a priori*, with some adjustments made to ensure that only a single hoop net was set at a sampling area at any given time.

For each hoop net, sampling effort (i.e., set duration, configuration), and supporting GPS coordinates were recorded (Appendix Table C.6.2). Supporting measures also included vertical depth profiles of *in situ* water quality measures at the two deep basins of Polley Lake and supporting habitat data (see Section 3.8.1 for details). Captured fish were identified and enumerated to characterize the fish community. Species and catch totals were recorded on field sheets.

3.6.4 Fish Processing

Target species that were captured during the spring and fall surveys were retained for non-lethal evaluation of total length and weight. Target sample sizes for non-lethal measures were n ≥ 30 per lake (Polley and Bootjack lakes) for rainbow trout and longnose sucker in the spring (Appendix Tables C.6.3 to C.6.6). In the fall, non-lethal measurements were completed for rainbow trout, longnose sucker, and redside shiner (*Richardsonius balteatus*) from Polley Lake; target sample sizes were n ≥ 100 fish for longnose sucker and redside shiner (Appendix Tables C.6.7 and C.6.8). For rainbow trout, physical measurements were recorded for n ≥ 100 each of juvenile and adults to ensure collection of measurements from a relatively large sample size across the entire size range of rainbow trout captured (Appendix Table C.6.9). Prior to the collection of measurements in the field, rainbow trout were assigned as juvenile or adult based on the presence (juvenile) or absence (adult) of observable parr marks and/or body length (i.e., rainbow trout ≥ 25 cm in fork length were typically assigned as adults). This approximation was for field-based determination of maturity only. Incidental mortalities were disposed of in an approved manner. All other fish were released live immediately following capture.

Fish retained for non-lethal sampling were anesthetized using clove oil solution and measured for fork length, total length, and body weight (Appendix Table C.6.3 to C.6.9). A measuring board was used to measure fork and total length to the nearest millimeter. Fresh body weight was measured using a set of Pesola™ spring scales (depending on fish weight). The Pesola™ scales were demarcated at intervals of 1 to 2% of the total scale range, providing an accuracy of ± 0.3% of the fish mass. The Pesola™ spring scale for individual weight measurement was selected so that the fish weight was near the top of the scale's range to ensure that measurements achieved a resolution near 1%.

In May, a subset of eight female rainbow trout and longnose sucker from each lake (Polley Lake and Bootjack Lake) were sacrificed for the assessment of condition, tissue metal concentrations, and age distribution. See Section 3.7.1 for details of the processing methods for these fish.

3.6.5 Data Analysis

Three endpoints were used to evaluate the health of rainbow trout, longnose sucker, and redside shiner populations from Polley Lake over time (2014 to 2022). Firstly, cumulative relative frequency distributions (CRFD) of fork lengths were used as an indicator of recruitment (rainbow trout, longnose sucker, and redside shiner). Secondly, weight-at-age was used as an indicator of energy use (rainbow trout and longnose sucker). Thirdly, condition (weight-at-length) was used as an indicator of energy storage (rainbow trout and longnose sucker). CRFD included data from the randomized sampling efforts conducted in the fall only, when fish are not aggregating for spawning (which could influence the CFRD results). Condition and weight-at-age were analyzed separately for spring and fall sampling events (for years and seasons in which the necessary data were collected) and were analyzed for males and females separately (if data on sex was available) or for both sexes combined. For rainbow trout and longnose sucker, condition analyses in spring and fall were initially conducted using all fish captured; condition was then analyzed again using only fish with the greatest overlap in size (i.e., fork length) among years. Interpretation of condition analysis results was focused on the tests which included individuals with the greatest overlap in fork length (i.e., those tests that only included fish larger than a given fork length) to ensure interpretation of temporal contrasts were based on the analyses with the most robust and temporally comparable data sets.

Summary statistics (sample size, mean, SD, minimum and maximum value) were calculated separately by area and species for each measurement variable recorded in 2022 (weight, length, and age where available).

3.6.5.1 Weight-at-Age and Condition

Rainbow trout and longnose sucker condition and weight-at-age (females in spring only) were compared among years (i.e., 2016 to 2022 for spring surveys and 2014 to 2022 for fall surveys) using an Analysis of Covariance (ANCOVA) with $\log_{10}$-transformed body weight as the response, Year as a factor, and $\log_{10}$-transformed age or fork length as a covariate. Significant interactions between the covariate and year (i.e., the assumption of homogeneity of regression slopes among years) in the ANCOVA were assessed using $\alpha = 0.1$.

When the interaction term was significant, the coefficients of determination (R^2) of the interaction model and parallel slope model were compared to assess whether the slopes were practically significant. Briefly, if the R^2 was >0.8 and within 0.02 between the two models, then the conclusion was that the interaction model and parallel slope models were practically the same (Environment Canada 2012b) and the ANCOVA proceeded with the parallel slope model. Influence was also assessed using Cook's distance statistic when a significant interaction was detected. If the interaction was driven by influential points, these were removed from the analysis (Environment Canada 2012b). If the interaction could not be removed by comparison of R^2 values or removal of influential points, the conclusion was that the difference in the response variable between areas was dependent on the covariate values. When the interaction term was not significant it was removed from the model and the parallel slope ANCOVA model was fit.

Statistical comparisons were run as all pairwise contrasts over time. Statistically significant *post hoc* contrasts were identified at $\alpha = 0.1$ using Tukey's Honestly Significant Difference. The results of the pairwise comparisons among years were expressed using a compact letter system. Capital letters were assigned to years (e.g., A, B, and C) such that years that share a letter are not significantly different. The letters were assigned such that the year with the highest mean was assigned the letter "A."

Statistical outliers were defined to be observations with Studentized residuals with magnitude > 4 (Environment Canada 2012b) and statistical analyses were completed with these outliers excluded and an inventory of excluded outliers was provided with the analyses results.

A MOD was calculated for each endpoint in each year relative to the baseline year (defined as the minimum year used in the statistical comparison) as:

$$\text{MOD} = \frac{\bar{x}_{\text{i}} - \bar{x}_{\text{baseline}}}{\bar{x}_{\text{baseline}}} \times 100\% \text{ ,}$$

where $\bar{X}_i$ is the mean of a given year, and $\bar{X}_{Baseline}$ is the mean of the baseline (earliest) year (for ANOVA), or the covariate-adjusted mean (for ANCOVA, without interaction). When an interaction was observed, the MOD was estimated for small and large fish at the minimum and maximum values of the overlap in covariate values between areas using the predicted values of

the response variables from the interaction ANCOVA regression model (Environment Canada 2012b). When response variables were log_{10}-transformed, means were reported in the original data units (i.e., anti-logged), equivalent to geometric means.

Weight-at-age and condition were plotted using scatterplots with regression lines separated by year. The statistical analyses and regression model fitting for these endpoints were completed with the outliers excluded (as outlined above) and outliers were identified in plots as symbols with an "×" through them. All statistical analyses and plots were conducted using R (R Core Team 2022).

3.6.5.2 Length Frequency Distributions

Length frequency distributions of data from the randomized sampling efforts conducted in the fall were plotted using histograms and CRFD. The CRFD is a plot of the proportion of fish on the y-axis and length on the x-axis and shows the proportion of fish that have a length less than the length value on the x-axis. Statistical comparisons of length frequency distribution between years were conducted using the two-sample Kolmogorov-Smirnov (K-S) test. The two-sample K-S test compares the maximum difference in the CRFDs between areas and evaluates whether this maximum difference varies significantly among years ($p < 0.1$).

3.7 Fish Tissue Quality

Fish tissue quality monitoring in 2022 was completed in Polley Lake with Bootjack Lake serving as a reference (Figure 3.4), Quesnel Lake exposed and reference areas, and Quesnel River (Figure 3.6, Table 3.8), in accordance with the CEMP (MPMC 2019). Two fish tissue quality monitoring surveys were completed in 2022, one in spring in Polley and Bootjack lakes and one in fall in Quesnel Lake and Quesnel River. The spring (May) sampling in Polley and Bootjack lakes targeted the collection of one sport-fish species (rainbow trout) and one small home-range species (longnose sucker; Table 3.9). The fall (October) sampling targeted the collection of two small home-range species (northern pikeminnow [*Ptychocheilus oregonensis*] and peamouth chub [*Mylocheilus caurinus*]) from Quesnel Lake, and the collection of one sport fish species from each of Quesnel Lake and Quesnel River (lake trout [*Salvelinus namaycush*] and rainbow trout, respectively; Tables 3.8 and 3.9). As outlined in the CEMP (MPMC 2019), the frequency of fish tissue quality monitoring of these species in these waterbodies is annual, and monitoring following this design was last completed in 2021 (Minnow 2022a).

Sample collection and analysis methods for 2022 are described herein and are consistent with the CEMP (MPMC 2019). For details pertaining to prior sampling years, refer to the references listed in Table 3.8.

	Quesnel Lake near Grain Creek (Reference)			
Spring 2017 (Minnow 2018e)	Polley Lake	longnose sucker (LSU), rainbow trout (RB)	8	muscle, liver, ovary
	Bootjack Lake (Reference)	longnose sucker (LSU), rainbow trout (RB)	8	muscle, liver, ovary
Fall 2017 (Minnow 2018e)	Quesnel River	rainbow trout (RB)	8	muscle, liver, kidney
	Quesnel Lake West Arm near Hazeltine Creek	northern pikeminnow (NSC)	8	whole body
Spring 2018 to 2022 (Annually) (Minnow 2019a, 2020a, 2021a, 2022a)	Polley Lake	longnose sucker (LSU), rainbow trout (RB)	8	muscle, liver, kidney, ovary
	Bootjack Lake (Reference)	longnose sucker (LSU), rainbow trout (RB)	8	muscle, liver, kidney, ovary
Fall 2018 (Minnow 2019a)	Quesnel Lake West Arm near Poquette Creek	kokanee (KO)	8	muscle, liver, kidney, ovary (if present)
	Quesnel Lake North Arm near Mitchell River (Reference)	kokanee (KO)	8	muscle, liver, kidney, ovary (if present)
Fall 2018 to 2022 (Annually) (Minnow 2019a, 2020a, 2021a, 2022a)	Quesnel Lake West Arm near Hazeltine Creek	northern pikeminnow (NSC)	8	whole body
		peamouth chub (PCC)	8	muscle, liver, kidney, ovary (n=7)
	Quesnel Lake West Arm near Cedar Point	lake trout (LT)	8[b]	muscle, liver, kidney, ovary (n=5)
	Quesnel Lake near Grain Creek (Reference)	northern pikeminnow (NSC)	8	whole body
		peamouth chub (PCC)	8	muscle, liver, kidney, ovary (n=6)
	Quesnel Lake East Arm near Blue Lead Creek (Reference)	lake trout (LT)	8	muscle, liver, kidney, ovary (n=1)
	Quesnel River	rainbow trout (RB)	8	muscle, liver, kidney, ovary (n=5)

Grey shading indicates fish tissue sampling completed in 2022.

[a] The target for these collections was n = 8 ovary samples. For the spring 2015 and 2016 data set, this resulted in more than 8 muscle and liver samples.

[b] The target for these collections was n = 8 samples of each tissue type. For the fall 2019 data set, this resulted in more than 8 muscle, liver, and kidney samples for lake trout.

[c] The target sample size indicated was achieved in 2022 for each species and target tissue unless otherwise indicated. Ovary sample sizes that differed from the target sample size in 2022 are indicated in parentheses (e.g., n=5).

Table 3.9: Life History and Habitat Preferences of Target Fish Species in the Vicinity of the Mount Polley Mine[a]

	Lake Trout (LT)	Longnose Sucker (LSU)	Northern Pikeminnow (NSC)	Peamouth Chub (PCC)	Rainbow Trout (RB)
	Salvelinus namaycush	*Catostomus catostomus*	*Ptychocheilus oregonensis*	*Mylocheilus caurinus*	*Oncorhynchus mykiss*
Home Range	move within lake to spawning sites.	move to spring spawning sites, but tagged fish have often been re-captured close to where they were originally captured.	move to spring spawning sites, but and considered to have small home range (tagged fish in the Columbia River were generally found within 3 km of the tagging location).	move to spawn in spring. Movement limited to diel inshore movement in evening and offshore in morning.	move from lake habitat to spawning creeks (generally tributaries to, or outlets of, their native lake).
Spawning	in the fall (September-November), usually at night, when water temperatures drop below 10 °C , usually in lakes over boulder or rubble bottom from depths ranging from 0.3 to 12 m, although some populations spawn in rivers.	in spring shortly after ice-out at a threshold temperature of 5 °C, although some populations in the Peace and Cariboo regions delay to a water temperature of 15 to 16 °C. Usually spawn in streams over gravel substrates in moderate currents.	in the spring at a threshold temperature of 12 °C (April to July), typically in gravel or cobble of inlet streams, generally close to the lake.	in spring/early summer (April-July) at water temperatures between 9 and 15 °C. Typically in lake inlet or outlet streams in areas of flowing water over gravel substrate. Rarely more than a few hundred metres from the lake.	in spring (April-June) at water temperatures between 8 and 15 °C. Triggered by rising water temperature above 5 °C. In fine gravel of riffle areas of tributary streams, typically at depths of 0.15 to 2.5 m and water velocity of 0.3 to 0.9 m/s. Can also spawn on gravel beaches in lakes.
Growth	growth is highly variable; in some lakes 2+ fish were in the 20 cm range.	3 to 6 cm by end of first growing season.	3.5 to 6.5 cm by end of first growing season.	3.5 to 6.0 cm by end of first growing season.	growth is highly variable depending on habitat type, productivity and food chain structure.
Maximum Age and Size	>20 years is common; oldest aged was 62 years; 75 cm.	19 years (probable under-estimate); 50 cm.	20 years; 50+ cm; females live longer and grow larger than males.	males live up to 8 years and females live up to 19 years; 25 cm.	8 years; maximum size is highly variable depending on habitat type, productivity and food chain structure.
Age at Maturity	between 5 and 13 years; males 1 to 2 years before females.	males - 5 to 6 years females - 6 to 7 years	males - 3 to 4 years females - 5 to 6 years	males - 3 years females- 4 years	3 to 5 years; as early as 1 year by males and as late as 6 years by females.
Food	young-of-year forage on plankton and aquatic insect larvae, adding larger benthic organisms as they grow. At a length of 35 to 40 cm, switch to piscivore if an appropriate prey species is available.	are benthivores as adults, but early stages forage in shallow water for a variety of prey, most commonly zooplankton. Mouth shifts from terminal to ventral with development. As adults, most common food is chironomid larvae and pupae.	mostly aquatic insects when small; diets include fish after 10 cm size. Are mostly piscivorous when larger than 30 cm (although they will eat almost any prey of suitable size).	juveniles consume a wide variety of prey (planktonic crustaceans, chironomid pupae, benthic invertebrates). Consume larger prey as they grow; adults primarily eat invertebrates, but occasionally eat fish.	in creeks, fry and juveniles forage on drifting aquatic insects. In lakes, fry forage on bottom and water column invertebrates; juveniles and adults have similar diets, but adults take larger prey and more adult insects. Large adults (> 40 cm) in large lakes often become piscivorous.
Habitat - Early Life Stages	young seek out deeper water within a month of being hatched, and prefer deeper water than adults (possibly due to cannibalism). When surface waters are cool, juveniles can also be found in shallow water about 1 to 2 m offshore.	young-of-year stay near shore near cover (vegetation or woody debris). Fry transition to deeper water.	young-of-year are typically found around lake margins in shallow water close to cover. Juveniles tend to move offshore into deeper water in the fall.	young-of-year are typically found in shallow water, and tend to move offshore at night. Juveniles also occupy shallow water, but generally deeper than young-of-year.	alevins take 1 to 4 weeks to emerge. Fry may move immediately to lakes, or reside in the stream as many as 3 years. Fry staying in the stream are territorial, and initially occupy slow, shallow areas (shallower than other species), moving to deeper and faster water as they get older.
Habitat - Adults	prefer cool water (below approximately 10 °C); during warmer summer months adults inhabit the hypolimnion (below the thermocline) and disperse throughout the lake during the winter months.	habitat generalists, found in lakes and rivers. In lakes, tend to forage inshore at night, but remain below the thermocline in the day.	often in the littoral zone about 1 m off the bottom and at the offshore side of weed beds. Move into deeper water in the fall.	habitat use changes seasonally. Generally near bottom in the winter. Move inshore in the spring and after spawning, exhibit a diel migration, moving inshore in the evening and offshore in the morning.	in lakes, prefer cool (7 to 18 °C) temperatures and high dissolved oxygen; tend to stay below the 18 °C isotherm. Spend most of the time within 3 m of surface and are often in cover in the lower littoral zone.

Notes: km = kilometres, °C = degrees Celsius, m = metres, m/s = metres per second, cm = centimetres, + = plus, > = greater than.

[a] Based on information in Scott and Crossman (1998), Roberge et al. (2001, 2002), McPhail (2007) and Barrett and Munkittrick (2010).

3.7.1 Sample Collection

Spring fishing in Polley and Bootjack lakes was completed from May 26 to 30, 2022 under FNLRORD Fish Collection Permit WL22-714043, using hoop nets to capture rainbow trout and longnose sucker (Figure 3.4), as described in Section 3.6.2. Fishing was completed in the spring to support collection of ripe ovary tissue from these two species, which is a key tissue for selenium monitoring (see Section 3.7.3.1).

Fall fishing in Quesnel Lake and Quesnel River was completed from October 1 to 6, 2022 under FLNRORD Permit WL22-714043 and Department of Fisheries and Oceans Canada (DFO) Permit XR 113 2022. Hoop nets were used specifically to target the species with small home ranges (i.e., northern pikeminnow and peamouth chub) in the exposed (West Arm-near Hazeltine Creek) and reference areas (North Arm-near Grain Creek) of Quesnel Lake (Figure 3.6, Table 3.8). Hoop netting was completed from October 3 to 6, 2022, with hoop nets set for 1 to 2 nights. Fishing to specifically target lake trout was completed in the exposed (West Arm-near Cedar Point) and reference (East Arm-near Blue Lead Creek) areas of Quesnel Lake using gill nets with mesh sizes ranging from 3 to 5 inches stretched mesh (Figure 3.6). Gill netting activities were restricted to daylight hours from October 3 to 6, 2022. The duration of gill net deployment was limited to less than 1.5 hours in accordance with the DFO permit conditions and to minimize incidental mortalities and nets were deployed using Summer Profundal Index Netting (SPIN) methods (Sandstrom and Lester 2009). Gill nets were deployed perpendicular to shore in benthic habitat at depths from 3 m (i.e., nearest to shore) to 37 m. Fish were captured from the Quesnel River (Figure 3.6, Table 3.8) by angling on October 1 and 2, 2022.

For each sampling area, the target sample size per species (e.g., rainbow trout) and tissue type (e.g., muscle, ovary, liver, and kidney, or whole-body[25]) was n = 8 to facilitate meaningful statistical comparison of fish tissue chemistry between exposed and reference areas (Table 3.8).

Supporting data recorded for the 2022 fish tissue monitoring in lake habitats included GPS coordinates of each fishing location (net set or angling effort), level of effort (net deployment and retrieval times, angling duration), *in situ* water quality measurements (i.e., depth profiles of temperature, pH, dissolved oxygen, conductivity, and specific conductance), and habitat data (see Section 3.8.1; for details).

Upon collection of fishing gear, captured fish were identified to species. Target species that were captured in the hoop nets, gill nets, or by angling and were of an appropriate size were retained for processing. Incidental mortalities were disposed of in an approved manner. All other fish were released live immediately following capture. Fish retained for lethal sampling were

[25] The tissue types collected varied by species and location; see Table 3.8.

anesthetized using a clove oil solution or euthanized with a decisive blow to the head and spinal severance and measured for fork length, total length, and body weight as described in Section 3.6.4.

Fish retained for lethal sampling were opened using dissecting scissors and any internal abnormalities were noted. All dissected fish were also examined internally to confirm sex. Internal tissues (liver, kidney, and ovary if available[26]) were then removed using dissecting tweezers and scissors, weighed to the nearest 0.001 g (±1% precision) using an analytical balance and placed in labelled Whirl-Pak™ bags. A boneless, skinless muscle sample was also collected and placed in a clean, labeled Whirl-Pak™ bag. Tissue samples were collected using clean implements (cutting boards, filet knives, and tweezers). Duplicate (split) samples were collected at a target frequency of 10% for QA/QC purposes and were evenly distributed among fish species and tissue types. Whirl-Pak™ bags containing whole carcasses (northern pikeminnow) or individual tissue samples (all other species) were stored frozen until shipment (on ice) to the analytical laboratory.

Aging structures from lethally sampled fish were then collected for age determination; specific age structures that were retained included:

- Otoliths (rainbow trout, lake trout, peamouth chub) or whole heads (northern pikeminnow);
- Pectoral fins (longnose sucker)[27]; and
- Scales as a secondary age structure.

For rainbow trout, longnose sucker, lake trout, and peamouth chub, age structures were removed, wrapped in waxed paper, placed in labelled coin envelopes, and frozen until shipment to the laboratory for aging analyses. For juvenile northern pikeminnow (that are typically smaller in size), whole heads were removed, stored, frozen, and shipped (on ice) to the aging laboratory for otolith extraction and age determination.

3.7.2 Laboratory Analysis

Laboratory analysis of fish tissue quality samples was completed by ALS Environmental (Burnaby, BC) using the same methods and QA/QC measures outlined in Section 3.4.2.

[26] Fully-developed ovaries were sampled from mature females. During fishing efforts in Quesnel Lake and Quesnel River, additional fish (i.e., more than n = 8 per area) were not targeted and sacrificed to achieve an n = 8 sample size for ovary tissue.

[27] Catostomidae spp. are known to have low-quality otoliths for aging, therefore fin rays are the preferred structure with which to derive age estimates.

Determination of fish ages using aging structures was completed by AAE Tech Services in La Salle, Manitoba. Sample shipments were accompanied by COC forms. Prior to aging, samples were thawed and otoliths were extracted from fish heads, as required. Otolith pairs for each relevant fish were examined under magnification for any issues related to structural integrity (e.g., cracks, fractures, etc.) and deformation (e.g., crystallization or misshapen lobes). Based on this evaluation, one otolith of the pair was selected for processing and embedded in Cold Cure epoxy resin, then allowed to cure for 48 hours before sectioning and polishing. Age estimation was carried out by submerging the otolith section in water under magnification with the polished surface facing up.

Pectoral fin rays from longnose sucker were processed and analyzed using a similar sectioning method to that used for the otoliths. Fin rays were embedded in Cold Cure epoxy resin to increase the structural integrity of the sample and prevent damage or degradation of the sample during processing. Samples were cured for 48 hours before sectioning. A minimum of three sections were taken to compensate for misalignment or staggering of the rays, due to shifting during the embedding process, or the inherent shape of the structure. The analysis of multiple rays enables age verification and improves the reliability of the age estimate, especially in the case of heavy checking or faint/thin annuli. The three sections were then submerged in a dish of water under magnification with the ageing surface facing up. Orientation was matched across all three sections to ensure accurate comparison.

For both otoliths and pectoral fin rays, ages were recorded with a corresponding Confidence Index value based on otolith/fin ray section condition, annuli assessment, and the confidence of the reader in the age determination. Scales that were collected as backup structures were used for age analysis only if an otolith or pectoral fin was damaged or otoliths were not collected successfully during sample processing. Data reports were provided to Minnow and MPMC as an Adobe Acrobat PDF file and Microsoft Excel spreadsheet (Appendix G).

3.7.3 Data Analysis

Fish catch data were compiled and summarized to provide a catch list for each sampling area and gear type. The catch compilations, along with data on fishing efforts completed in May and October 2022, were used to calculate CPUE for each species and sampling area. For hoop netting efforts, CPUE was expressed as number of fish per day. For gill nets, CPUE was calculated based on the number of fish captured per square meter-hour. For angling, CPUE was calculated as the number of fish per angler day. Fish length, weight, and age data were also compiled and summarized by calculating the mean, median, SD, and total range (minimum and maximum) by species and area.

Upon receipt of the chemical data from ALS, a DQR was performed. This included the assessment of field precision, laboratory precision, and laboratory accuracy against data quality objectives (DQOs) established at the outset of the project. Following the DQR, summary statistics were calculated for each analyte (% moisture, metals), species, tissue type (i.e., muscle, liver, ovary, and kidney or whole-body), and area. Summary statistics included the sample size, % of samples less than the LRL, mean, SD, minimum, median, and maximum. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1.

3.7.3.1 Data Screening

Fish tissue quality data were evaluated in comparison to tissue quality guidelines for human health and/or for aquatic ecosystem health (available for mercury and selenium) and the tissue quality of fish collected from reference areas. Tissue quality guidelines included the Canadian Food Inspection Agency/Health Canada mercury guideline for the protection of human health (0.5 milligrams per kilogram wet weight [mg/kg ww]; CFIA 2015) and the BC selenium guidelines (BCMOE 2014). Selenium guidelines for BC include guidelines for the protection of human health, which are based on fish consumption levels (7.3 mg/kg dw for subsistence consumers, 14.5 mg/kg dw for the general population, and 75 mg/kg dw for the recommended two servings of fish per week). The intermediate (general population) and subsistence consumption rate was selected as most applicable for evaluation of Polley Lake, Quesnel Lake, and Quesnel River fish tissue quality (i.e., the guideline of 7.3 and 14.5 mg/kg dw, respectively). Selenium guidelines for BC also include guidelines for the protection of aquatic life, which are 4 mg/kg dw in muscle tissue and whole-body samples, and 11 mg/kg dw in egg/ovary tissues.

Scientific consensus is that the best tissues for evaluating the potential adverse effects of selenium to fish (which are considered to be the most selenium sensitive organisms) are ripe ovaries or eggs (Luoma and Presser 2009; Janz et al. 2010; Stewart et al. 2010; DeForest et al. 2012; Janz 2012). Therefore, ovary tissues were used as the primary basis for evaluating potential effects of selenium on aquatic life. The BC guideline for selenium in egg/ovary tissue (11 mg/kg dw) includes a two-fold uncertainty factor that may not be justified given a very steep dose-response curve (DeForest et al. 2012), therefore selenium concentrations in fish ovaries were also compared to the threshold (5^{th} percentile of the distribution of 10^{th} percentile Effect Concentrations [EC_{10}]) for reproductive effects in eggs and ovaries (20 mg/kg dw; DeForest et al. 2012).

3.7.3.2 Statistical Analyses

Statistical analyses of metal concentrations in fish tissues were conducted using post-breach data (i.e., 2015 to 2022) to answer the following questions:

1. Have mean analyte concentrations at the exposed area changed over time relative to the reference area?[28]
2. Are there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?

To answer these questions, data were grouped into two categories for separate tabular and graphical presentation and statistical analyses:

1. Polley Lake (exposed) compared to reference (Bootjack Lake).
2. Quesnel Lake exposed (near Hazeltine Creek or near Cedar Point) compared to reference (near Grain Creek or East Arm).[29]

Questions 1 and 2 were answered by conducting a two-way ANOVA assessing the exposed:reference ratios of results, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA was competed as detailed in Section 3.4.3 (for Questions 1 and 2) to address the same questions. Similar statistical comparisons were also completed for fish ages, lengths, and weights to answer the question: is there a difference in mean fish length between exposed and reference areas, and does the difference depend on year? The comparisons of lengths, weights and age followed the two-way ANOVA methods listed above with the exception that data were fit with least-squares estimation (i.e., not MLE) because data were all uncensored (i.e., not < LRL) and data were analyzed as $\log_{10}$-transformed (length and weight) or untransformed (Age) response variables.

When reference area data were not collected concurrently with the exposed area over time (i.e., for Quesnel River), statistical comparisons of concentrations of metals in fish tissues were conducted to answer the following question:

Is there a difference in mean concentration at the exposed area over time?

The question was answered by conducting a one-way ANOVA with *Year* as the factor. Due to the prevalence of analyte results which were below the LRL (i.e., censored data), analyses of tissue metal concentration data were completed using a censored regression one-way ANOVA fit with MLE and assuming a lognormal distribution. Length, weight, and age data did not contain censored data and thus were fit with least-squares estimation (i.e., not MLE) and were analyzed as $\log_{10}$-transformed (length and weight) or untransformed (age) response variables. The MOD

[28] i.e., has the ratio of concentrations (exposed:reference) changed over time?

[29] Data from Quesnel River were considered separately since these data do not have an associated reference for comparison (i.e., statistical contrasts can be temporal only).

between the exposed area in each year relative to the first year of data collection was estimated as:

$$MOD = \frac{MCT_{Year} - MCT_{First\ Year}}{MCT_{First\ Year}} \times 100\%$$

where MCT is the measure of central tendency for the statistical test (i.e., back-transformed marginal means).

R software (R Core Team 2022) was used to conduct all statistical analyses. Censored regressions (i.e., MLE) were completed using the *survreg* function in the survival package (Therneau 2017) in R and contrasts were completed using the methods described in Oehlert (2010). Marginal means were estimated using the *emmeans*() function in R and were used to calculate MODs for the two-way ANOVA analyses. These estimates of the mean are equivalent to geometric means because the ANOVA analyses were completed on log-transformed concentrations. Consequently, the means used for the MOD calculations were not the same as the K-M mean concentrations reported in Appendix C.7 (see Section 3.8.3.1 for description of the K-M method).

Mercury concentrations were analyzed using units of mg/kg ww, in keeping with the reporting units for mercury guidelines. Mercury analyses were completed using ANCOVA with $\log_{10}$(fork length) as a covariate when the covariate was a significant predictor of mercury concentration, since mercury is known to bioaccumulate (i.e., larger fish have higher tissue concentrations; Kidd and Batchelar 2012). If fork-length was not a significant covariate ($\alpha = 0.05$) in the ANCOVA, the analysis proceeded using the ANOVA methods described above, consistent with the other analytes.

Statistical comparisons were completed for all available analytes; however, data interpretation focused on primary and secondary analytes (see Table 2.4). Plots of data that support the two-way ANOVA were presented for primary and secondary analytes that: 1) had a significant *Area* × *Time* interaction in the analyses; and 2) lacked a significant *Area* × *Time* interaction in the analyses but had a positive MOD (i.e., exposed concentrations were significantly higher than reference and the difference did not depend on year). Years with more than 50% of the data at the LRL for any given year were excluded from the analysis.

3.8 Supporting Measures

A variety of supporting physical and chemical information was used to support the interpretation of sediment and aquatic biological data collected from lakes as part of the CEMP. This information falls into two categories: 1) supporting information that was collected by Minnow during field collections of sediment, plankton, benthic invertebrates, and fish; and 2) supporting information

that was collected routinely by MPMC as part of ongoing CEMP monitoring and provided to Minnow. Unless otherwise specified, the supporting measures outlined below belong to the first category (measures collected by Minnow). Data analysis approaches for the supporting information are also detailed below.

3.8.1 Measures Collection

Supporting spot water samples were collected from specific depths using a water sampling bottle (Beta bottle or Van Dorn sampler) in support of data interpretation of the lake monitoring programs. During sediment sampling, spot water samples were collected from just above the sediment water interface (≤ 0.5 m above) at the shallow exposed (POL-S and QUL-LNF; n = 5 per area) and reference (BOL-S and QUL-LREF1; n = 5 per area) sediment sampling areas (Figures 3.1 and 3.2). The purpose of this sampling was to support the interpretation of sediment toxicity results from these shallow monitoring areas.

Water samples collected using a sampling bottle (Beta bottle or Van Dorn sampler) were obtained as follows. Prior to sampling, the sampling bottle was rinsed with site water and then lowered to the desired depth. For the collection of samples where the sampling bottle was not visible during sampling, a 5 kg steel weight was attached approximately 0.5 m below bottle to assist with collecting the sample at the appropriate depth. Once at the appropriate depth, the sampling bottle was moved side to side gently without disturbing the substrate (to ensure a representative sample was collected) prior to tripping the closure mechanism with a steel messenger. Upon retrieval, water samples were collected from a spigot fitted to the bottle. Samples collected into precleaned bottles were then preserved immediately (as required). Duplicate (split) water samples were collected at a target frequency of 10% for QA/QC purposes. Water samples were kept on ice in the field and refrigerated until being shipped (on ice) to ALS Environmental (Burnaby, BC).

One depth-integrated water sample was collected at each plankton monitoring area, during each sampling event, to support the interpretation of zooplankton tissue quality results (Appendix Table A.1.3). Samples were collected using a depth-integrated tube sampler (length ~13 m) as described in Section 3.3.1.1. Upon retrieval, the water samples were poured into a clean bucket (to collect *in situ* measures) before being decanted in pre-cleaned sample bottles, preserved (as required), stored, and shipped to the analytical laboratory as described above. Duplicate (split) depth-integrate water quality samples were collected at a target frequency of 10% for QA/QC purposes.

In addition to the spot water quality samples collected in 2022 by Minnow, water quality samples were collected routinely by MPMC staff as part of their ongoing water quality monitoring program (MPMC 2019) and were used to support data interpretation (see routine water quality monitoring station locations in Figure 3.3). These data were subjected to an internal DQR by MPMC,

including screening of laboratory QA/QC data, sample integrity issues, detection limits achieved, data accuracy, as well as potential outliers/extreme values. As such their quality were not further assessed in this report. Data were provided to Minnow by MPMC as a Microsoft Excel file.

Additional supporting information collected at each lake monitoring station in 2022 included GPS coordinates, date and time of sampling efforts, sampling depth, field meter measurements of temperature, specific conductance, dissolved oxygen, and pH at surface and bottom[30] and site and sample photographs (Appendix Tables A.1.1 to A.1.3). At one station per area per monitoring event, a minimum of one vertical depth profile of *in situ* water quality measures was recorded (Appendix Figures A.1.1 to A.1.6), as well as at least one Secchi depth measure. *In situ* water quality measures were collected using a YSI EXO™ handheld portable field meter equipped with a YSI EXO1™ or YSI EXO2™ sonde which was calibrated at least every second day. Field notes that would aid interpretation were also recorded. For sediment quality and benthic invertebrate sampling these included notes on the presence or absence of aquatic vegetation in sediment, other physical observations of sediment (sediment texture, colour, density, etc.). For fish monitoring these included notes on the habitat present (Appendix Tables A.1.4 and A.1.5).

3.8.2 Laboratory Analysis

Upon receipt of water samples, ALS opened the coolers, measured temperature to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique identification code. A SRN was then sent to MPMC and Minnow for verification.

Laboratory analyses included the parameters in the CEMP routine surface water quality monitoring program (MPMC 2019): dissolved organic carbon (DOC), total metals, dissolved metals, anions (nitrate, nitrite, sulphate, chloride, and fluoride), ammonia, total nitrogen, total phosphorus, dissolved phosphorus, orthophosphate, alkalinity, hardness, turbidity, total suspended solids, total dissolved solids, pH, and conductivity. Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow as an Adobe Acrobat PDF file and Microsoft Excel spreadsheet (Appendix G)[31].

[30] Surface and bottom *in situ* water quality measures were collected at each monitoring station sediment and benthic invertebrate community sampling stations only.

[31] Data reports for spot water quality sampling are included in Appendix G. Data from routine water quality monitoring completed by MPMC were provided to Minnow in Microsoft Excel format from the MPMC database and these are not included in Appendix G.

3.8.3 Data Analysis

3.8.3.1 Summary Statistics

Summary statistics (means, percentiles, and SDs) were calculated for select chemical parameters using the K-M method (Helsel 2012). Additional information about the application of this summary statistic calculation method (i.e., which monitoring components and analytes this method was applied to) are found within the methods sections for analysis of chemical data above (Sections 3.1.3, 3.4.3, and 3.7.3).

The K-M method (Helsel 2012) involves transforming left-censored data (i.e., data prefaced with a "<" symbol) to right-censored data (i.e., values prefaced with a greater than [>] symbol), and then using the K-M estimator (used to estimate the mean survival time in survival analysis) to estimate the mean. The calculation was completed using the *survfit*() function in the survival package (Therneau 2017) in R software (R Core Team 2022) and involves calculating the area under the K-M survival curve.

The K-M method is non-parametric and can accommodate multiple LRLs. This method of estimating the mean is equivalent to using the distribution of detected values below the maximum LRL to represent values that are <LRL. For example, the mean of the data set {1, 2, <4, 5} is estimated as the mean of 1, 2, [½×1 + ½×2], and 5 which is 2.375. The value <4 is replaced by the distribution of values below 4 (i.e., 1 and 2 with equal weight of ½). Similarly, the mean of the data set {1, 1.6, 2, 2.1, <4, 5} is estimated as the mean of 1, 1.6, 2, 2.1, [¼×1 + ¼×1.6 + ¼×2 + ¼×2.1], and 5 which is 2.229. Again, the value <4 is replaced by the distribution of values below 4 (i.e., 1, 1.6, 2, and 2.1 with equal weight of ¼). If the minimum value in the data set is <LRL, it is replaced with the LRL. Therefore, if there is only one LRL and no detected values <LRL, the K-M estimate of the mean is equivalent to replacing the value <LRL with the LRL (i.e., the best guess for the values <LRL is the LRL). If a SD could not be estimated (e.g., all data <LRL), then one was not reported.

For percentiles, estimates were first calculated using K-M estimator based on survival analyses. The percentiles were calculated using the quantile() function for a survival model generated in the survival package in R software (R Core Team 2022). Estimates of percentiles cannot be generated for highly censored data using the K-M method, and so a second method was used to provide practical estimates of the percentiles. For example, for the data set: <2, <2, <2, <2, 5; the K-M method will not produce an estimate of the median. However, the median value of this data set is clearly <2. The second method of estimating percentiles was used whenever the K-M method could not generate an estimate. This method involved calculating the percentile after

substitution with the LRL, then identifying the value in the dataset equal to this value (or the next detected value in the dataset that is below this value).

Summary statistics for biological endpoints (sediment toxicity, plankton community and productivity, benthic invertebrate community, and fish community and population health; Sections 3.2.3, 3.3.3, 3.5.3, and 3.6.5) were calculated using standard methods and formulae.

3.8.3.2 Water Quality Guideline Screening

Results of spot water quality samples were screened against available approved or working BCWQG (collectively termed "BCWQG"; Appendix Table C.1.1; BCMOECCS 2021a,b). For guidelines that are dependent on other water quality parameters (e.g., hardness-based, pH, temperature), concurrent water quality parameter values were used in their calculation (BCMOECCS 2021a,b). If hardness was outside the accepted range, then the bound of that range (either upper or lower) was used to calculate the guideline (BCMOECCS 2021a,b). If concurrent data were not available, the conservative values were chosen using the historical data for that station (e.g., the minimum hardness recoded for that station was used). Surficial water quality samples collected by MPMC staff from Polley, Bootjack, and Quesnel Lake routine water quality stations (Figure 3.3) were also screened against BCWQG with the results of this screening presented in plots. Plots of routinely collected water quality samples relative to BCWQG were limited to total and dissolved concentrations of primary and secondary analytes (Table 2.4). In addition, temperature and nutrient results (total phosphorus, dissolved phosphorus, orthophosphate, total nitrogen, and nitrate) were plotted for Polley, Bootjack, and Quesnel Lake routine water quality stations (Figure 3.3) to help support the interpretation of plankton community results. Tabular and graphical screening against BCWQG was completed using R (R Core Team 2022).

3.8.3.3 Biotic Ligand Model-derived BCWQG for Copper

The BCWQG Biotic Ligand Model (BLM)-based software was used to calculate acute and chronic guidelines for dissolved copper (BCMOECCS 2019d,e). This was used to support interpretation of zooplankton tissue quality by evaluating surface waters of Polley Lake and Quesnel Lake.

The BLM integrates exposure and toxicity modifying factors other than hardness that are known to modify copper bioavailability. Using this approach, the BLM defines dissolved copper concentrations below which chronic adverse effects would not be expected under the specific water quality that co-occurs with the copper concentration. Specifically, the BCWQG BLM produces acute and chronic guidelines for dissolved copper that are based on the 12 modifying water chemistry inputs required to run the model: temperature, pH, DOC, humic acid content,

calcium, magnesium, sodium, potassium, sulphate, chloride, alkalinity, and hardness (BCMOECCS 2019d).

If required input parameters for the BCWQG BLM were missing for a data set, these data were replaced to increase the sample size, when possible. This was done using professional judgement to replace the missing data as closely as possible or by using a conservative replacement value. Data missing for the parameters chloride, pH, and DOC were replaced by substituting the mean value from sampling events conducted in close temporal proximity to the missing data or using the most conservative values (e.g., using the minimum value collected at a station). Temperature data were missing for entire years for some stations. Thus, a conservative approach was used to estimate seasonal temperatures. The maximum temperature was taken in each month for the bottom and surface monitoring stations in each lake. These temperatures were used for samples taken in their respective months for each station to ensure that changes in guideline calculations were not driven by differences in the availability of temperature data.

3.8.3.4 Water Quality Trends

Temporal trends in surface water quality data were evaluated to support interpretation of chemical monitoring components. Specifically, surface water quality data collected routinely by MPMC post-breach (i.e., 2015[32] to 2021) in Polley Lake and Quesnel Lake were evaluated to support the interpretation of zooplankton tissue quality from these areas (refer to Section 3.4.3). This evaluation was completed using the seasonal Kendall test detailed below and included evaluation of aqueous total and dissolved concentrations of primary and secondary analytes (Table 2.4), and acute and chronic Guideline Exceedance Factors (GEFs) for copper (the ratio of observed dissolved copper concentrations divided by BCWQG BLM-derived guidelines).

The non-parametric seasonal Kendall test described by Hirsch et al. (1982) was used to evaluate temporal trends in surface water quality data from the north and south basins of Polley Lake (POL-P1 and POL-P2, respectively) and from three stations in Quesnel Lake (QUL-18 and QUL-2a [exposed], and QUL-120a [reference]; Figure 3.3). The seasonal Kendall test assesses temporal trends separately for each season (or month in this case) and combines

[32] Routine water quality data prior to 2015 are available for Polley Lake, Bootjack Lake, and Quesnel Lake but were excluded from plots and statistical analyses to distinguish between short-term effects from potential long-term effects of the breach on water quality trends analysis in these waterbodies. The exclusion of data prior to January 2015 was based on the rationale explained in Minnow (2019a). Briefly, laboratory turbidity data resulting from the suspension of fine particulate matter immediately after the breach were used to qualitatively identify a “breach” period (i.e., a period characterized by short-term effects on water quality). By late 2014, laboratory turbidity had decreased to values more similar to pre- breach. Based on these results, the 'breach” period was defined as beginning on August 4, 2014, and ending in December 2014. Therefore, use of data starting in January 2015 should be effective in excluding short-term breach effects on water quality.

the results for each season into an overall test for trend. The test is non-parametric and assesses whether there is a monotonic increasing or monotonic decreasing trend over time. The test is conducted by calculating the test statistic S_i which is equal to the sum of the number of increases and decreases from a time period t to all time periods after t for each observation in season i. The overall test statistic S is computed as the sum of S_i for all seasons. The significance of the observed S is determined by comparing it to a critical value of S (at the significance level α = 0.05) determined from the exact sampling distribution of S (calculated by determining all possible permutations and combinations of S based on the increases and decreases from the number of pairwise comparisons made; Hirsch et al. 1982). If more than 45 pairwise comparisons are made (equivalent to the number of pairwise comparisons for n = 10 in a single season), then the normal approximation is used to calculate a p-value and to assess significance (Hirsch et al. 1982). The standard normal deviate Z is calculated as:

$$Z = \begin{cases} \frac{S-1}{\sqrt{\sigma_S}} if\ S > 0 \\ 0 \quad if\ S = 0 \\ \frac{S+1}{\sqrt{\sigma_S}} if\ S < 0 \end{cases}$$

where $\sigma_S = \sum_{i=1}^{k} \frac{n_i(n_i-1)(2n_i+5) - \sum_{T_i} t_i(t_i-1)(2t_i+5)}{18}$ and n_i is the number of samples in month i, t_i is the number of tied values for each tied value T_i, and k is the number of seasons (Hirsch et al. 1982).

An estimate of the trend slope over time was calculated by computing the median of all slopes between data pairs within the same month (Helsel and Hirsch 2002). The slope was reported as a change in concentration per year and as a percentage change in concentration per year. The intercept of a line through the time series was estimated as the median intercept of all lines through each point with the estimated slope (Pohlert 2016). The trend analysis was only conducted with a minimum number of 5 pairwise comparisons, the minimum number required for all consecutive increases or decreases to be significant at α = 0.05.

4 METHODS – CREEK HABITAT

4.1 Sediment Quality

Sediment quality monitoring of creek habitats in 2022 targeted one area in upper Hazeltine Creek (HAC-U) and one area in lower Hazeltine Creek (HAC-D), with areas in upper and lower Edney Creek serving as reference (EDC-U and EDC-D, respectively; Figure 4.1, Table 4.1), in accordance with the CEMP (MPMC 2019). Channel remediation works in the vicinity of HAC-U and HAC-D were completed in 2017 and 2021, respectively (Table 4.1). As outlined in the CEMP (MPMC 2019), the frequency of sediment quality monitoring in creek habitats is annual, and monitoring at these areas was last completed in 2021 (Minnow 2022a).

Sample collection and analysis methods for 2022 are described herein. For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Table 4.1.

4.1.1 Sample Collection

Sediment samples were collected from Hazeltine Creek and Edney Creek between August 4th and 7th, 2022. Five replicate stations were sampled to represent each monitoring area (Figure 4.1, Table 4.1; Appendix Table A.2.1).

Hazeltine Creek and Edney Creek are predominantly erosional (HKP 1996, 1997a; Minnow 2007) and there are few locations of true sediment deposition. The limited sediment within these creeks tends to wash through during spring freshet and deposit as a thin layer of fines in quiescent areas on the lowering hydrograph. Due to the non-uniform nature of sediment deposition in these erosional areas, wetted locations that support some accumulation of fine materials (i.e., small pools, backwaters, or interstices between boulders) were selected opportunistically for sample collection. Collection of true sediment (i.e., fines in the silt and clay size category) could not be completed by conventional grab sampling due to the dominant presence of sand, gravel, and cobble in these areas. Sediment fines were therefore targeted using a clean stainless-steel- spoon.

At each sampling station selected, the location was approached by foot in a manner that did not disturb the sediment prior to sampling. Surficial sediment was then collected carefully by slowly placing the spoon on the sediment surface in a manner that minimized disturbance and inserting

Table 4.1: Overview of Sediment Quality Monitoring in Creek Habitats in the Vicinity of the Mount Polley Mine, 1995 to 2022 [a]

Waterbody		Area Type	Area Code	Baseline			Pre-Breach					Post-Breach						
				1995 (HKP 1996)	1996 (HKP 1997a)	1999 (Beak 2000)	2007 (Minnow 2009)	2009 (Minnow 2011)	2010 (Minnow 2011)	2012 (Minnow 2013a)	2013 (Minnow 2013b)	2014 (Minnow 2015a)	2015 (Minnow 2015b)	2018 (Minnow 2019a)	2019 (Minnow 2020a)	2020 (Minnow 2021a)	2021 (Minnow 2022a)	2022
Hazeltine Creek	Upper	Exposed (Remediated 2017)	HAC-U (W7 2009 to 2018; ST16 in 2014; W7 Pond in 2012; UHC in 2007; W6 in 1999 W7 in 1995 and 1996)	6	6	3	3	5	5	8	8 (W7) 5 (USW7-Pond) 16[b] (W7 Pond)	5	-	5	5	5	5	5
	Lower	Exposed (Remediated 2020/2021)	HAC-D (ST02 in 2014; DSW11 in 2012 LHC in 2007; W11 in 1995, 1996, 1999 and 2010)	6	6	3	3	-	5	5[c]	-	5	-	5	5	5	5	5
Edney Creek	Upper	Reference	EDC-U (W8 in 2012; UEC in 2007; W8, W8a, and W9 in 1995, 1996; W9 and W8 in 1999)	6 (W9) 6 (W8) 6 (W8a)	6 (W9) 6 (W8) 6 (W8a)	3 (W9) 3 (W8)	3	-	-	5[c]	-	-	-	5	5	5	5	5
	Lower	Reference	EDC-D (W10 prior to 2015)	6	6	-	-	-	-	-	-	-	5[d]	5	5	5	5	5

Sediment quality samples collected in 1996 had unusually high concentrations for some parameters. Values are suspect and were not used in data analyses, display, or interpretation.

Notes: "-" = not sampled/not applicable. Sediment Quality analyses included: metals and Total Organic Carbon (TOC) in <63 µm fraction, moisture, particle size, pH, total nitrogen, and total sulphur, for sampling completed between 2014 and 2021. Prior to 2019, sediment geochemistry, porewater quality, Polycyclic Aromatic Hydrocarbon (PAH), and oil and grease analyses were also employed, but are not displayed herein. For details of these alternate analyses, see Minnow 2019a, 2020a, 2021a.

[a] Numbers indicate the number of stations sampled per area. Where multiple areas were sampled in a given year, the area is identified in parentheses after the number of stations. Only sampling areas that were monitored in 2022 are displayed, as well as historical data for these areas.

[b] Eight samples were collected in separate spring and fall sampling events.

[c] Selenium was the only parameter reported.

[d] Sediment quality data for EDC-D in 2015 were not used in the calculation of post-breach summary statistics in Minnow (2015b). See Minnow (2019a) for presentation of raw data.

the spoon into the sediment to capture sediment to a depth of no greater than 3 cm.[33] The spoon was then moved horizontally until full, and slowly retrieved to the surface to avoid sample washout.

The contents of each spoonful were inspected to ensure that it was predominantly fine sediment (i.e., silt and clay), and, if acceptable, was placed into one or more pre-labelled 250 mL glass sampling jars. This procedure was repeated approximately 20 times at each station to form a composite sample representative of the sampling station and to collect sufficient sample material for analysis (Appendix Table A.2.1). Sampling equipment was rinsed between all stations using site water. Duplicate sediment samples were collected at a target frequency of 10% for QA/QC purposes. Samples were kept on ice in the field then stored in a refrigerator until shipment (on ice) to the analytical laboratory.

Supporting information was collected at each sampling station to support data interpretation (see Section 4.5.1 for details).

4.1.2 Laboratory Analysis

Laboratory analysis of sediment quality samples from creek habitats was completed by ALS Environmental (Burnaby, BC) using the same methods and QA/QC measures described for sediment quality samples from lakes (Section 3.1.2).

4.1.3 Data Analysis

4.1.3.1 Data Screening and Analytes of Interest

Upon receipt of the analytical data, a DQR was completed, including an examination of data completeness, LRLs achieved, laboratory precision, laboratory accuracy, and field precision. Following completion of the DQR, raw data were summarized by area by calculating mean, median, SD, minimum, and maximum. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1.

Sediment quality data were evaluated relative to British Columbia WSQG (BCMOECCS 2021a,b) and relative to reference and pre-breach 95th percentile concentrations (as described for lake sediment quality samples in Section 3.1.3.1). Guidelines and pre-breach/reference values were used in a two-way screening to identify analytes at exposed areas with mean concentrations that exceeded WSQG as well as reference and pre-breach 95th percentile values. Reference and pre-breach data used for screening values were compiled and calculated separately. Reference data included all available post-breach results (excluding data from 2015)

[33]Collection depth was often less than 3 cm, as fines often settle in a thin layer over coarser material, (and sampling seeks to avoid coarse material).

from Edney Creek, and pre-breach data included all results from Hazeltine Creek prior to 2014 (excluding data from 1996; Table 4.1; Appendix Tables D.2.1, D.2.2, D.2.3, D.2.4 and D.2.5).

All analytes (including primary and secondary analytes) were screened against the WSQG and reference/pre-breach 95th percentile values as described above (and as described in Section 3.1.3.1). Analytes at exposed areas with mean concentrations that exceeded all the following criteria were termed "Analytes of Interest": 1) the WSQG, 2) the associated reference 95th percentile value, and 3) the associated pre-breach 95th percentile value (if available). Analytes of Interest were determined separately for each monitoring area (i.e., separately for upper [HAC-U] and lower [HAC-D] areas of Hazeltine Creek). Concentrations of the Analytes of Interest, along with TOC, were the focus of more detailed interpretation which included graphical plots, formal statistical contrasts of temporal changes in concentrations, and examination of relationships to physical and chemical sediment variables.

4.1.3.2 Statistical Analyses

Statistical analyses of Analyte of Interest and TOC concentrations in creek sediments were conducted using post-breach data (i.e., 2018 to 2022) to answer the following questions:

1. Have mean analyte concentrations at the exposed area changed relative to the reference area?[34]
2. Are there differences in mean analyte concentrations between exposed and reference areas, and does the difference depend on year?
3. Have mean analyte concentrations at the exposed area changed over time since the breach?

To answer these questions, data were grouped into two categories for separate tabular and graphical presentation and statistical analyses:

1. Upper Hazeltine Creek (HAC-U) compared to an upper creek reference area (Upper Edney Creek; EDC-U).
2. Lower Hazeltine Creek (HAC-D) compared to a lower creek reference area (Edney Creek; EDC-U).

Questions 1 to 3 were answered by using the same statistical approach (i.e., two-way ANOVA with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year)* described for lake sediments in Section 3.1.3.2. Sediment concentrations from 2014 were excluded from temporal comparisons because this sediment represented freshly deposited breach-material that was removed during remediation efforts in 2015.

[34] i.e., has the ratio of concentrations (exposed:reference) changed over time?

Analytes of Interest and TOC concentrations were plotted to support the two-way ANOVA results. Where relevant, these plots included comparison of post-breach data (i.e., those data included in the analyses) to WSQG and reference/pre-breach 95th percentile values. Pre-breach data were also included in a sub-set of the plots for context.

Relationships between the Analytes of Interest concentrations and physical variables (particle size) and other chemical variables (TOC, total nitrogen, and total sulphur content) were evaluated using Spearman correlation analysis described for lake sediment (Section 3.1.3.2). Correlation analysis was completed using data from 2018 to 2022 combined from upper and lower areas of Hazeltine Creek. These data were combined because the upper and lower areas of Hazeltine Creek are connected, and the objective was to evaluate these relationships over time within the entire exposed area.

All sediment statistical analyses and plots were completed using R (R Core Team 2022).

4.2 Periphyton Community and Productivity

Periphyton community and productivity monitoring of creek habitats in 2022 targeted two areas of upper Hazeltine Creek (HAC-R1, HAC-U), with one area of upper Edney Creek (EDC-U) serving as reference (Figure 4.2, Table 4.2), in accordance with the CEMP (MPMC 2019). Channel remediation works in the vicinity of HAC-R1 and HAC-U were completed in 2016 and 2017, respectively (Table 4.2). As outlined in the CEMP (MPMC 2019), the frequency of periphyton community and productivity monitoring in upper creek habitats is annual, and monitoring at these areas was last completed in 2021 (Minnow 2022a). The frequency of periphyton community and productivity monitoring in lower creek habitats is every second year, and monitoring at these areas was also last completed in 2021 (Minnow 2022a).

Periphyton productivity monitoring was also completed in 2022 in an additional area of upper Hazeltine Creek Reach 3 (HAC-R3; remediated in 2019) and an area of Frypan Creek (reference; FPC-R3) for the specific purpose of providing data to support the evaluation of fish habitat in upper Hazeltine Creek (Figures 4.2 and 4.3, Table 4.2; MPMC 2019). Frypan Creek differs from upper Hazeltine Creek in terms of habitat and flow, and the upper Edney Creek area (EDC-U) is a more suitable reference for evaluating periphyton productivity and community in upper Hazeltine Creek outside of the specific focus on evaluating fish habitat. For the above reasons, periphyton productivity data collected from Frypan Creek (FPC-R3) and upper Hazeltine Creek Reach 3 (HAC-R3) are presented in tabular form only in the present report and are excluded from data analyses and interpretation. These data will be interpreted in a separate report which focuses on the assessment of Hazeltine Creek as fish habitat (Minnow 2023).

Periphyton and Benthic Invertebrate Monitoring Areas, Frypan Creek, 2022[a]

Date: January 2023
Project 227202.0029

minnow environmental inc.

Figure 4.3

Document Path: C:\Users\CApol\Trinity Consultants, Inc\Imperial Metals - 227202.0029 - 2022 MPMC\D - GIS\Task 6\22-29 Figure 4.3 Periphyton and BI, Frypan Creek.mxd

Sample collection and analysis methods for 2022 are described herein. For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Table 4.2.

4.2.1 Sample Collection

Periphyton samples for the assessment of community and productivity (chlorophyll-a and ash free dry mass [AFDM]) were collected between August 5 and August 10, 2022. Five stations were sampled in each area (Figures 4.2 and 4.3, Table 4.2), and each station was established at a minimum distance of approximately three bankfull widths from adjacent stations. Periphyton sampling stations coincided with those for benthic invertebrate community monitoring. Sampling was completed at each station by selecting five representative submerged rocks (excluding those that were too small, highly angular, or uncharacteristic in surface texture). Selected rocks were taken to shore for processing as described below for productivity and community sample collection (Sections 4.2.1.1 and 4.2.1.2, respectively).

A concerted effort was made to ensure that habitat characteristics (water depth, velocity, and substrate characteristics) were comparable among sampling stations and areas to minimize natural influences on the variability of productivity and community endpoints. From 2018 to 2022, the flow of water in Hazeltine Creek in 2022 was modified by controlling the discharge of water to the creek from Polley Lake (using a weir), and by pumping water from below the thermocline in Polley Lake into the creek for the specific purpose of maintaining conditions that support the use of upper Hazeltine Creek as fish habitat. This supplemental pumping increased water depth and velocity in Hazeltine Creek relative to natural conditions. This made matching habitat conditions between the remediated (Hazeltine Creek) and reference (Edney Creek) areas particularly challenging. Despite these challenges, remediated and reference sampling locations were matched for habitat as closely as possible in 2022. The flow augmentation to Hazeltine Creek also presented challenges for matching remediated and reference area conditions in previous years of monitoring (Minnow 2019a, 2020a, 2021a, 2022a).

Supporting measures were collected at each periphyton sampling station to support data interpretation. Refer to Section 4.5.1 for additional details about supporting measures.

4.2.1.1 Productivity

Periphyton samples were collected for chlorophyll-a analysis using methods consistent with technical guidance (BCMOE 2013, 2016) and the CEMP (MPMC 2019). Briefly, samples were collected at each station by firmly placing a thin acetate template with a 2x2 cm (4 cm²) opening in the middle of each selected rock and scraping off the periphyton within this area using a stainless-steel razor blade or scalpel. This was completed for the five rocks selected at each

sampling station. Sample material scraped from each of the five rocks was then transferred from the razor blade or scalpel to a large (47 mm) 0.45 µm pore diameter MCE filter paper until a single composite sample of approximately 200 mg to 1 g wet weight was obtained per station. If material collected from the five rocks sampled was insufficient (i.e., <200 mg), additional rocks from the same location and habitat characteristics were sampled until the required sample volume was obtained. The total area scraped at each station was recorded (0.002 m²: 5 x 4 cm², or any deviations from this surface area) to allow calculation of chlorophyll-a concentration per-unit area for comparison to the BCWQG (100 mg/m²; BCMOECCS 2021b). The filter paper was then folded and placed into a labeled opaque centrifuge tube. This process was repeated for each of the five stations per monitoring area.

The same five rocks sampled for chlorophyll-a analysis (and additional rocks if they were required) were used to collect separate scrapings for analysis of AFDM. Sampling methods for AFDM followed those outlined above for chlorophyll-a (0.002 m² per station); however, material on the razor blade or scalpel from scraping of each rock was rinsed into a small pre-labelled plastic jar with additional water added to cover the tissue (as necessary). Immediately after collection, all chlorophyll-a and AFDM samples were stored in a cooler with ice packs until being frozen prior to shipment (on ice) to the analytical laboratory.

4.2.1.2 Community

Periphyton community samples were collected from the same five rocks used for productivity sampling whenever possible (and additional rocks if they were required), or from rocks of a similar size collected from the same general location and habitat (i.e., depth and velocity). Sample collection methods were similar to those outlined for AFDM (Section 4.2.1.1). Periphyton was collected from a 2x2 cm area on five rocks at each station to form a single composite sample representing 0.002 m² (5 x 4 cm²) surface area. The periphyton was removed from each rock using a scalpel and/or brush and a squirt bottle filled with site water (BCMOE 2013, 2016; Stevenson and Bahls 2006). This process was repeated for each of the five stations per monitoring area. Immediately after collection, the sample was preserved with Lugol's iodine solution until the sample was the colour of weak tea (approximately 1 mL of Lugol's per 250 mL of sample; BCMOE 2013, 2016) and was mixed gently by inverting the sampling jar. All samples were stored at room temperature prior to shipment to the laboratory for taxonomic analyses.

4.2.2 Laboratory Analysis

4.2.2.1 Productivity

Laboratory analysis of periphyton productivity (chlorophyll-a and AFDM) was completed by ALS Environmental (Burnaby, BC). Upon receipt, laboratory staff opened the coolers, measured temperature to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique sample identification code. A SRN was then sent to MPMC and Minnow for verification.

Analysis of chlorophyll-a followed procedures adapted from USEPA Method 445.0 (USEPA 1997). Briefly, chlorophyll-a concentration was determined by routine acetone extraction followed by fluorescence detection using a non-acidification procedure (a method that is not subject to interferences from chlorophyll-b). Determination of total AFDM followed procedures adapted from APHA Method 10200 I (APHA 2010). Total AFDM was calculated as the difference between the dried sample weight and the ash weight, both determined gravimetrically. Dry weight was determined following drying at 105°C. The remaining sample was subsequently ignited at 500°C, rewetted to hydrate clays and minerals and brought to a constant weight at 104°C to determine ash weight. Laboratory QA/QC included reagent blanks and laboratory control samples. Upon completion of the analyses, data reports were provided by ALS Environmental to MPMC and Minnow electronically as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G).

4.2.2.2 Community

Taxonomic identification and enumeration of periphyton community samples was completed by Biologica Environmental Services Ltd. in Victoria, BC. Briefly, samples were homogenized by sonication, settled in Ütermohl chambers for 24 hours, and all cells within randomly selected FOV were enumerated until a minimum count of 300 algal units (1 unit = >1 cell for colonial or filamentous taxa) were enumerated or until 80 FOV were scanned. Cell units were enumerated rather than individual cells, due to colonial/filamentous algae species containing hundreds of cells per unit. Identification was performed using an inverted phase contrast microscope at 400x magnification, and algal taxa were identified to a minimum of genus-level (whenever possible) according to the most up-to-date taxonomic references (see laboratory methods description in Appendix G). Periphyton density (cells/cm^2) was determined using the number of units counted, number of cells per unit, proportion subsampled, and the total area of the selected fields of view.

Laboratory QA/QC included a re-analysis of at least 10% of samples and a calculation of percent agreement among results. Upon completion of the analyses, the data and quality control reports

were provided by Biologica to MPMC and Minnow electronically as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G).

4.2.3 Data Analysis

Upon receipt of the 2022 analytical data, a DQR was performed, including assessments of laboratory internal quality control checks, data completeness, calculations and unit conversions, and laboratory precision. Following completion of the DQR for the periphyton productivity endpoints, productivity results were analyzed as described below. In 2021, the DQR of periphyton community resulted in a request for an investigation of the data by the laboratory that ultimately led to the reissuing of periphyton cell density data from 2018 to 2021 (see Minnow 2022a for details). Once the quality of the 2022 periphyton community data were confirmed through the DQR process, periphyton community results were analyzed as described below, with the corrected periphyton community results from 2018 to 2021 used for all analyses (Minnow 2022a).

4.2.3.1 Metrics

The periphyton community was evaluated using the metrics of organism density, taxon richness, Simpson's Evenness and Diversity, diatom richness, and the density and relative density (%) of dominant taxa groups. These metrics were calculated using LPL taxonomy as outlined in Section 3.5.3.1. Taxonomic groups evaluated included major ecological groups (Diatoms, Chlorophytes [green algae], Chrysophytes [golden algae], Cyanobacteria [blue-green algae], Dinoflagellates, Phaeophytes [brown algae], Rhodophytes [red algae])[35].

Periphyton productivity was evaluated using chlorophyll-a and AFDM data, which were converted to standard area-based measurements (mg/m^2 and g/m^2, respectively). Chlorophyll-a concentrations were compared to water quality guidelines for eutrophic conditions (BCWQG = 100 mg/m^2; BCMOECCS 2021b) and a classification for moderately enriched streams (21 mg/m^2; Biggs 1996). Periphyton and community endpoints were summarized by area and year, including sample size, mean, median, minimum, maximum, and SD.

[35] Periphyton data were classified as "Other" taxa in laboratory results issued in 2018 and although the taxonomic groups contained in this category were unknown (i.e., unknown taxonomic identification of these organisms), they were suspected to include Phaeophytes, Chrysophytes, and Rhodophytes. Temporal statistical contrasts therefore excluded 2018 data for these taxon groups (Phaeophytes, Chrysophytes, and Rhodophytes) which were reported as absent from all samples in 2018 data. See Minnow 2019a for detailed laboratory results for 2018. Data reported in 2018 for this "Other" category was therefore excluded from data presentation and analyses in the present report. Periphyton taxonomy results have not been reported in an "Other" category by the laboratory since 2018.

Total richness, diatom richness, Simpson's Evenness, and Diversity were calculated under the assumption that each taxonomic group identified by the lab was unique. As a result, richness values reported herein differ slightly from those reported directly by the laboratory (see Appendix G), which considers only taxa that are certainly unique. For example, for the purposes of this report, the taxa Pennate Diatoms and *Diatoma sp.* were considered as two separate taxa, whereas the richness calculations completed by the laboratory were considered as one taxon. Although this approach may slightly overestimate richness, this is consistent across data sets.

Evaluation of the periphyton community and productivity included comparison to baseline and pre-breach samples collected at the same areas as post-breach samples, where possible. However, the comparability of 2018 to 2022 periphyton community data with historic (1995, 1996, 2011) datasets is limited due to differences in taxonomic practices and sampling effort across these years. Specifically, the use of multiple taxonomic laboratories since 1995 may have resulted in problems related to misidentifications and/or the use of multiple naming conventions for a single taxon (see Minnow 2019a for details). Furthermore, the taxonomic resolution of historic data was lower than 2018 to 2022 taxonomic analysis, limiting the potential for comparison. The periphyton community data from 2018 to 2022 has greater taxonomic resolution and is considerably more reliable than the historic datasets. The use of varying degrees of qualitative taxonomic analysis (categorizing the degree to which taxa were present as opposed to enumerating them) in 1995 (HKP 1996), 1996 (HKP 1997a), and 2011 (Minnow 2012), substantially limited comparisons that could be made with these data.[36] Due to these data limitations, periphyton metrics for baseline (1995, 1996) and pre-breach (2011) data excluded Simpson's Evenness and Diversity, and also excluded density based metrics for baseline results. Furthermore, statistical comparisons that included baseline and pre-breach data were limited to chlorophyll-a results only.

4.2.3.2 Statistical Analyses

Statistical comparisons of periphyton community and productivity metrics were conducted using baseline (1995, 1996) and pre-breach (2011) data (for chlorophyll-a only) and post-breach data (i.e., 2018 to 2022) to answer the following questions:

[36] Periphyton taxonomy data from 1995, 1996, and 2011 were qualitative, mostly consisting of characterization of presence/absence ("predominant", "common", "abundant," etc.) as opposed to discrete density values. In 1995 and 1996, proportions were reported for some dominant genera and groupings, however the degree to which those data represent quantitative data is unknown without density data. Even in 2011, when data were presented as density, many taxa were presented with "less than" values because the methodology employed by the taxonomist (Fraser Environmental Services) involved some qualitative elements.

1. Are there differences in periphyton community and productivity between exposed and reference areas in 2022?
2. Has the periphyton community and productivity of exposed areas changed among years relative to changes at the reference area over this time, and where pre-breach data exist, has the community recovered to pre-breach conditions?

To answer these questions, results from upper Hazeltine Creek (HAC-R1 and HAC-U) were compared to reference (EDC-U), and to pre-breach (W7; 1995, 1996, 2011, for productivity endpoints only), including calculation of community metrics, tabular and graphical presentation, and statistical analyses.

Periphyton productivity (AFDM and chlorophyll-a) data collected from upper Hazeltine Creek Reach 3 (HAC-R3; 2020 to 2022) and Frypan Creek (FPC-R3; 2017 to 2022) were excluded from data analyses and interpretation (see Section 4.2 for details and rationale) and are presented in tabular form only in the present report (Appendix Tables D.3.4 and D.3.5). These data will be interpreted in a separate report which focused on the re-opening of Hazeltine Creek as fish habitat (Minnow 2023).

Statistical comparisons of productivity and community endpoints were completed using two-way ANOVAs with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year*. The analyses were completed using the two-way ANOVA methods described in Section 3.3.3.1.2 with baseline, pre-breach, and post-breach (exposed [remediated] and reference) data from the creeks.

Periphyton productivity results (chlorophyll-a) from post-breach monitoring were compared to baseline data from 1995 (HKP 1996) and 1996 (HKP 1997a), and pre-breach data from 2011 (Minnow 2012) where possible (see Table 4.2). In addition, baseline data (1995 and 1996) were compared between upper Hazeltine (W7) and upper Edney (W9) creeks to evaluate the baseline condition in these areas. Pre-breach data from upper Hazeltine Creek (W7; 2011) were treated as a separate area from HAC-R1 and HAC-U in the two-way ANOVA of chlorophyll-a because baseline and pre-breach data from W7 (2011) were used in comparison to both HAC-R1 and HAC-U. Pairwise contrasts were conducted as described in Section 3.3.3.1.2, except for those completed for upper Hazeltine Creek (HAC-R1, HAC-U). If the *Area* term was significant for the ANOVA, temporal pairwise contrasts were completed among the areas (EDC-U, W7, HAC-R1 and HAC-U; as though a significant interaction had been detected) due to the inherent temporal contrasts of the *Area* term (i.e., baseline and pre-breach data for W7 compared to post-breach data for HAC-R1 and HAC-U). Results of the contrasts of chlorophyll-a from HAC-R1 and HAC-U to data from W7 were shown on plots with an "*" for 1995, a "†" for 1996, and a "‡" for 2011.

All statistical comparisons were conducted using R (R Core Team 2022). Statistically significant differences in periphyton community and productivity between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were identified as potentially ecologically meaningful in both statistical analyses results and in data interpretation (Environment Canada 2012b[37]). Densities and relative densities (%) of major periphyton taxon groups were plotted as stacked bar charts.[38] Periphyton community and productivity metrics were plotted to support the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2022). As outlined above, periphyton community endpoints for baseline and pre-breach were excluded from statistical contrasts due to data quality limitations but were included in plots for visualization purposes only.

4.3 Benthic Invertebrate Community and Productivity

Benthic invertebrate community and productivity monitoring of creek habitats in 2022 targeted two areas of upper Hazeltine Creek (HAC-R1, HAC-U), with one area of upper Edney Creek (EDC--U) serving as reference (Figure 4.2, Table 4.3), in accordance with the CEMP (MPMC 2019). Channel remediation works in the vicinity of HAC-R1 and HAC-U were completed in 2016 and 2017, respectively (Table 4.3). As outlined in the CEMP (MPMC 2019), the frequency of benthic invertebrate community and productivity monitoring in upper creek habitats is annual, and monitoring at these areas was last completed in 2021 (Minnow 2022a). The frequency of benthic invertebrate community and productivity monitoring in lower creek habitats is every second year, and monitoring at these areas was also last completed in 2021 (Minnow 2022a).

Benthic invertebrate community and productivity monitoring was also completed in 2022 in an additional area of upper Hazeltine Creek Reach 3 (HAC--R3; remediated in 2019) and an area of Frypan Creek (reference; FPC-R3) for the specific purpose of providing data to support the evaluation of fish habitat in upper Hazeltine Creek (Figures 4.2 and 4.3, Table 4.3; MPMC 2019). The benthic invertebrate community and productivity data collected from upper Hazeltine Creek Reach 3 (HAC-R3) and Frypan Creek (FPC-R3) are presented in tabular form only in the present report. These data will be interpreted in a separate report which focuses on the re-opening of Hazeltine Creek as fish habitat (Minnow 2023).

[37] Environment Canada (2012b) identifies a CES of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community. This criterion has been applied here to the interpretation of periphyton community.

[38] In 2018 and earlier, Chrysophytes, Phaeophytes, and Rhodophytes were grouped into an 'Other' category in stacked bar charts. Periphyton data were classified as "Other" taxa in laboratory results issued in 2018 but the taxonomic groups contained in this category were unknown (i.e., unknown taxonomic identification of these organisms), but suspected to include Phaeophytes, Chrysophytes, and Rhodophytes. See Minnow 2019a for detailed laboratory results for 2018. Periphyton taxonomy results have not been reported in an "Other" category by the laboratory since 2018."

Table 4.3: Overview of Benthic Invertebrate Community and Productivity Monitoring in Creek Habitats in the Vicinity of the Mount Polley Mine, 1995 to 2022[a]

Waterbody		Area Type	Area Code	Baseline[b]			Pre-Breach		Post-Breach

Laboratory analysis did not include determination of total wet and dry biomass.

Notes: "-" = not applicable, LPL = Lowest Practicable Level taxonomy. Only monitoring efforts that used the following methodology are displayed: Surber/ Hess sampler, 3-grab composite, 250 µm sieve, LPL. Prior to 2019, alternate sampling methodologies were employed. See Minnow 2019a for a detailed list of these alternate sampling methods.

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored in 2022 are displayed, as well as historical data for these areas. Collection of benthic invertebrate biomass data was initiated in 2017.

[b] In 1995 and 1996, each sample was a single grab collected by Surber with 243 µm mesh (HKP 1996, 1997a). In 1999, each sample was a composite of 3 Surber grabs with a 250 µm mesh (Beak 2000).

[c] Monitoring was not completed at the upper Edney Creek reference area (EDC-U) in 2020 due to differences in habitat variables (water depth and velocity) relative to the remediated areas of upper Hazeltine Creek (HAC-R1 and HAC-U) for which it is a reference.

Sample collection and analysis methods for 2022 only are described herein. For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Table 4.3.

4.3.1 Sample Collection

Benthic invertebrate community samples were collected between August 5 and 10, 2022. Five stations were sampled in each area (Figures 4.2 and 4.3, Table 4.3), and each station was established at a minimum distance of approximately three bankfull widths from adjacent stations. This level of replication provides adequate statistical power to detect differences of ± two SDs at α and β of 0.10. Sampling methods were in accordance with technical guidance (BCMOE 2013, 2016) and the CEMP (MPMC 2019). One sample was collected at each station, and each sample was a composite of three sub-samples to ensure that each sample was representative of the sampling station.

Samples were collected using a Hess sampler in Hazeltine Creek (HAC-R1, HAC-U, HAC-R3; 0.1 m^2) and a Surber sampler in Edney Creek (EDC-U) and Frypan Creek (FPC-R3; 30.5 x 30.5 cm square; 0.093 m^2). The samplers were each equipped with 250 µm mesh, which was selected to allow comparability to pre-breach data (Minnow 2009). Each sub-sample was collected from by carefully inserting the base of the sampler into undisturbed substrate. Cobble and gravel contained within the sampler was carefully washed, allowing the current to carry dislodged organisms into the collection net. Once the organisms were rinsed into the collection net, the sampler was moved to the next sub-sampling location within a station. This procedure was repeated until three sub-samples were collected from a station to complete the collection of a single sample (i.e., approximately 0.300 m^2 and 0.279 m^2 of total creek surface area for a Hess and Surber sampler, respectively). Material and organisms retained in the collection net were then carefully transferred to 1 L wide mouth plastic jars that were internally and externally labelled. This transfer was completed using a wash bottle over a plastic tub to avoid any potential loss of organisms. Any organisms that fell into the tub or adhered to the sieve bag were removed and added to the sample. Each sample was preserved with buffered formalin solution to achieve a nominal concentration of 10% and stored at room temperature until shipment to the laboratory.

A concerted effort was made to ensure that water depth, water velocity, and substrate characteristics were comparable among sub-samples, stations, and sampling areas, to minimize the influence of natural variability on benthic invertebrate community and productivity endpoints. As outlined for periphyton (see Section 4.2.1), the flow of water in Hazeltine Creek in 2022 was modified by controlling the discharge of water to the creek from Polley Lake (using a weir), and by pumping water from below the thermocline in Polley Lake into the creek for the specific purpose

of maintaining conditions that support the use of upper Hazeltine Creek as fish habitat. This supplemental flow in Hazeltine Creek presented challenges for matching habitat conditions between the exposed (Hazeltine Creek) and reference (Edney Creek) areas in 2022 similar to previous years of monitoring (Minnow 2019a, 2020a, 2021a, Minnow 2022a).

Supporting measures were collected at each sampling station to support data interpretation. Refer to Section 4.5.1 for additional details about supporting measures.

4.3.2 Laboratory Analysis

Taxonomic identification of benthic invertebrate community samples from creek habitats was completed by Cordillera Consulting using the standard methods and QA/QC measures described in Section 3.5.2 for benthic invertebrate community samples from lakes.

Following taxonomic identification, the wet and dry biomass of each sample was determined as follows[39]. For wet biomass, samples were poured out of their storage vials onto a piece of pre-weighed 212 µm Nitex mesh and were dried gently using absorbent paper. Each sample was then weighed to the nearest 0.0001 g using a Sartorius Secura Analytical balance, and the total sample wet weight was determined by subtracting the weight of the mesh from the total weight. For dry biomass, samples were placed on a piece of pre-dried and pre-weighed glass fiber filter before being dried at 160°F for 6 hours. Following a standardized short period of cooling, samples were weighed as described above, and total sample dry weight was calculated.

Laboratory QA/QC measures and the delivery of data were completed as described in Section 3.5.2 for lake benthic invertebrate community samples

4.3.3 Data Analysis

Upon receipt of the analytical data, a DQR was performed, including an examination of data completeness, organism sorting efficiency, subsampling precision and accuracy error, and taxonomic identification error (see Appendix B). Following completion of the DQR, benthic invertebrate community results were analyzed as described below.

4.3.3.1 Metrics

Benthic invertebrate community condition was evaluated using metrics of organism density, taxon richness, Simpson's Diversity and Evenness, and the density and relative density of dominant taxa groups. These endpoints were calculated at the LPL of taxonomy, following taxa exclusions, application of the decision key, and the collapsing of taxonomic data to maintain consistency among years as outlined in Section 3.5.3.1. Further analysis of benthic community structure using

[39] Total wet and dry biomass analysis was initiated in 2017 (Table 4.3).

multivariate analyses (CA) was not completed because differences in community structure between the remediated areas and pre-breach or reference conditions were easily identifiable without use of these techniques. Benthic invertebrate productivity was evaluated using total wet and dry biomass, which was converted to a standard area-based measurement (g/m^2). Benthic invertebrate community metrics were calculated for each monitoring area in each year[40] and were summarized by area and year using the following statistics: sample size, mean, median, minimum, maximum, and SD.

Evaluation of the benthic invertebrate community of upper (HAC-R1 and HAC-U) Hazeltine Creek included comparison of post-breach results to samples collected from a similar location during pre-breach monitoring in 2007 (UHC; Minnow 2009; Table 4.3). Methods employed in post-breach monitoring were consistent with those used during pre-breach sampling in 2007, enabling comparisons to pre-breach conditions (Table 4.3). Post-breach results were not compared to baseline results from HAC-U and EDC-U in 1989, 1995, and 1996 (W7 and W9, respectively; Table 4.3) because differences in sample collection methods and in taxonomic resolution precluded comparison. Adequate baseline for comparison to post-breach results is provided by the 2007 results.

Despite the consistencies between pre-breach and post-breach data, comparison of these results is still challenging due to the use of different laboratories for the taxonomic analyses, and the large time span (15 years) between data collection for the two studies (over which general improvements in laboratory protocols have occurred). A major difference between the pre-breach and post-breach data is that aquatic mites were not identified to a taxonomic level more specific than Subclass (Acari) in 2007 but were identified to genus in post-breach data, and spring-tails were identified to Class (Collembola) in 2007 but were identified to Family in post-breach data. Therefore, to keep data consistent and comparable to the pre-breach (2007) results, the aquatic mite and spring-tail data were collapsed to Class (Arachnida and Collembola, respectively). These reassignments were all completed prior to calculation of benthic community endpoints described above.

4.3.3.2 Statistical Analyses

Statistical analyses of benthic invertebrate community and productivity metrics were conducted using pre-breach (2007) and post-breach (2018 to 2022) to answer the following questions:

1. Are there differences in benthic invertebrate community and productivity between exposed and reference areas in 2022?

[40] Total biomass data are not available prior to initiation of biomass monitoring in 2017.

2. Has the benthic invertebrate community and productivity of exposed areas changed among years relative to changes at reference areas over this time, and where pre-breach data exist, has the community recovered to pre-breach conditions?

To answer these questions, results from upper Hazeltine Creek (HAC-R1 and HAC-U) were compared to reference (EDC-U), and to pre-breach (UHC; 2007), including calculation of community metrics, tabular and graphical presentation, and statistical analyses.

Benthic invertebrate community and productivity data collected from upper Hazeltine Creek Reach 3 (HAC-R3; 2020 to 2022) and Frypan Creek (FPC-R3; 2017 to 2022) were excluded from data analyses and interpretation (see Section 4.3 for details and rationale) and are presented in tabular form only in the present report (Appendix Tables D.4.1 to D.4.4). These data will be interpreted in a separate report which focused on the re-opening of Hazeltine Creek as fish habitat (Minnow 2023).

Statistical comparisons were completed using two-way ANOVAs with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year*. The analyses were completed using the two-way ANOVA methods described in Section 3.3.3.1.2 with pre-breach and post-breach (exposed [remediated] and reference) data from the creeks. Comparisons between the exposed areas of upper Hazeltine Creek (HAC-R1 and HAC-U) and the associated reference (EDC-U) were completed for each year that remediated and reference data were available (i.e., 2018 to 2022; see Table 4.3). In addition, pre-breach data (2007) were compared between upper Hazeltine (UHC) and upper Edney (UER) creeks to evaluate the baseline condition in these areas. As described in Section 4.2.3.2, UHC (pre-breach data; 2007) was treated as a separate area from HAC-R1 and HAC-U in the upper Hazeltine Creek two-way ANOVA analyses because pre-breach data from UHC was used in comparison to both HAC-R1 and HAC-U. Pairwise contrasts were conducted as described in section 3.3.3.1.2, except for those completed for upper Hazeltine Creek (HAC-R1, HAC-U). If the *Area* term was significant for the ANOVA, temporal pairwise contrasts were completed among the areas (EDC-U, UHC, HAC-R1 and HAC-U; as though a significant interaction had been detected) due to the inherent temporal contrasts of the *Area* term (i.e., pre-breach data for UHC compared to post-breach data for HAC-R1 and HAC-U). Pairwise comparisons to pre-breach data in tables are shown using the standard letter display (years that share a letter were not significantly different). Results of the contrasts of HAC-R1 and HAC-U to pre-breach data from UHC (2007) are shown on figures with an asterisk "*" indicating a significant difference relative to pre-breach.

Interpretation of benthic invertebrate community metrics was enhanced by inspection of raw data and taxonomic proportions to detect patterns of ecologically relevant differences between the exposed and pre-breach areas. Ecological and habitat requirements of benthic invertebrates, as

outlined in standard references (Clarke 1981; Edmunds et al. 1976; Weiderholm 1983; Wiggins 1996; Vieira et al. 2006, Merritt et al. 2008) were used in data interpretation. All statistical comparisons were conducted using R (R Core Team 2022). Statistically significant differences in benthic invertebrate community between areas were identified using an α of 0.1 (as used for evaluation of all biological data in this report). Significant differences with a MOD that exceeded ±2 SD/MAD were identified as potentially ecologically meaningful in statistical analyses results and in data interpretation (Environment Canada 2012b[41]). Densities and relative densities (%) of major benthic invertebrate groups were plotted as stacked bar charts. Benthic invertebrate community metrics were plotted to support the two-way ANOVA results. Untransformed data were plotted for ease of interpretation and plots were generated using R (R Core Team 2022).

Correlation analyses were completed for upper Hazeltine Creek (HAC-R1, HAC-U) using data from 2018 to 2022 to investigate the relationships between benthic invertebrate community metrics and supporting measures of physical and chemical conditions in these areas that have been recovering since 2016 and 2017, respectively (following the completion of remediation works). Benthic invertebrate community metrics were compared to the environmental variables water depth, velocity, temperature, dissolved oxygen (concentration and %), pH, specific conductivity, and substrate size using Spearman's Rank correlation (as described in Section 3.5.3.2). A Bonferroni-type correction (i.e., α [0.05] divided by the total number of independent variables) was applied to minimize the risk of declaring false positive correlations. Statistically significant correlations found at the Bonferroni-adjusted p-value were further investigated using scatter plots to determine if a continuous distribution of data was realized (possible causal relationships) or if these relationships were leveraged by outlying points (or groups of points).

4.4 Periphyton and Benthic Invertebrate Tissue Quality

Periphyton and tissue quality monitoring of creek habitats in 2022 was completed in accordance with the CEMP (MPMC 2019) and targeted upper (HAC-R1, HAC-U) and lower (HAC-D) areas of Hazeltine Creek and an impacted area of lower Edney Creek (E1), with un-impacted areas of upper (EDC-U) and lower (EDC-D) Edney Creek serving as reference (Figure 4.2, Table 4.4). Channel remediation works in the vicinity of HAC-R1 and HAC-U were completed in 2016 and 2017, respectively, and in 2020/2021 in the vicinity of HAC-D and E1[42] (Table 4.4).

[41] Environment Canada (2012b) identifies a CES of ± 2 SDs for evaluating ecologically meaningful changes in benthic invertebrate community.

[42] Monitoring stations within the remediated lower creek areas (HAC-D and E1) were relocated in 2021 relative to previous years due to the recent remediation efforts in these areas (Minnow 2022a). Briefly, in the case of HAC-D, this included relocation of the monitoring stations further upstream within the lower Hazeltine Creek. In the case of E1, this

Table 4.4: Overview of Periphyton and Benthic Invertebrate Tissue Quality Monitoring in Creek Habitats in the Vicinity of the Mount Polley Mine, 2009 to 2022[a]

Shading indicates only selenium was monitored.
Shading indicates stations were exposed to effluent being conveyed by Hazeltine Creek to Quesnel Lake.

Notes: "-" = not applicable/not sampled.

[a] Numbers indicate the number of stations sampled per area. Only sampling areas that were monitored in 2022 are displayed, as well as historical data for these areas.

[b] Composite-taxa benthic invertebrate samples were collected from 2009 to 2015. In 2016 and 2017, stoneflies and caddisflies were sampled at reference and remediated areas, respectively. In 2018 to 2022, both composite-taxa samples and single taxon (caddisfly) samples were collected at all areas.

[c] Eight samples for stoneflies and eight samples for caddisflies were sampled at a total of 12 stations.

As outlined in the CEMP (MPMC 2019), the frequency of periphyton and benthic invertebrate tissue quality monitoring in creek habitats is annual, and monitoring at these areas was last completed in 2021 (Minnow 2022a).

Some temporal differences exist in the composition of benthic invertebrate samples, including the collection of composite-taxa and/or single taxon (caddisfly) sample types (Table 4.4). Composite-taxa samples are representative of the range of taxa present at a sampling area and are reflective of dietary exposure for fish, therefore may be used in assessment of fish habitat. Single-taxon samples represent one taxon group and were collected to decrease the potential variability in results related to differences among benthic invertebrate taxa in tissue quality. Both single taxon (caddisfly) and composite-taxa samples were collected at each sampling area from 2018 to 2022, consistent with the CEMP (MPMC 2019). Prior to 2018, either composite-taxa (2009 to 2015) or single taxon (2016 and 2017) benthic invertebrate tissue quality samples were collected (see Table 4.4 and Minnow 2018c, 2019a for details).

Sample collection and analysis methods for 2022 are described herein. For details pertaining to prior sampling years, including equivalent historic sampling areas, refer to the references listed in Table 4.4.

4.4.1 Sample Collection

Periphyton and benthic invertebrate tissue samples were collected from 8 replicate stations within each area (Figure 4.2, Table 4.4) between August 2 and 10, 2022. Periphyton tissue samples were collected at each station by scraping periphyton from the surface of at least five rocks using a scalpel until a sufficient sample weight (i.e., more than 0.5 g wet weight) was attained for analysis. Periphyton scrapings were placed in labeled scintillation vials.

Benthic invertebrate tissue samples were collected at each station using a combination of kick-and-sweep and hand picking. The kick-and-sweep method involved a field technician moving upstream and across the stream channel (in a zig-zag pattern) while holding a kick net (a net with a triangular opening and a 400 µm mesh bag) immediately downstream and disturbing the substrate with their feet to dislodge benthic organisms into the net. The net was then rinsed with water to move all debris and invertebrates to the collection cup at the bottom of the net.

included relocation of the monitoring stations in lower Edney Creek to upstream of the confluence with Hazeltine Creek which was constructed in summer 2020 (Minnow 2022a). Monitoring station locations for HAC-D in 2022 were returned to similar locations to previous monitoring years (i.e., prior to 2021) and monitoring station locations for E1 in 2022 were consistent with the relocated locations sampled in 2021 (i.e., remained upstream of the confluence with Hazeltine Creek (Figure 4.2).

The collection cup was removed and the contents (i.e., invertebrates and debris) were poured into a white tub. Benthic invertebrates were then picked free of debris and transferred to labelled scintillation vials. Hand picking entailed overturning rocks in the streambed and collecting any benthic invertebrates observed. Both kick-and-sweep and hand-picking methods were employed at each erosional sampling station to collect benthic invertebrate samples. Two types of benthic invertebrate tissue samples were collected from each station: composite-taxa and single taxon (caddisfly).

Duplicate (split) samples were collected at a target frequency of 10% for QA/QC purposes and were evenly distributed among sampling areas and tissue types. Following collection, samples were stored in a cooler with ice packs until being frozen prior to shipment (on ice) to the analytical laboratory.

4.4.2 Laboratory Analysis

Laboratory analysis of periphyton and benthic invertebrate tissue quality samples was completed by ALS Environmental (Burnaby, BC) using the same methods and QA/QC measures outlined in Section 3.4.2.

4.4.3 Data Analysis

Upon receipt of periphyton and benthic invertebrate tissue chemistry data, a DQR was completed, including an examination of data completeness, LRLs achieved, laboratory precision, laboratory accuracy, and field precision (Appendix B).

Benthic invertebrate tissue quality data collected from 2022 were screened against the British Columbia selenium guideline for the protection of aquatic life (for invertebrate tissue) of 4 mg/kg dw (BCMOE 2014). Summary statistics were calculated for each analyte by area and tissue type for 2022 and for prior years (2010 to 2021) that were used in analyses, and included mean, SD, minimum, median, and maximum values. Summary statistics were calculated using the K-M method as described in Section 3.8.3.1. Data analysis and interpretation of periphyton and benthic invertebrate tissue quality focused on primary and secondary analytes representing a mine influence (see Table 2.4).

4.4.3.1 BCF and TTF Calculation

Concentrations of the primary and secondary analytes in periphyton tissue and benthic invertebrate were evaluated relative to concentrations in water. The ratio of ([tissue sample concentration]/ [dissolved water concentration]) is referred to as a Bioconcentration Factor (BCF). These ratios are often used to describe the extent to which an analyte is taken up by an organism from the surrounding environment through exposure routes

other than diet (i.e., Arnot and Gobas 2006) and are applicable to erosional areas where sediment is generally rare. BCFs were calculated using mean tissue metal concentrations (dry weight) and mean aqueous dissolved metal concentrations from routine water quality monitoring stations near each tissue sampling area (Figure 4.2). Mean aqueous analyte concentrations were calculated as described in Section 3.8.3.1) using data from the one-year period prior to sampling (i.e., September 2021 to August 2022). Mean values at the LRL were replaced with the LRL for the calculation of the BCF ratios. For EDC-U, routine water quality data were not collected by MPMC, and so BCFs were calculated using data from the spot water samples collected during tissue collection.

Concentrations of primary and secondary analytes in benthic invertebrate tissue were also evaluated relative to concentrations in periphyton tissue. These ratios of concentrations are referred to as Trophic Transfer Factors (TTFs) and can be estimated for benthic invertebrates assuming they inhabit a single trophic level above periphyton (i.e., TTF = [benthic invertebrate sample]/[periphyton sample]). TTFs can be used to describe the extent to which analyte concentrations increase between lower and higher trophic levels (e.g., Presser and Luoma 2010). Paired observations of benthic invertebrate and periphyton tissue chemistry were used to calculate TTFs for each replicate station in 2022 (i.e., 8 replicate TTFs per area in 2022). In addition, data collected in prior years (2010 [pre-breach], and 2017 to 2021 (post-breach; in years when both periphyton and benthic invertebrate tissue samples were collected) were also used to calculate TTFs in Hazeltine Creek (refer to previous reports outlined in Table 4.4). If an analyte concentration for either the nominator (benthic invertebrate tissue metal concentration) or denominator (periphyton tissue metal concentration) in the TTF calculation was censored (i.e., < LRL), the TTF was not calculated. These calculated TTFs were then summarized by year and area calculating the mean, SD, median, minimum, and maximum.

4.4.3.2 Statistical Analyses

Statistical analyses of metal concentrations in 1) periphyton tissue, 2) composite-taxa benthic invertebrate tissue, and 3) caddisfly tissue samples of TTFs were conducted using pre-breach (2010) and post-breach (2015 to 2022) data to answer the following questions:

1. Have mean analyte concentrations or TTFs at the exposed area changed over time relative to the reference area?[43]
2. Are there differences in mean analyte concentrations TTFs between exposed and reference areas, and does the difference depend on year?

[43] i.e., has the ratio of concentrations (exposed:reference) changed over time?

3. Do mean analyte concentrations or TTFs at exposed areas differ from pre-breach conditions?

To answer these questions, data were grouped into three categories for separate tabular and graphical presentation and statistical analyses:

1. The exposed areas of upper Hazeltine Creek (HAC-R1 and HAC-U; 2018 to 2022 for periphyton and composite and single-taxon benthic invertebrates) compared to reference (EDC-U; 2018 to 2022 for periphyton and composite and single-taxon benthic invertebrates).
2. The exposed area of lower Hazeltine Creek (HAC-D; 2017 to 2022 for periphyton, 2015 and 2018 to 2022 for composite-taxa and 2018 to 2022 for single-taxon benthic invertebrates) compared to reference (EDC-D; 2017 to 2022 for periphyton, 2015 and 2018 to 2022 for composite-taxa and 2018 to 2022 for single-taxon benthic invertebrates).
3. The exposed area of lower Edney Creek (E1; 2019 to 2022 for periphyton and composite and single-taxon benthic invertebrates) compared to reference (EDC-U; 2019 to 2022 for periphyton and composite and single-taxon benthic invertebrates).

Questions 1 and 2 were answered by conducting a two-way ANOVA assessing the exposed:reference ratios of results, with *Area* and *Year* as factors and assessing the interaction between *Area* and *Year.* The two-way ANOVA was competed *as* detailed in Section 3.4.3 (for Questions 1 and 2) to address the same questions.

Post-breach results (2015 to 2022) were also statistically contrasted to pre-breach data, where possible. Pre-breach data were collected for periphyton and composite-taxa benthic invertebrate tissue quality from HAC-U and HAC-D in 2010 (Table 4.4).[44] The comparisons to pre-breach were conducted using a censored one-way ANOVA with *Year* as the factor as described in Section 3.7.3.2 and were used to contrast post-breach results for periphyton tissue quality, composite-taxa benthic invertebrate tissue quality, and TTFs to pre-breach conditions. TTF data (calculated as described in Section 4.4.3.1) did not contain censored (i.e., < LRL) values, therefore the ANOVA models for comparison of TTFs were fit with least-squares estimation (i.e., not MLE) and $\log_{10}$ transformed response variables. Data used in these comparisons included the following:

[44] Pre-breach periphyton and composite-taxa benthic invertebrate tissue quality samples were also collected in 2011 to 2013 at HAC-U and HAC-D, and from HAC-U in 2009. Reported data for these samples included selenium as the only analyte, therefore these results were not included in statistical contrasts to pre-breach data.

1. Post-breach periphyton tissue quality, composite-taxa benthic invertebrate tissue quality, and TTF results from HAC-R1 and HAC-U compared to pre-breach results from HAC-U; and
2. Post-breach periphyton tissue quality, composite-taxa benthic invertebrate tissue quality, and TTF results from HAC-D compared to pre-breach results from HAC-D.

Although statistical analyses were conducted for all metals detected in the chemical analyses, data presentation, interpretation, and discussion were focused on the identified primary and secondary analytes (see Table 2.4). Plots of data that support the two-way ANOVA were presented for primary and secondary analytes that: 1) had a significant *Area* × *Time* interaction in the analyses; and 2) lacked a significant *Area* × *Time* interaction in the analyses but had a positive MOD (i.e., exposed concentrations were significantly higher than reference and the difference did not depend on year). Results of the contrasts to pre-breach (2010) are shown on the two-way ANOVA figures with an "*" indicating a significant difference relative to pre-breach.

All statistical analyses were conducted using R software (R Core Team 2022). A significance level $\alpha = 0.05$ was used for statistical comparisons, as was used for the evaluation of all chemical data in this report.

4.5 Supporting Measures

A variety of supporting physical and chemical information was used to support the interpretation of sediment and aquatic biological data collected from creeks as part of the CEMP. This information falls into two categories: 1) supporting information that was collected by Minnow during field collections; and 2) supporting information that was collected routinely by MPMC as part of ongoing CEMP monitoring components. Unless otherwise specified, the supporting measures outlined below belong to the first category (measures collected by Minnow).

4.5.1 Measures Collection

Supporting single spot water samples were collected from creek stations concurrent with periphyton community, benthic invertebrate community, and tissue quality sampling for comparison to BCWQG. These samples were collected on August 8, 2022 (not concurrent with biological sample collection) to ensure sample arrival at the laboratory was within the recommended hold times. Water samples were collected by wading into a mid-channel area, moving from downstream to upstream, so as not to collect water downstream of disturbed substrates, and collecting the samples from approximately half of the total water depth. Water quality data collected routinely by MPMC staff at stations near to the biological monitoring areas were also used in support of data interpretation (Figure 4.2). These data were subjected to an internal DQR by MPMC and were not further assessed for data quality in this report

(for details refer to Section 3.8.1). Immediately after collection, both spot and routine water quality samples were placed into a cooler with ice packs before being stored in a refrigerator until shipment (on ice) to the analytical laboratory (as detailed in Section 3.8.1).

Supporting measures and sampling information were collected at each of the creek monitoring stations to support data interpretation (Appendix Figure A.2.1, Appendix Tables A.2.1 to A.2.5). These included those described in Section 3.8.1 (excluding vertical depth profiles and Secchi depth) as well as the following: water velocity, substrate size (20 randomly selected substrate pieces measured per station), and general habitat characteristics assessed once for each monitoring area (channel measures, canopy cover, instream cover, periphyton coverage, and substrate characteristics) using methods adapted from Environment Canada (2012a).

4.5.2 Laboratory Analysis

Laboratory analyses of supporting spot and routine water quality samples were completed as described in Section 3.8.2 and included the parameters outlined in the CEMP routine surface water quality monitoring program (MPMC 2019). Upon completion of the analyses, a data report was provided by ALS to MPMC and Minnow as an Adobe Acrobat PDF file and a Microsoft Excel spreadsheet (Appendix G)[45].

4.5.3 Data Analysis

4.5.3.1 Summary Statistics

Summary statistics were calculated for water, sediment, and tissue quality parameters following the K-M methods described in Section 3.8.3.1. Additional information on specific parameters and applications of the summary statistics for chemical data are found within the methods sections for analysis of these data above (Sections 4.1.3 and 4.4.3 above). Summary statistics for biological endpoints (periphyton and benthic invertebrate community and productivity) were calculated using standard methods and formulae.

4.5.3.2 Water Quality Guideline Screening

Results of spot water quality sampling were screened against BCWQG (Appendix Table D.1.1; BCMOECCS 2021a,b) as outlined in Sections 3.8.3.2 and 3.8.3.3. Results of creek water quality sampling completed routinely by MPMC staff in the year preceding monitoring (i.e., September 2021 to August 2022) were also screened against BCWQG (see Sections 3.8.3.2 and 3.8.3.3 for details). These routine water quality data were also summarized by calculating sample size,

[45] Data reports for spot water quality sampling are included in Appendix G. Data from routine water quality monitoring completed by MPMC were provided to Minnow in Microsoft Excel format from the MPMC database and are these not included in Appendix G.

mean, SD, minimum, maximum, and % LRL values as described in Section 3.8.3.1. Plots comparing total and dissolved concentrations of primary and secondary analytes to BCWQG were prepared for routinely collected water quality samples (Table 2.4). Tabular screening against BCWQG was completed using Microsoft Excel and plots were generated using R (R Core Team 2022).

5 RESULTS – LAKE HABITAT

5.1 Polley Lake

5.1.1 Sediment Quality

Sediment quality monitoring in 2022 was completed in a shallow exposed area of Polley Lake (POL-S) with a similar shallow area of Bootjack Lake (BOL-S) serving as reference (Figure 3.1, Table 3.1). A review of 2022 sediment data quality (Appendix B) indicated that the data met the established DQOs. Specifically, the data were characterized by appropriate LRLs, negligible analyte concentrations in MB samples, excellent laboratory precision and field sampling precision, and excellent laboratory accuracy. Overall, the 2022 sediment quality data can be used with a high level of confidence for interpretation. A review of 2022 supporting water data quality (Appendix B) indicated the data were characterized by appropriate LRLs, negligible analyte concentrations in MB samples, and excellent laboratory precision and field sampling precision. Laboratory accuracy for supporting water samples was considered acceptable since all laboratory control samples met the DQO, although some matrix spikes (MS) results could not be detected due to high background concentrations. Hold time exceedances occurred for four analytes in six separate samples. Most of these hold time exceedances occurred after receipt of the samples by the laboratory (i.e., samples were received by the laboratory in sufficient time for analysis). For two samples, the hold times were exceeded prior to laboratory receipt due to a combination of challenges associated with the logistics of expedited sample shipments from a remote area and the short hold times. Analyte results with hold time exceedances were similar to those samples without hold time exceedances 2022 and were within the range of historic results, suggesting little if any impact of the hold time exceedances on analyte results. Overall, the 2022 water quality data can be used with a good level of confidence for interpretation.

Sediments collected from the shallow monitoring area of Polley Lake (POL-S) in 2022 were composed of predominantly silt and sand (mean = 53.7% and 38.5%, respectively) while the reference area sediments had higher sand and lower silt content (station BOL-S; mean = 50.7% and 41.9%, respectively; Table 5.1; Appendix Tables C.2.1 to C.2.3). Sediments from POL-S in 2022 had a lower sand and higher silt content than in 2019 when the area was last sampled (mean = 67.0% and 29.8%, respectively). The mean TOC and total nitrogen content of POL-S sediments in 2022 (mean = 1.03% and 0.0958%, respectively) were lower than the associated reference sediments (mean = 8.80% and 0.447%, respectively), as was also observed in 2019 (Table 5.1; Appendix Tables C.2.2 and C.2.3). For TOC content, the lower content in POL-S sediments was significant in both 2019 and 2022, and the exposed TOC content of POL-S

Table 5.1: Summary of Sediment Quality Data for Polley Lake (POL-S; Exposed) and Bootjack Lake (BOL-B2; Reference) Shallow Areas, 2019 to 2022

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: "-" = no data, SD - Standard Deviation. ***Bold/Italics -*** Exposed value (Polley Lake) is > reference 95th percentile values (<5th percentile value for pH).

[a] British Columbia Working Sediment Guidelines (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b).

[b] For calculation of reference 95th percentile values (2019 to 2022) see Appendix Table C.2.1.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

sediments did not change significantly between the two sampling events, relative to reference (Figure 5.1; Appendix Tables E.1.1 and E.1.2).

The mean concentration of 17 out of 34 analytes in POL-S sediments (<63 µm fraction) in 2022 exceeded the reference (BOL-S) 95th percentile concentrations. Among these analytes, arsenic, copper, and iron were the only analytes with mean concentrations in 2022 that exceeded both the WSQG and the reference 95th percentile values (Analytes of Interest; Table 5.1; Appendix Tables C.2.2 and C.2.3). Mean arsenic concentrations in POL-S sediments exceeded the lower WSQG by 2.4 times, and mean copper and iron concentrations exceeded the upper WSQG by 3.4 and 1.5 times, respectively (Table 5.1; Appendix Table C.2.3). Copper concentrations at the reference area (BOL-S) also exceeded the lower WSQG by 2.5 times, indicating sediments in the region have naturally elevated copper concentrations (Figure 5.1; Appendix Table E.1.2).

Mean concentrations of these three Analytes of Interest in POL-S sediments were significantly elevated relative to reference sediments in 2019 and 2022, and the exposed:reference ratio was temporally stable between 2019 and 2022 (i.e., exposed concentrations did not differ temporally relative to reference (Figure 5.1; Appendix Table E.1.1). Mean iron concentrations, were substantially lower in 2022 (mean = 64,820 mg/kg) than in 2019 (mean = 136,800 mg/kg), but not significantly so, due to the high variability observed in 2019 (range = 55,800 to 221,000 mg/kg; Table 5.1; Appendix Tables E.1.1, E.1.2, C.2.3).

Arsenic, copper, and iron concentrations were significantly negatively correlated with TOC and total nitrogen content when sediments from both POL-S and BOL-S were considered (Appendix Table E.1.3, Appendix Figure E.1.1). These results were highly leveraged by the highest analyte concentrations and lowest TOC content occurring in POL-S sediments and highest TOC and total nitrogen content occurring in BOL-S sediments (Appendix Figure E.1.1). These relationships are consistent with a breach-related influence defined by the input of inorganic sediments with elevated analyte concentrations to Polley Lake.

5.1.2 Sediment Toxicity

Sediment toxicity testing using *H. azteca* in 2022 (14-day standard test) was completed at a shallow exposed area of Polley Lake (POL-S), with a similar shallow area of Bootjack Lake (BOL-S) serving as reference (Figure 3.1; Section 3.3). A review of sediment toxicity test data quality indicated that tests met control acceptability criteria and all water quality parameters remained within acceptable ranges throughout the tests (Nautilus 2022; Appendix G). Reference toxicant test results fell within the acceptable range and therefore the sensitivity of organisms used in the tests was considered appropriate (see the DQR for details; Appendix B). All ammonia concentrations were at levels that are not expected to cause adverse effects to *H. azteca* (Appendix G). Examination of laboratory bench sheets indicated that temperature,

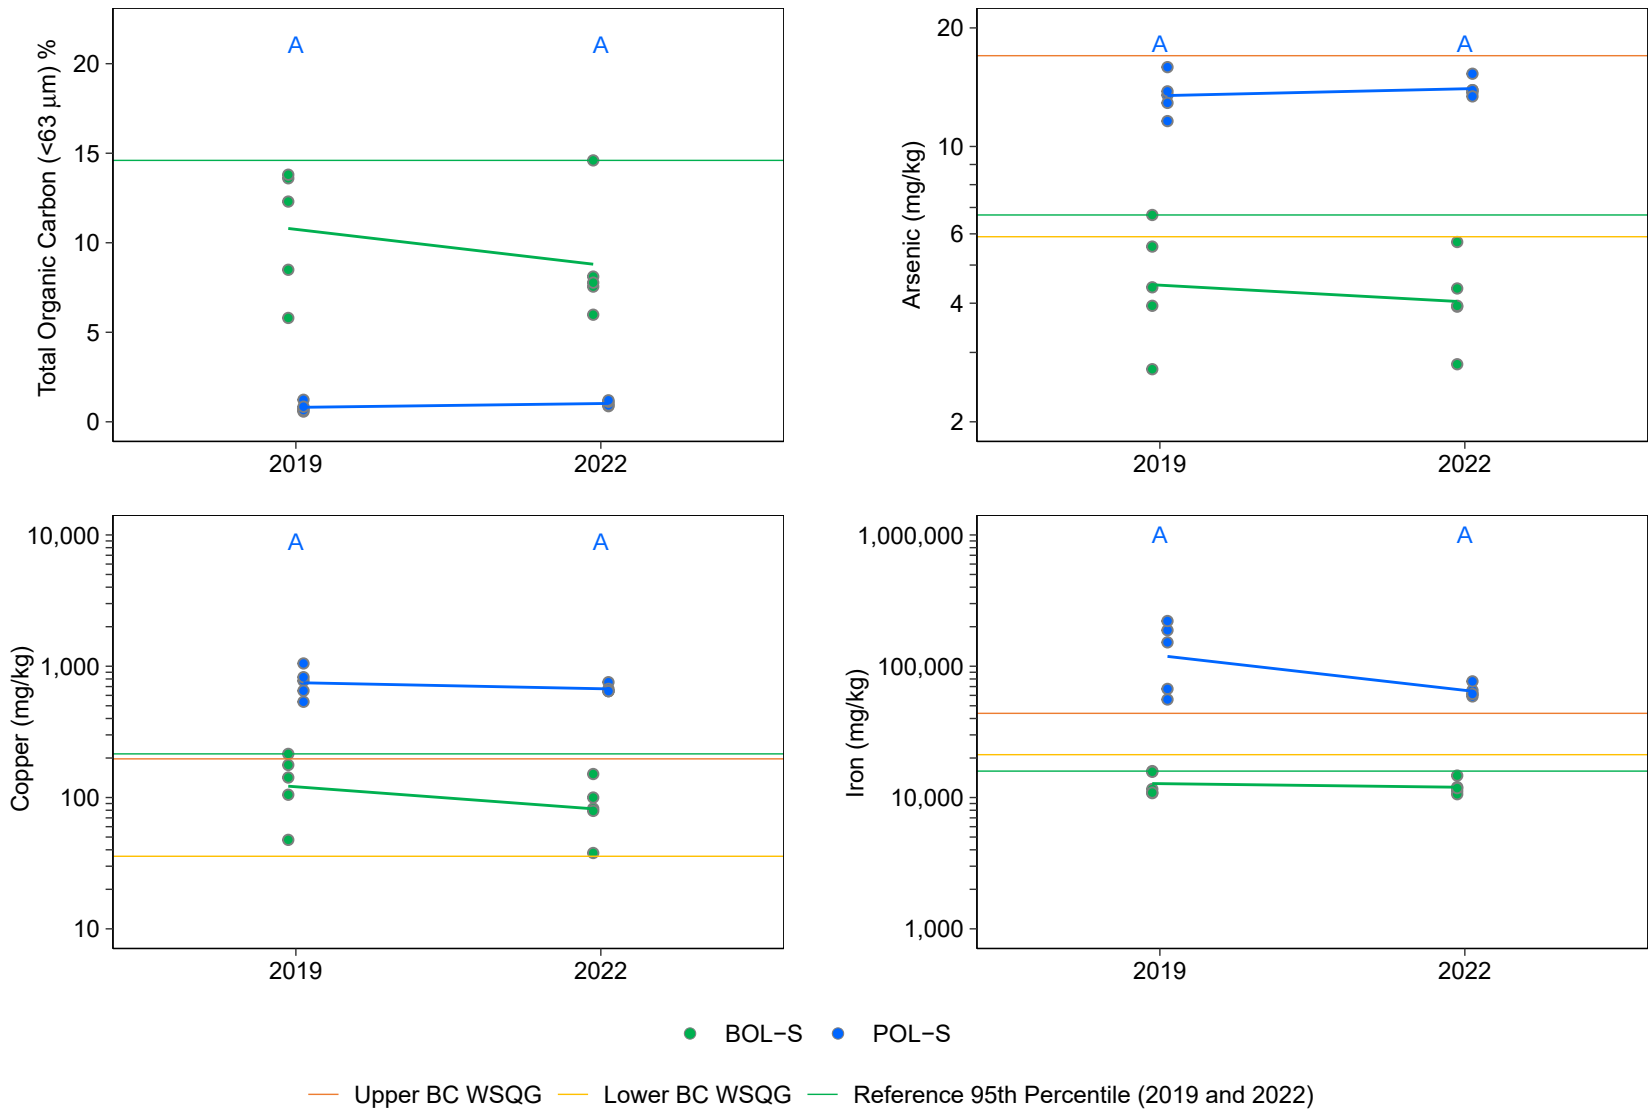

Figure 5.1: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for Polley Lake (POL-S; Exposed) and Bootjack Lake (BOL-B2; Reference) Shallow Areas, 2019 to 2022

Notes: BC WSQG = British Columbia Working Sediment Quality Guideline (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b). The reference 95th Percentile was calculated using data from 2019 and 2022. Green represents reference areas and blue represents exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and $\log_{10}$-transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences - TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

dissolved oxygen, conductivity, and pH were all stable over the course of the toxicity tests (Appendix G).

Survival of *H. azteca* exposed to POL-S sediments in 2022 showed no unacceptable response relative to the reference sediments (BOL-S) and the laboratory control. Growth of *H. azteca* exposed to POL-S sediments also showed no unacceptable response, with growth 14% greater than reference (BOL-S) sediments and 26% greater than the laboratory control (Table 5.2). The survival and growth responses observed in 2022 were similar to those in 2019 (Figure 5.2); which indicated a low survival response relative to the lab sand control (but no unacceptable response relative to the reference sediments) and no unacceptable growth response (Minnow 2020a).

The overlying water of the bioassay test vessels in 2022 had concentrations of dissolved copper that were notably higher for POL-S sediments (mean = 0.028 mg/L measured on day 14 of the test; Appendix G) than the overlying waters for reference sediments (BOL-S; 0.0049 mg/L). Dissolved copper concentrations in the bioassay test vessels for POL-S sediments were also notably higher than those documented in field-collected water samples (mean = 0.0036 mg/L; Appendix Table C.1.2). This suggests some copper mobilization in the test set-up that has either not occurred *in situ* or has attenuated over time. Despite the elevated dissolved copper concentations in the bioassay test vessels relative to *in situ* conditions, the absence of survival or growth effects to *H. azteca* in toxicity testing indicates the shallow exposed sediments from Polley Lake are able to support benthic invertebrate organisms.

5.1.3 Plankton Community and Productivity

Plankton community and productivity monitoring in 2022 was completed three times (June, July, and August) in Polley Lake (POL-P2) and at a corresponding reference area (Bootjack Lake; BOL-B2; Figure 3.3, Tables 3.4 and 3.5). A review of the 2022 plankton data quality (Appendix B) indicated that the data met the established DQOs. Specifically, the data were characterized by good agreement between laboratory duplicates for both phytoplankton and zooplankton community results, indicating good laboratory precision and accuracy. Additionally, phytoplankton productivity measurements (chlorophyll-a) results were of acceptable detectability (above the LRL), negligible analyte concentrations in MB samples, excellent laboratory precision, and excellent laboratory accuracy. Chlorophyll-a sample hold times were exceeded by one day in one sample from August due to a combination of field sampling logistics (field filtration was not possible), challenges associated shipping from a remote area, and the short (two day) recommended hold time for unfiltered chlorophyll-a samples (see Appendix B for details). The chlorophyll-a result for the single sample that exceeded the hold time was similar to results from samples without hold time exceedances 2022 and were

Table 5.2: Summary of *Hyalella azteca* 14-day Survival and Growth Responses for Sediment Toxicity Testing of Polley Lake (POL-S; Exposed) and Bootjack Lake (BOL-S; Reference) Shallow Areas, 2022

Results and Classification	Polley Lake	
	POL-S	
	Survival	Growth[a]
	%	mg
Raw Area Result	94.0 ± 8.9	0.24 ± 0.03
Raw Laboratory Control Result	96.5 ± 5.50	0.19 ± 0.03
Raw Reference Result (BOL-S)	90.0 ± 7.10	0.21 ± 0.01
Control Normalized Response	97%	126%
Reference Normalized Response	104%	114%
Statistically Significant Reduction from Control	N	N
Statistically Significant Reduction from Reference	N	N
CLASSIFICATION	**NR**	**NR**

no unacceptable response (<20% reduction) - **NR**.
low response (20-50% reduction) and not significantly different than control and reference - **LR**.
moderate response (20-50% reduction) and significantly different than control and reference - **MR**.
high response (>50% reduction) - **HR**.

Note: Y = Yes, N = No.

[a] Growth = dry weight per surviving organism (mg).

[b] Where comparisons to mean laboratory control result and the mean field reference result did not fall into the same response classification, the result was discussed relative to both the control and the field reference.

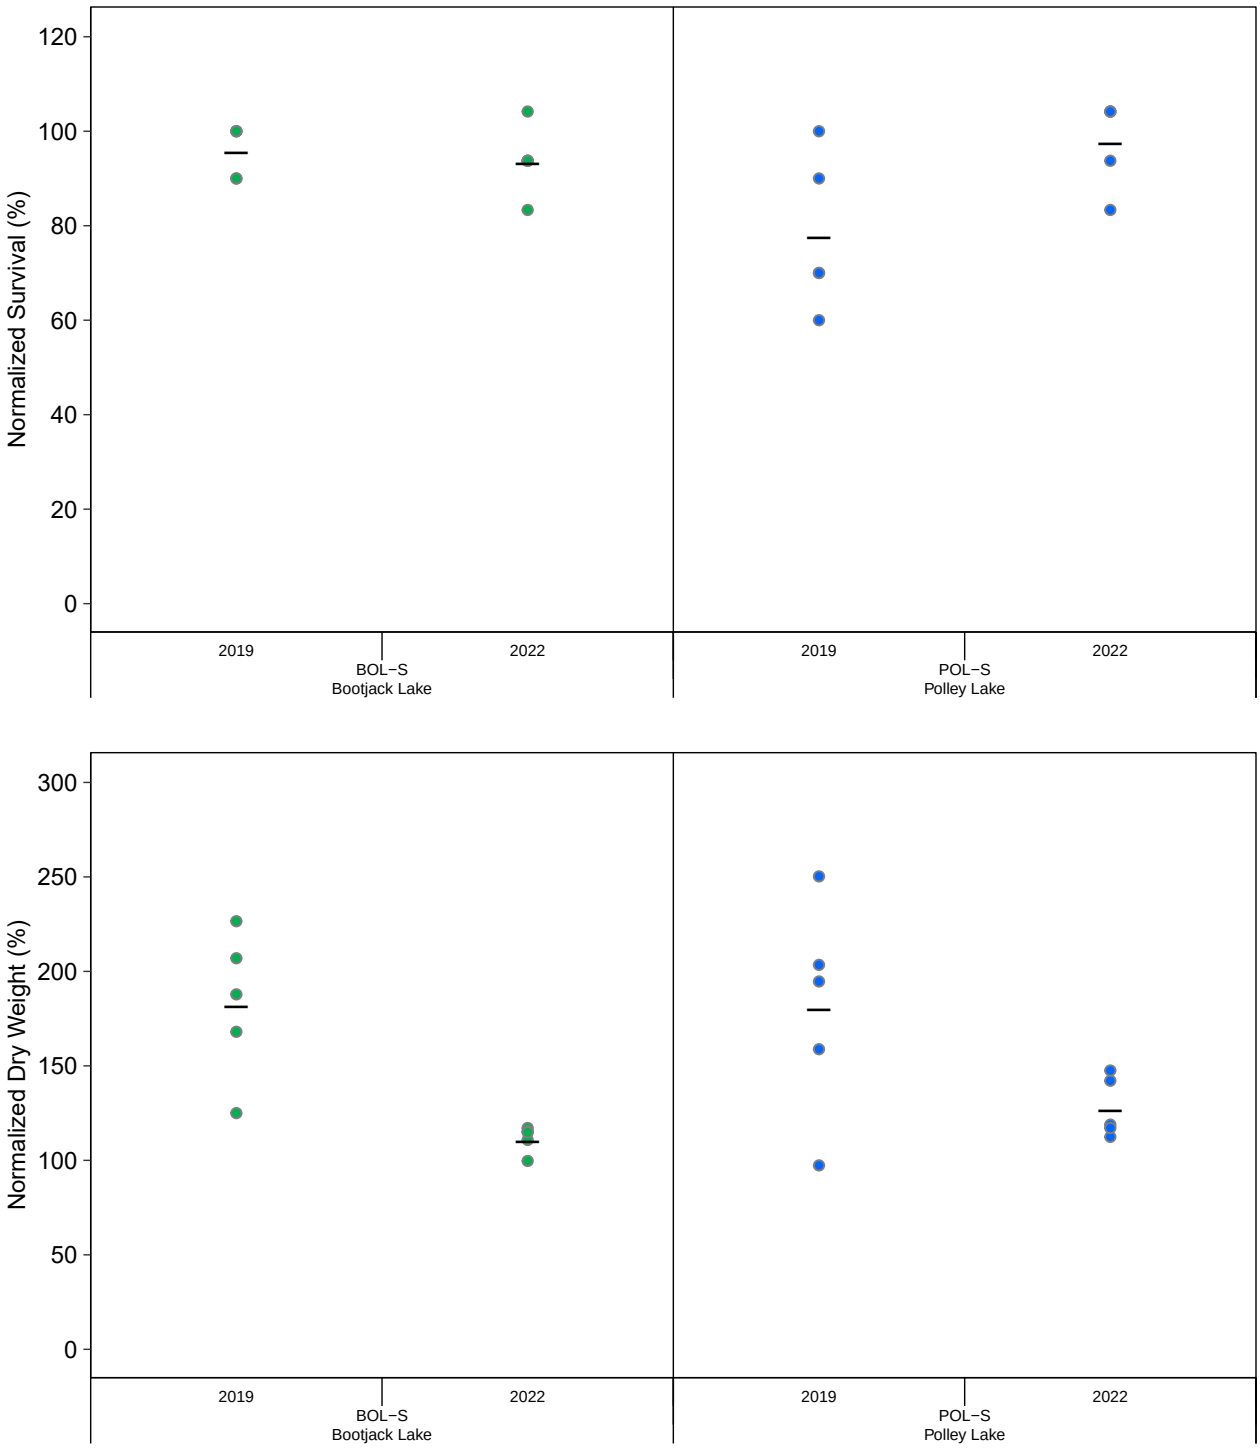

Figure 5.2: *Hyalella azteca* 14-day Survival and Growth Responses for Sediment Toxicity Testing of Polley Lake (POL-S; Exposed) and Bootjack Lake (BOL-S; Reference) Shallow Areas, 2019 to 2022

Notes: Plots are only included for primary or secondary analytes with a significant postive exposed - reference difference in 2022 or in all monitoring years. Survival data were normalized to the control acceptance criteria, and the samples were calculated as a percentage of normalized control performance. Growth data were normalized to laboratory controls run during the test with the reference site for that area.

within the range of historic results, suggesting little if any impact of the hold time exceedances on analyte results. Overall, the plankton community and productivity data for Polley Lake can be used with a high level of confidence for data interpretation. A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

5.1.3.1 Phytoplankton

5.1.3.1.1 Community

Phytoplankton densities in Polley Lake (POL-P2) in 2022 were highest in August and were mid-range in July, while densities at Bootjack Lake (reference area; BOL-B2) in 2022 were highest in July. The taxon richness reported in June was within the range observed in July at both POL P2 and BOL-B2 in 2022, but richness in both lakes was highest in August (Appendix Figure E.2.1, Appendix Table C.3.1). Phytoplankton density, and Simpson's Diversity and Evenness were significantly higher at POL-P2 compared to BOL-B2 in July 2022, while taxon richness was significantly lower (Figure 5.3, Table 5.3; Appendix Tables C.3.1, C.3.2). Total phytoplankton density at POL-P2 was higher than at BOL-B2 in 2022 due to the combined effects of higher densities of Chlorophytes, Chrysophytes, and Cryptomonads (Appendix Figure E.2.2, Appendix Table E.2.1).

Temporal analyses indicated variability in density and Simpson's Diversity and Evenness at POL-P2 from 2019 to 2022, but these endpoints were largely similar to or higher than reference over that period. Taxon richness showed temporal stability from 2019 to 2022 and was similar to or lower than reference over that period. Specifically, mean phytoplankton density at POL-P2 in 2022 was significantly lower than in 2019 and 2020; however, a similar significant decrease in density was observed at BOL-B2 among these years (Figure 5.3, Table 5.3). Densities were also lower in 2021 compared to 2019 in both lakes. The significant decrease in phytoplankton densities at both POL-P2 and BOL-B2 in 2022 relative to previous years (relative to 2019 and 2020 at POL-P2 and relative to 2019 to 2020 at BOL-B2; Figure 5.3, Table 5.3) was driven by decreased densities of Cyanobacteria at both locations since 2019 (Appendix Figure E.2.2, Appendix Table E.2.1). Given that the densities of Cyanobacteria decreased in a similar manner in both waterbodies, it is likely that this decrease was related to local environmental factors (e.g., water temperature), with seasonal fluctuations in surface water temperature being very similar in both waterbodies (Appendix Figures A.1.1, C.1.1). Taxon richness at POL-P2 from 2019 to 2022 was lower than at BOL-B2 except in 2020, was temporally stable over this period, was generally within the range of post-breach (2015 to 2018) and was lower than baseline at both POL-P2 and BOL-B2 (Figure 5.3, Table 5.3; Appendix Figure E.2.1). It is possible that some of the variability in richness among the baseline (1995 and 1996), post-breach (2015 to 2018),

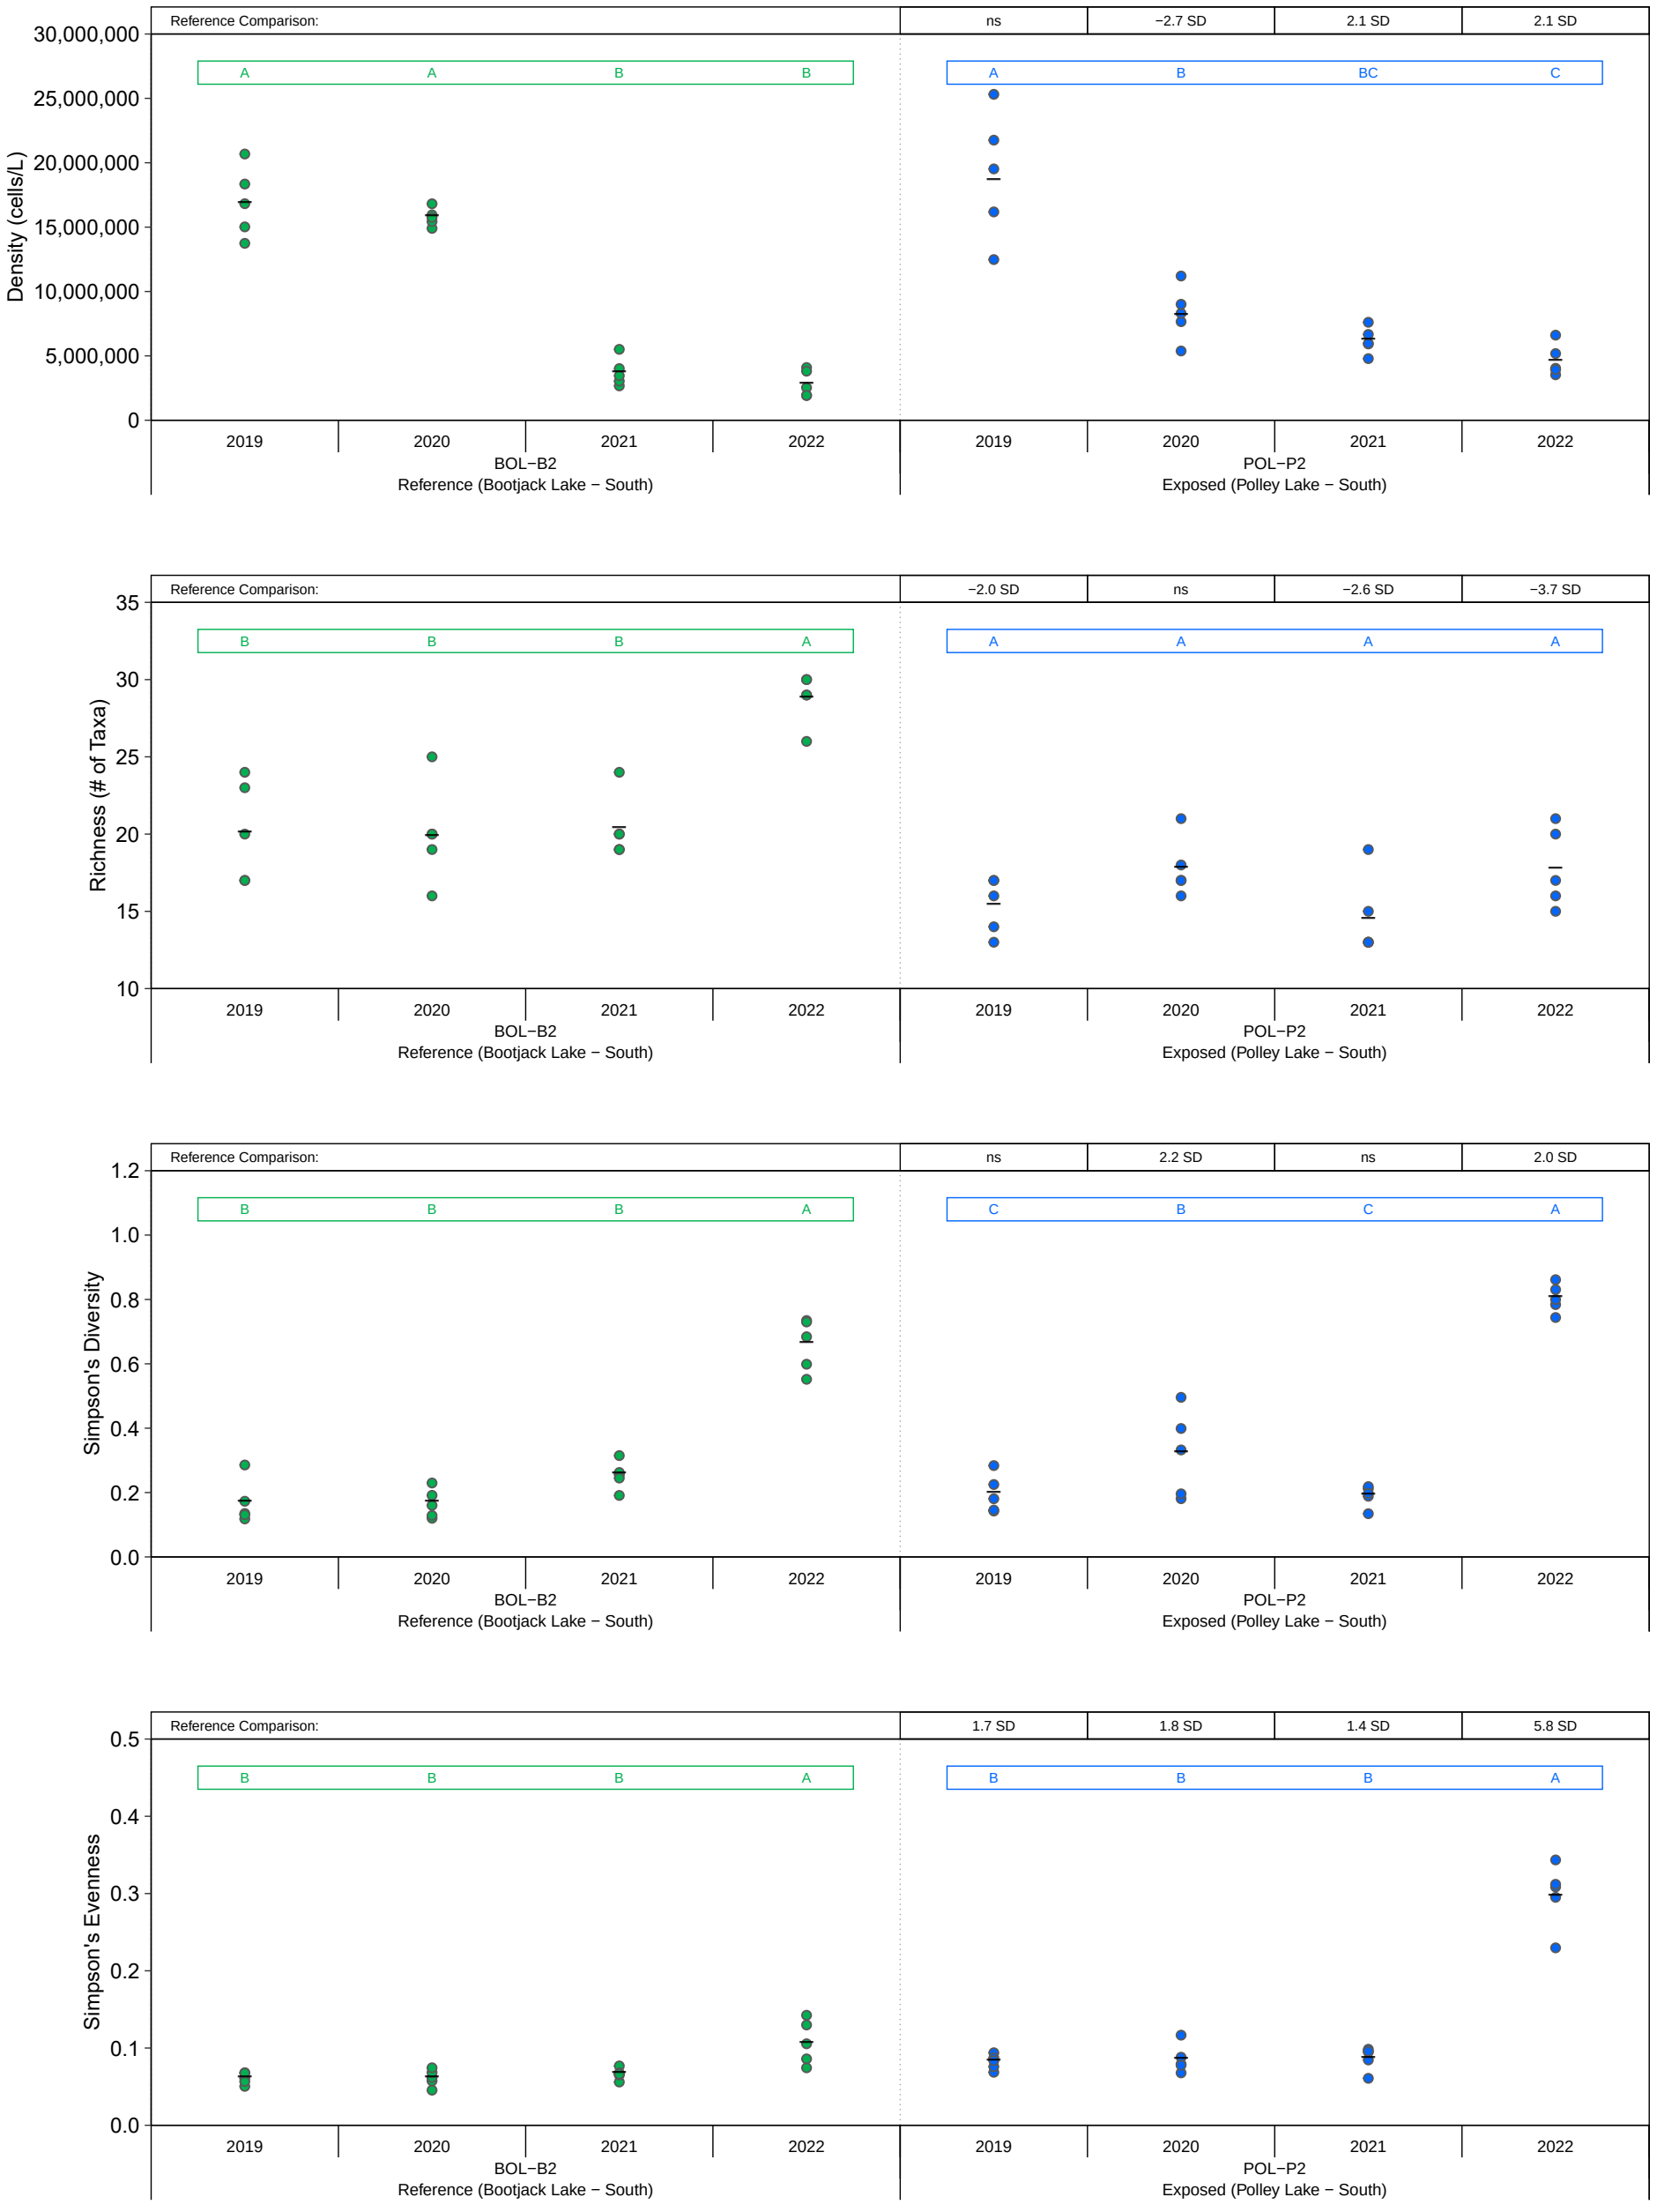

Figure 5.3: Phytoplankton Community Endpoints for Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, $\log_{10}$−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of phytoplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated phytoplankton results collected in June and August 2022, see Appendix Table C.3.1.

Magnitude of Difference (MOD) < -2.
Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available, nc = no comparison, ns = no significance, nm = contrast Magnitudes of Difference (MODs) could not be calculated because the Median Absolute Deviation (MAD) = 0, cells/L = Cells per litre. µg/L = micrograms per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log $_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

and 2019 to 2022 sampling periods was related to changes in phytoplankton taxonomists (see Minnow 2020a for details). Simpson's Diversity was higher in 2022 compared to previous years (2019 to 2021) at POL-P2 and was either similar to (in 2019 and 2021) or significantly higher (2020 and 2022) than at BOL-B2. Similarly, Simpson's Evenness at POL-P2 was higher in 2022 compared to previous years (2019 to 2021) and was consistently higher than at BOL-B2 from 2019 to 2022 (Figure 5.3, Table 5.3; Appendix Tables C.3.1, C.3.2).

In 2022, the phytoplankton community at POL-P2 was dominated by Cyanobacteria in July and August but was dominated by Diatoms and Chlorophytes in June (Figure 5.4; Appendix Tables C.3.1 and C.3.2). At BOL-B2, the phytoplankton community was dominated by Cyanobacteria in June, July, and August, although the extent of community dominance was lowest in June (Figure 5.4; Appendix Tables C.3.1 and C.3.2). The mean relative densities (%) of the dominant phytoplankton taxa (Chlorophytes and Chrysophytes) were similar or higher at POL-P2 compared to BOL-B2 in July 2022, except Cyanobacteria which was significantly lower. Specifically, % Cyanobacteria decreased significantly at both POL-P2 and BOL-B2 in 2022 relative to previous years (2019 to 2021) and was lower at POL-P2 than reference in 2020 and 2022. The relative densities of Chrysophytes and Chlorophytes were significantly higher at both POL-P2 and BOL-B2 in 2022 compared to 2019 to 2021. The relative density of Chrysophytes was higher at POL-P2 than at BOL-B2 from 2019 to 2022 while the relative density of Chlorophytes was higher in 2020 and 2022 (Figure 5.4; Appendix Figure E.2.2, Appendix Tables C.3.1, C.3.2). Cryptomonad relative density was significantly higher from 2020 to 2022 at POL-P2 compared to 2019, and the relative density of Cryptomonads at POL-P2 has varied compared to BOL-B2 across these monitoring years but was similar to reference in 2022. The relative density of Diatoms at POL-P2 decreased significantly between 2019 and 2021, but significantly increased in 2022 compared to previous years at both POL-P2 and BOL-B2. Diatom relative density at POL-P2 was not significantly different than at BOL-B2 in 2022, despite being higher and lower than BOL-B2 in 2020 and 2021, respectively (Figure 5.4; Appendix Figures E.2.2, Appendix Tables C.3.1, C.3.2, E.2.1). The increases observed in Diatom, Chlorophyte, and Chrysophyte relative densities in 2022 relative to prior years were a direct result of lower Cyanobacteria densities and therefore relative densities. The absence of compensatory increases in the densities of Diatoms, Chlorophytes, and Chrysophytes indicates that this decline in Cyanobacteria densities did not lead to a significant increase in the densities of other types of phytoplankton within the community (Appendix Figure E.2.2, Appendix Tables C.3.1, C.3.2, E.2.1), which is reflected in the decreased total density in Polley Lake in 2022 compared to prior years (2019 and 2020; Table 5.3).

Phytoplankton density data at POL-P2 showed patterns that were generally similar to those for relative densities, with the following exceptions. The relative densities of Diatoms, Chlorophytes,

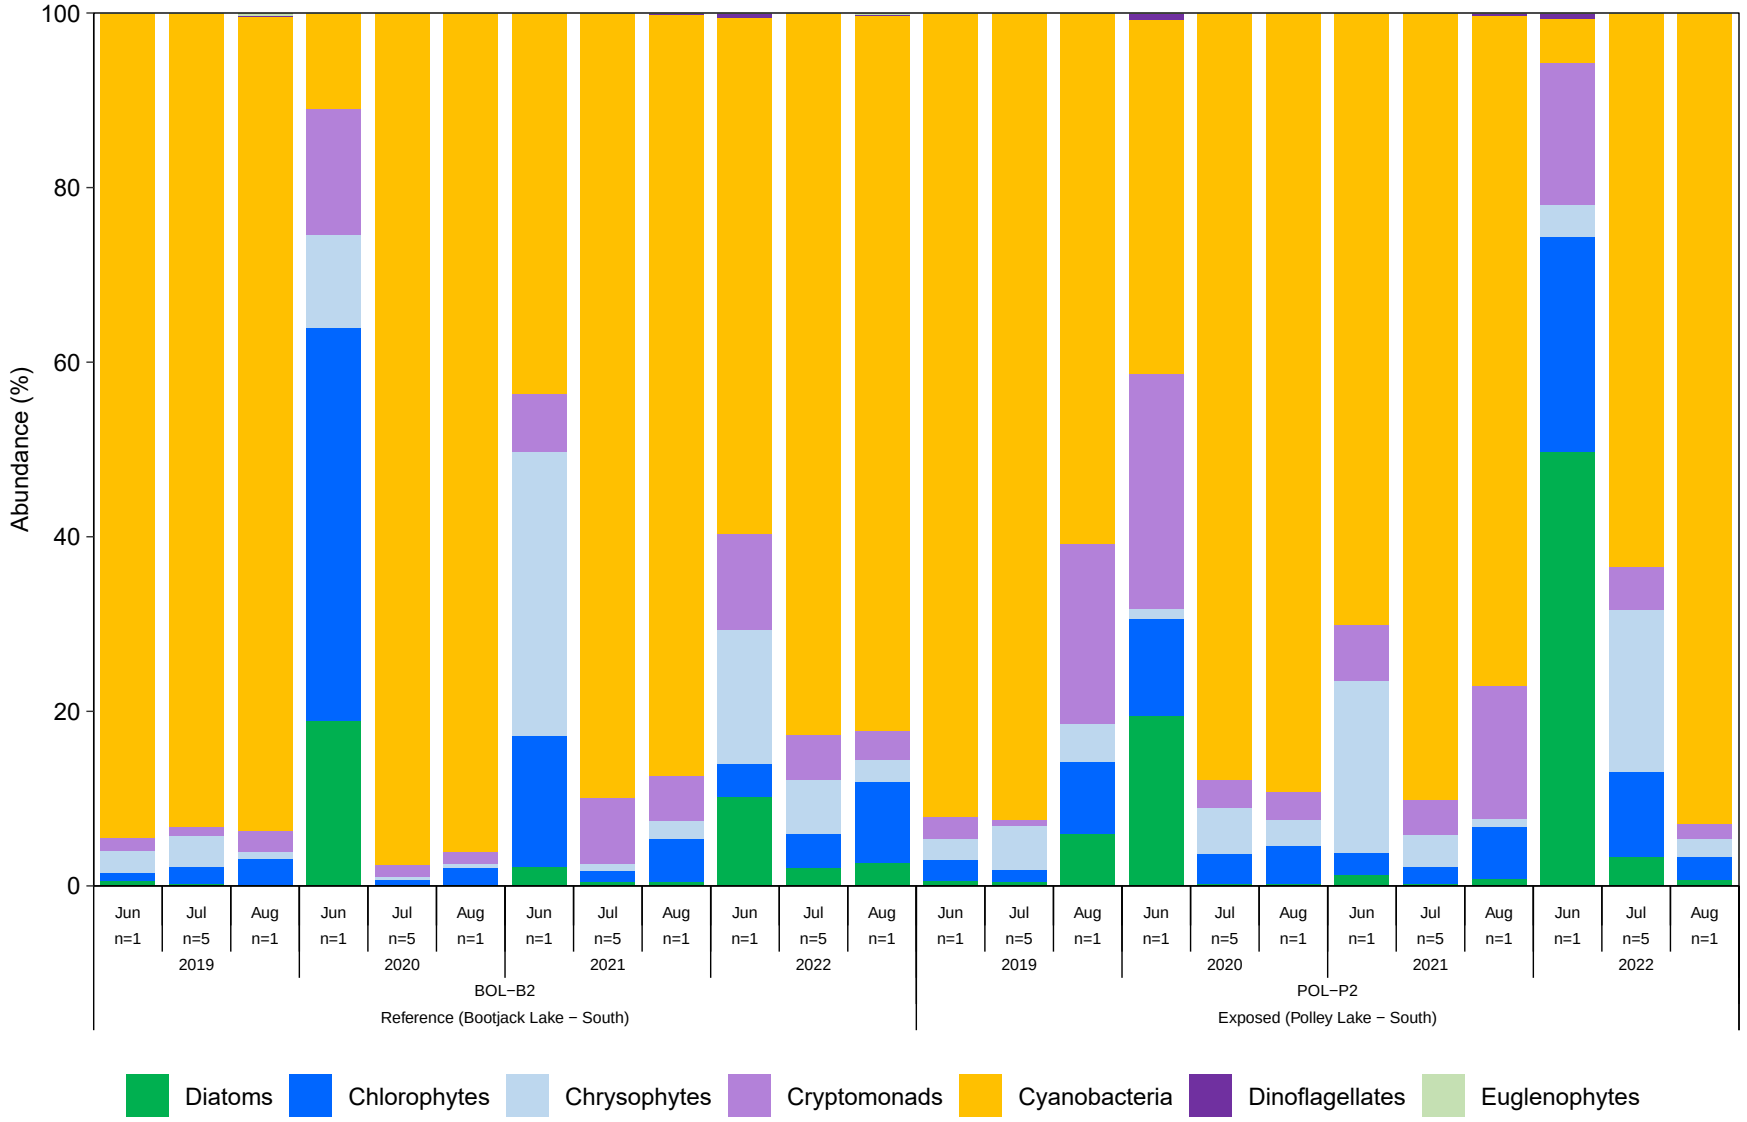

Figure 5.4: Relative Mean Densities of Major Phytoplankton Community Taxonomic Groups for Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Areas, 2019 to 2022

and Chrysophytes at POL-P2 and BOL-B2 increased between 2019 and 2022 but cell densities of these groups in 2022 were similar to cell densities in 2019 (Appendix Figures E.2.2, E.2.3, Appendix Tables C.3.1, C.3.2, and E.2.1). The density of Cryptomonads was higher at POL-P2 than at BOL-B2 in 2022 while the relative density of Cryptomonads was similar between the two areas. The relative density of Cyanobacteria was lower at POL-P2 than at BOL-B2 in 2022 while the density of Cyanobacteria was similar between the two areas. Cyanobacteria density decreased significantly at POL-P2 in 2022 relative to 2019 to 2021, and as outlined above, this was the primary driver for the corresponding decreases in total density among the same years (Appendix Figure E.2.2, Appendix Table C.3.1, C.3.2, E.2.1). As in previous years, phytoplankton densities and relative densities at both POL-P2 and BOL-B2 show a succession towards communities being more dominated by Cyanobacteria as the summer progressed from June to August (Figure 5.4; Appendix Table C.3.1), which was likely a result of increasing water temperatures (Appendix Figures A.1.1, C.1.1; Schnurr and Allen 2015).

Overall, the phytoplankton community in Polley Lake in July 2022 was characterized by total densities, and Simpson's Diversity and Evenness that were significantly higher than Bootjack Lake (reference), but taxon richness that was significantly lower than reference. Total density in Polley Lake was lower in July 2022 than in 2019 and 2020, a decrease that was driven by decreased Cyanobacteria densities that was also observed at the reference. Both Polley and Bootjack Lake experienced succession to Cyanobacteria dominance of the phytoplankton community in July and August, likely due to higher water temperatures in the photic zone in late summer which favour Cyanobacteria. Taxon richness was lower in Polley Lake compared to the reference area from 2019 to 2022, except for 2020 when richness was similar between the two areas. Simpson's Diversity and Evenness in Polley Lake was similar to or higher than the reference area in each monitoring year (2019 to 2022). Phytoplankton community composition in Polley Lake has consistently (i.e., in each year from 2019 to 2022) been characterized by higher relative densities of Chrysophytes compared to Bootjack Lake while the differences in relative densities between Polley Lake and Bootjack Lake in other taxonomic groups (i.e., Diatoms, Chlorophytes, Cyanobacteria, and Cryptomonads) have been variable over time. The similarity or higher result for most primary endpoints in Polley Lake compared to reference (density, Simpson's Diversity and Evenness), and the temporal stability (either within Polley Lake or relative to the reference area) for those endpoints in Polley Lake that were lower than reference (e.g., taxon richness), are suggestive of a lack of mine-related influence on the phytoplankton community of Polley Lake.

5.1.3.1.2 Productivity

Chlorophyll-a concentrations were highest in July and August at POL-P2 and highest in June at BOL-B2 in 2022, with the mean of July samples similar to June at POL-P2 and similar to August at BOL-B2 (Appendix Table C.3.1, Appendix Figure E.2.1). Chlorophyll-a concentrations were significantly higher at POL-P2 than at BOL-B2 in July 2022 despite being significantly lower in 2021, and similar between the two lakes in 2019 and 2020. Although chlorophyll-a concentrations have been consistent at BOL-B2 from 2020 to 2022, they have fluctuated across these years at POL-P2, which has largely driven the variability in comparisons between the two lakes (Figure 5.5, Table 5.3; Appendix Tables C.3.1 and C.3.2). Changes in phytoplankton productivity at POL-P2 over time may be related to local natural variability in physical (e.g., light exposure and water temperatures) and chemical factors (e.g., nutrient concentrations) that has affected the two lakes differently. For instance, the peak summer temperature reported in Polley Lake exceeded that in Bootjack Lake in 2022, while nutrient (nitrogen and phosphorus) concentrations were similar (Appendix Figure C.1.1; Appendix Table C.1.3).

A lake's trophic status classification corresponds to its overall productivity in terms of algal biomass (chlorophyll-a) and nutrient concentration (Wetzel 2001). The trophic statuses of Polley Lake and Bootjack Lake in 2022, based on July chlorophyll-a concentrations (range = 2.46 to 3.78 µg/L for POL-P2, 1.82 to 2.5 µg/L for BOL-B2, were classified as mesotrophic (2.5 to 8.0 µg/L) and oligotrophic (<2.5 µg/L; Vollenweider and Kerekes 1982), respectively (Figure 5.5; Appendix Tables C.3.1 and C.3.2). Total chlorophyll-a concentrations in 2022 in Polley Lake and Bootjack Lake were within the range of baseline (1995 and 1996) and post-breach values for both lakes, except for a single anomalous result at BOL-B2 in June 2022 which was higher than most previous results (except the June 2021 result; Appendix Figure E.2.1, Appendix Tables C.3.1 and C.3.2). While the trophic state of Polley Lake increased from oligotrophic to mesotrophic between 2021 and 2022 (based on July data), this represented a return to the same mesotrophic status observed in 2019 (Figure 5.5; Appendix Tables C.3.1 and C.3.2).

5.1.3.2 Zooplankton

5.1.3.2.1 Community

Zooplankton densities in 2022 in Polley Lake (POL-P2) and Bootjack Lake (BOL-B2) were highest in July and June, respectively, while densities at both lakes were lowest in August (Appendix Figure E.2.4, Appendix Tables C.3.3, C.3.4). Zooplankton taxon richness at POL-P2 in 2022 was highest in July and lowest in both June and August, while richness at BOL-B2 was

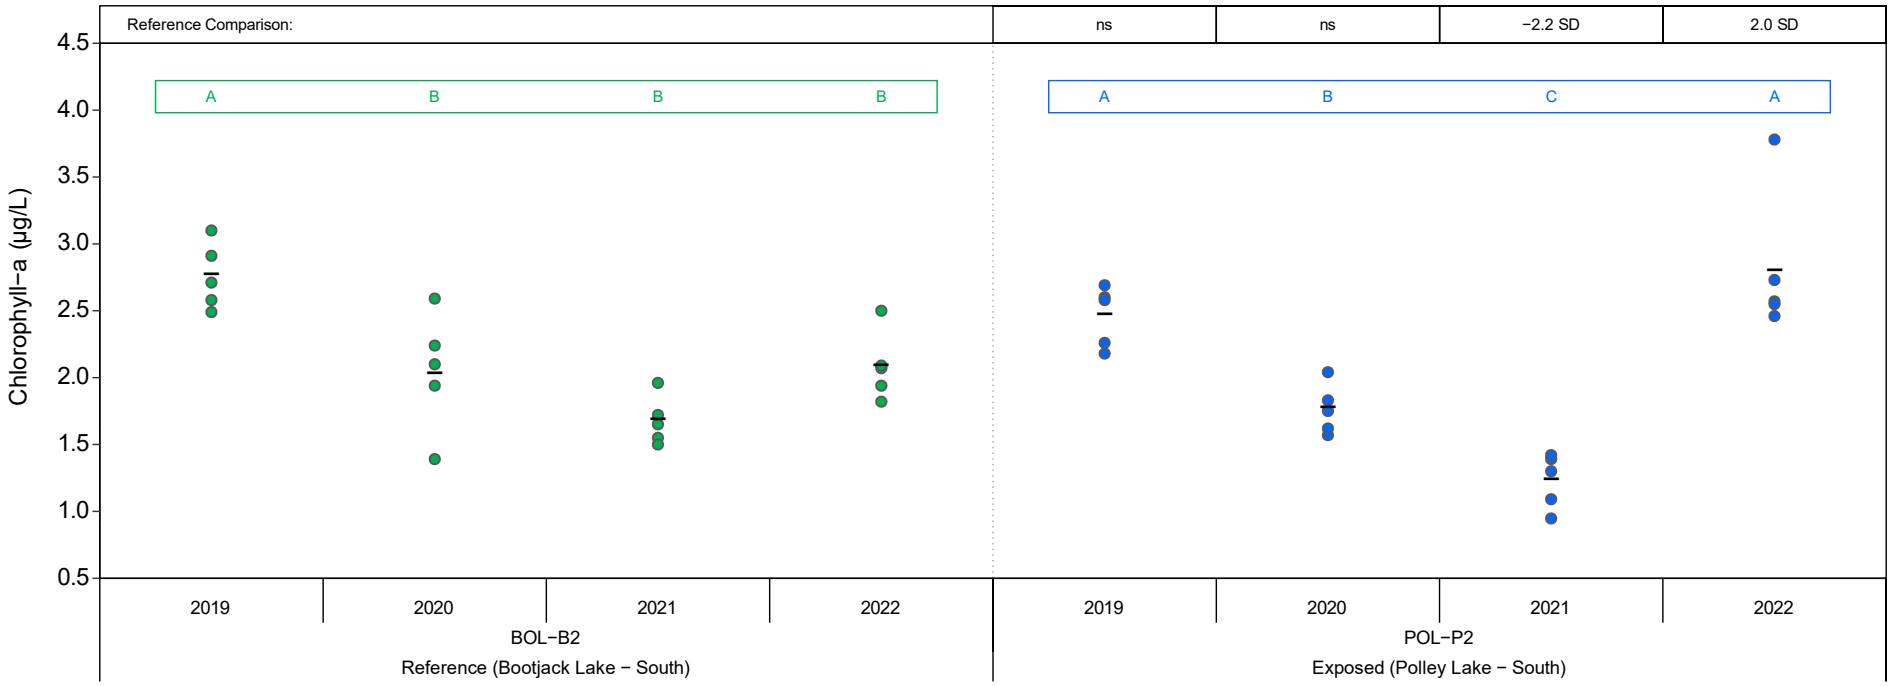

Figure 5.5: Phytoplankton Chlorophyll−a Concentrations for Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of phytoplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated phytoplankton results collected in June and August 2022, see Appendix Table C.3.1.

highest in August and lowest in July. Zooplankton density, taxon richness, and Simpson's Diversity and Evenness at POL-P2 were similar to BOL-B2 in July 2022 (Figure 5.6, Table 5.4).

Temporal analyses indicated that mean zooplankton density at POL-P2 in July 2022 was significantly higher than in 2019 or 2021 but similar to 2020. Density at POL-P2 was also similar to BOL-B2 in both 2020 and 2022 despite within-lake temporal variation at POL-P2. This temporal variability was reflected in part in temporal changes of zooplankton densities at BOL-B2, where density in 2022 was also higher than in 2019 (Figure 5.6, Table 5.4; Appendix Tables C.3.3, C.3.4). Taxon richness at POL-P2 was significantly higher in 2022 compared to 2020 but was similar to richness in 2019 and 2021, while richness at BOL-B2 was higher in 2022 compared to 2019 but similar in 2020 and 2021 (Figure 5.6, Table 5.4). Simpson's Diversity and Evenness at POL-P2 in 2022 was similar to prior monitoring years (2019 to 2021; Figure 5.6, Table 5.4). While Simpson's Diversity and Evenness were lower at POL-P2 than at BOL-B2 in 2019 and 2020, the lack of change in these indices at POL-P2 over time combined with decreasing Diversity and Evenness at BOL-B2 has led to the similarity of these endpoints between the two areas in 2021 and 2022.

The zooplankton community at POL-P2 in 2022 was dominated by Rotifera in June, Copepod Nauplii and Rotifera in July, and Copepod Nauplii and Cyclopoida in August, which differed from the dominance of Rotifera observed in June, July, and August at BOL-B2 (Figure 5.7; Appendix Tables C.3.3, C.3.4). In July 2022, the relative densities (%) of Calanoida, Cladocera, and Copepod Nauplii were significantly higher at POL-P2 than at BOL-B2, while the relative densities of Cyclopoida and Rotifera were similar and significantly lower, respectively (Appendix Figure E.2.5, Appendix Tables C.3.4 and E.2.2). The relative densities of Copepod Nauplii and Rotifera have been consistently higher and lower, respectively, at POL-P2 compared to BOL-B2 in each year from 2019 to 2022, while the relative densities of Calanoida, Cladocera, Copepod Nauplii, and Cyclopoida have been more variable (Appendix Figure E.2.5, Appendix Table E.2.2). The consistently lower relative density of Rotifera at POL-P2 than at BOL-B2 could potentially be due to differing predation on crustacean zooplankton in Polley Lake versus Bootjack Lake. Planktivorous fish species, including rainbow trout and longnose sucker which occur in both Polley and Bootjack lakes, can decrease populations of the larger crustacean zooplankton by predation, freeing smaller Rotifera from competition and predation (Brooks and Dodson 1965, Fussman 1996). Relative densities of Cyclopoida and Rotifera at POL-P2 were lower and higher, respectively, in 2022 than from 2019 to 2021, while the relative densities of the remaining taxa were either stable from 2019 to 2022 or similar in 2022 to 2019 (indicating temporal stability; Appendix Figure E.2.5, Appendix Table E.2.2). The temporal increase in Rotifera relative density was also observed at Bootjack Lake from 2019 to 2022, suggesting this was related to natural environmental factors. The decrease in Cyclopoida relative density at POL-P2 in 2022 relative to

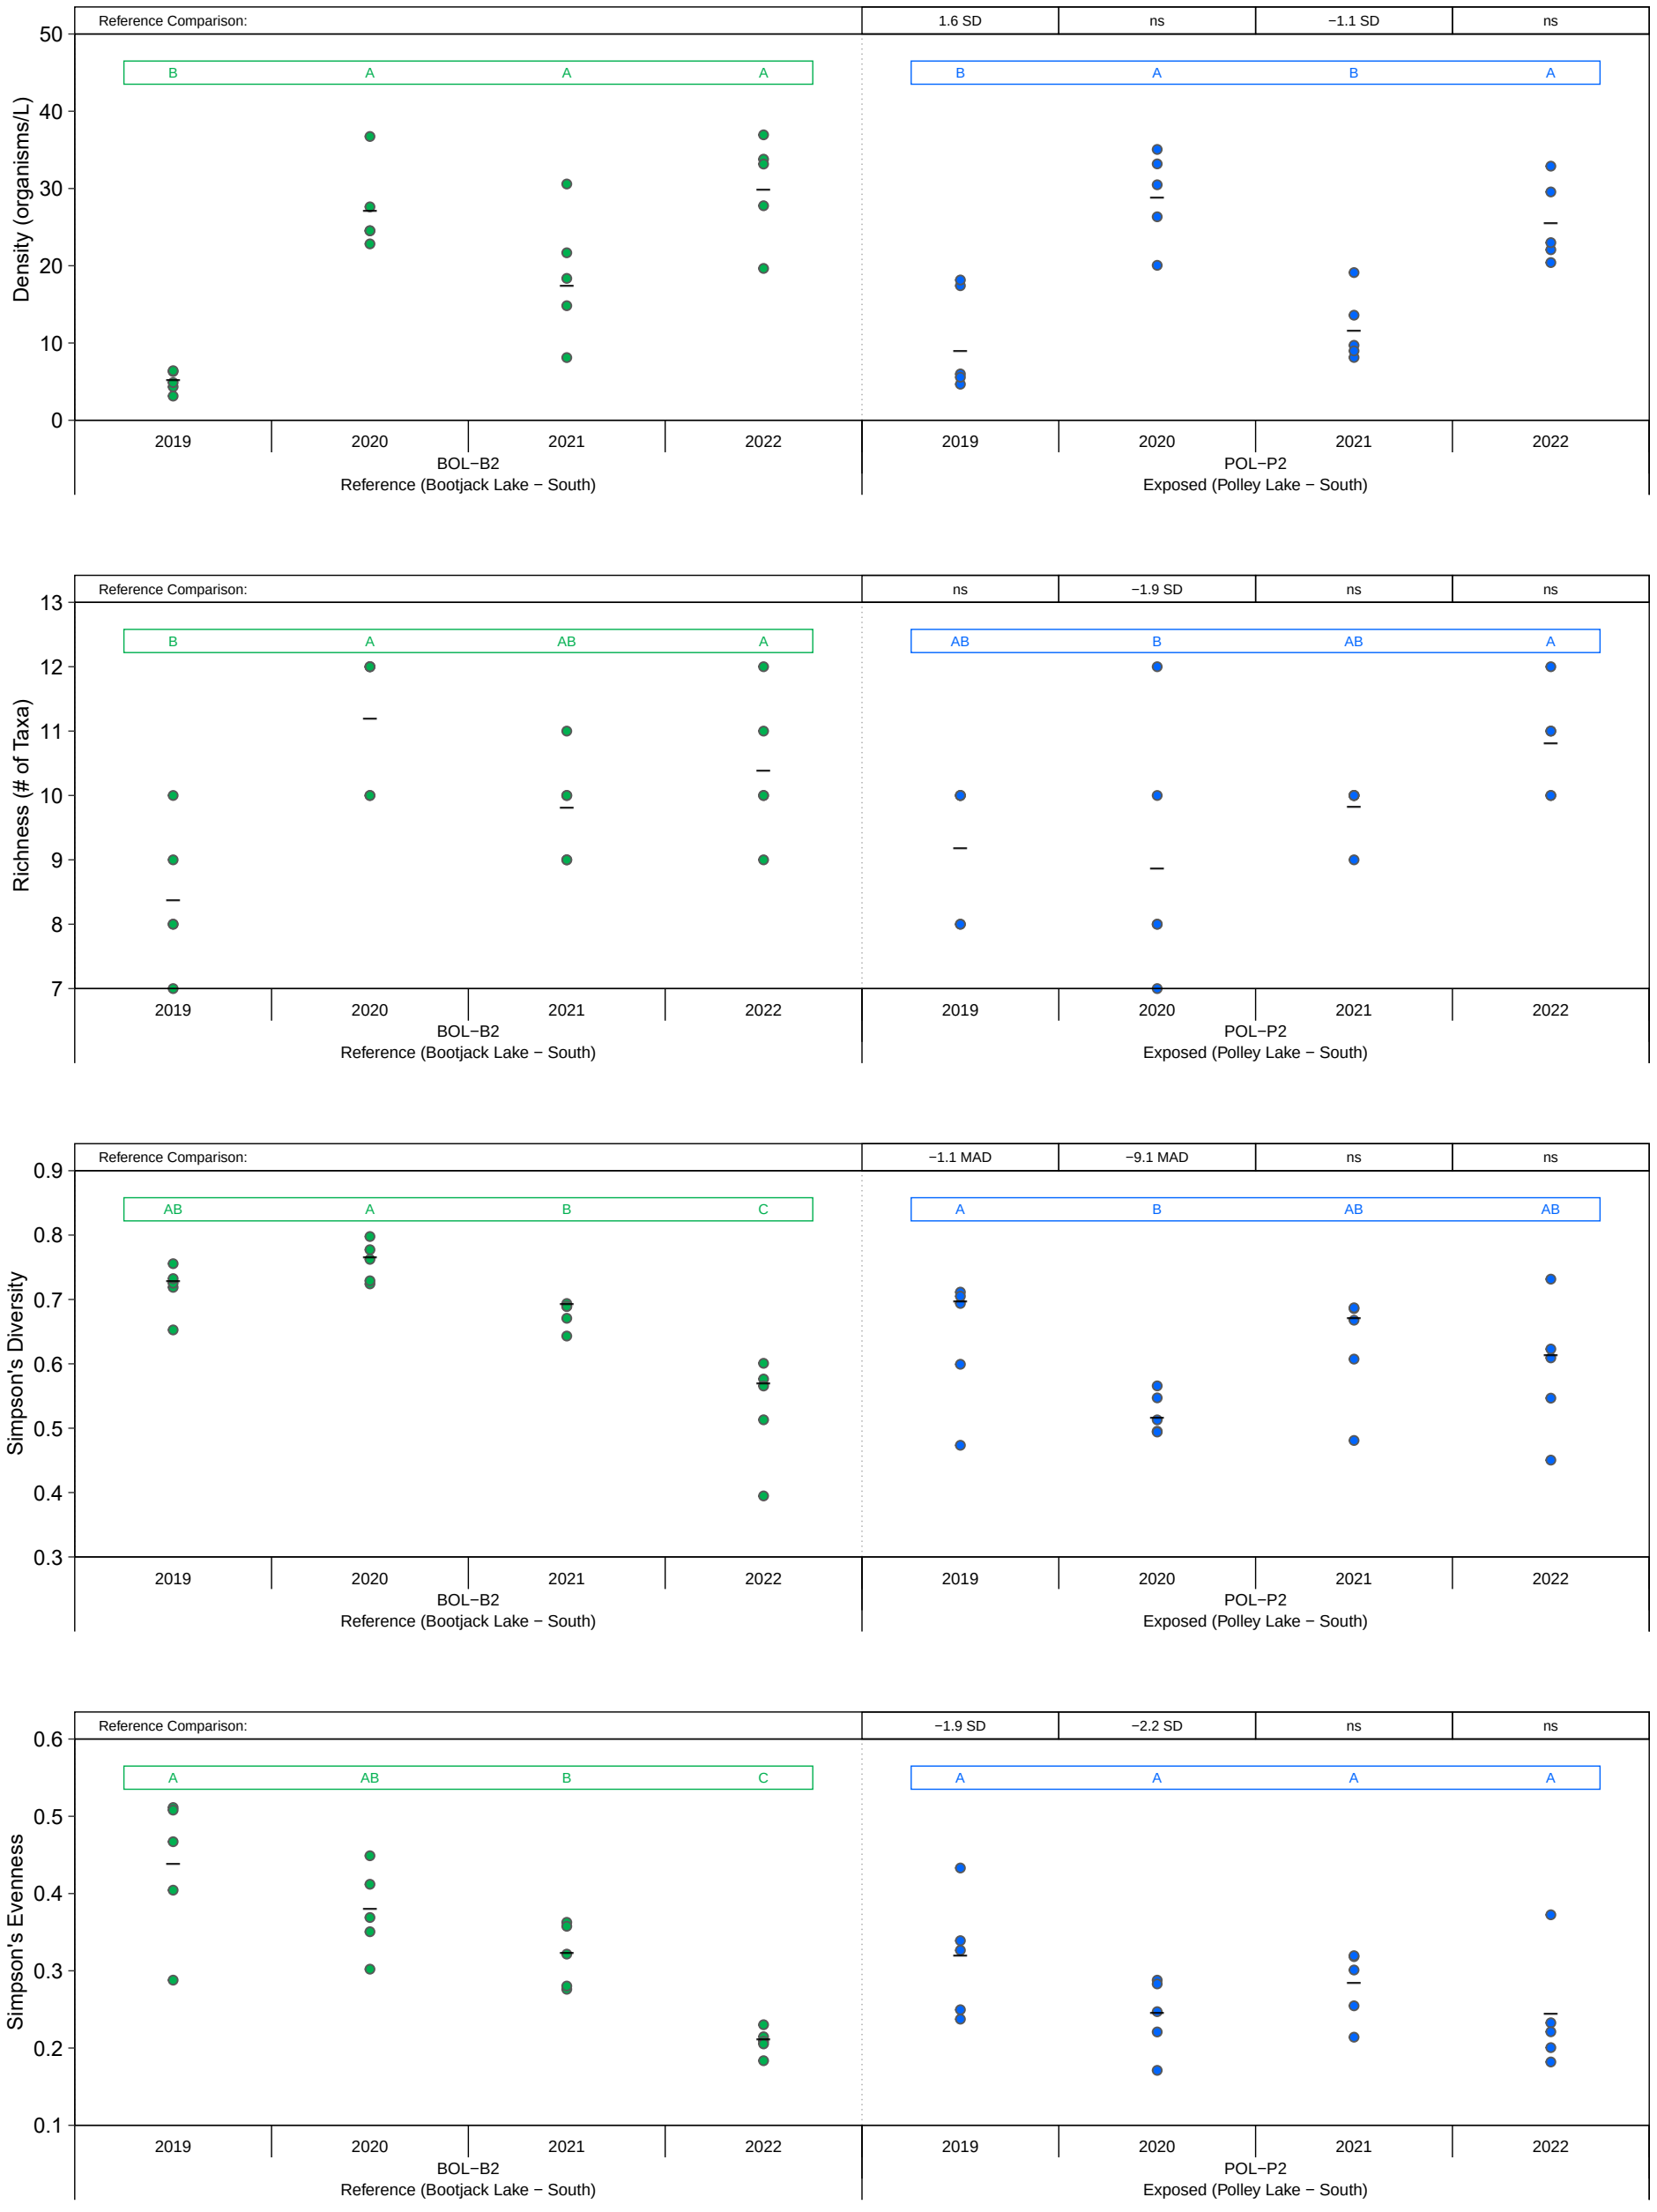

Figure 5.6: Zooplankton Community Endpoints for Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, $\log_{10}$− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of zooplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated zooplankton results collected in June and August 2022, see Appendix Table C.3.3.

Magnitude of Difference (MOD) < -2.

Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available, nc = no comparison, ns = no significance, nm = contrast Magnitudes of Difference (MODs) could not be calculated because the Median Absolute Deviation (MAD) = 0, organisms/L = organisms per litre. mg/L = milligrams per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log $_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

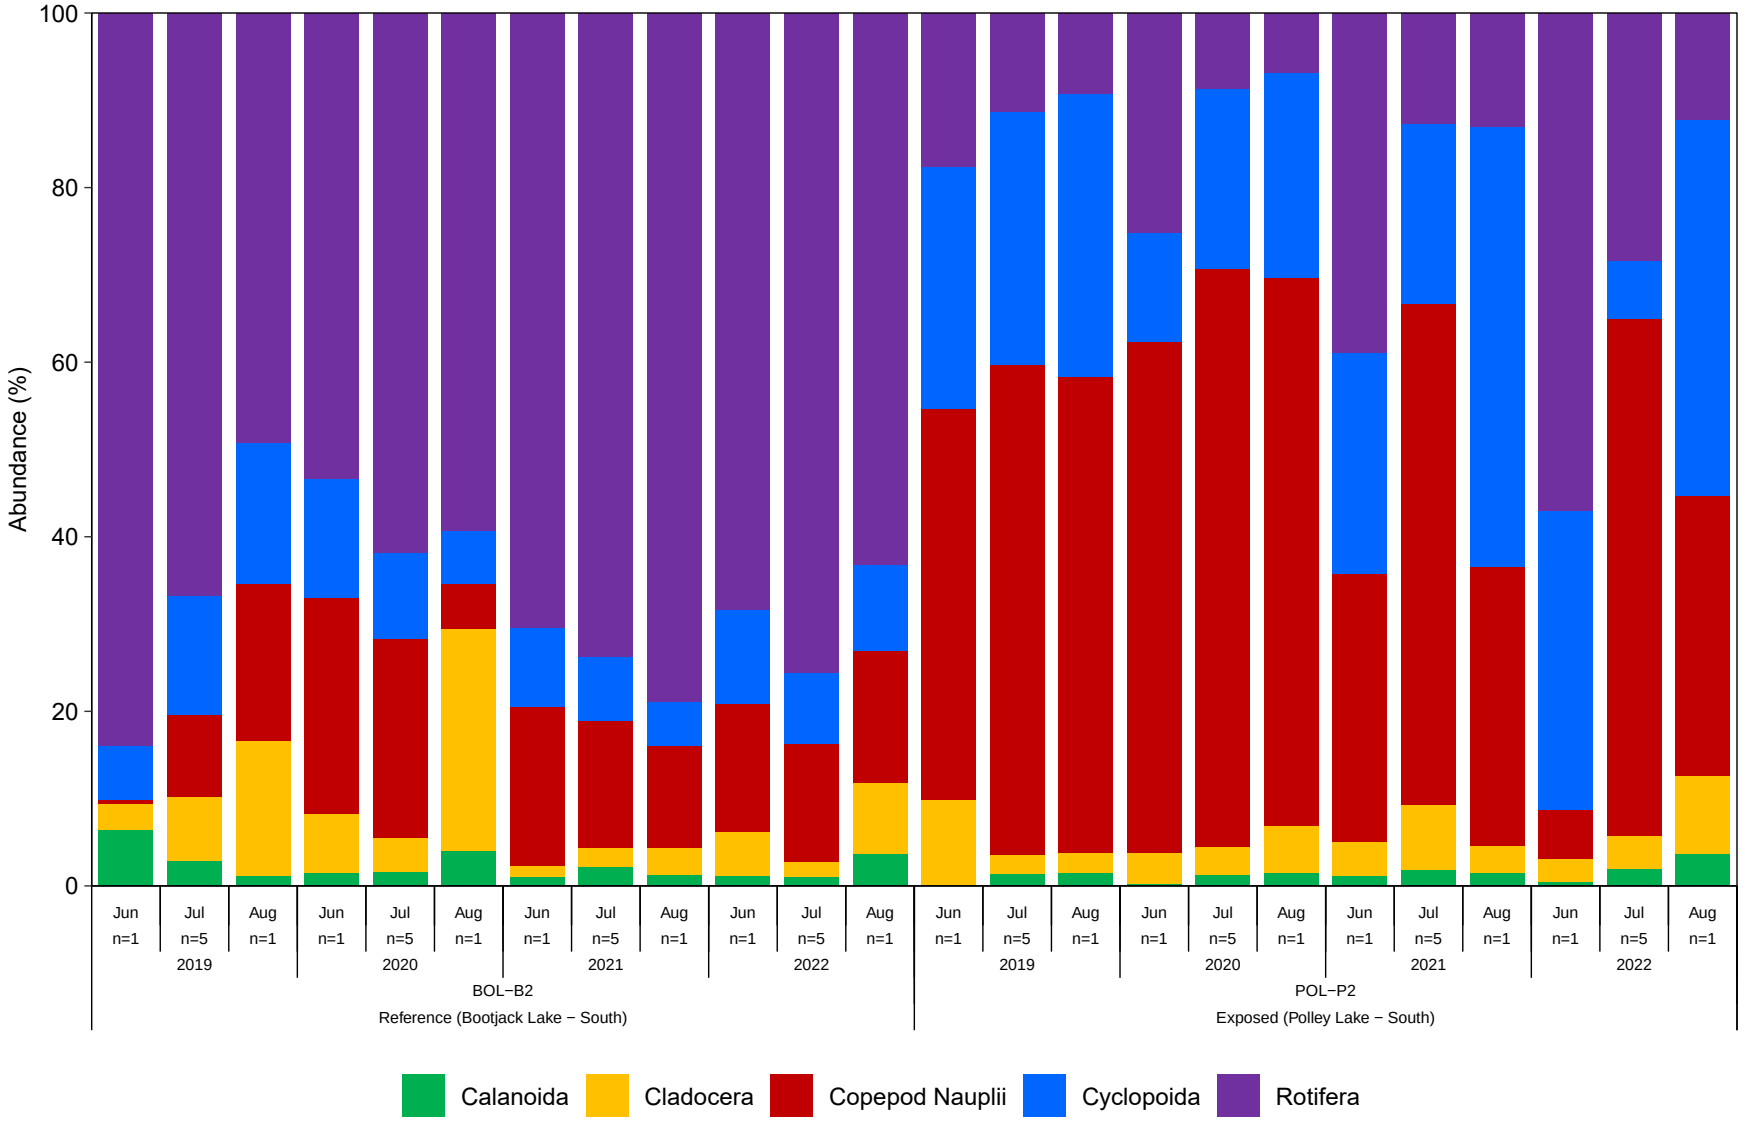

Figure 5.7: Relative Mean Densities of Major Zooplankton Community Taxonomic Groups for Polley Lake (POL−P2; Exposed) and Bootjack Lake (BOL−B2; Reference) Areas, 2019 to 2022

Notes: Results displayed for POL-P2 (August 2019) in the current figure differ from those presented in previous reports (Minnow 2020a, 2021a, 2022a) for the same sampling area and date. This discrepany is due to an incorrect calculation for these results in the prior reporting years.

previous years (2019 to 2021) reflected a change from results that were greater than reference in 2019 to 2021 to results in 2022 that were similar to reference conditions (Appendix Figure E.2.5, Appendix Table E.2.2).

Densities of major taxonomic groups generally followed the same pattern of spatial and temporal differences described above for the relative densities of major taxonomic groups, with the following exceptions. In July 2022, densities of Calanoida and Cyclopoida at POL-P2 were similar to and lower, respectively, than at BOL-B2. Densities of Calanoida have also increased from 2019 to 2022 at POL-P2, while densities of Cladocera have been stable from 2020 to 2022 and densities of Cyclopoida have been stable from 2019 to 2022, except for an increase in 2020 (Appendix Figure E.2.5, Appendix Table E.2.2).

Overall, the zooplankton community of Polley Lake was similar to the reference area in terms of total density, taxon richness, and Simpson's Diversity and Evenness in July 2022. From 2019 to 2022, the zooplankton community of Polley Lake differed from the reference area in terms of significantly higher and lower density in 2019 and 2021, respectively, lower taxon richness in 2020, and lower Simpson's Diversity and Evenness in 2019 and 2020. Zooplankton community composition in Polley Lake has consistently (i.e., in most years from 2019 to 2022) been characterized by higher relative densities of Cyclopoida and Copepod Nauplii and lower relative densities of Rotifera compared to Bootjack Lake. The consistent differences in zooplankton community composition between Polley and Bootjack Lakes suggests that these differences are likely driven by natural variability in environmental parameters (e.g., water temperature, nutrient availability, phytoplankton community, predation) in each of the two lakes.

5.1.3.2.2 Productivity

Zooplankton total biomass (dw) in 2022 in Polley Lake (POL-P2) and Bootjack Lake (BOL-B2) was highest in July and June, respectively, and lowest in August at both areas (Appendix Figure E.2.4, Appendix Table C.3.3). Mean total zooplankton biomass at POL-P2 was similar to that at BOL-B2 in July 2022 (Figure 5.8, Table 5.4; Appendix Table C.3.4). This was consistent with the similarity in zooplankton total biomass between POL-P2 and BOL-B2 in 2021 and similar changes in zooplankton biomass over time in both lakes, including a significant decrease in biomass at both POL-P2 and BOL-B2 in 2021 (relative to 2020) and a significant increase in biomass between 2021 and 2022. Zooplankton total biomass at POL-P2 was significantly higher than at BOL-B2 in 2019 and 2020 (Figure 5.8, Table 5.4; Appendix Table C.3.4). The consistently similar or significantly higher total biomass of zooplankton in Polley Lake compared to the reference area (Bootjack Lake) is indicative of a healthy lentic system, providing critical habitat for fish (Jeppesen et al. 2011).

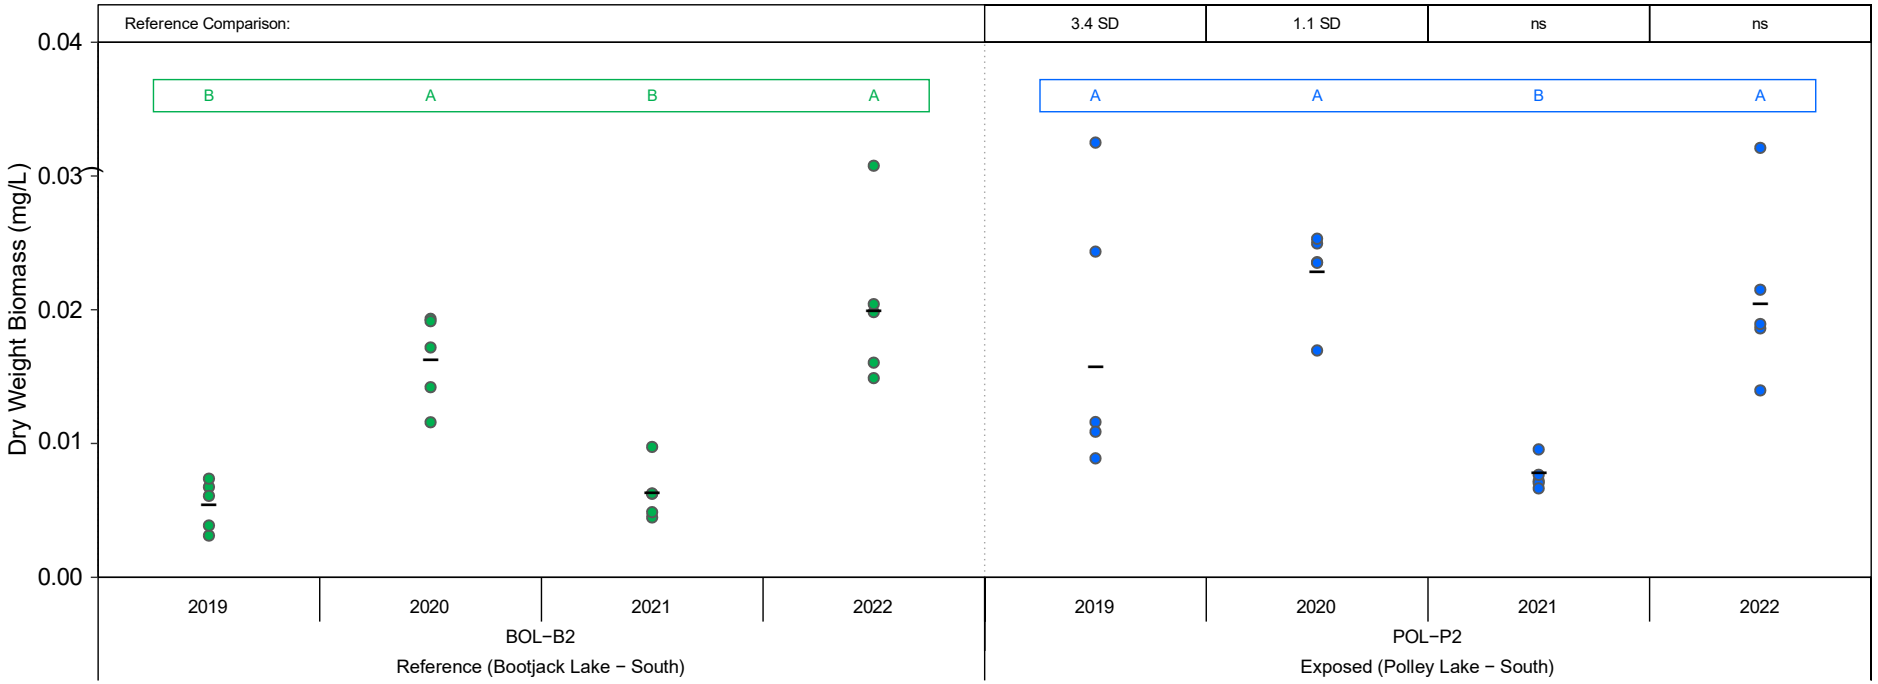

Figure 5.8: Zooplankton Biomass (Total Dry Weight) for Polley Lake (POL−P2; Exposed) and Bootjack L ake (BOL−B2; Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, o r median depending o n if analysis was conducted o n untransformed, log_{10}-transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box o f the same colour d o not differ significantly within a n area. A number above the plot indicates significant exposed vs. reference post −hoc comparisons within a given year. The magnitude o f difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non −significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of zooplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated zooplankton results collected i n June and August 2022, see Appendix Table C.3.3.

5.1.4 Zooplankton Tissue Quality

Zooplankton tissue quality monitoring in 2022 was completed three times (June, July, and August) in Polley Lake (POL-P2) and at a corresponding reference area in Bootjack Lake (BOL-B2; Figure 3.3, Table 3.6). Replicated results from July (n=5) were used for statistical comparisons (see Section 3.4.3). A review of the 2022 zooplankton tissue data quality (Appendix B) indicated that the data largely met the established DQOs. Specifically, the data were characterized by appropriate detectability, with LRLs for selenium remaining below the BC interim guidelines (4 mg/kg dw; Appendix B). Laboratory accuracy and field sampling precision were excellent, with fewer than 20% of analytes from each duplicate set exceeding the DQO of 30% RPD. Several analytes of interest exceeded the DQO for RPD in one or more laboratory sets, but not in all of them. This variability suggests some natural heterogeneity. Laboratory precision could not be properly assessed, since data review was limited to one analyte in a single laboratory duplicate sample. A combination of insufficient sample volume, high moisture content in samples, and laboratory protocols (sample dilution, sample weight used for analysis, etc.) prevented the analysis of additional laboratory duplicate samples. The intentional collection of greater sample volume in future monitoring efforts will allow for a more thorough assessment of laboratory precision. Overall, the 2022 zooplankton tissue quality data can be used with a high level of confidence for interpretation, although the occurrence of some natural heterogeneity in analyte results were considered during data interpretation. A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

As indicated in Section 3.4.3, data interpretation was focused on primary and secondary analytes (Table 2.4) with a significantly positive exposed-reference difference (i.e., analytes with exposed concentrations significantly higher than reference) in 2022 (if the analysis *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant[46]). The secondary analyte sodium was the only primary or secondary analyte with concentrations in zooplankton tissue that were higher in Polley Lake than Bootjack Lake in 2022 or in all monitoring years. Sodium concentrations did not exhibit a significant *Area*×*Year* interaction (Figure 5.9; Appendix Table E.3.1), indicating temporal stability in the ratio of exposed:reference concentrations (i.e., the geometric mean concentration at the exposed area was trending the same as at the reference area). Therefore, sodium concentrations were significantly higher in zooplankton tissue from Polley Lake than Bootjack Lake from July 2019

[46] If no significant change was detected in the exposed-reference difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from 2019 to 2022 were combined for the analyses.

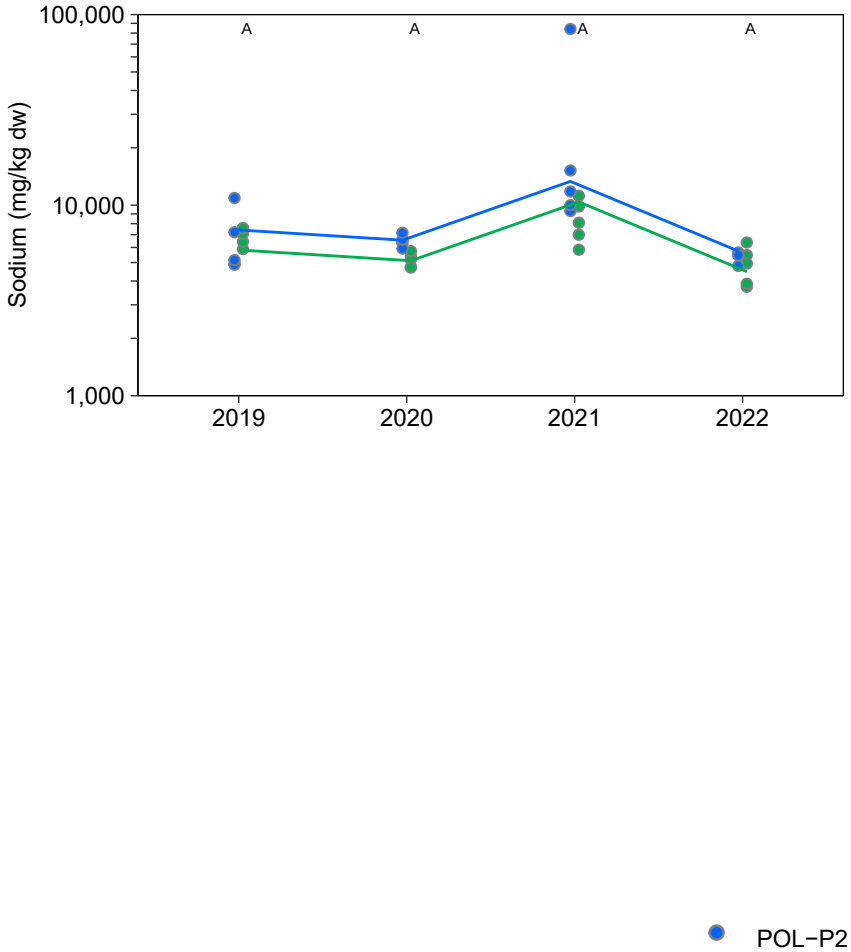

Figure 5.9: Zooplankton Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Areas in July, 2019 to 2022

Notes: dw = dry weight. Plots are only included for primary or secondary analytes with a significant postive exposed - reference difference in 2022 or in all monitoring years. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed : Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed : Reference). Only years with samples from both reference and exposed areas are plotted.

to 2022 (MOD = 28%; Table 5.5; Appendix Table E.3.1) but remained within the range of tissue sodium concentrations since the initiation of monitoring in 2015 (Appendix Figure C.4.1).

The remaining primary and secondary analytes had concentrations that were either similar to or significantly lower than reference in 2022 (if the *Area×Year* interaction was significant) or in all monitoring years (if the *Area×Year* interaction was not significant; Appendix Figure E.3.1, Appendix Table E.3.1). In addition, concentrations of two primary (arsenic and copper) and three secondary analytes (manganese, mercury, molybdenum) in zooplankton tissue from Polley Lake were significantly lower in 2022 compared to the baseline year (2019), relative to reference (Appendix Table E.3.1). Selenium concentrations were lower in 2022 compared to 2020 and 2021 (but not 2019), relative to reference, and decreased to concentrations in 2022 that were similar to reference (Appendix Table E.3.1). In previous monitoring years, cadmium, selenium, tin, and zinc concentrations were significantly higher than reference in 2020 and 2021 (as well as in 2019 for selenium), while concentrations of calcium, copper, molybdenum, phosphorous, and strontium were significantly higher than reference either 2020 or 2021, but not both (Appendix Table E.3.1). The concentrations of these analytes that were significantly higher in Polley Lake zooplankton tissue than reference in previous years (2020 and/or 2021) did not continue to significantly exceed reference concentrations in 2022, except for sodium (Table 5.5; Appendix Table E.3.1). Despite these temporal fluctuations in 2020 and 2021, analyte concentrations in 2022 were similar to 2019 (baseline year) for all primary and secondary analytes, except those noted above which decreased in 2022 relative to baseline (arsenic, copper, manganese, mercury, molybdenum; Appendix Table E.3.1). Except for copper, this is supported by temporal trends in surface water quality which showed similarly stable or decreasing concentrations for all aqueous primary and secondary analytes except copper and vanadium, as outlined below.

Temporal evaluation of post-breach (2015 to 2022) surface water quality trends in Polley Lake indicated that, except for total and dissolved copper and vanadium, the surface aqueous concentrations (total and dissolved) of primary and secondary analytes in Polley Lake either decreased significantly or did not change significantly over time (Appendix Figures C.1.2 to C.1.4, C.4.1, Appendix Table E.3.2). Concentrations of both aqueous dissolved and total copper and vanadium concentrations increased significantly in the surface waters of both the north and south basins of Polley Lake (POL-P1 and POL-P2) between 2015 and 2022 (Appendix Figures C.1.2 to C.1.4, Appendix Table E.3.2). A BCWQG does not exist for vanadium (Appendix Table C.1.1), and comparison of dissolved copper to the BCWQG is discussed below. Aqueous total selenium concentrations at POL-P2 were less than half the BCWQG for total selenium from 2015 to 2022 (2 µg/L; BCMOECCS 2021b; Appendix Figure C.1.4). Aqueous total and dissolved concentrations of arsenic, manganese, molybdenum, and selenium decreased significantly in

Table 5.5: Summary of Statistical Contrasts of Exposed - Reference Relative Differences for Zooplankton Tissue Primary and Secondary Analyte Concentrations for Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Areas in July, 2019 to 2022

Analyte	Magnitude of Difference in (Exposed – Reference) Relative to Baseline Period (%)[a]				Magnitude of Difference for Polley Mean Relative to Bootjack (%)[b]			
	Post-Breach Period				Post-Breach Period			
	2019	2020	2021	2022	2019	2020	2021	2022
Sodium	baseline	ns	ns	ns	28			

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: ns = not significant, baseline= first year of data included in analysis, ANOVA = two way analysis of variance. Data were analysed in units of mg/kg dry weight. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Only years with samples from both reference and exposed were included in the analysis.

[a] Magnitude of difference (MOD) calculated on backtransformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted}) / (Exp_{predicted}) \times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[b] Magnitude of difference (MOD) calculated on backtransformed least-squares means as (Exp-Ref)/Ref x 100%.

Polley Lake surface waters from 2015 to 2022 (Appendix Table E.3.2). This corroborates the decrease in zooplankton tissue concentrations of these analytes between 2019 and 2022 for arsenic, manganese, molybdenum, and from 2020/2021 to 2022 for selenium (Appendix Tables E.3.1, E.3.2).

To evaluate the potential impact of copper concentrations on aquatic life in Polley Lake, dissolved concentrations were compared to the relevant BLM-based BCWQG to calculate GEFs for dissolved copper (refer to Section 3.8.3.3 for details). The copper GEFs in surface water increased significantly from 2015 to 2022 at both the north and south basins of Polley Lake (Appendix Figure C.1.3, Appendix Table E.3.2). Though a significant increase has been observed since 2015, the GEFs observed for Polley Lake in 2022 were typically within the range of previous years and results largely remained within the range of copper GEFs reported for the reference (Bootjack Lake), which suggests there is little risk to aquatic life in the near term (Appendix Figure C.1.3). As outlined above, copper concentrations in zooplankton tissue from Polley Lake were lower in 2022 than in 2019 (when replicated sampling was initiated), relative to reference (Appendix Table E.3.1), indicating a decrease risk to aquatic life. A BCWQG for vanadium does not exist (BCMOECCS 2021a,b), therefore aqueous concentrations of this analyte could not be contrasted to guideline values but zooplankton tissue concentrations of vanadium in Polley Lake did not differ significantly from reference (Bootjack Lake; Appendix Table E.3.1).

Selenium concentrations in zooplankton tissue results from both Polley Lake and Bootjack Lake in 2022 were below the BC interim guideline for selenium of 4 mg/kg dw and were within the range of results reported since 2015 (BCMOECCS 2021b; Appendix Figure C.4.1, Appendix Table C.4.1). Tissue concentrations of selenium in 2022 from Polley and Bootjack lakes ranged from 2.14 to 3.34 mg/kg dw (Appendix Table C.4.1). In prior years, individual zooplankton tissue results from both exposed and reference areas have exceeded the BC guideline, though mean concentrations have remained below the guideline since 2019 (when replicated sampling was initiated), except in 2021 for Polley Lake[47] (Appendix Figure C.4.1). The variability among years in zooplankton tissue selenium concentrations may be due to environmental factors such as differences in feeding/uptake rates or species composition of the zooplankton tissue samples, which is supported by the absence of a significant temporal trend for selenium in water quality results (Appendix Table E.3.2).

[47] In 2021, one zooplankton replicate from Polley Lake had a selenium concentration of 35.2 mg/L; approximately 6 times higher than the median concentration of 5.54 mg/kg dw (see Minnow 2022a).

5.1.5 Fish Usage and Population Health

Fish usage and population health were evaluated for rainbow trout, longnose sucker, and redside shiner at Polley Lake in 2022, with Bootjack Lake serving as a reference (Figures 3.4 and 3.5), consistent with previous monitoring (see Section 3.7 for details).

5.1.5.1 Community and Catch

Spring fishing in 2022 in Polley and Bootjack lakes was undertaken after ice-out when lake water temperatures were approximately 5 °C. Similar to previous years, rainbow trout and longnose sucker were caught in both Polley and Bootjack lakes whereas redside shiner were caught in Polley Lake only (Table 5.6; Appendix Table C.6.1). Two largescale sucker (*Catostomus macrocheilus*) were also caught in Bootjack Lake in spring 2022. Largescale sucker have previously been caught in low numbers in Bootjack Lake (in 2019 and 2021) but have never been caught in Polley Lake.

The CPUE for Polley Lake rainbow trout in spring was higher in 2022 than all previous years since 2016 (2.0- to 5.0-fold) and was similar to CPUE in Bootjack Lake (Table 5.6). Spring fish collections each year have targeted rainbow trout spawners aggregating near the mouth of Hazeltine Creek and Bootjack Creek (Figure 3.4). From 2019 to 2021, temporal changes in CPUE indicated progressively fewer rainbow trout aggregated for spawning (Table 5.6) which is consistent with the observation that most spawners present in 2018 would have reached the end of their life expectancy in 2021, with low replacement by recruits from 2014 to 2017 when Hazeltine was inaccessible to spawning rainbow trout (see Section 3.6 for details). Natural mortality of older age classes and decreasing number of spawners observed in Hazeltine Creek during spawning surveys since 2018 resulted in fewer recruits being added to the population in each year (Minnow 2023). However, because rainbow trout generally begin spawning between age three and five (Scott and Crossman 1998), it was anticipated that some portion of the 2018 cohort would reach sexual maturity by 2021 and that most would be sexually mature by 2022, which is consistent with the result for spring CPUE.

Since 2016, the CPUE for longnose sucker in spring has varied in Polley Lake but declined from 2020 to 2022 to the lowest CPUE among monitoring years except 2019 (Table 5.6). As described above, spring sampling targets specific locations where fish have been known to aggregate prior to spawning, therefore differences in CPUE over time may be due in part to the non-random sampling design implemented during this period (Appendix Table C.6.1). Moreover, longnose sucker CPUE was slightly higher in Polley Lake than Bootjack Lake in spring 2022. The CPUE for redside shiner in spring has also varied over time and is likely due to non-random sampling in spring (Table 5.6; Appendix Table C.6.1).

Table 5.6: Catch-Per-Unit-Effort Results for Hoopnetting Collections in a) Spring and b) Fall for Polley Lake (POL; Exposed) and Bootjack Lake (BOL; Reference), 2016 to 2022

a)

[a] CPUE - Catch-per-unit-effort (# fish / trap / day).

Fish collections in the fall in Polley Lake followed a randomized design using a standardized level of effort (see Section 3.6.3). The randomized sampling methods used in the fall (which reflect the CPUE of the whole fish population) differ from the methods used in spring that specifically target aggregating spawners (and which largely reflect the CPUE of the spawning population).

Fall rainbow trout CPUE initially decreased from 2016 to 2018, likely reflecting the lower recruitment of YOY (as previously discussed). However, CPUE was higher in 2019 (2-fold greater than 2016); many rainbow trout captured in Polley Lake in 2019 were likely age-2 or younger based on length (Minnow 2020a) suggesting that the higher CPUE was due to successful recruitment after restoration of access to Hazeltine Creek spawning habitat in 2018. Rainbow trout CPUE in the fall was relatively consistent from 2019 to 2021 but was lower in 2022 while remaining higher in 2022 than in 2016 and 2018 (Table 5.6; Appendix Table C.6.2). Temporal comparisons of CPUE are subject to variability resulting from several factors that can affect the success of netting efforts, such as weather, water temperature, water level, and year-to-year variability in net placement and efficacy. This is true even when considering the fish collection methods employed in the fall in Polley Lake (2016 to 2022) that follow a randomized design using a standardized level of effort. Continued annual monitoring is planned in Polley Lake using the randomized design which will help to evaluate whether the lower CPUE observed in 2022 is part of a longer-term trend. Additionally, the assessment of rainbow trout size distribution results from 2016 to 2022 provides a more comparable means for temporally evaluating the population recovery in Polley Lake, with the distribution of rainbow trout in 2022 having a similar pattern to 2016 (see Section 5.1.5.2.2). Although the fall CPUE for rainbow trout was lower in 2022 than the previous three years, the number of adult rainbow trout observed during spawning surveys in Hazeltine Creek in the spring of 2022 was the highest since 2019 as most of the remaining individuals from the 2018 cohort reached maturity in 2022 (Minnow 2020b, 2021b, 2022b). Subsequently, the mean density of YOY in Hazeltine Creek from closed-station electrofishing in 2022 (62 to 119 fish/100 m^2) was also substantially higher than 2021 (2 to 12 fish /100 m^2) and 2020 (36 to 98 fish /100 m^2; Minnow 2023).

Similar to the rainbow trout CPUE, longnose sucker CPUE in Polley Lake was lower in fall 2022 than 2021 (2.1-fold) and has generally decreased over time since 2016 (approximately 5.0-fold difference in CPUE between 2016 and 2022; Table 5.6). As indicated above, temporal variability in CPUE can be the result of several factors that may influence the success of hoop netting efforts, some of which may have influenced, at least in part, the changes in longnose sucker observed from 2016 to 2022 (Table 5.6). As described above for rainbow trout, continued annual monitoring is planned in Polley Lake using the randomized design which will help to evaluate whether the lower CPUE observed in 2022 is part of a longer-term trend. The CPUE of redside shiner in fall

has varied since 2016 but decreased from 2020 to 2022. Redside shiner CPUE in 2022 was 1.7 to 5.4-fold lower than in 2019 to 2021 but was 1.2-fold higher than in 2018 (Table 5.6).

5.1.5.2 Fish Population Health

5.1.5.2.1 Spring

Spring condition (weight-at-length) of all rainbow trout in Polley Lake in 2022 was statistically similar to 2018 to 2021 but significantly lower than 2016 and 2017 although the difference relative to the baseline year (2016) was only 4.9%. When the analysis was constrained to the length range that overlapped among all seven years (greater than 23 cm fork length [FL]) condition in 2022 was signficantly lower than all years from 2016 to 2020 except 2019, but the difference relative to baseline was still less than 10% (Table 5.7; Appendix Figure E.5.1, Appendix Tables C.6.3, C.6.10, E.5.1, E.5.2). Analysis by sex showed that condition of females (constrained to individuals selected for lethal sampling; *n* = 8) in 2022 was similar to 2021 but significantly lower in 2016 to 2020, with a difference relative to the baseline year (2016) of 9.0% (Table 5.7; Appendix Figure E.5.1). Growth (weight-at-age) of lethally sampled female rainbow trout in 2022 (the only group with available age data) was similar to all prior years except 2020 (Table 5.7; Appendix Figure E.5.2, Appendix Table E.5.1). Condition of male rainbow trout was not assessed for spring of 2022 since sex was not identified for non-lethally sampled rainbow trout (and lethal sampling targeted female rainbow trout).[48]

For longnose sucker, whether assessed for all fish sampled or constrained by the subset of fish greater than 32 cm FL (i.e., greatest overlap among years), spring condition of longnose sucker from Polley Lake in 2022 was statistically similar to 2021 and significantly lower than all other years, although the MOD relative to baseline (2016) was less than 10% in both cases (Table 5.7; Appendix Figure E.5.3, Appendix Tables C.6.4, C.6.11, E.5.1). Examining only females (constrained to lethally sampled fish; *n* = 8), condition in 2022 was not significantly different from 2021, 2019, or baseline, but was significantly lower than other years; the outcome of the analysis was the same when constraining the data to fish greater than 32 cm FL (Table 5.7; Appendix Figure E.5.3). Growth (weight-at-age) of longnose sucker females in spring of 2022 was statistically similar to all years except 2018 (Table 5.7; Appendix Figure E.5.2, Appendix Table E.5.1). Examining only males (constrained to lethally sampled fish; *n* = 9), condition in 2022 was not significantly different from 2021, but was significantly lower than other years; when

[48] In previous years, the sex of male rainbow trout was confirmed during the lethal collection of tissue quality samples. Fish tissue quality sampling in Polley Lake (and reference) targets the collection of samples from females (see Section 3.7.1). Historically, some male rainbow trout were collected as incidental mortalities while targeting collection of tissue quality samples from female rainbow trout. In 2022, no males were collected as incidental mortalities during the tissue quality sampling process, therefore the sex of male rainbow trout could not be confirmed.

Table 5.7: Summary of Statistical Comparisons of Condition and Weight-at-Age of Rainbow Trout and Longnose Sucker for Polley Lake in Spring and Fall, 2014 to 2022

Season	Endpoint	Group	Rainbow Trout								Longnose Sucker							
			2014	2016	2017	2018	2019	2020	2021	2022	2014	2016	2017	2018	2019	2020	2021	2022

Notes: Different letters signify that an endpoint is significantly different among years while the value in brackets indicates the magnitude of difference between the given year and the baseline year (baseline year is 2016 for spring and 2014 for fall data); "na" = not applicable or no sampling was conducted in the given year; "=" = no statistically significant difference in the endpoint across years; "-" = insufficient data available to conduct comparisons.

[a] Analysis conducted only on individuals with fork length greater than 23 cm for rainbow trout and 32 cm for longnose sucker.

[b] Analysis conducted only on individuals with fork length greater than 30 cm for longnose sucker.

[c] Analysis conducted only on individuals with fork length greater than 12 cm for rainbow trout and 11 cm for longnose sucker.

constraining the data to fish greater than 32 cm FL, condition was statistically similar across all years (Table 5.7; Appendix Figure E.5.3). Growth (weight-at-age) of longnose sucker males in spring of 2022 was not estimated due to data limitations (Table 5.7; Appendix Figure E.5.2, Appendix Table E.5.1).

5.1.5.2.2 Fall

The condition of rainbow trout from Polley Lake, whether including or excluding YOY fish (i.e., fork length less than 12 cm) was significantly lower in 2022 than all other monitoring years except 2016, including a 13% difference from baseline (2014), though condition was generally consistent from 2018 to 2021 (Table 5.7; Appendix Figure E.5.4, Appendix Table C.6.7, E.5.1). Interannual differences in fall condition during post-breach monitoring has frequently exceeded 7% (Table 5.7; Appendix Table E.5.1). Growth dynamics and weight-length relationships of fish species can be quite variable in the life stages that precede maturity. Given the average size (sub-mature) of rainbow trout in Polley Lake captured over the duration of post-breach monitoring efforts (for which condition is being reported), such variance is not unexpected.

Aging data was not available for rainbow trout in 2022 to assess weight-at-age. In years prior to 2019 aging was completed opportunistically via incidental mortalities that occurred during gill netting, but gill netting has not been conducted since 2018 (see Minnow 2022a for details). In the absence of recent age data, length frequency distributions and predicted length-at-age provide an indication of recruitment and survival over time. Comparison of length frequency distributions for rainbow trout caught from fall hoop netting from 2016 to 2022 show an encouraging trend for both recruitment and sustainability of the Polley Lake population, with significantly more smaller fish than in 2016 and a more even distribution of fish lengths in 2022 than in prior years (Appendix Figure E.5.5, Appendix Table E.5.3).

In 2016, the rainbow trout population in Polley Lake was dominated by age 3+ individuals (Figure 5.10), an artifact of low recruitment from 2014 to 2017 when spawning habitat in Hazeltine Creek was inaccessible. In 2018, the first year after access to Hazeltine Creek was restored, the population continued to be dominated by older fish (age-4+), however recruits from the 2018 cohort were also present. These recruits subsequently became the dominant year class in 2019 with the likely higher mortality of older fish, most of which had likely reached the end of their life expectancy (Figure 5.10). In 2020 and 2021, the population continued to shift towards a more balanced distribution among size classes with the survivorship of the 2018 and 2019 cohorts and further successful recruitment of individuals from the 2020 and 2021 cohorts. In 2022, the length frequency distribution resembled 2016 but with a lower frequency of age 3+ fish in lieu of greater strength of younger age classes. The lengt frequency distribution in 2022 had greater

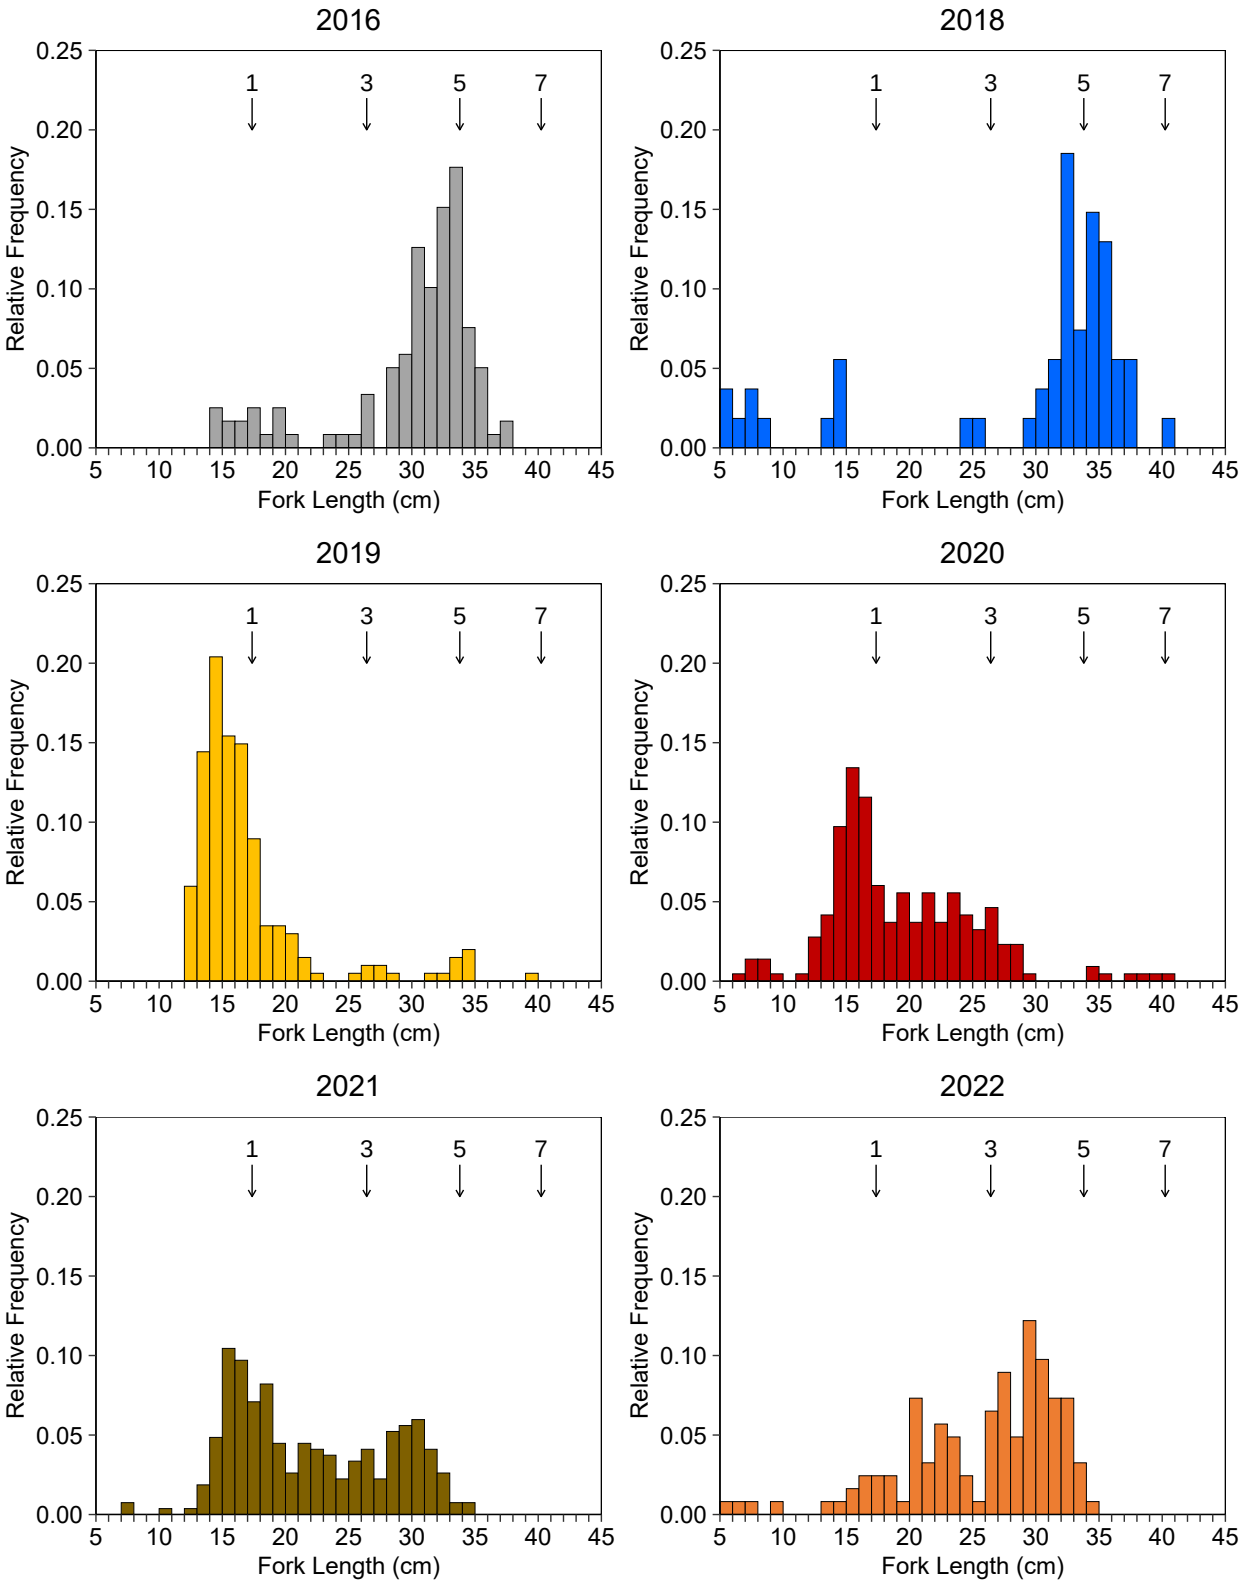

Figure 5.10: Rainbow Trout Length Frequency Distributions for Randomized Fall Hoopnetting in Polley Lake, 2016 to 2022

Notes: Numbers and arrows along the tops of figures represent predicted fork lengths at various ages from a linear model: $\log_{10}$(Fork Length) = 1.0569 + $\log_{10}$(Age+1)x0.6064, with R^2 = 0.79. The linear model to predict fork lengths at various ages uses fish collected in spring and fall, but the fork length frequency data presented for each year includes data from fall only.

resemblance to 2016 than the length frequency distributions from any of the other years (2018 to 2021; Figure 5.10), suggesting the population has returned to a pre-breach size class distribution. The relative frequency of age-1 rainbow trout decreased from 2019 to 2022 (Figure 5.10) as expected. It is likely that the mortality rate of rainbow trout spawners was higher from 2018 to 2022 (due to the cohort age) combined with low replacement of younger spawning recruits from 2014 to 2017 which resulted in progressively fewer spawners observed in Hazeltine Creek during each spawning survey since 2018 and subsequently, lower YOY densities observed in Hazeltine Creek (Minnow 2022b). However, as described above, the number of adults observed in Hazeltine Creek in spring of 2022 was the highest since 2019 as it would be expected that the individuals from the 2018 cohort would reach maturity in 2022 and subsequently, the YOY density in Hazeltine Creek was also higher than the previous two years (Minnow 2023).

Condition of longnose sucker in fall 2022, whether including or excluding YOY, was statistically similar to the previous two years of monitoring and 2016, but significantly lower than the remaining years (including baseline). However, the MOD of 2022 condition relative to 2014 (baseline) was low (less than 10%) in ecological terms, suggesting relative stability in the energy pathways supporting the longnose sucker population (Table 5.7; Appendix Figure E.5.4, Appendix Tables C.6.8, E.5.1). Similar to rainbow trout, comparison of length-frequency distributions showed that significantly more smaller fish were caught in 2022 compared to 2016, as was the case in 2018, 2020, and 2021 (Appendix Figure E.5.5, Appendix Table E.5.3). Length-frequency histograms for longnose sucker in Polley Lake from 2016 to 2022 showed that from 2016 through 2018, and to a lesser extent in 2019, catches were dominated by age-4 and age-5 fish (Figure 5.11). Moreover, 2016 and 2018 showed evidence of strong within year recruitment (high frequency of YOY and age-1; Figure 5.11). In 2020, catches shifted to a higher frequency of younger age classes (including the 2018 and 2019 cohorts, the first recruited age classes following restored access to Hazeltine Creek) and this pattern persisted in catches from 2021 and 2022 (Figure 5.11).

Redside shiner length-frequency distribution was also significantly different in 2022 compared to 2016, with more smaller fish caught in 2022 than in 2016, which was also the case each year from 2018 to 2021 (Appendix Figure E.5.5, Appendix Tables C.6.9 and E.5.3). Examination of cumulative relative frequency distributions also indicated that more smaller fish were caught in 2022 than all previous monitoring years (Appendix Figure E.5.6). The absence or near absence of small redside shiner in 2016 and 2018 and subsequent lower numbers of larger individuals in 2019 and 2020 is likely indicative of low recruitment in the years immediately following the breach. It is likely that the 2018 cohort that appears dominant in 2019 to 2021, and reached maturity in 2022, produced a strong YOY class that dominated catches in fall. Relative to 2016 and 2018

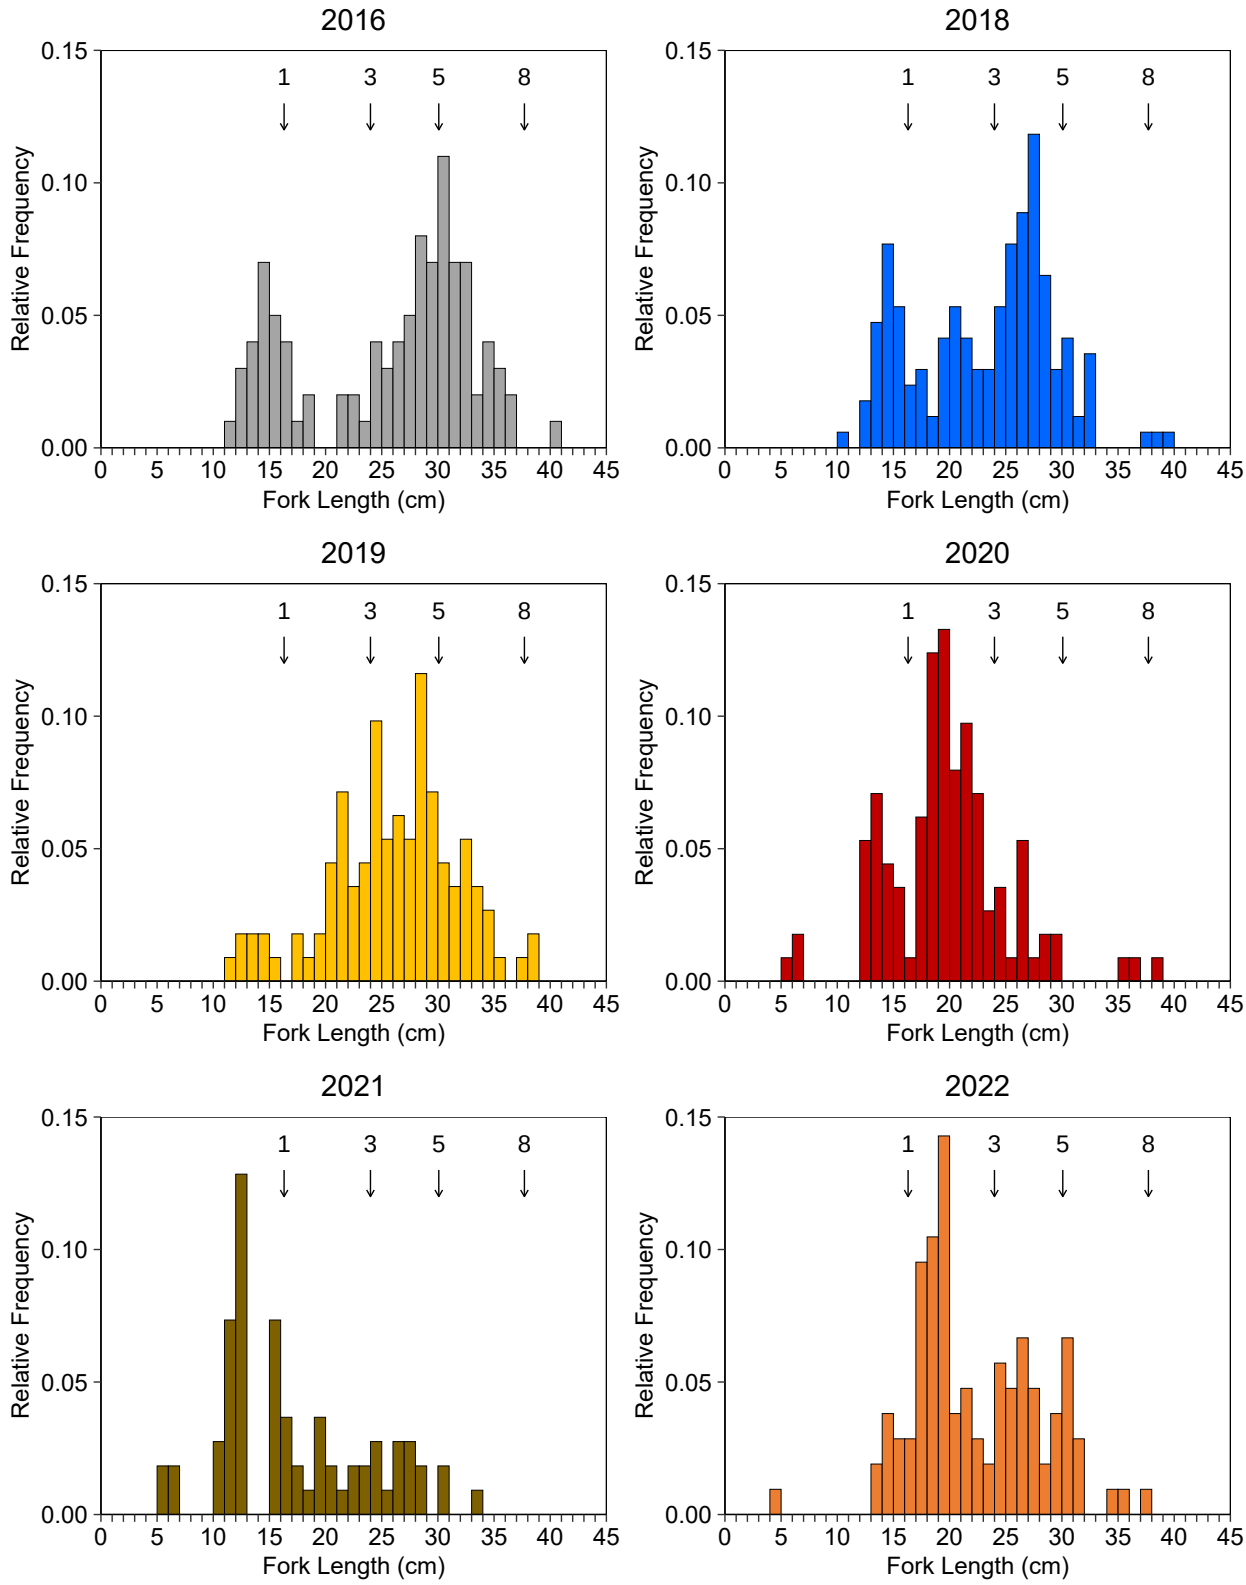

Figure 5.11: Longnose Sucker Length Frequency Distributions from Randomized Fall Hoop Netting in Polley Lake, 2016 to 2022

Notes: Numbers and arrows along the tops of figures represent predicted fork lengths at various ages from a linear model: $\log_{10}(\text{Fork Length}) = 1.0446 + \log_{10}(\text{Age}+1) \times 0.5573$, with $R^2 = 0.88$. The linear model to predict fork lengths at various ages uses fish collected in spring and fall, but the fork length frequency data presented for each year includes data from fall only.

when they were almost entirely absent from Polley Lake, over 50% of the catch in 2022 was comprised of younger fish (smaller than 7 cm; Appendix Figures E.5.5, E.5.6, Appendix Table C.6.9).

5.1.6 Fish Tissue Quality

Fish tissue quality was evaluated for rainbow trout and longnose sucker from Polley (exposed) and Bootjack (reference) lakes in 2022 (Figure 3.4, Table 3.4). A review of the 2022 fish tissue data quality (Appendix B) indicated that data collected in the spring (from Polley and Bootjack Lakes) and the fall (from Quesnel Lake and Quesnel River) had appropriate LRLs, good detectability and excellent laboratory accuracy. Field precision was moderate, with just under half of field duplicate sets having >20% of analyte comparisons above the DQO of 30%. Kidney samples had the most DQO exceedances while ovary and liver had the fewest. This suggests natural heterogeneity within the tissue samples and between tissue types (muscle, liver, kidney, and ovary); however, the level of replication employed (n = 8 per tissue type) serves to help capture this variability. Laboratory data precision was excellent, with most duplicate samples meeting DQOs. Overall, the 2022 fish tissue quality data can be used with a high level of confidence for interpretation, although the occurrence of some natural heterogeneity in analyte results were considered during data interpretation. Historic data used for comparisons are also considered high quality; however, it is considered likely that a subset of the selenium concentrations measured in fish tissues collected by MPMC in 2015 (rainbow trout ovary from exposed area Frypan Creek; included in the Polley Lake analysis) were subject to laboratory error or contamination (Minnow 2017e).

5.1.6.1 Comparison to Guidelines and Thresholds

Mean mercury concentrations in muscle from rainbow trout and longnose sucker were below the mercury guideline for human health (0.5 mg/kg ww) for both Polley and Bootjack lakes in 2022 (Table 5.8). This result was consistent with those for rainbow trout and longnose sucker captured from Polley and Bootjack lakes in 2015 to 2021 (Table 5.8). Moreover, mercury concentrations in individual samples were below the guideline for all fish captured in 2022 (Appendix Tables C.7.1 to C.7.4). In 2021, a single rainbow trout exceeded the guideline; however, individual mercury concentrations were below the guideline for all rainbow trout and longnose sucker captured from 2015 to 2020 (Table 5.8). For selenium, mean and individual tissue concentrations in muscle of rainbow trout and longnose sucker collected from both lakes were consistently below the human health guideline for moderate fish consumption (i.e., a consumption rate of 110 g per day), consistent with sampling completed between 2015 and 2021 (Table 5.8; Appendix Tables C.7.1 to C.7.4). In Polley Lake, the mean selenium concentration in rainbow trout muscle was also below the guideline for high consumption in 2022 but the guideline

Table 5.8: Fish Muscle Mercury and Selenium Concentrations from Polley Lake (Exposed) and Bootjack Lake (Reference) Relative to Human Health Consumption Guidelines, 2015 to 2022

Waterbody or Area	Species	Year/Season	Sample Size	Mercury (Hg) mg/kg ww		Selenium (Se) mg/kg dw

Indicates mean mercury concentration greater than Health Canada's Human Health guideline for muscle tissue in fish (0.5 mg/kg dw; CFIA 2015).

Indicates mean selenium concentration greater than the BCMOE Human Health guideline for moderate fish consumption (14.5 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than the BCMOE Human Health guideline for high fish consumption (7.3 mg/kg dw; BCMOE 2014).

Notes: mg/kg ww = milligrams per kilogram wet weight; mg/kg dw = milligrams per kilogram dry weight; BCMOE = British Columbia Ministry of Environment; > = greater than; % = percent.

was exceeded in a single individual (7.41 mg/kg dw; Appendix Table C.7.1). The mean selenium concentration in muscle tissue of longnose sucker from Polley Lake marginally exceeded the high consumption guideline in 2022 (mean = 7.84 mg/kg dw; Appendix Table C.7.3) with 63% of the samples exceeding the guideline, consistent with rates in Polley Lake from 2016 to 2021 (25 to 100%; Table 5.8). However, the likelihood that longnose sucker would be consumed at a high rate (i.e., subsistence consumers) is low.

Mean selenium concentrations in muscle of rainbow trout and longnose sucker from Polley Lake in 2022 were higher than the guideline for the protection of aquatic life (4 mg/kg dw; Table 5.9). The guideline was exceeded in 50% of rainbow trout and all longnose sucker muscle tissue samples, consistent with rates in Polley Lake from 2015 to 2021 (63% to 100% of fish sampled each year). Selenium concentrations remained below the guideline in all fish muscle tissue samples from Bootjack Lake (Table 5.9; Appendix Tables C.7.1 to C.7.4). The mercury guideline for fish muscle tissue is specific to human health and a mercury guideline for the protection of aquatic life does not exist.

Embryo toxicity is the primary mechanism of selenium-associated effects to egg laying vertebrates, the most selenium-sensitive organisms, and ovary tissue is recommended for assessing the potential effects of selenium on fish (e.g., Luoma and Presser 2009, Janz et al. 2010, DeForest et al. 2012, Janz 2012). The mean concentration of selenium in ovary tissue of rainbow trout collected from Polley Lake in 2022 (8.27 mg/kg dw) was lower than the 11 mg/kg dw guideline for the protection of aquatic life[49]. The mean concentration in 2022 was also lower than those reported from 2016 to 2021, representing the lowest post-breach mean concentration recorded in Polley Lake for rainbow trout ovary tissue (BCMOE 2014; Table 5.10; Appendix Table C.7.1). Of the ovaries collected from Polley Lake in 2022, one rainbow trout sample had a concentration above the guideline for the protection of aquatic life, and only marginally so (11.1 mg/kg dw; Appendix Table C.7.1). Furthermore, the mean and individual ovary selenium concentrations of rainbow trout from Polley Lake in 2022 (8.27 mg/kg dw) and in previous years were well below the 20 mg/kg dw effect threshold developed by DeForest et al. (2012; Table 5.10). Selenium concentrations in ovaries of rainbow trout from Bootjack Lake (2015 to 2022) were consistently below the tissue-specific selenium guideline for the protection of aquatic life and the threshold for reproductive effects (DeForest et al. 2012; Table 5.10; Appendix Table C.7.2). From 2016 to 2022, mean selenium concentrations in ovaries of longnose sucker captured from Polley and Bootjack lakes were lower than the tissue-specific guideline for

[49] This guideline includes a two-fold uncertainty factor (BCMOE 2014).

Table 5.9: Fish Muscle Selenium Concentrations from Polley Lake (POL; Exposed) and Bootjack Lake (BOL; Reference) Relative to the British Columbia Guideline for the Protection of Aquatic Life, 2015 to 2022

Indicates mean selenium concentration greater than the BCMOE guideline for ovary tissue in fish (11 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than DeForest et al (2012) threshold for ovary tissue in fish (20 mg/kg dw) and the BCMOE guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight, > = greater than, BCMOE = British Columbia Ministry of Environment, % = percent.

[a] Data are considered suspect and are likely influenced by laboratory error or contamination (Golder 2016b; Minnow 2017g).

the protection of aquatic life, as well as the 20 mg/kg dw threshold for reproductive effects (DeForest et al. 2012, BCMOE 2014; Table 5.10; Appendix Tables C.7.3, C.7.4).

5.1.6.2 Spatial and Temporal Comparisons

Data collected from Polley and Bootjack lakes in baseline (1995; HKP 1996), pre-breach (2009; Minnow 2011), and post-breach monitoring studies (2015 to 2021; Table 3.9)[50] were compared spatially (exposed versus reference) and temporally (annual change; see Section 3.7.3.2). These comparisons included up to 36 elements[51], two species (rainbow trout and longnose sucker), and four tissues (muscle, liver, ovary, and kidney; Appendix Figures E.6.1 to E.6.8, Appendix Tables E.6.1 to E.6.8).

Age and morphological measures (fork length and body weight) of rainbow trout and longnose sucker captured from Polley and Bootjack lakes between 2015 and 2022 are summarized in Table 5.11 (see Appendix Tables C.6.10 to C.6.11 for detailed 2022 data). Statistical comparisons of these physical measures exhibited a significant *Area*×*Year* interaction for rainbow trout fork length and body weight (based on data from 1995 to 2022; Table 5.12; Appendix Table E.6.1).[52] Rainbow trout sampled from Polley Lake were similar in size and age to those sampled those from Bootjack Lake in 2022. This was also true in prior years except 2015, 2019, 2020 when rainbow trout from Polley Lake were significantly longer (8% to 17%) and heavier (27% to 46%) than those from the reference lake (Table 5.12; Appendix Table E.6.1). The greater size and weight of rainbow trout collected from Polley Lake in 2015, 2019, and 2020 relative to Bootjack Lake may be related to limited rainbow trout recruitment associated with Hazeltine Creek being inaccessible for spawning and rearing from 2014 to 2017 (see Section 3.6.1). Conversely, longnose sucker collected from Polley Lake were significantly younger (90% in all years) and lighter (30% in 2022) than longnose sucker from Bootjack Lake (Table 5.12; Appendix Table E.6.2). In previous monitoring years, longnose sucker from Polley Lake were younger, and either not significantly different in size or were shorter and/or lighter compared to those from Bootjack Lake, consistent with trends observed during baseline data collection for size and weight (i.e., 1995; Table 5.12; Appendix Table E.6.2).

[50] The reference area (Bootjack Lake) was not sampled in 2016; therefore, statistical comparisons were not completed for 2016 (i.e., concurrent exposed and reference data are required; see Section 3.7.3.2).

[51] Silver and titanium were added to fish tissue analyses in 2020.

[52] Results of the two-way ANOVA for age, fork length, and body size may differ among tissue types for the same species in the same area due to sub-sampling (i.e., the number of females sampled for ovary tissue may be a subset of the total samples) or differences in data availability across years for the different tissue types (e.g., rainbow trout kidney data were collected from 2018 to 2022 compared to 1995 to 2022 for rainbow trout muscle tissue). For all species sampled for tissue in 2022, discussion of age and body size is focused on results of two-way ANOVA for muscle and ovary tissues.

Table 5.11: Age and Body Size Data of Fish Collected for Tissue Quality Monitoring from Polley Lake (Exposed) and Bootjack Lake (Reference), 2015 to 2022

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: "-" = no data available for analysis (i.e., either no data was collected for the given time period or the data were <LRL and could not be analysed); "<LRL" = greater than 50% LRL data for both stations so the time period was omitted from the analysis, "ns" = not significant; "ww" = wet weight; "Exp" = exposed; "Ref" = reference; "ANOVA" = Analysis of Variance; "MLE" = Maximum Likelihood Estimation. Data were analysed in units of mg/kg dry weight. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Age, fork length, and body weight results are those that are associated with muscle tissue analyses.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Table E.6.1 to E.6.8). This table only presents results for primary and secondary analytes that had a significant postive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types in one or both species.

[b] Organ in which the specific metal is known to accumulate (references in Appendix Table E.6.22).

[c] Magnitude of difference (MOD) calculated on back transformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted}) \times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[d] Magnitude of difference (MOD) calculated on back transformed least-squares means as (Exp-Ref)/Ref x 100%.

[e] MOD is inflated because data for one of the groups in the comparison were entirely < LRL, leading to an underestimate of the mean for the <LRL result and a consequent increase in MOD between the two groups.

Table 5.12: Summary of Statistical Contrasts of Exposed - Reference Relative Differences of Fish Tissue Primary and Secondary Analyte Concentrations for Polley Lake (Exposed) and Bootjack Lake (Reference), 1995 to 2022[a]

	Parameter	Tissue	Rainbow Trout: Two-way ANOVA																			Longnose Sucker: Two-way ANOVA														
			Magnitude of Difference in (Exposed - Reference) Relative to Baseline Period (%)										Magnitude of Difference for Polley Lake (Exposed) Mean Relative to Bootjack Lake (Reference) (%)										Magnitude of Difference in (Exposed - Reference) Relative to Baseline Period (%)										Magnitude of Difference for Polley Lake Mean Relative to Bootjack Lake (%)									
			Before Period	Uncontrolled Release Period	Post-Release Period	Post-Breach Period							Before Period	Uncontrolled Release Period	Post-Release Period	Post-Breach Period							Before Period	Post-Release Period	Post-Breach Period							Before Period	Post-Release Period	Post-Breach Period						
			1995	2009	2012	2015	2017	2018	2019	2020	2021	2022	1995	2009	2012	2015	2017	2018	2019	2020	2021	2022	1995	2012	2017	2018	2019	2020	2021	2022	1995	2012	2017	2018	2019	2020	2021	2022

Contrast is significant (α = 0.05) and magnitude of difference is positive.

Contrast is significant (α = 0.05) and magnitude of difference is negative.

Notes: "-" = no data available for analysis (i.e., either no data was collected for the given time period or the data were <LRL and could not be analysed); "<LRL" = greater than 50% LRL data for both stations so the time period was omitted from the analysis, "ns" = not significant; "ww" = wet weight; "Exp" = exposed; "Ref" = reference; "ANOVA" = Analysis of Variance; "MLE" = Maximum Likelihood Estimation. Data were analysed in units of mg/kg dry weight. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Age, fork length, and body weight results are those that are associated with muscle tissue analyses.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Table E.6.1 to E.6.8). This table only presents results for primary and secondary analytes that had a significant postive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types in one or both species.

[b] Organ in which the specific metal is known to accumulate (references in Appendix Table E.6.22).

[c] Magnitude of difference (MOD) calculated on back transformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted})\times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[d] Magnitude of difference (MOD) calculated on back transformed least-squares means as (Exp-Ref)/Ref x 100%.

[e] MOD is inflated because data for one of the groups in the comparison were entirely < LRL, leading to an underestimate of the mean for the <LRL result and a consequent increase in MOD between the two groups.

As indicated in Section 3.7.3, data interpretation was focused on primary and secondary analytes (Table 2.4) with a significant positive exposed-reference difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2022 (if the analysis *Area×Year* interaction was significant) or in all monitoring years (if the *Area×Year* interaction was not significant[53]). Increasing concentrations at exposed areas relative to reference areas over time, or consistently elevated concentrations at the exposed area relative to reference, were not detected for most metals (Appendix Figures E.6.1 to E.6.8, Appendix Tables E.6.1 to E.6.8). The primary analytes arsenic, copper, iron, and selenium, and secondary analytes cobalt, manganese, molybdenum, nickel, sodium, tin, vanadium met the criteria for inclusion in data interpretation outlined above (Table 5.12). Of these primary and secondary analytes, only sodium concentrations were consistently higher in zooplankton from Polley Lake than reference (Bootjack Lake) between 2019 and 2022 (Table 5.5), while concentrations of arsenic, copper, manganese, and molybdenum in zooplankton tissue from Polley Lake decreased significantly between 2019 and 2022 (Appendix Table E.3.1). In previous years, concentrations of three of these analytes were also higher in zooplankton from Polley Lake than reference (Bootjack Lake) in one (copper and molybdenum) or two (zinc) years from 2019 to 2021 (Appendix Table E.3.1). Selenium concentrations in zooplankton tissue from Polley Lake in 2022 were similar to reference after being significantly higher than reference from 2019 to 2021 and were significantly lower in 2022 compared to 2020 and 2021 (but not 2019), relative to reference (Appendix Table E.3.1; see Section 5.1.4 for details).

Significant *Area×Year* interactions were detected for selenium concentrations in exposed rainbow trout and longnose sucker for most tissue types except for kidney in rainbow trout. The significant *Area×Year* interaction indicates that the ratio of exposed:reference concentrations differed among years (i.e., the geometric mean concentrations at the exposed area were not trending the same as the geometric mean concentrations at the reference area). The timing of the interactions indicated that selenium accumulation began between 1995 and 2009 (i.e., may be associated with the 2006 to 2009 uncontrolled surface runoff to Polley Lake; Figure 5.12, Table 5.12; Appendix Tables E.6.1 to E.6.8). In general, selenium concentrations in tissues did not continue to increase after the post-release period (2012), except for tissue selenium concentrations in rainbow trout ovary that were significantly higher, relative to reference, in 2015 compared to 2012

[53] If no significant change was detected in the exposed-reference difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

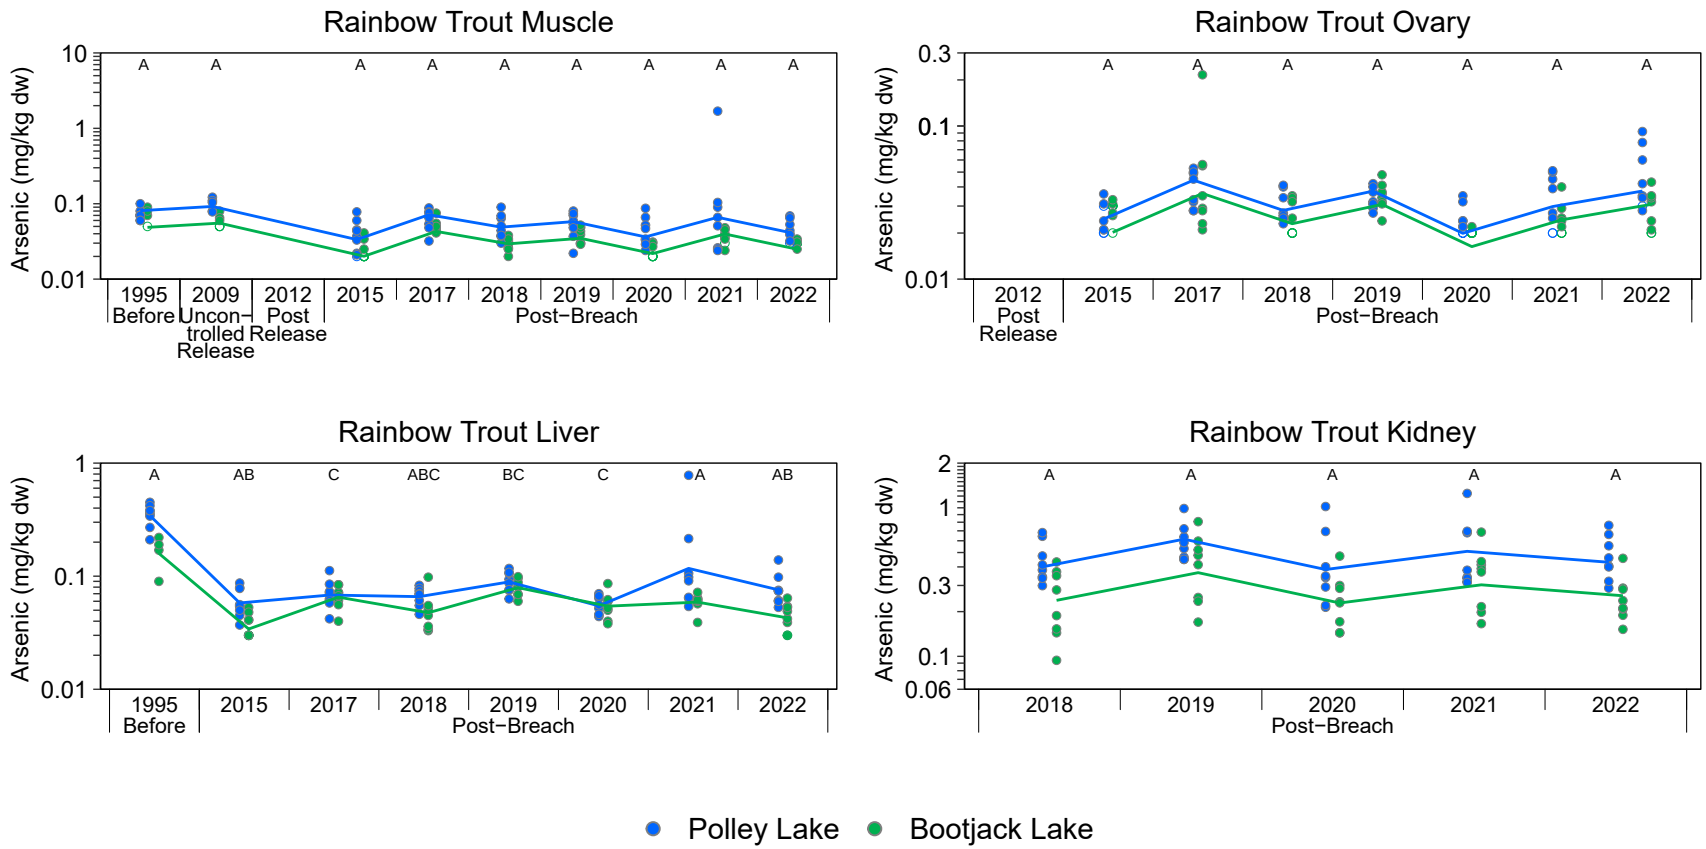

Figure 5.12: Fish Tissue Primary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Polley Lake (Exposed) and Bootjack Lake (Reference), 1995 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. Plots are only included for primary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022, or had no significant interaction but had a higher exposed magnitude of difference across all years for a given species and tissue type. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least-squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Polley Lake:Bootjack Lake) that do not differ significantly (p−value <0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Polley Lake:Bootjack Lake). Only years with samples from both reference and exposed areas are plotted.

(Figure 5.12, Table 5.12; Appendix Table E.6.3)[54]. It is possible that the 2015 peak in rainbow trout ovary selenium concentrations may reflect a short-term impact associated with the breach or possible laboratory error (previously mentioned) that cannot be separated from potential mine influence between 1995 and 2015.

Post-breach selenium concentrations in rainbow trout muscle, ovary, liver, and kidney have been consistently higher than reference (67% to 564%; Table 5.12), although there is no indication that selenium is consistently increasing in rainbow trout tissue over time. In fact, the exposed:reference ratios in muscle and liver concentrations in 2022 were at their lowest since 2017 relative to baseline, and differences between areas for ovary and kidney were not significantly different from baseline (Figure 5.12, Table 5.12; Appendix Tables E.6.1, E.6.3, E.6.4, E.6.8). In addition, selenium concentrations in rainbow trout muscle and ovary tissues were both significantly lower in 2022, relative to reference, than in 2017 to 2019 (Figure 5.12). Tissue selenium concentrations in longnose sucker have been consistently higher than reference in each year since the breach (33% to 229% across tissue types). However, selenium concentrations in longnose sucker tissues (i.e., muscle ovary, liver, and kidney) have shown temporal stability or have decreased in Polley Lake relative to Bootjack Lake since the post-release period (2012). For instance, selenium concentrations in longnose sucker ovary tissues were significantly lower in 2022, relative to reference, than reported in 2015 to 2020 (Figure 5.12, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7).

Concentrations of the primary analytes arsenic, copper, and iron were significantly higher in most rainbow trout tissues (muscle, ovary, liver, and kidney) from Polley Lake compared to Bootjack Lake in 2022 (or in all monitoring years if the *Area×Year* interaction was not significant), with two exceptions. These two exceptions are that copper in rainbow trout muscle and iron in rainbow trout ovary did not differ between the waterbodies in 2022 (Figure 5.12, Table 5.12; Appendix Tables E.6.1, E.6.3, E.6.4, E.6.8). Arsenic, copper, and iron concentrations in rainbow trout tissues were unchanged over time (i.e., temporally stable) in most instances, relative to reference. Where temporal changes occurred, the magnitude of the exposed:reference ratio in 2022 was either similar to or lower than baseline (Figure 5.12; Appendix Tables E.6.1, E.6.3, E.6.4, E.6.8). Therefore, there is no evidence that arsenic, copper, and iron concentrations in rainbow trout tissues from Polley Lake are increasing over time due to mine-related influence.

In longnose sucker tissues, arsenic concentrations in liver and kidney, copper concentrations in all tissues except ovary, and iron concentrations in kidney were significantly higher in samples

[54] It is considered likely that a subset of the selenium concentrations measured in exposed rainbow trout ovaries from 2015 were subject to laboratory error or contamination, resulting in reporting of increased selenium concentrations (Minnow 2017e).

from Polley Lake relative to Bootjack Lake in 2022 (or in all monitoring years; Figure 5.12, Table 5.12). However, these exposed:reference ratios in 2022 did not differ significantly from baseline, with three exceptions (Figure 5.12, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7). Specifically, copper concentrations in muscle and liver and iron concentrations in kidney tissues of longnose sucker had exposed:reference ratios that were significantly higher in 2022 compared to 2017 (baseline) to 2020 for copper in muscle and liver and compared to 2018 (baseline) and 2019 for iron in kidney (Figure 5.12, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7). The lack of consistency in the observed increases of copper and iron concentrations among longnose sucker tissue types (i.e., increases not observed in all tissues) suggests that these results are somewhat equivocal. In addition, the increases in copper and iron concentrations in longnose sucker tissues from Polley Lake in 2022 are not supported by the results of zooplankton monitoring which have indicated that copper and iron concentrations in zooplankton tissues from Polley Lake were either similar to or lower than reference in 2022 (see Section 5.1.4; Appendix Table E.3.1). Despite these inconsistencies, continued monitoring and evaluation will help to understand whether these changes were isolated or are part of a longer-term pattern.

Of the secondary analytes, cobalt, manganese, molybdenum, nickel, sodium, tin, vanadium, and zinc had significant *Area×Year* interaction terms for one or more tissue types in rainbow trout and/or longnose sucker and/or were elevated in fish caught in Polley Lake relative to Bootjack Lake in 2022 (Figure 5.13, Table 5.12; Appendix Tables E.6.1 to E.6.8). For most secondary analyte-tissue combinations, for either species, this difference was not indicative of an increase in concentrations over time due to mine influence. This is because the significant positive exposed-reference differences in 2022 were either not significantly different from prior years, or the *Area×Year* interaction and significant positive exposed-reference difference in 2022 was only reported in one tissue type in one species. For simplicity, only those secondary analyte-tissue combinations with a significant positive exposed-reference difference in 2022 or in all years (if the *Area×Year* interaction was not significant) in more than one tissue type within a species are discussed further (i.e., nickel, sodium, and tin were not discussed further).

Cobalt concentrations in rainbow trout ovary, liver, and kidney have been consistently higher in Polley Lake compared to Bootjack Lake since 2018, though cobalt concentrations in exposed tissues, relative to reference, have not changed significantly since monitoring began (Figure 5.13, Table 5.12; Appendix Tables E.6.3, E.6.4, E.6.8). For rainbow trout muscle, 2022 represents the first time since initiation of monitoring that cobalt concentrations were significantly greater in Polley Lake relative to reference. Despite this, the cobalt concentrations in rainbow trout muscle from Polley Lake, relative to reference, have been stable (i.e., did not change significantly) since 2018 (Figure 5.13, Table 5.12; Appendix Table E.6.1). Manganese concentrations in

Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log-normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Polley Lake:Bootjack Lake) that do not differ significantly (p-value <0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Polley Lake:Bootjack Lake). Only years with samples from both reference and exposed areas are plotted.

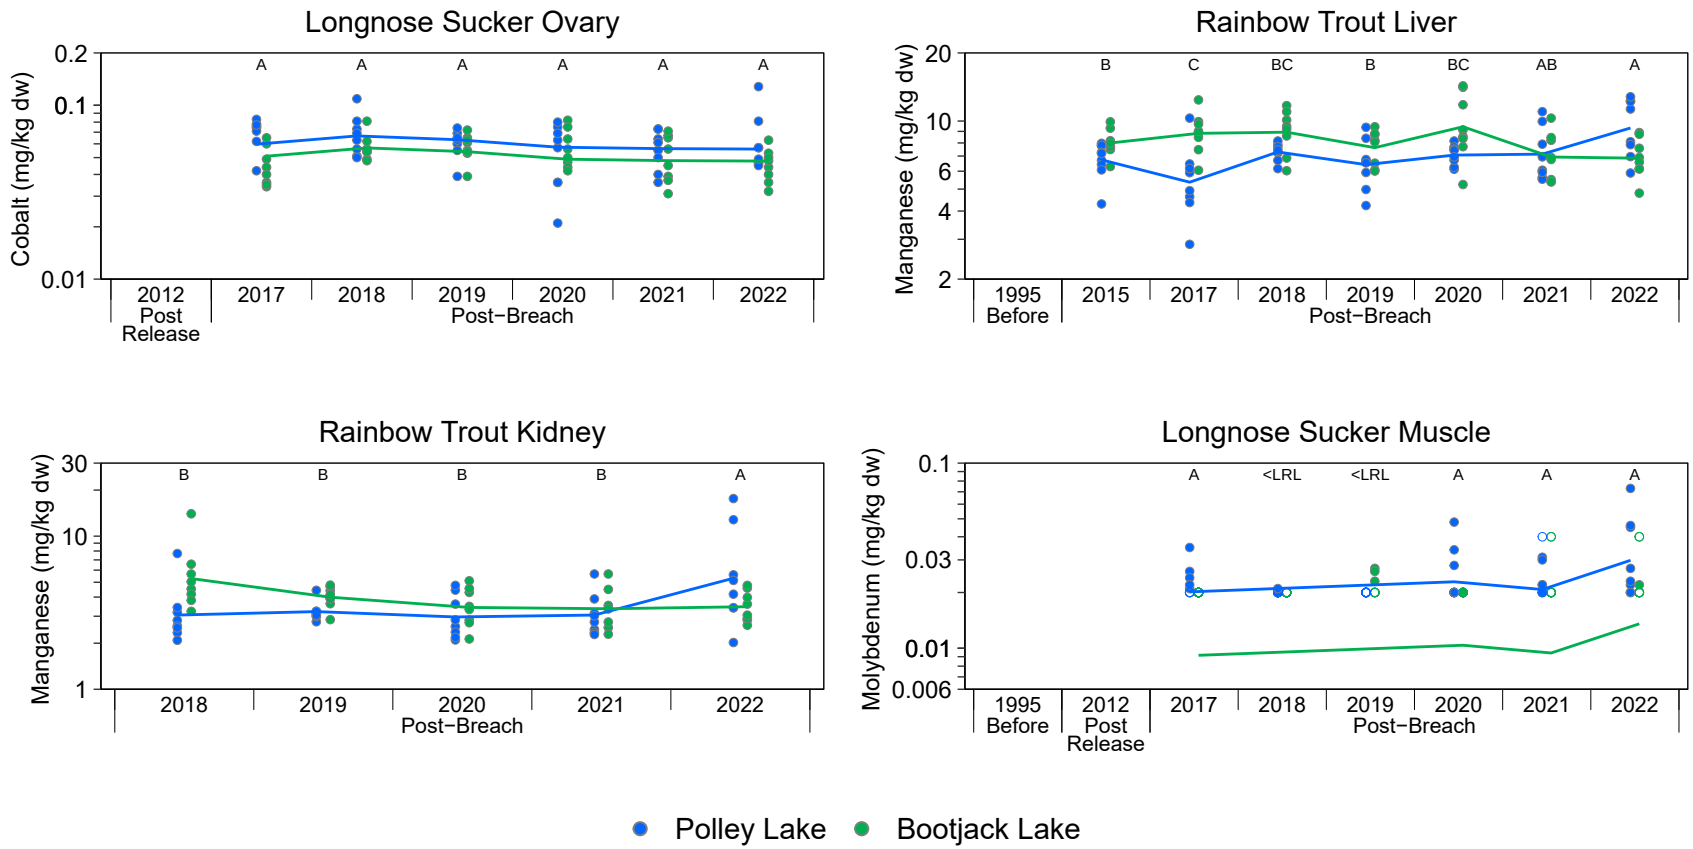

Figure 5.13: Fish Tissue Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Polley Lake (Exposed) and Bootjack Lake (Reference), 1995 to 2022

Notes: dw = dry weight. Plots are only included for primary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022, or had no significant interaction but had a higher exposed magnitude of difference across all years for a given species and tissue type. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log-normal distribution. rainbow trout liver and kidney were higher in Polley Lake relative to Bootjack Lake in 2022 and the exposed:reference ratios were also significantly greater in 2022 compared to 2015 to 2020 for liver and compared to 2018 to 2021 for kidney (Figure 5.13, Table 5.12; Appendix Tables E.6.4 and E.6.8). Molybdenum concentrations in all longnose sucker tissue types were significantly higher in the fish from Polley Lake relative to reference in 2022. However, molybdenum concentrations in exposed longnose sucker tissues in 2022 were similar to the baseline year, relative to reference, except for liver which had significantly higher concentrations in 2022 than baseline (compared to reference; Figure 5.13, Table 5.12; Appendix Tables E.6.2, E.6.5 to E.6.7). Vanadium concentrations were significantly greater in rainbow trout and longnose sucker liver and kidney in Polley Lake relative to reference, but the exposed:reference ratios in 2022 did not differ significantly from the baseline period. Zinc concentrations in Polley Lake were significantly greater than in Bootjack Lake across all longnose sucker tissues as well as rainbow trout liver; however, in no instance was the exposed:reference ratio in 2022 significantly different from the baseline period (Figure 5.13, Table 5.12; Appendix Tables E.6.4, E.6.8). The lack of consistency in secondary analyte results among tissues, between species, and temporally, suggests the observed changes in secondary analyte concentrations are unlikely to be the result of any persistent mine related effect and could be related to natural variability.

Overall, the results of Polley Lake rainbow trout and longnose sucker tissue quality analysis suggest that selenium concentrations in Polley Lake fish tissue increased in response to the uncontrolled surface runoff (2006 to 2009), and concentrations have remained elevated relative to reference conditions. Selenium concentrations in muscle and ovaries of rainbow trout in 2022 were significantly lower than in 2017 to 2019, relative to reference, and represent their lowest levels throughout the post-breach period. Selenium concentrations in longnose sucker tissues in 2022 were either similar to or lower than in most years since 2017. Increases in the concentrations of other analytes (i.e., arsenic, copper, iron, cobalt, manganese, molybdenum, sodium, vanadium, and zinc) in fish tissues from Polley Lake were also observed (relative to reference) but were inconsistent among tissues, species, and temporally, and are considered equivocal and inconclusive at this time. Continued post-breach monitoring will evaluate potential future changes in metal concentrations in Polley Lake rainbow trout and longnose sucker tissues.

5.1.7 Summary

Sediments were collected from the shallow area of Polley Lake (and reference) in 2022 to support the evaluation of sediment toxicity. Sediments from this area were characterized by concentrations of arsenic, copper, and iron greater than reference concentrations and WSQG. Copper was the most substantially elevated Analyte of Interest, with a mean concentration 3.4

times the upper WSQG. Copper was also the only Analyte of Interest to exceed the lower WSQG in reference sediments, which it exceeded by approximately 2.5 times. Arsenic, copper, and iron concentrations in shallow Polley Lake sediments in 2022 were similar to those reported in the previous sampling event (i.e., 2019), relative to reference, indicating temporal stability of these analyte concentrations. The TOC content of Polley Lake shallow sediments in 2022 was significantly lower than reference and did not change from 2019 to 2022, relative to reference. Overall, the 2022 sediment quality results from the shallow area of Polley Lake indicate temporal stability in the physical and chemical characteristics of these sediments since initiation of monitoring in 2019.

Sediment toxicity testing of the shallow area of Polley Lake (and reference) in 2022 indicated no unacceptable response to survival or growth of *H. azteca* relative to the reference area or the sand control. The survival and growth responses observed in 2022 were similar to those in 2019 when sampling was initiated. Conditions of the CEMP outlined that sediment toxicity testing of the shallow Polley Lake area must be continued "*unless MPMC can clearly show that copper concentrations in all Polley Lake shallow sediment samples are below the 95th percentile of the copper concentrations in the Bootjack Lake reference area shallow sediment samples.*" (BCMOECCS 2021c). This condition was not met in 2022 in Polley Lake shallow sediments, indicating that toxicity testing of these shallow sediments must be completed in three years (in 2025) in accordance with the CEMP conditions.

Phytoplankton community and productivity monitoring in Polley Lake in 2022 indicated that phytoplankton productivity (in terms of chlorophyll-a concentrations) was higher than reference, despite being significantly lower in 2021 and similar between the two lakes in 2019 and 2020. The chlorophyll-a results characterize Polley Lake as mesotrophic and reference (Bootjack Lake) as oligotrophic. While the trophic state of Polley Lake increased from oligotrophic to mesotrophic between 2021 and 2022, this represented a return to the same mesotrophic status observed in Polley Lake in 2019. The phytoplankton community in Polley Lake in 2022 was characterized by higher total density, lower taxon richness, higher Simpson's Diversity and Evenness, higher relative densities of Chlorophytes and Chrysophytes, and lower relative densities of Cyanobacteria compared to reference. Overall, result for most primary endpoints in Polley Lake were similar to or higher than reference in 2022 (density, Simpson's Diversity and Evenness), while those endpoints that were lower than reference (e.g., taxon richness) were temporally stable, suggesting there is no mine-related influence on the phytoplankton community of Polley Lake.

Zooplankton community and productivity monitoring in Polley Lake in 2022 indicated that total zooplankton biomass (dw) was similar to reference, which is consistent with prior years

(2019 to 2021) when biomass was either similar to or higher than reference. The consistently similar or significantly higher total biomass of zooplankton in Polley Lake compared to the reference is indicative of a healthy lentic system, providing critical habitat for fish. The zooplankton community of Polley Lake in 2022 was characterized by total density, taxon richness, and Simpson's Diversity and Evenness that were similar to reference. From 2019 to 2022, the zooplankton community of Polley Lake differed from the reference area in terms of significantly higher and lower density in 2019 and 2021, respectively, lower taxon richness in 2020, and lower Simpson's Diversity and Evenness in 2019 and 2020. Community composition from 2019 to 2022 has consistently been characterized by higher relative densities of Copepod Nauplii and Cyclopoida, and lower relative densities of Rotifera compared to reference. The consistent differences in zooplankton community composition between Polley Lake and the reference area suggests that temporal changes in community composition (which were similar in both areas over time) were likely driven by natural variability in environmental parameters (e.g., water temperature, nutrient availability, phytoplankton community).

Zooplankton tissue quality monitoring in Polley Lake in 2022 indicated that concentrations of primary and secondary analytes in tissues from Polley Lake were similar to or lower than reference except for sodium. Sodium concentrations were significantly greater than reference between 2019 and 2022 but demonstrated temporal stability relative to reference (i.e., did not differ between 2019 and 2022). Concentrations of two primary analytes (arsenic and copper) and three secondary analytes (manganese, mercury, molybdenum) in zooplankton tissue from Polley Lake in 2022 were significantly lower, relative to reference, than in 2019 when replicated sampling was initiated. Concentrations of selenium in zooplankton tissue from Polley Lake were below the BC interim guideline for aquatic life in 2022, which contrasts with prior years when individual zooplankton tissue selenium results have exceeded the guideline (2016, 2017, 2019, and 2021). Selenium concentrations in zooplankton tissue from Polley Lake in 2022 were similar to reference and were significantly lower than in 2020 and 2021 (but not 2019), relative to reference. The temporal stability or decreases in primary and secondary analyte concentrations in zooplankton tissue from Polley Lake in 2022 compared to 2019 was supported by trend analyses of surface water quality data which similarly showed stable or decreasing concentrations for all aqueous primary and secondary analytes except copper and vanadium.

Fish community and population health assessments undertaken from 2019 to 2022 documented the influence of the temporary loss of Hazeltine Creek due to the breach (August 2014 to April 2018), which previously supported the majority of fish recruitment to Polley Lake. Rainbow trout CPUE in spring was higher in 2022 than in all previous years since 2016. Prior to 2022, spring CPUE progressively decreased from 2019 to 2021, and was also substantially lower in all three years than in 2016, consistent with loss of recruitment and

natural mortality of older fish since the breach. As such, the spring CPUE in 2022 suggests that most of the remaining 2018 and a portion of the 2019 cohort has reached maturity which is further supported by spring spawning surveys conducted in Hazeltine Creek that documented the highest abundance of adults since 2019 (Minnow 2023). In the fall of 2022, when fishing was randomized in Polley Lake, CPUE was lower than from 2019 to 2021. However it should be noted that temporal comparisons of CPUE are subject to variability resulting from several factors that can affect the success of netting efforts, which is true even when considering the randomized and standardized fish collection methods employed. The assessment of rainbow trout size distribution provides a more comparable basis for temporally evaluating the population recovery in Polley Lake. Length frequency distributions for rainbow trout over time showed a proportional shift towards smaller and younger fish in 2019, a continued to shift towards a more balanced distribution among size classes with the survivorship of the 2018 and 2019 cohorts, and in 2022, a size class distribution more closely resembling 2016. The length frequency distribution in 2022 had greater resemblance to 2016 than the length frequency distributions from any of the other years (2018 to 2021), suggesting the population has returned to a pre-breach size class distribution. Condition of female rainbow trout in spring 2022 was similar to 2021 but lower than in all prior years (2016 to 2020) whereas growth rate in 2022 was similar to prior years but lower than in 2020. CPUE for longnose sucker in the spring has varied without evidence of a consistent directional trend over time, but CPUE in the fall has progressively decreased from 2016 to 2022. As indicated above, there are several sources of variability that can affect temporal comparisons of CPUE. Length frequency distributions for longnose sucker in Polley Lake from 2016 to 2022 showed more smaller fish were caught in 2022 compared to 2016, as was the case in 2018, 2020, and 2021, suggesting ongoing recruitment success despite the decrease in CPUE since 2016. Condition of longnose sucker females in spring has varied since 2016 but in 2022 was similar to baseline (2016) and weight-at-age also varied, although growth rate in 2022 did not significantly differ from prior years.

Fish tissue quality, evaluated in four tissues (muscle, liver, kidney, and ovary) from rainbow trout and longnose sucker, indicated that mean mercury and selenium concentrations in muscle tissue in 2022 were below guidelines for the protection of human health based on moderate consumption (i.e., indicating that fish are safe for moderate human consumption). The mean selenium concentration in muscle of longnose sucker from Polley Lake in 2022 exceeded the guideline for the protection of human health based on high consumption, which was consistent with data from 2016 (except 2017 and 2021). However, the likelihood that longnose sucker would be consumed at a high rate (i.e., subsistence consumers) is low. Selenium concentrations in ovary tissue in 2022 (the tissue most valuable in the assessment of potential selenium-associated effects on fish) for both species were lower than the BCWQG for the protection of aquatic life in

all individuals except one rainbow trout in 2022 and were below the threshold for reproductive effects in all fish. Selenium concentrations in muscle tissue of rainbow trout and longnose sucker were moderately greater than the guideline for aquatic life, which was consistent with data from 2015 to 2021. Overall, selenium concentrations in Polley Lake fish tissue have remained elevated relative to reference conditions since the uncontrolled runoff from 2006 to 2009 but the difference has not increased over the post-breach period. In fact, selenium concentrations in rainbow trout muscle and ovary tissues were significantly lower in 2022, relative to reference, than in 2017 to 2019. Additionally, selenium concentrations in longnose sucker ovary tissues were significantly lower in 2022, relative to reference, than in 2015 to 2020. This decrease in fish tissue selenium concentrations in Polley Lake corresponds with a decrease in the selenium concentrations in zooplankton tissue (i.e., dietary exposure) in 2022 compared to 2020 and 2021, and with a significant decrease in total and dissolved selenium concentrations in surface waters of Polley Lake from 2015 to 2022. Evidence of a persistent mine influence was not detected for most other analytes assessed in fish tissue in 2022. All primary analytes (arsenic, copper, iron, and selenium), and the secondary analytes cobalt, manganese, molybdenum, nickel, sodium, tin, vanadium, and zinc were elevated relative to reference in 2022 in at least one tissue type in one or both species. However, results for most these analytes (excluding selenium) were inconsistent among tissues and species, and/or were temporally stable or decreased relative to reference, indicating that the weight of evidence does not support a pattern of increasing analyte concentrations over time due to mine-exposure.

5.2 Quesnel Lake

5.2.1 Sediment Quality

Sediment quality monitoring in 2022 was completed at deep (QUL-PNF) and shallow (QUL-LNF1) exposed areas of Quesnel Lake. An unimpacted shallow (QUL-LREF1) area served as reference for the corresponding shallow exposed area (Figure 3.2, Table 3.2). An unimpacted deep reference area (QUL-PREF1) was not sampled in 2022 because monitoring of the deep impacted area (QUL-PNF) focused on evaluating temporal changes within the exposed area. Comparisons to the deep reference area results from prior years (2014 to 2021) are incorporated to support qualitative data interpretation where appropriate (see Section 3.1.3 for details of data analyses). A review of the 2022 sediment and supporting water data quality (Appendix B) indicated that these data can be used with a high or good level of confidence for interpretation, respectively (see Section 5.1.1 for details).

5.2.1.1 Deep Lake Areas

Sediments collected from the exposed deep near-field area (QUL-PNF) of Quesnel Lake in 2022 were composed primarily of silt and clay particles (mean = 46.0% and 43.8%, respectively; Table 5.13). Although QUL-PNF sediment is predominantly fine grained, and has been since 2014, sediments in 2022 had the highest sand content (mean = 10.2%) since initiation of monitoring in 2014 (Table 5.13). Sediments from the deep reference station were not collected in 2022, however, sediments from QUL-PREF1 were composed primarily of silt and sand in 2021 (mean = 68.7% and 20.1%, respectively) and had higher sand content than QUL-PNF sediments (Table 5.13; Appendix Tables C.2.4 and C.2.5). The TOC and total nitrogen content of sediments from QUL-PNF in 2022 (0.614% and 0.0786 %, respectively) were lower than those reported for the reference area in 2021 (2.10% and 0.154%, respectively). Although the TOC content of QUL-PNF has not changed significantly since 2015 (Figure 5.14), mean TOC has increased steadily (but not significantly) from 0.29% in 2015 to 0.61% in 2022 (Table 5.13; Appendix Table E.1.5).

Mean concentrations of 25 out of 34 metal analytes in QUL-PNF sediments (<63 µm fraction) collected in 2022 exceeded reference 95th percentile values (Table 5.13). Among these elements, four (arsenic, copper, iron, and manganese) had mean concentrations which also exceeded the WSQG values (Table 5.13; Appendix Table C.2.5). Specifically, mean arsenic concentrations were greater than the lower WSQG by 2.6 times and mean copper, iron, and manganese concentrations exceeded the upper WSQG by 4.2, 1.03, and 1.2 times, respectively (Figure 5.14, Table 5.13). Mean arsenic, copper, iron, and manganese concentrations in reference sediments collected in 2021 were naturally elevated above the lower BC WSQG (Table 5.13; Appendix Table C.2.4), demonstrating that these elements are somewhat naturally elevated in parts of Quesnel Lake. The mean concentrations of arsenic, copper, and iron in QUL-PNF sediments collected in 2022 were similar to those reported in 2014, and the mean manganese concentration in 2022 was similar to 2015 (Figure 5.14; Appendix Table E.1.5) indicating temporal stability of these analytes in the exposed sediments.

In the fine exposed sediments from QUL-PNF, arsenic and copper were positively correlated with % clay and total sulphur content, and manganese was positively correlated with % clay and total nitrogen and sulphur content (Appendix Figure E.1.4, Appendix Table E.1.11). The correlation of higher analyte concentrations in QUL-PNF sediments with higher clay content (% clay) is consistent with the input of fine tailings-influenced sediments with elevated analyte concentrations to the deep near-field area of Quesnel Lake.

Table 5.13: Summary of Sediment Quality Data for Quesnel Lake at QUL-PNF (Exposed) and QUL-PREF1 (Reference) Deep Areas, 2014 to 2022

Analyte	Units	BC Working Sediment Quality Guidelines [a]		Reference 95th Percentile[b]	Reference QUL-PREF1

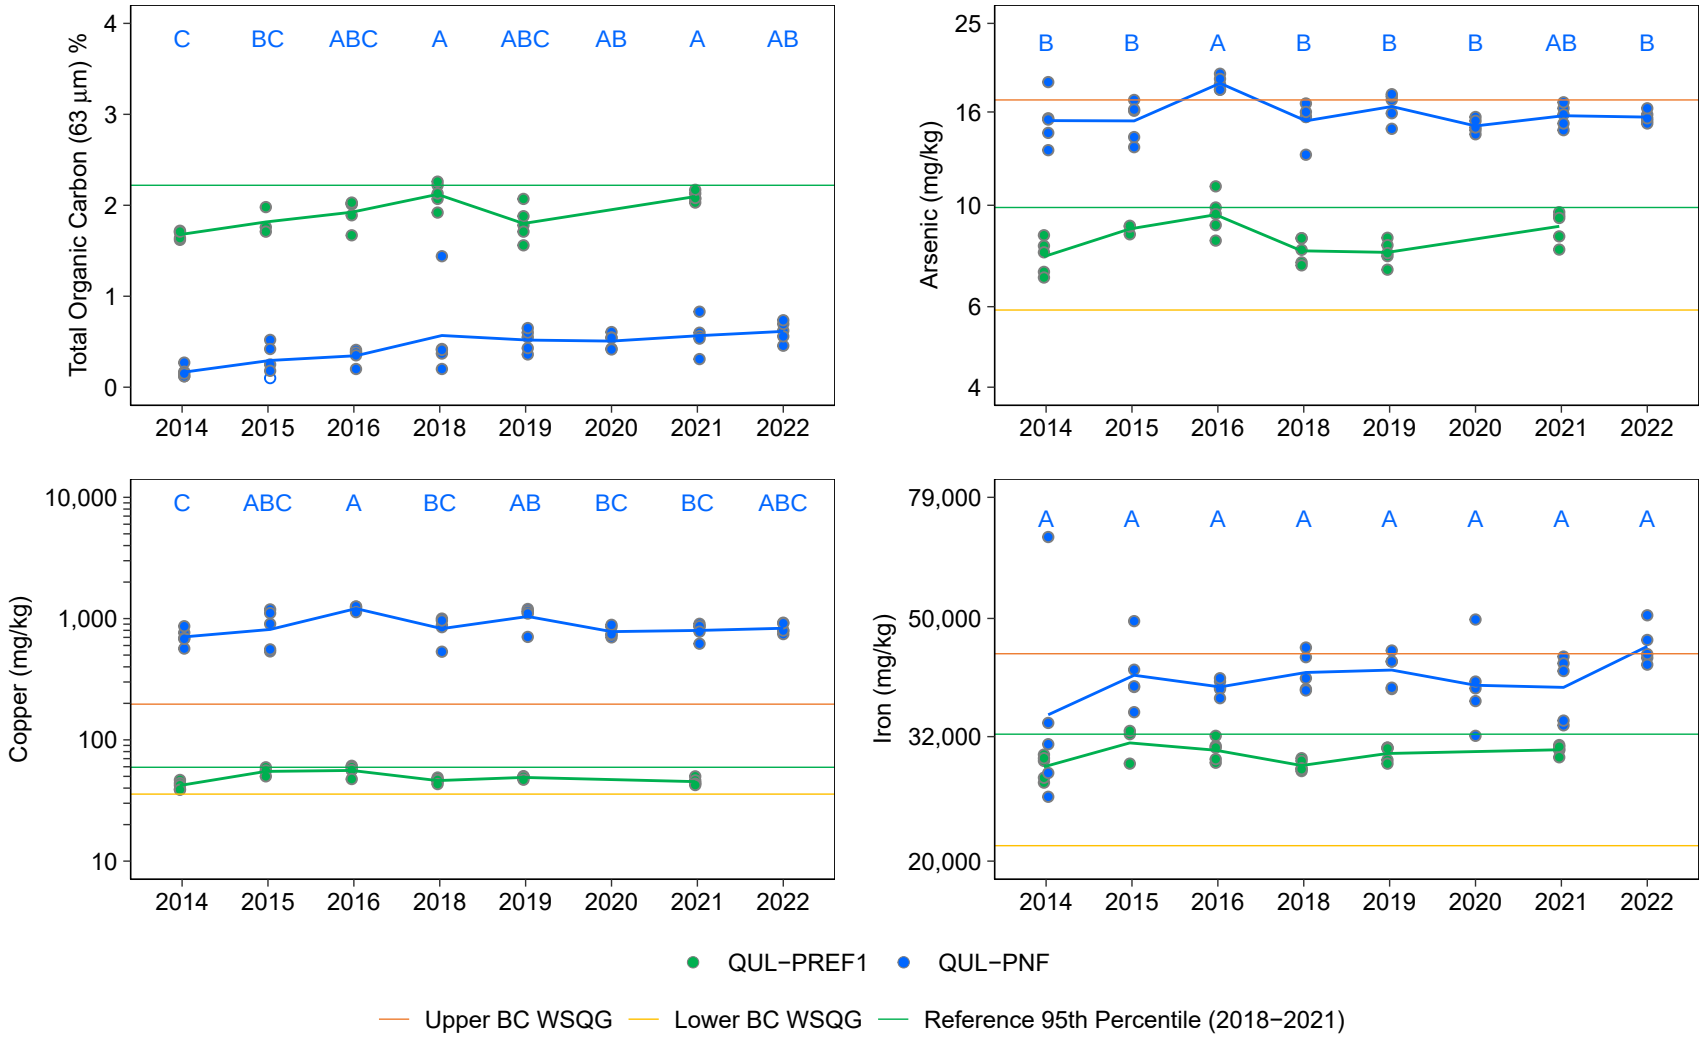

Figure 5.14: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for Quesnel Lake at QUL-PNF (Exposed) and QUL-PREF1 (Reference) Deep Areas, 2014 to 2022

Notes: BC WSQG = British Columbia Working Sediment Quality Guideline (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b). The reference 95th Percentile (QUL-PREF1) was calculated using data from 2014 to 2021. Green represents reference areas and other colours represent exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Years that share a letter (e.g., A,B,C) have concentrations that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest concentration.

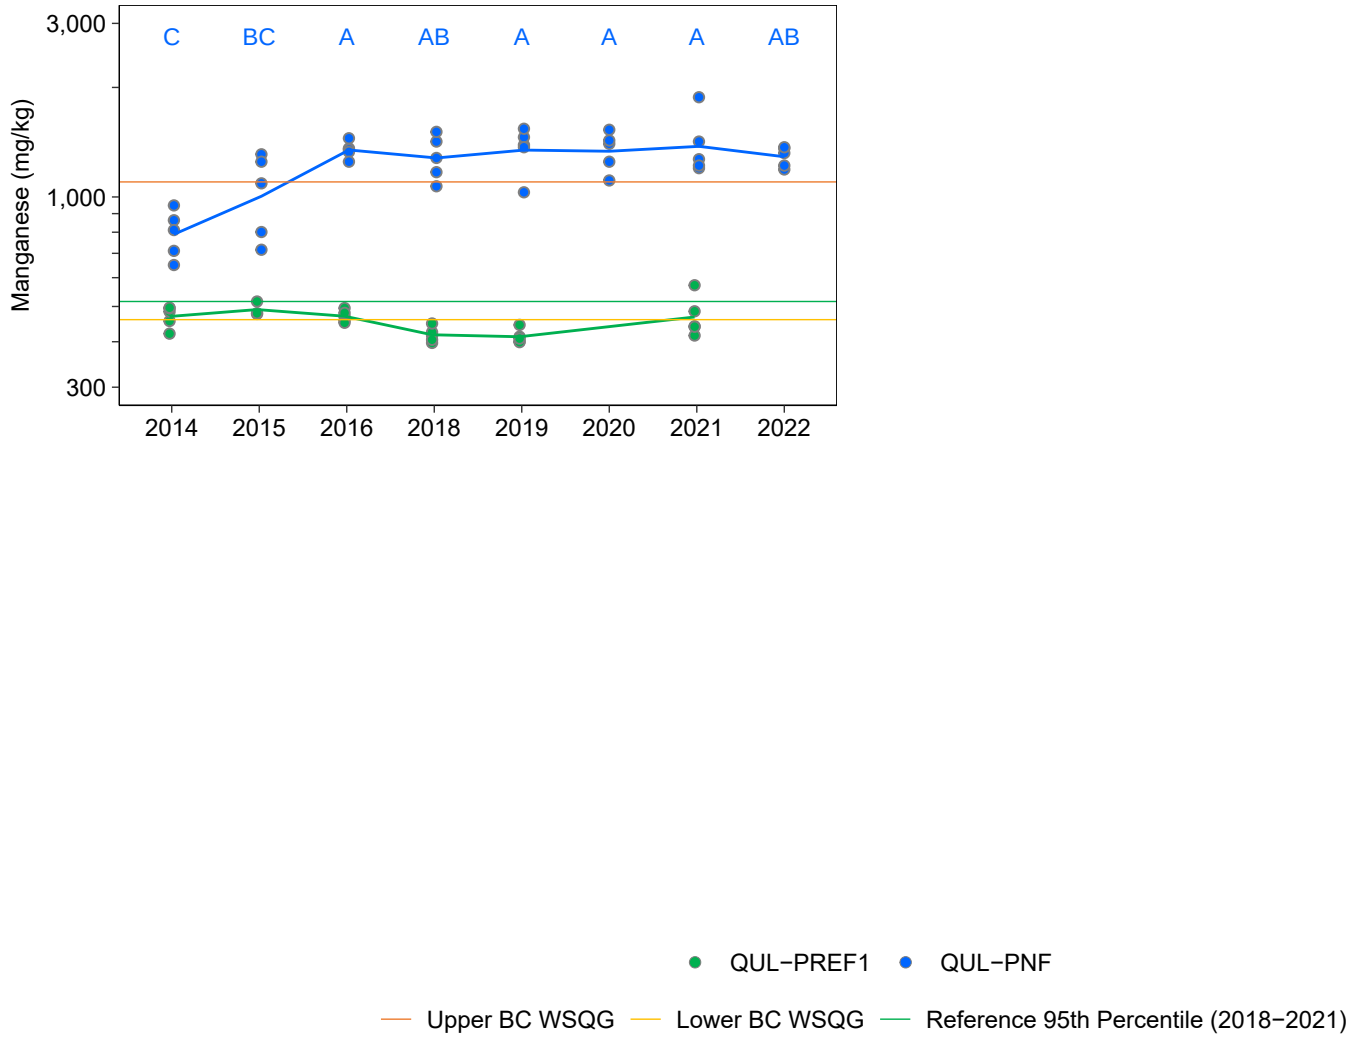

Figure 5.14: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for Quesnel Lake at QUL-PNF (Exposed) and QUL-PREF1 (Reference) Deep Areas, 2014 to 2022

The 2022 monitoring results indicate that physical and chemical characteristics of the exposed near-field sediments appear stable, with few changes occurring since post-breach monitoring began. This is consistent with the low sediment deposition rate observed at this deep exposed area, with approximately 1 cm of fresh sediment deposition after 7 to 10 years (Minnow 2019a).

5.2.1.2 Shallow Lake Areas

Sediments collected from the shallow near-field exposed area of Quesnel Lake (QUL-LNF1) in 2022 were predominantly sand with some silt (mean = 92.8% and 6.02%, respectively) which was consistent with the sediments collected from this area in previous post-breach years (2015 to 2021; Table 5.14). The high sand content was visually evident during sample collection and was likely a result of continued washing of fine particles from these shallow sampling locations towards deeper areas of the lake. The exposed sediments in 2022 were higher in sand content and lower in silt content than the corresponding reference sediments (QUL-LREF1; mean = 61.4% sand, 32.5% silt; Table 5.14), which were also consistent with the sediments collected from prior years (2014 to 2021; Table 5.14; Appendix Tables C.2.7 to C.2.9). The TOC and total nitrogen content of the shallow near-field exposed sediment collected in 2022 (mean = 0.826% and 0.0236%, respectively) were lower than in the reference sediment (mean = 1.40% and 0.078%, respectively; Table 5.14; Appendix Tables C.2.7 and C.2.9), which was consistent with the dominance of sand at this exposed area. Mean TOC concentrations of QUL-LNF1 sediments have been stable, relative to reference, since the initiation of sampling in 2014 (Figure 5.15; Appendix Table E.1.9). Although not significant relative to reference, mean TOC concentrations at QUL-LNF1 have been slightly higher since 2019 (compared to 2014 to 2016; Appendix Table E.1.10), when the shallow near-field area was relocated[55] due to low water levels in Quesnel Lake (see Minnow 2020a for details).

The mean concentrations of 22 out of 34 analytes in the exposed sediments (<63 µm fraction) collected in 2022 at QUL-LNF1 exceeded both reference and pre-breach 95th percentile values (Table 5.14; Appendix Tables C.2.7 and C.2.8). Among these elements, five analytes (arsenic, copper, iron, manganese, and silver) also had mean concentrations that exceeded the WSQG (Figure 5.15, Table 5.14; Appendix Table C.2.9). Specifically, arsenic and silver concentrations in QUL-LNF1 sediments exceeded the lower WSQG by 2.6 and 1.04

[55] The shallow near-field area of Quesnel Lake (QUL-LNF1) was moved in 2019 from its previous location due to variable water levels in the lake. Specifically, QUL-LNF1 stations that were originally sampled in 2015 to 2016 were either dry in 2019 or only very shallow (<0.5 m depth). As such, the QUL-LNF1 monitoring locations were moved in 2019 to adjacent locations that were deeper and continually submerged. These sediment stations established in 2019 were resampled in 2020, 2021, and 2022 (see Minnow 2020 for details).

Table 5.14: Summary of Sediment Quality Data for Quesnel Lake at QUL-LNF1 (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2007 to 2022

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: "-" = no data, ***Bold/Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (<5th percentile value for pH); SD - Standard Deviation. Mean values reported as < the laboratory reporting limit were not screened against guidelines or reference 95th percentile. Pre-breach values that were reported as < the laboratory reporting limit were not used for screening.

[a] British Columbia Working Sediment Guidelines (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b).

[b] The 5th percentile is reported and screened for the pH reference data. Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. For calculation of reference 95th percentile values see Appendix Table C.2.2 and for calculation of pre-breach 95th percentile values see Appendix Table C.2.4.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: "-" = no data, ***Bold/Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (<5th percentile value for pH); SD - Standard Deviation. Mean values reported as < the laboratory reporting limit were not screened against guidelines or reference 95th percentile. Pre-breach values that were reported as < the laboratory reporting limit were not used for screening.

[a] British Columbia Working Sediment Guidelines (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b).

[b] The 5th percentile is reported and screened for the pH reference data. Pre-breach values that were reported as < the laboratory reporting limit were not used for screening. For calculation of reference 95th percentile values see Appendix Table C.2.2 and for calculation of pre-breach 95th percentile values see Appendix Table C.2.4.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

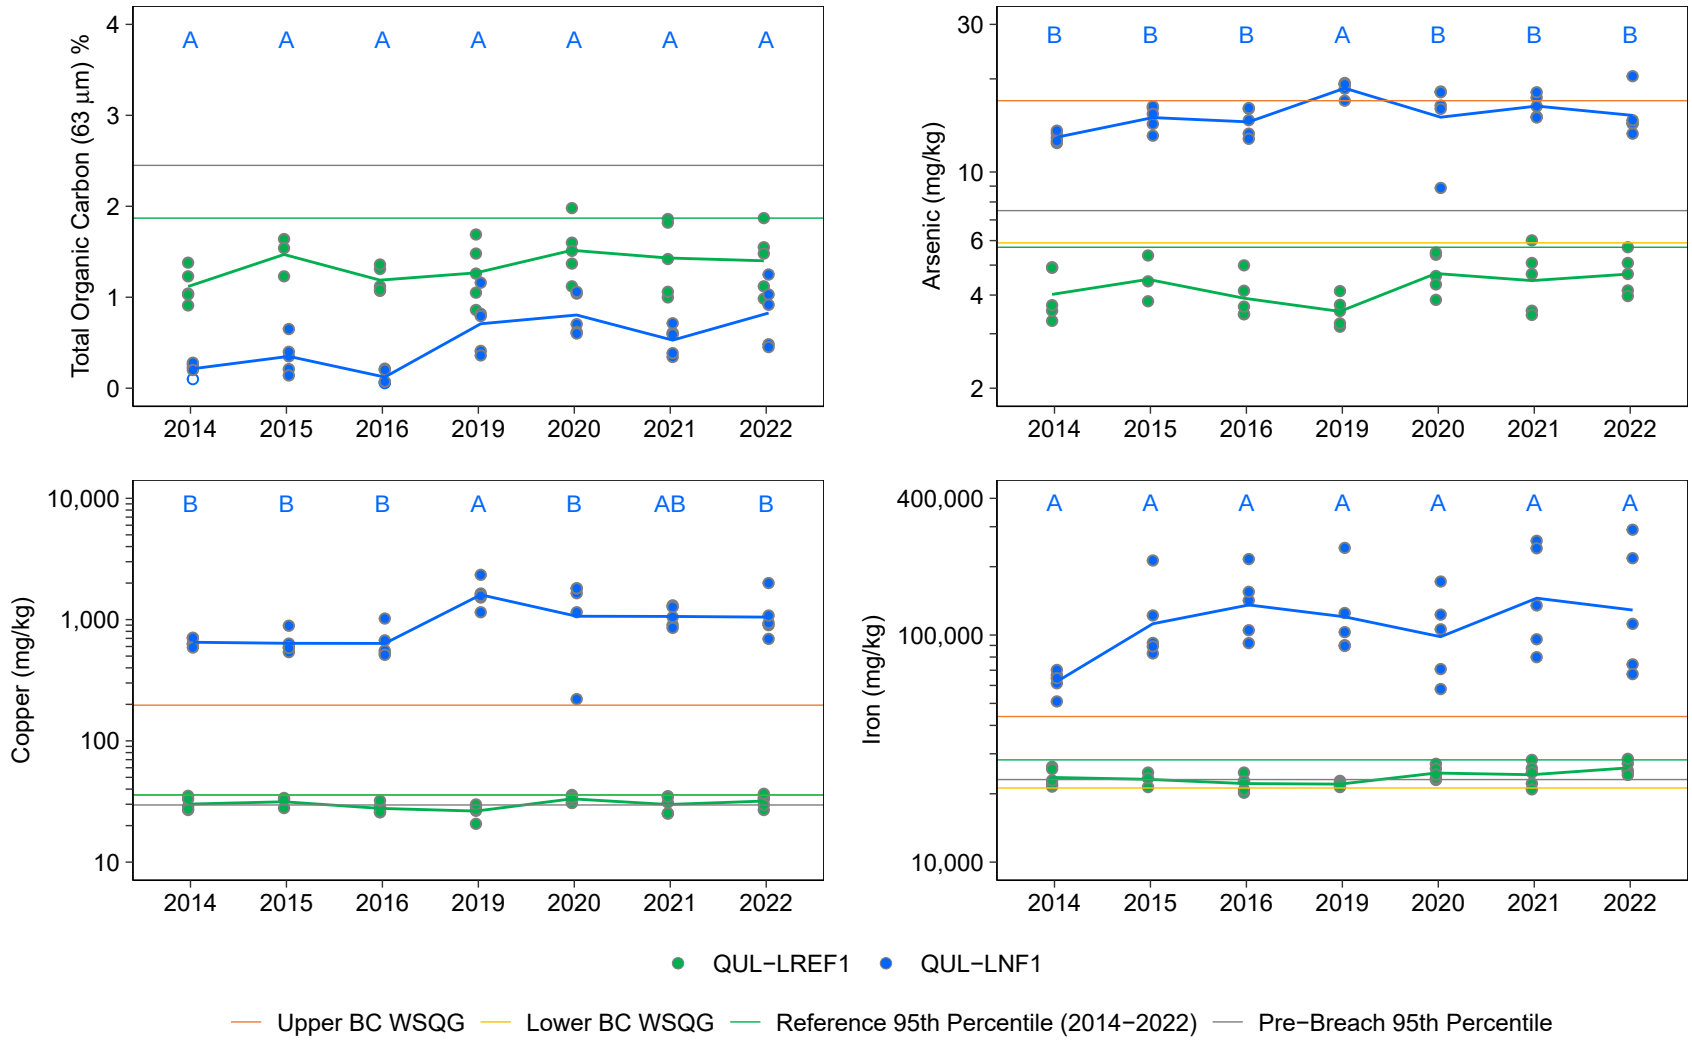

Figure 5.15: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for Quesnel Lake at QUL-LNF1 (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2014 to 2022

Notes: BC WSQG = British Columbia Working Sediment Quality Guideline (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b). The reference 95th Percentile was calculated using data from 2014 to 2022. Green represents reference areas and other colours represent exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences – TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

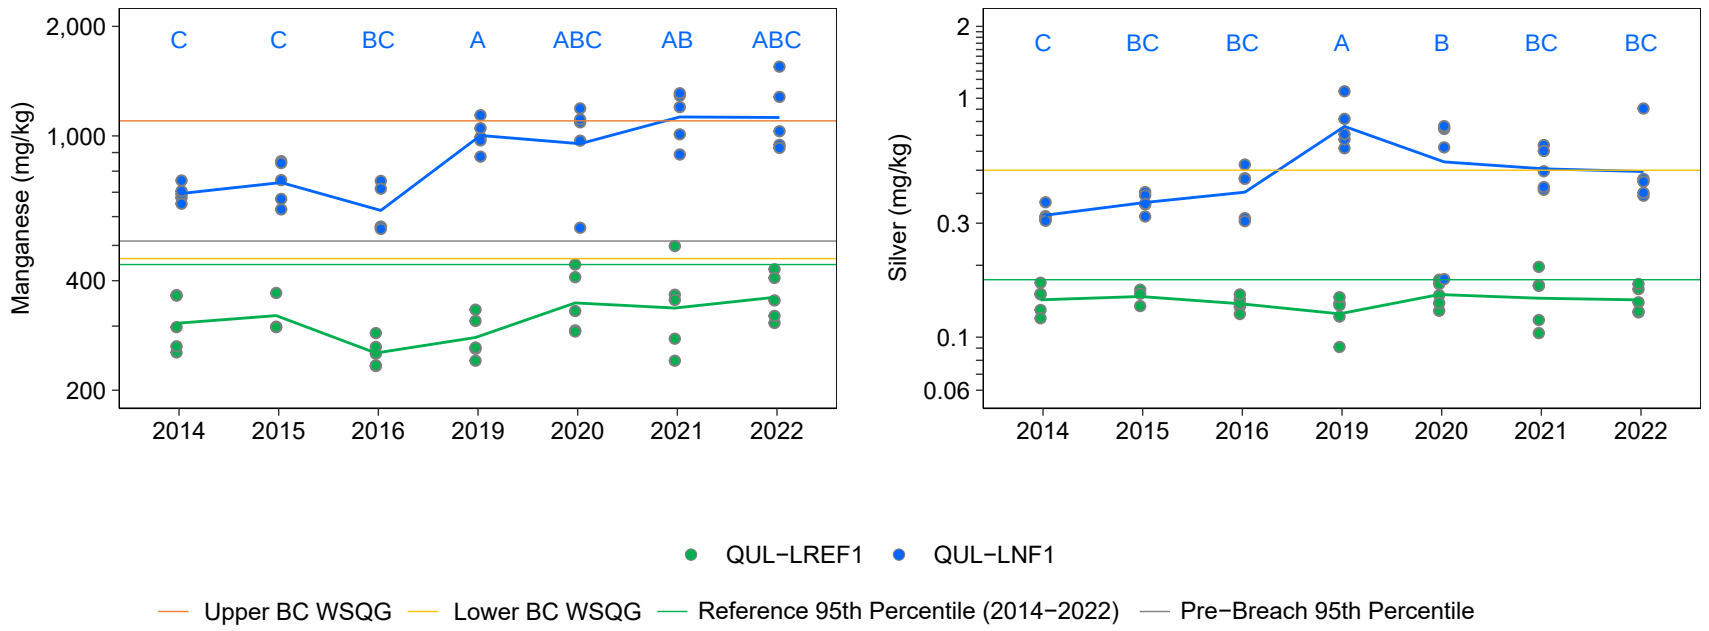

Figure 5.15: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for Quesnel Lake at QUL-LNF1 (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2014 to 2022

Notes: BC WSQG = British Columbia Working Sediment Quality Guideline (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b). The reference 95th Percentile was calculated using data from 2014 to 2022. Green represents reference areas and other colours represent exposed areas. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year and log10 transformed data for all analytes except Total Organic Carbon (TOC) (no transformation). Years that share a letter (e.g., A,B,C) have ratios (or differences – TOC) of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio (or difference) of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

times, respectively, and copper, iron, and manganese exceeded the upper BC WSQG by 5.7, 3.5, and 1.04 times, respectively (Table 5.14; Appendix Table C.2.9). In previous monitoring years (2019) chromium had also exceeded both reference and pre-breach 95th percentile values and been identified as an Analyte of Interest, however chromium was not identified as such in 2022 because it did not exceed the reference 95th percentile value. In 2022, the mean iron concentration in reference sediment was naturally elevated above the lower BC WSQG (Table 5.14; Appendix Table C.2.6), demonstrating that this element is naturally elevated in parts of Quesnel Lake.

The mean concentrations of arsenic, copper, iron, manganese, and silver in QUL-LNF1 sediments have been higher than reference concentrations since monitoring began in 2014. Temporal comparisons indicated that the concentrations of these five analytes in QUL-LNF1 sediments have been temporally stable from 2014 to 2022, relative to reference, except for increased arsenic, copper, and manganese concentrations in 2019 when the QUL-LNF1 sampling location was moved (Figure 5.15; Appendix Table E.1.9).

In the exposed sediments from QUL-LNF1, copper and manganese concentrations were positively correlated with TOC and % clay content, and arsenic was positively correlated with clay content (Appendix Figure E.1.4, Appendix Table E.1.11). These significant correlations infer that the tailings-influenced sediments at the shallow sampling areas of Quesnel Lake with higher clay (% clay) and TOC content tend to have higher concentrations of Analytes of Interest (e.g., arsenic, copper).

5.2.2 Sediment Toxicity

Sediment toxicity testing using *H. azteca* in 2022 (14-day standard test) was completed at a shallow exposed area of Quesnel Lake (QUL-LNF1), with an unimpacted shallow area of Quesnel Lake serving as reference (QUL-LREF1; Figure 3.1; Table 3.3). A review of sediment toxicity test data quality indicated that tests met control acceptability criteria and all water quality parameters remained within acceptable ranges throughout the tests (Nautilus 2022; Appendix G). Reference toxicant test results fell within the acceptable range and therefore the sensitivity of organisms used in the tests was considered appropriate (see the DQR for details; Appendix B). All ammonia concentrations were at levels that are not expected to cause adverse effects to *H. azteca*. Examination of laboratory bench sheets indicated that temperature, dissolved oxygen, conductivity, and pH were all stable over the course of the toxicity tests (Appendix G).

Survival of *H. azteca* exposed to QUL-LNF1 sediments in 2022 showed a moderate response (44 to 45% mortality; Table 5.15) which is similar to results in 2021 (46% mortality), slightly lower survival than 2020 (39% mortality) and much higher survival than 2019 (100% mortality) for similar 14-day standard static tests (Figure 5.16; Minnow 2020a, 2021a, 2022a). Growth of *H. azteca*

Table 5.15: Summary of *Hyalella azteca* 14-day Survival and Growth Responses for Sediment Toxicity Testing of Quesnel Lake at QUL-LNF (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2022

Results and Classification	Quesnel Lake	
	QUL-LNF	
	Survival	Growth[a]
	%	mg
Raw Area Result	54.0 ± 23.0	0.04 ± 0.01
Raw Laboratory Control Result	96.5 ± 5.50	0.19 ± 0.03
Raw Reference Result (QUL-LREF1)	98.0 ± 4.50	0.17 ± 0.03
Control Normalized Response	56%	21%
Reference Normalized Response	55%	24%
Statistically Significant Reduction from Control	Y	Y
Statistically Significant Reduction from Reference	Y	Y
CLASSIFICATION[b]	**MR**	**HR**

no unacceptable response (<20% reduction) - **NR**.
low response (20-50% reduction) and not significantly different than control and reference - **LR**.
moderate response (20-50% reduction) and significantly different than control and reference - MR.
high response (>50% reduction) - **HR**.

Note: Y = Yes, N = No.

[a] Growth = dry weight per surviving organism (mg).

[b] Where comparisons to mean laboratory control result and the mean field reference result did not fall into the same response classification, the result was discussed relative to both the control and the field reference.

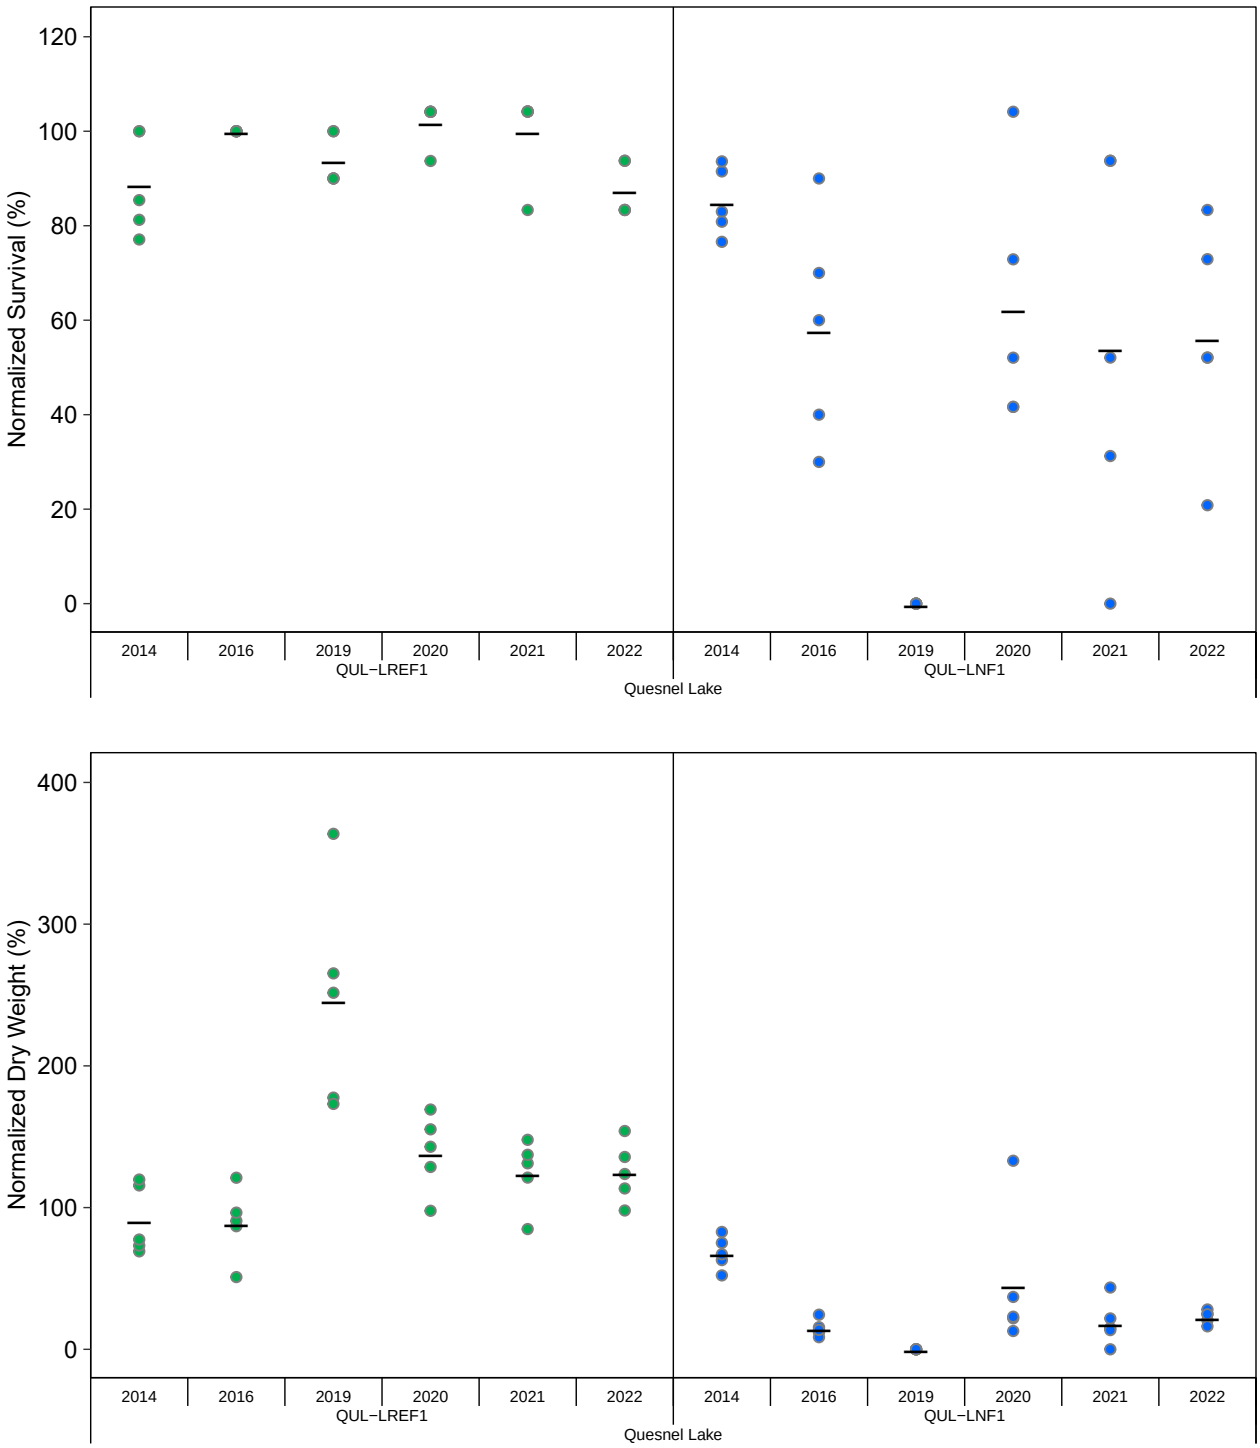

Figure 5.16: *Hyalella azteca* Survival and Growth Responses (14-day) for Sediment Toxicity Testing of Quesnel Lake at QUL-LNF (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2014 to 2022

Notes: Survival data were normalized to the control acceptance criteria, and the samples were calculated as a percentage of normalized control performance. Growth data were normalized to laboratory controls run during the test with the reference site for that area.

exposed to QUL-LNF1 sediments showed a high response (76 to 79% reduction in growth; Table 5.15), which is similar to results in 2021 (78 to 82% reduction) and a higher response (i.e., lower growth) than those in 2020 (50 to 65% reduction) for similar 14-day standard static tests (Figure 5.16; Minnow 2021a, 2022a).

Mean sediment copper concentrations at QUL-LNF1 in 2022 were 1,122 ± 510 mg/kg (Appendix C.2.9), which was similar to a laboratory determined copper 10-day LC50 of 1,078 mg/kg for *H. azteca* (Cairns et al. 1984). The corresponding dissolved aqueous copper LC50 concentration from Cairns et al. (1984) study was 39 µg/L, which was lower than the mean concentrations observed in overlying water of QUL-LNF1 toxicity testing vessels on day 14 of the test (74 µg/L ± 41 µg/L; Appendix G). Dissolved copper concentrations in the bioassay test vessels for QUL-LNF1 were higher than those in the test overlying waters for reference sediments (QUL-LREF1; 18 µg/L ± 3.3 µg/L) and were also notably higher than those documented in field-collected water samples (mean = 0.762 µg/L; Figure 5.17; Appendix Table C.1.4). This suggests copper mobilization in the test set-up that has either not occurred *in situ* or has attenuated over time *in situ*. In 2021, the 14-day *H. azteca* testing was conducted using static and static-renewal methods (i.e., renewing the testing waters during the course of the test) to better understand the evolution of dissolved copper to overlying test waters and associated implications to toxicity test results (Minnow 2022a). While static-renewal techniques reduced the overlying water concentrations of copper in bioassay vessels, and therefore provided more environmentally relevant testing conditions than static testing, the concentrations remained higher than *in situ* dissolved copper concentrations (by an average of 56-times; Minnow 2022a).

In 2022, overlying test water concentrations of dissolved copper were 97-times higher than *in situ* concentrations (Appendix C.1.4), which was relatively similar to previous toxicity test concentrations in 2020 (74-times) and 2021 (114-times), but much lower than 2019 (175-times; Figure 5.17; Minnow 2020a, 2021a, 2022a). Evaluation of regression relationships indicated that control-normalized survival and growth of *H. azteca* were positively related to sediment TOC content, and negatively related to sediment copper concentrations and to aqueous dissolved copper concentrations in the overlying water of bioassay vessels (Figure 5.18, Table 5.16). The relationships with copper concentrations (sediment and aqueous) had strong r^2 values of 0.48 to 0.65 (which are consistent with high descriptive power; Milton and Arnold 2002). These relationships infer lower *H. azteca* growth and survival at higher dissolved copper concentrations in the overlying water, which is consistent with the fact that *H. azteca* have been documented to derive little nutrition from sediment and to respond primarily to contaminants in overlying water (Wang et al. 2004).

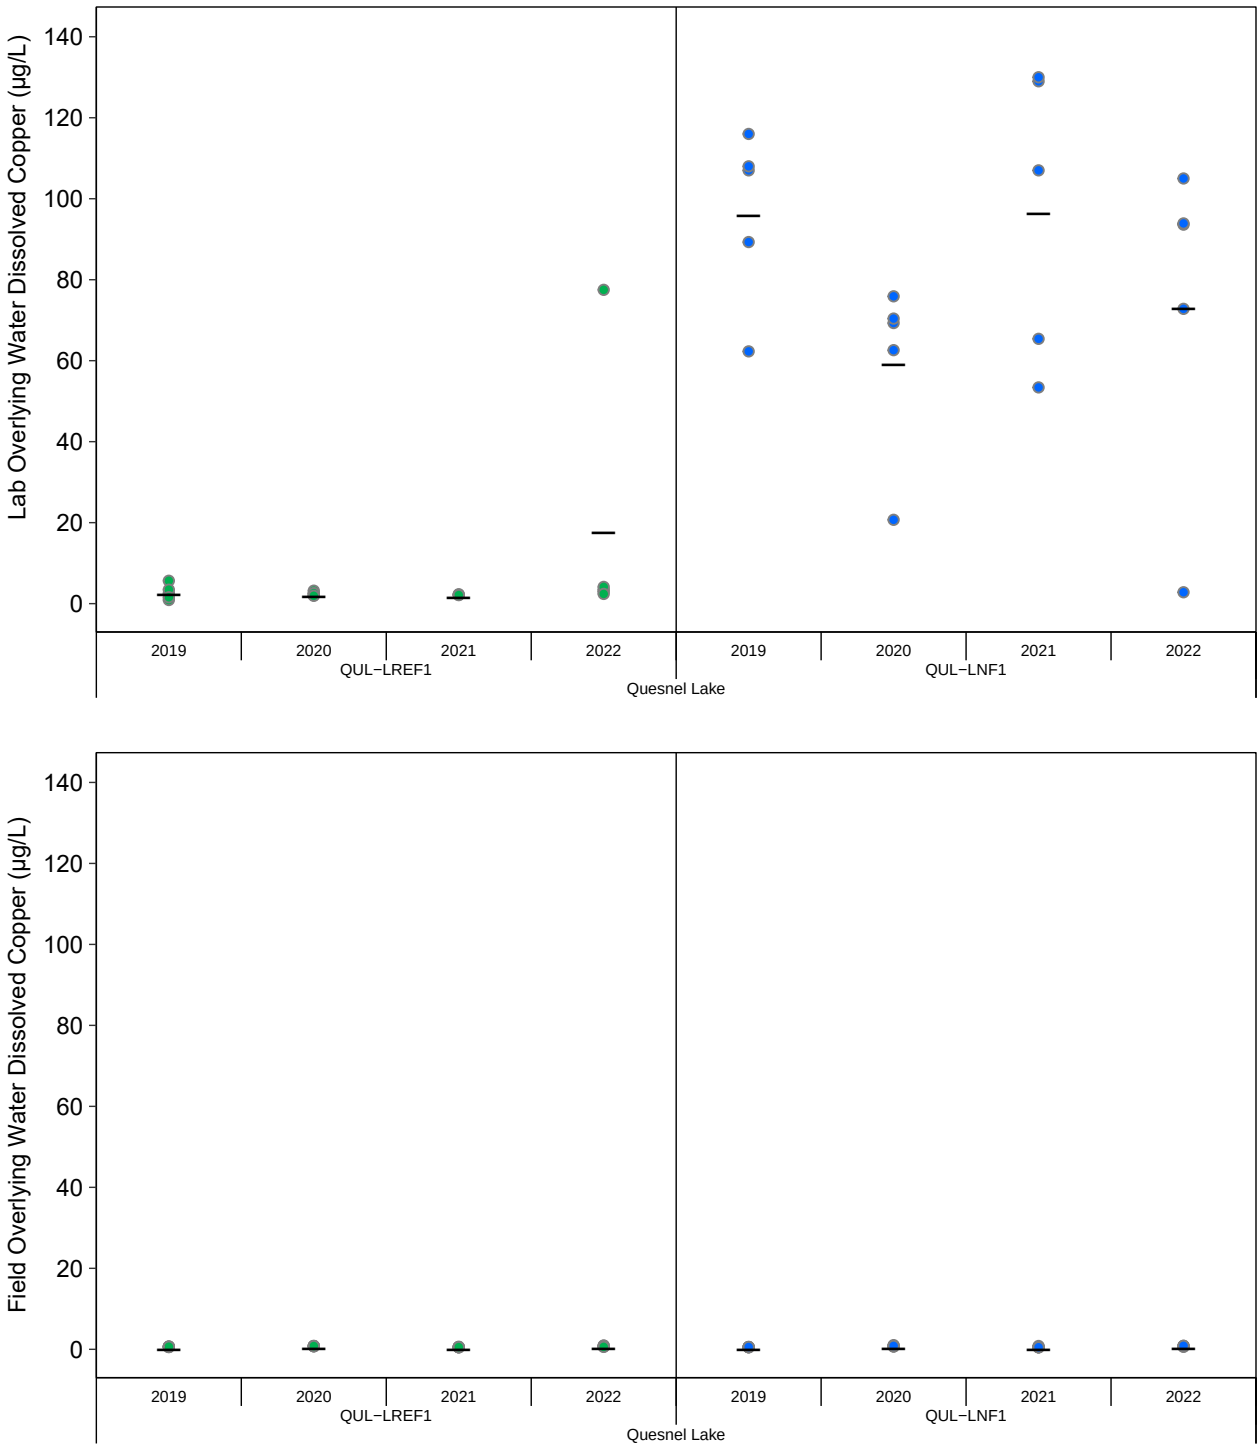

Figure 5.17: Dissolved Copper Concentrations in Laboratory and Field Overlying Water Associated with *Hyalella azteca* Survival and Growth (14-day) Sediment Toxicity Testing of Quesnel Lake at QUL-LNF (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2019 to 2022

Notes: Survival data were normalized to the control acceptance criteria, and the samples were calculated as a percentage of normalized control performance. Growth data were normalized to laboratory controls run during the test with the reference site for that area.

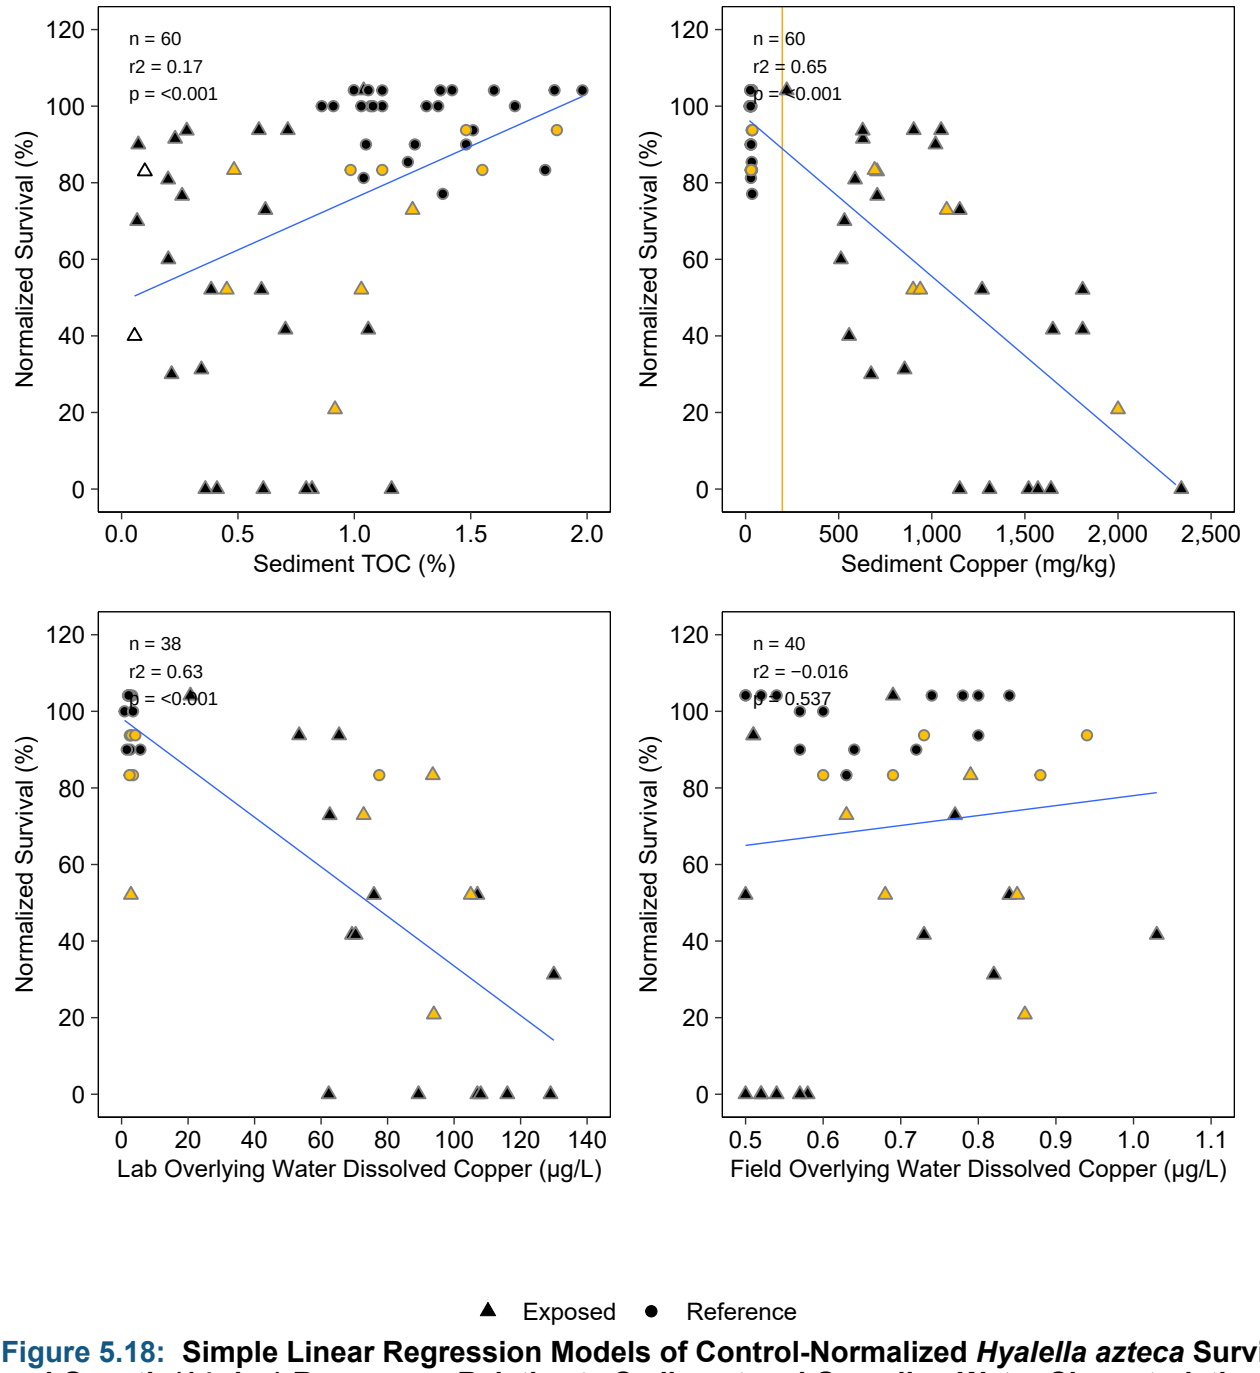

Figure 5.18: Simple Linear Regression Models of Control-Normalized *Hyalella azteca* Survival and Growth (14-day) Responses Relative to Sediment and Overyling Water Characteristics of Quesnel Lake at QUL-LNF (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2014 to 2022

Notes: Lab water and in−situ lake copper data are only available from 2019 to 2022. Outliers removed from analysis are noted with an ×. 2022 samples are plotted in orange. Censored values are shown as hollow symbols. Vertical orange lines indicate the Upper WSQG for copper (BCMOE 2017).

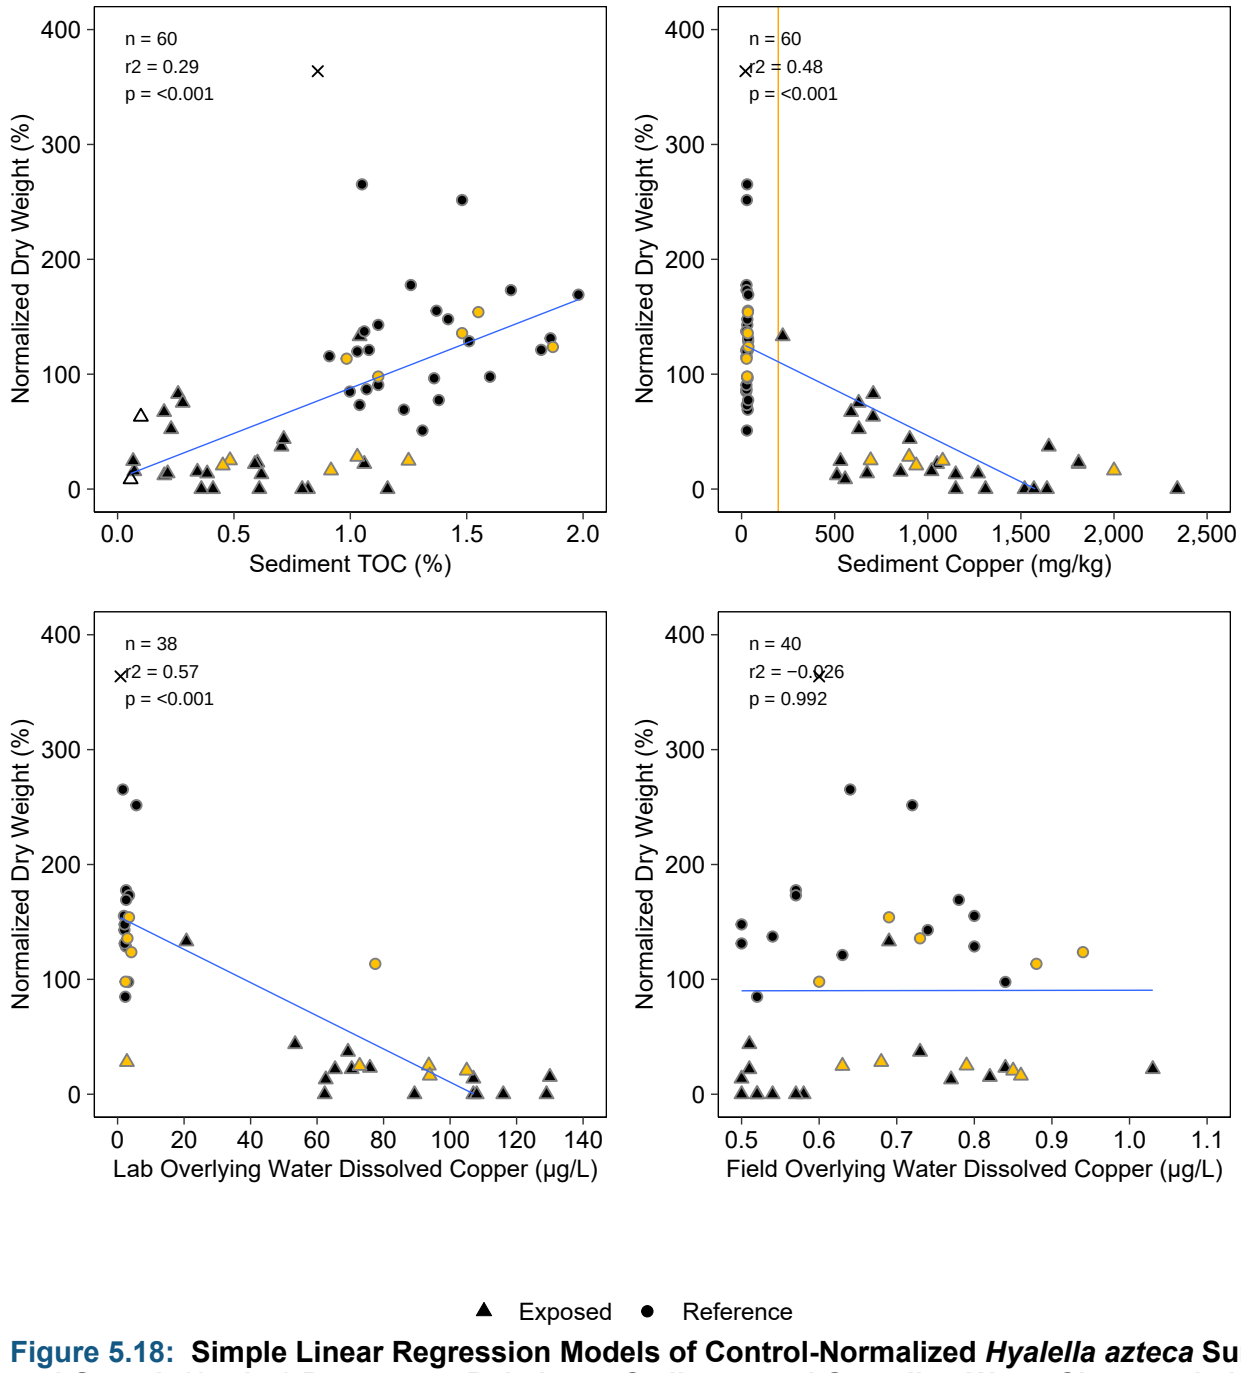

Figure 5.18: Simple Linear Regression Models of Control-Normalized *Hyalella azteca* Survival and Growth (14-day) Responses Relative to Sediment and Overyling Water Characteristics of Quesnel Lake at QUL-LNF (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2014 to 2022

Notes: Lab water and in−situ lake copper data are only available from 2019 to 2022. Outliers removed from analysis are noted with an ×. 2022 samples are plotted in orange. Censored values are shown as hollow symbols. Vertical orange lines indicate the Upper WSQG for copper (BCMOE 2017).

Table 5.16: Simple Linear Regression Models of Control-Normalized *Hyalella azteca* 14-day Survival and Growth Responses Relative to Sediment and Overlying Water Characteristics of Quesnel Lake at QUL-LNF (Exposed) and QUL-LREF1 (Reference) Shallow Areas, 2014 to 2022

Response	Predictor	Data Set	n	Slope	Intercept	P-value	r^2

	Field Overlying Water Dissolved Copper (µg/L)	Outliers excluded[a]	39	27.7	64.4	0.745	-0.024

P-value < 0.05

Notes: TOC = total organic carbon, mg/kg = milligrams per kilogram, µg/L = micrograms per liter. TOC content and copper concentrations measured in the <63 µm sediment fraction.

[a] One outlier was removed from the regression based on having Studentized residuals > 3.58 (Dohoo et al. 2009).

Overall, temporal trends of *H. azteca* toxicity test results suggest a residual breach-related influence on *H. azteca* toxicity for both growth and survival within the small shallow near-field area near the mouth of Hazeltine Creek. However, the substantial difference in overlying water chemistry between laboratory and field (as noted earlier) continues to raise questions about how well the laboratory results represent *in situ* (field) exposure.

5.2.3 Plankton Community and Productivity

Plankton community and productivity monitoring in 2022 was completed three times (June, July, and August) in exposed (QUL-ZOO-1) and reference (QUL-ZOO-7) areas of Quesnel Lake (Figure 3.3, Table 3.5). A review of the 2022 plankton community and productivity data quality (Appendix B) indicated that these data can be used with a good level of confidence for interpretation (see Section 5.1.3 for details). A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

5.2.3.1 Phytoplankton

5.2.3.1.1 Community

In 2022, phytoplankton densities at the exposed area (QUL-ZOO-1) and reference area (QUL-ZOO-7) of Quesnel Lake were highest in July compared to June and August (Appendix Figure E.2.7, Appendix Table C.3.5). Phytoplankton taxon richness at both QUL-ZOO-1 and QUL-ZOO-7 in 2022 was lowest in June and highest in August (Appendix Figure E.2.7, Appendix Table C.3.5). Phytoplankton density and richness were higher and lower, respectively, at QUL-ZOO-1 than at QUL-ZOO-7 in July 2022. Simpson's Diversity and Simpson's Evenness were similar between the two areas in 2022 (Figure 5.19, Table 5.17; Appendix Tables C.3.5 and C.3.6).

Temporal analyses indicated that mean phytoplankton density at QUL-ZOO-1 (exposed) was consistently higher than at QUL-ZOO-7 (reference) from 2019 to 2022, with similar temporal changes observed at each area over this period (Figure 5.19, Table 5.17). Higher densities of phytoplankton at QUL-ZOO-1 were attributed largely to greater densities of Chrysophytes and Dinoflagellates than at QUL-ZOO-7 (Appendix Figure E.2.8, Appendix Tables C.3.5 and E.2.3).

Taxon richness at QUL-ZOO-1 was stable and similar to reference from 2019 to 2021 but decreased significantly in 2022 to a mean result that was lower than the previous monitoring years (2019 to 2021) and lower than reference (Figure 5.19, Table 5.17; Appendix Tables C.3.5 and C.3.6). Although the lack of replication prior to 2019 prevented statistical comparisons of historic data, phytoplankton taxon richness at QUL-ZOO-1 in 2022 was lower than the range of results reported in previous post-breach years except August 2019 (2015 to 2021;

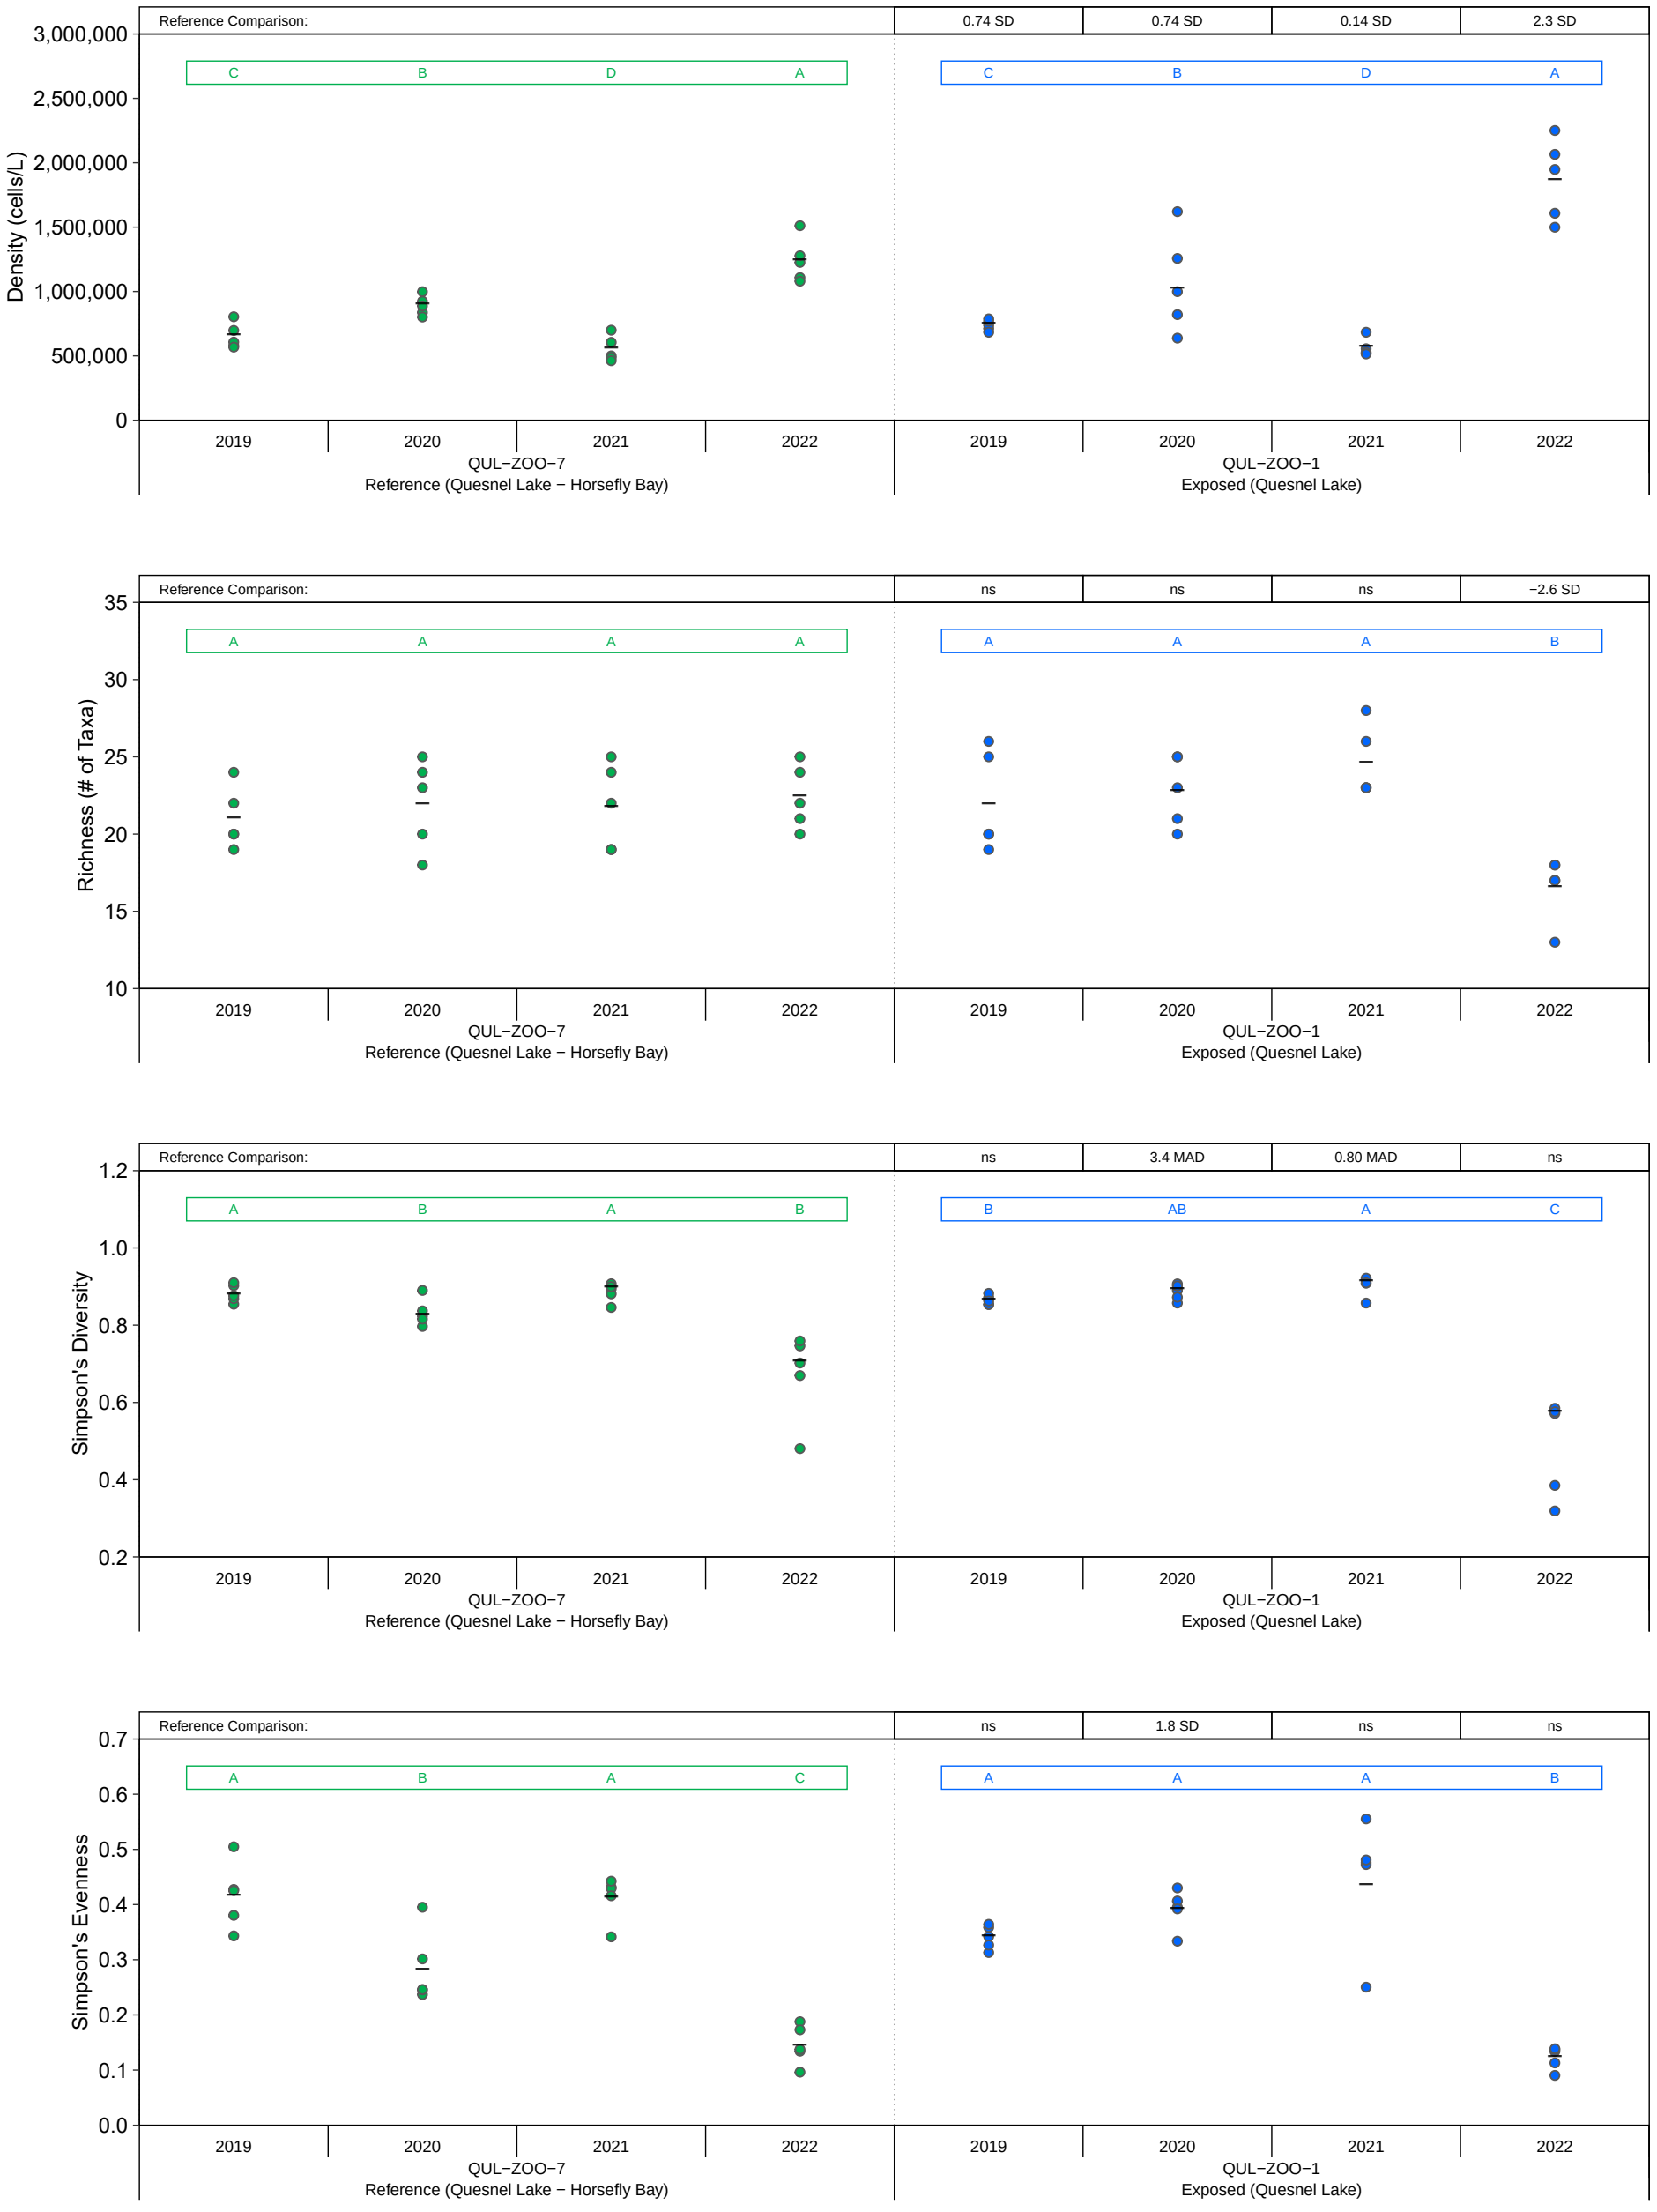

Figure 5.19: Phytoplankton Community Endpoints for Quesnel Lake at QUL−ZOO−1 (Exposed) and QUL−ZOO−7 (Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of phytoplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated phytoplankton results collected in June and August 2022, see Appendix Table C.3.5.

Magnitude of Difference (MOD) < -2.
Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available. "nc" = no comparison. "ns" = no significance. "nm" = Contrast MODs could not be calculated because the Median Absolute Deviation (MAD) = 0, cells/L = cells per litre, µg/L = micrograms per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, $\log_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

Appendix Figure E.2.7). The lower taxon richness observed at QUL-ZOO-1 compared to QUL-ZOO-7 in July 2022, and compared previous monitoring years, appears to be due to the absence of relatively rare (<1 % of total density) species in these samples (mostly Diatoms, Chlorophytes, and Chrysophytes; see laboratory data in Appendix G). The taxa that were absent from the QUL-ZOO-1 samples in July 2022 were distributed among different taxonomic groups; a fact that suggests their absence is not due to a discrete change in physical parameters at QUL-ZOO-1 in 2022 (that might preferentially affect one taxa) but rather that these relatively rare taxa were not captured by the five replicates collected during July sampling. This is supported by the consistent similarities in water temperature and nutrient concentrations between the exposed and reference areas in 2022 and at the exposed area over time (Appendix Figure C.1.5). In addition, the relative similarity of taxon richness results from August at QUL-ZOO-1 (22 taxa) and QUL-ZOO-7 (29 taxa) suggests this difference in taxon richness was temporary and possibly reflective of sampling variability (August results represent single samples that cannot be statistically compared; Appendix Table C.3.5). Three of the nine species of Diatoms, Chlorophytes, and Chrysophytes that were absent from QUL-ZOO-1 samples in July (but present in July QUL-ZOO-7 samples) were present QUL-ZOO-1 samples in August, providing further support that the absence of some these taxa from QUL-ZOO-1 samples in July 2022 was temporary. Continued monitoring will serve to confirm whether this decrease in richness at QUL-ZOO-1 is part of a longer-term trend at this exposed area or was reflective of a short-term community change. Mean Simpson's Diversity at QUL--ZOO-1 was similar to QUL-ZOO-7 from 2019 to 2022 except 2020 to 2021 when it was higher at the exposed area. Simpson's Evenness at QUL-ZOO-1 was also similar to QUL-ZOO-7 from 2019 to 2022 except 2020 when it was higher at the exposed area (Figure 5.19, Table 5.17; Appendix Table C.3.6).

The phytoplankton communities at QUL-ZOO-1 and QUL-ZOO-7 had a relatively even distribution of taxa in June 2022 and experienced succession toward more Chrysophytes in July and more Diatoms in August, with Diatoms becoming the dominant phytoplankton group at both monitoring areas by August (Figure 5.20; Appendix Table C.3.5). Seasonal succession observed at both areas was also characterized by a decrease in the relative densities of Chrysophytes and Cryptomonads from June to August. The above patterns in seasonal relative densities were also reflected in seasonal changes in cell densities (Appendix Figure E.2.9, Appendix Table C.3.5). Mean relative densities of Diatoms, Chlorophytes, and Cyanobacteria did not differ significantly between QUL-ZOO-1 and QUL-ZOO-7 in July 2022. Relative densities of Chrysophytes were significantly higher at QUL-ZOO-1 than at QUL-ZOO-7 in 2022, while the relative densities of Cryptomonads and Dinoflagellates were significantly lower (Appendix Figure E.2.8, Appendix Tables C.3.6 and E.2.3).

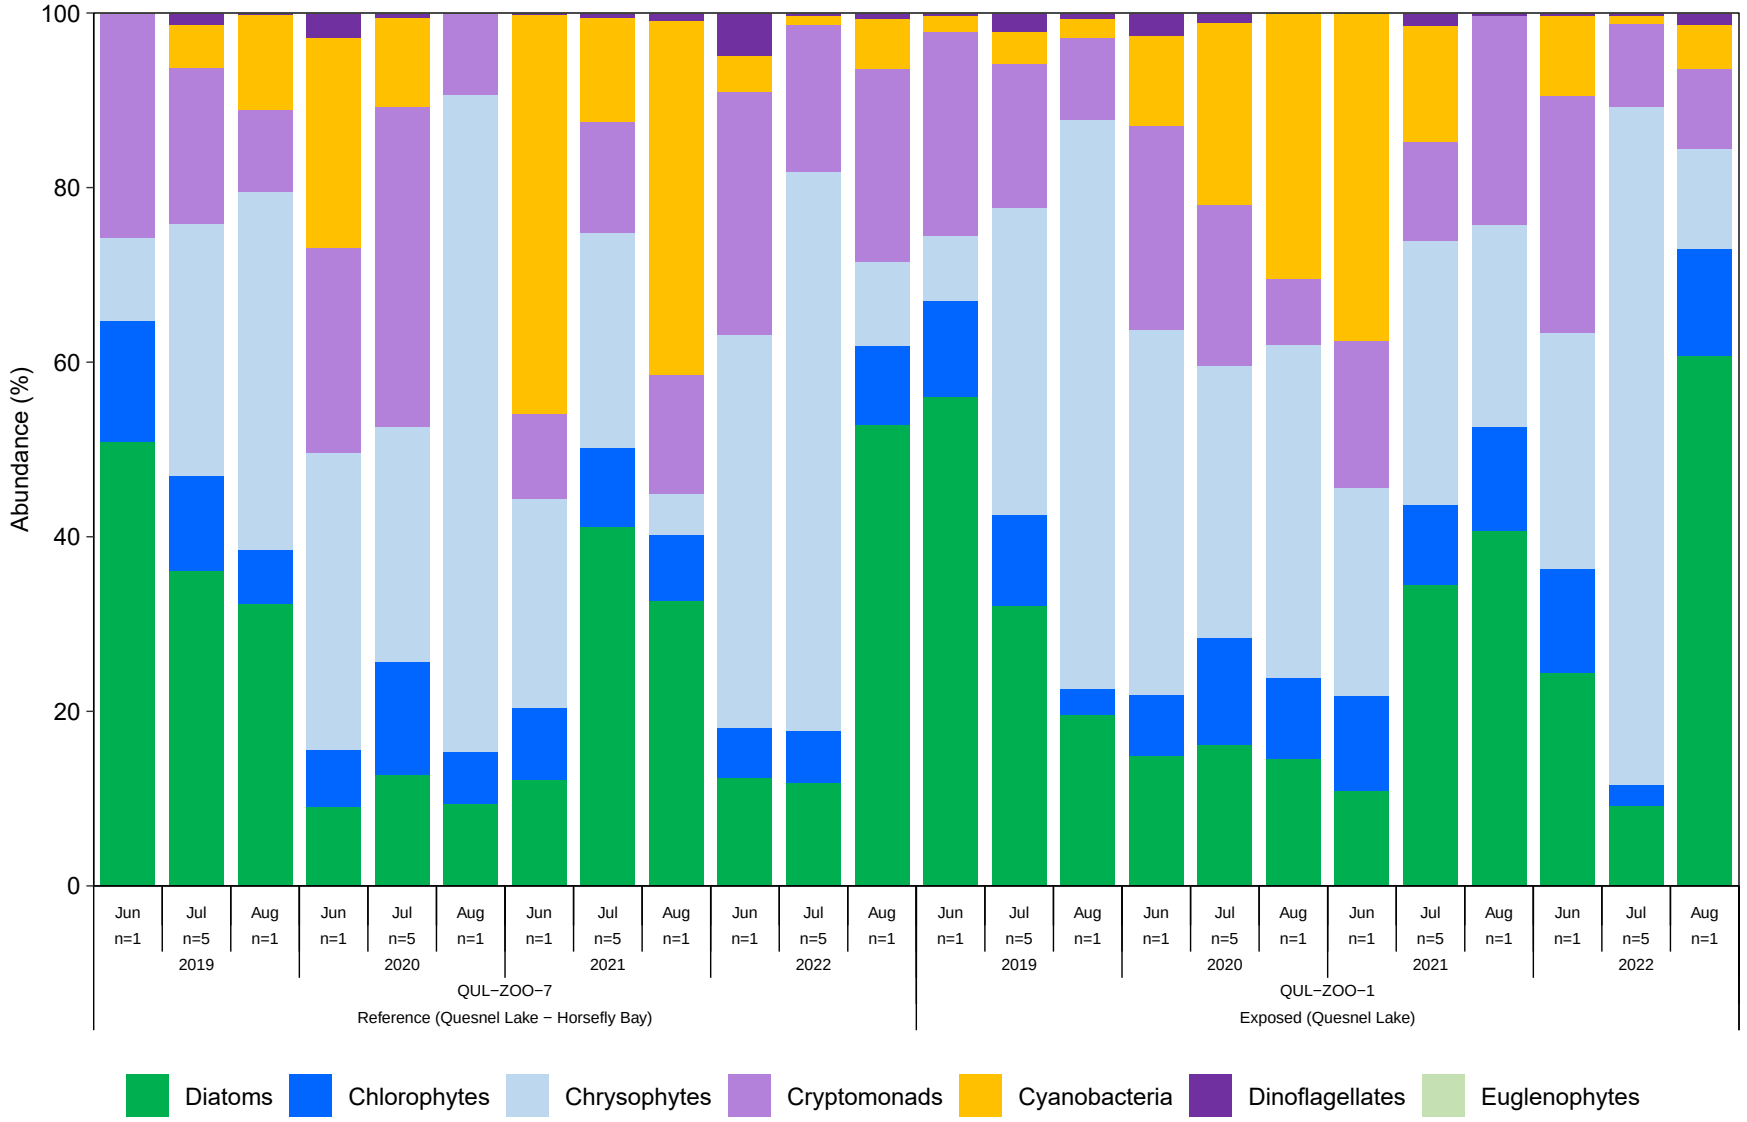

Figure 5.20: Relative Mean Densities of Major Phytoplankton Community Taxonomic Groups for Quesnel Lake at QUL−ZOO−1 (Exposed) and QUL−ZOO−7 (Reference) Areas, 2019 to 2022

The relative densities of Diatoms, Chlorophytes, and Cyanobacteria at QUL-ZOO-1 were consistently similar to those at QUL-ZOO-7 from 2019 to 2022. Mean relative densities of Chrysophytes were significantly higher at QUL-ZOO-1 compared to QUL-ZOO-7 from 2019 to 2022, suggesting that this difference may be an inherent natural difference in communities between the two areas (Appendix Figure E.2.8, Appendix Tables C.3.5, E.2.3). Relative densities of Cryptomonads at QUL-ZOO-1 were significantly lower than at QUL-ZOO-7 in 2020 and 2022 but similar in 2019 and 2021. This variability at the exposed area compared to reference for relative densities of Cryptomonads was driven by changes at the reference area (QUL-ZOO-7) given the temporal stability of QUL-ZOO-1 results from 2019 to 2022. The relative densities of Dinoflagellates at QUL-ZOO-1 were significantly higher than at QUL-ZOO-7 from 2019 to 2021 and significantly lower than in 2022 (Appendix Figure E.2.8, Appendix Tables C.3.5, E.2.3). The densities of the major phytoplankton taxonomic groups showed very similar spatial and temporal patterns as the relative density data for these groups (Appendix Figures E.2.8, E.2.9; Appendix Tables C.3.5, E.2.3). The similarities in the phytoplankton communities at the exposed and reference areas of Quesnel Lake observed from 2019 to 2022 can likely be attributed to similar water temperatures at the surface and throughout their photic zones, and nutrient concentrations (Appendix Figures A.1.5, C.1.5, Appendix Table C.1.5) which are known factors affecting phytoplankton communities (Schnurr and Allen 2015).

Overall, the phytoplankton community at the exposed area of Quesnel Lake (QUL-ZOO-1) in 2022 was characterized by total density that was higher than at reference (QUL-ZOO-7), a pattern that has persisted since 2019. Taxon richness was lower at QUL-ZOO-1 than at QUL-ZOO-7 in 2022, which reflected a significant decrease from results observed in 2019 to 2021, when richness was similar to reference. This decrease in richness was attributable to the absence of relatively rare phytoplankton taxa at QUL-ZOO-1 in July 2022, and appeared to be a temporary change based on the results of samples collected in August 2022 which included some of these relatively rare taxa. Continued monitoring will help to further understand whether the decrease in taxon richness in 2022 is part of a longer-term change or a single variable result. Simpson's Diversity and Evenness have shown some temporal variability at the exposed area but have been either similar to or higher than reference in each year since 2019. Phytoplankton community composition at both the exposed and reference areas was characterized by succession towards Diatom dominance by August in 2022, with concurrent decreases in the relative densities of Chrysophytes and Cryptomonads. The community composition at the exposed area has been similar to reference in terms of the relative densities of Diatoms, Cyanobacteria, and Chlorophytes from 2019 to 2022. The relative densities of Chrysophytes, Cryptomonads, and Dinoflagellates at the exposed area differed from reference in 2022 but showed temporal stability either within the exposed area or temporal stability in the difference relative to reference. The demonstrated

similarity of the phytoplankton community at the exposed and reference areas of Quesnel Lake for most endpoints, and the temporal stability throughout the study period for those endpoints that differed between the areas (excluding taxon richness), are suggestive of a lack of mine-related influence on the phytoplankton community of Quesnel Lake.

5.2.3.1.2 Productivity

In 2022, chlorophyll-a concentrations recorded in July at both QUL-ZOO-1 and QUL-ZOO-7 were higher than concentrations observed in June or August (Appendix Figure E.2.7, Appendix Table C.3.5). Mean chlorophyll-a concentrations at QUL-ZOO-1 were consistently similar to those at QUL-ZOO-7 from 2019 to 2022 (Figure 5.21, Table 5.17; Appendix Tables C.3.5, C.3.6). At both QUL-ZOO-1 and QUL-ZOO-7, mean chlorophyll-a concentrations successively decreased significantly each year from 2019 to 2021 but were higher in 2022 relative to previous years (2019 to 2021; Figure 5.21, Table 5.17; Appendix Tables C.3.5, C.3.6). The similarity in phytoplankton productivity between QUL-ZOO-1 and QUL-ZOO-7 can be attributed to their similar nutrient concentrations, surface water temperatures, and water temperatures throughout the photic zone (Appendix Figures A.1.5, C.1.5, Appendix Table C.1.5).

A lake's trophic status classification corresponds to its overall productivity in terms of phytoplankton biomass (chlorophyll-a) and nutrient concentration (Wetzel 2001). Based on the concentration of chlorophyll-a at QUL-ZOO-1 and QUL-ZOO-7 in 2022, Quesnel Lake can be classified as a mesotrophic system (2.5 to 8 µg/L; Vollenweider and Kerekes 1980; Figure 5.21; Appendix Figure E.2.7, Appendix Tables C.3.5 and C.3.6). The trophic status of Quesnel Lake in previous years post-breach (i.e., 2016 to 2018) was classified as ultraoligotrophic (<1 µg/L) while the status from 2019 to 2021 was classified as oligotrophic (<2.5 µg/L; Vollenweider and Kerekes 1980; Table 5.17; Appendix Figure E.2.7, Appendix Tables C.3.5). The increase in trophic status from oligotrophic in 2021 to mesotrophic in 2022 occurred at both the exposed (QUL-ZOO-1) and reference (QUL-ZOO-7) areas. The similarity in chlorophyll-a concentrations between the two areas in 2022 indicates this increase in productivity in 2022 (Figure 5.21, Table 5.17) was related to factors that influenced both areas in the same way (e.g., environmental factors such as temperature).

The higher chlorophyll-a concentrations observed in 2019 to 2022 compared to previous years may have resulted from a combination of different sampling timing in June and August/September (in 2016 to 2018) instead of July and changes in sampling methodology. Depth-integrated sampling methods were adopted in 2019 which differed from the surface grab sampling methods used in prior post-breach years (2016 to 2018). A specific investigation of these differing sampling methods in Quesnel Lake indicated either no difference or significantly higher chlorophyll-a concentrations in surface grabs compared to depth-integrated samples, but a similar investigation

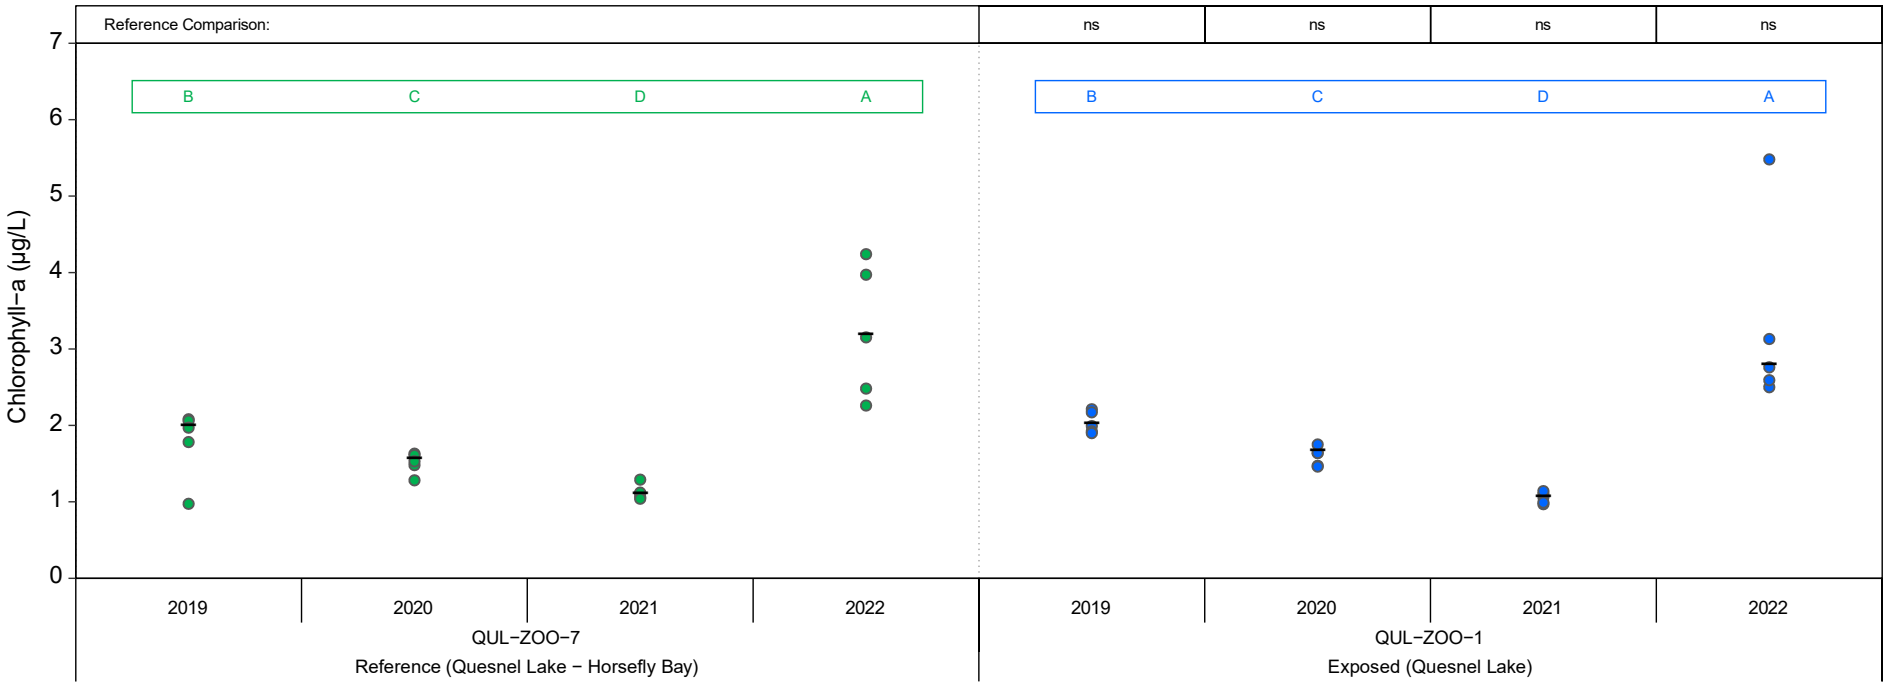

Figure 5.21: Phytoplankton Chlorophyll−a Concentrations for Quesnel Lake at QUL−ZOO−1 (Exposed) and QUL−ZOO−7 (Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log_{10}− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference.'n c' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of phytoplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated phytoplankton results collected in June and August 2022, see Appendix Table C.3.5.

in Polley and Bootjack lakes indicated significantly higher chlorophyll-a concentrations in samples collected using depth-integrated methods compared to surface sampling (Minnow 2020a). Therefore, it is plausible that the change in sampling methodology from 2019 to 2022 compared to 2016 to 2018 may have contributed to the observed increase in chlorophyll-a concentrations in 2019 to 2022.

5.2.3.2 Zooplankton

5.2.3.2.1 Community

Zooplankton densities at the exposed area (QUL-ZOO-1) and reference area (QUL-ZOO-7) of Quesnel Lake in 2022 were highest in July, while zooplankton taxon richness was highest in August at both monitoring areas (Appendix Figure E.2.10, Appendix Table C.3.7). Zooplankton density and Simpson's Evenness at QUL-ZOO-1 were both consistently similar to QUL-ZOO-7 in July from 2019 to 2022. Taxon richness was higher at QUL-ZOO-1 than at QUL-ZOO-7 in 2019, 2020, and 2022, but was lower in 2021. Simpson's Diversity at QUL-ZOO-1 was similar (2019 and 2021) or significantly higher (2020 and 2022) compared to QUL-ZOO-7 (Figure 5.22, Table 5.18; Appendix Tables C.3.7, C.3.8).

The zooplankton community at QUL-ZOO-1 (exposed) in 2022 was largely dominated by Copepod Nauplii and Rotifera in June, and by Rotifera in July and August. The June community and succession throughout summer at the exposed area was consistent with that observed at the reference area (Figure 5.23; Appendix Tables C.3.7, C.3.8). The relative density and density of dominant for zooplankton taxa groups have been similar at QUL-ZOO-1 and QUL-ZOO-7 for each of the monitoring years (2019 to 2022), with two exceptions. The relative density and density of Cyclopoida was lower at QUL-ZOO-1 than at QUL-ZOO-7 in 2019, and the relative density of Copepod Nauplii was higher at QUL-ZOO-1 than at QUL-ZOO-7 in each monitoring year and temporally stable at QUL-ZOO-1 from 2019 to 2022 (Appendix Figure E.2.11, Appendix Table E.2.4). Moreover, the relative densities of all major zooplankton taxonomic groups showed similar temporal changes from 2019 to 2022 at both QUL-ZOO-1 and QUL-ZOO-7 (Appendix Figure E.2.11, Appendix Table E.2.4). This similarity in temporal trends in community structure at the exposed and reference areas indicates these changes were likely driven by natural variability in environmental parameters that affected the two areas similarly (e.g., water temperature, nutrient availability, and phytoplankton community; Appendix Figures A.1.5, C.1.5; Appendix Table C.1.5). The densities of the major zooplankton taxonomic groups showed very similar spatial and temporal patterns to relative density data (Appendix Figure E.2.11; Appendix Tables C.3.7, C.3.8, and E.2.4).

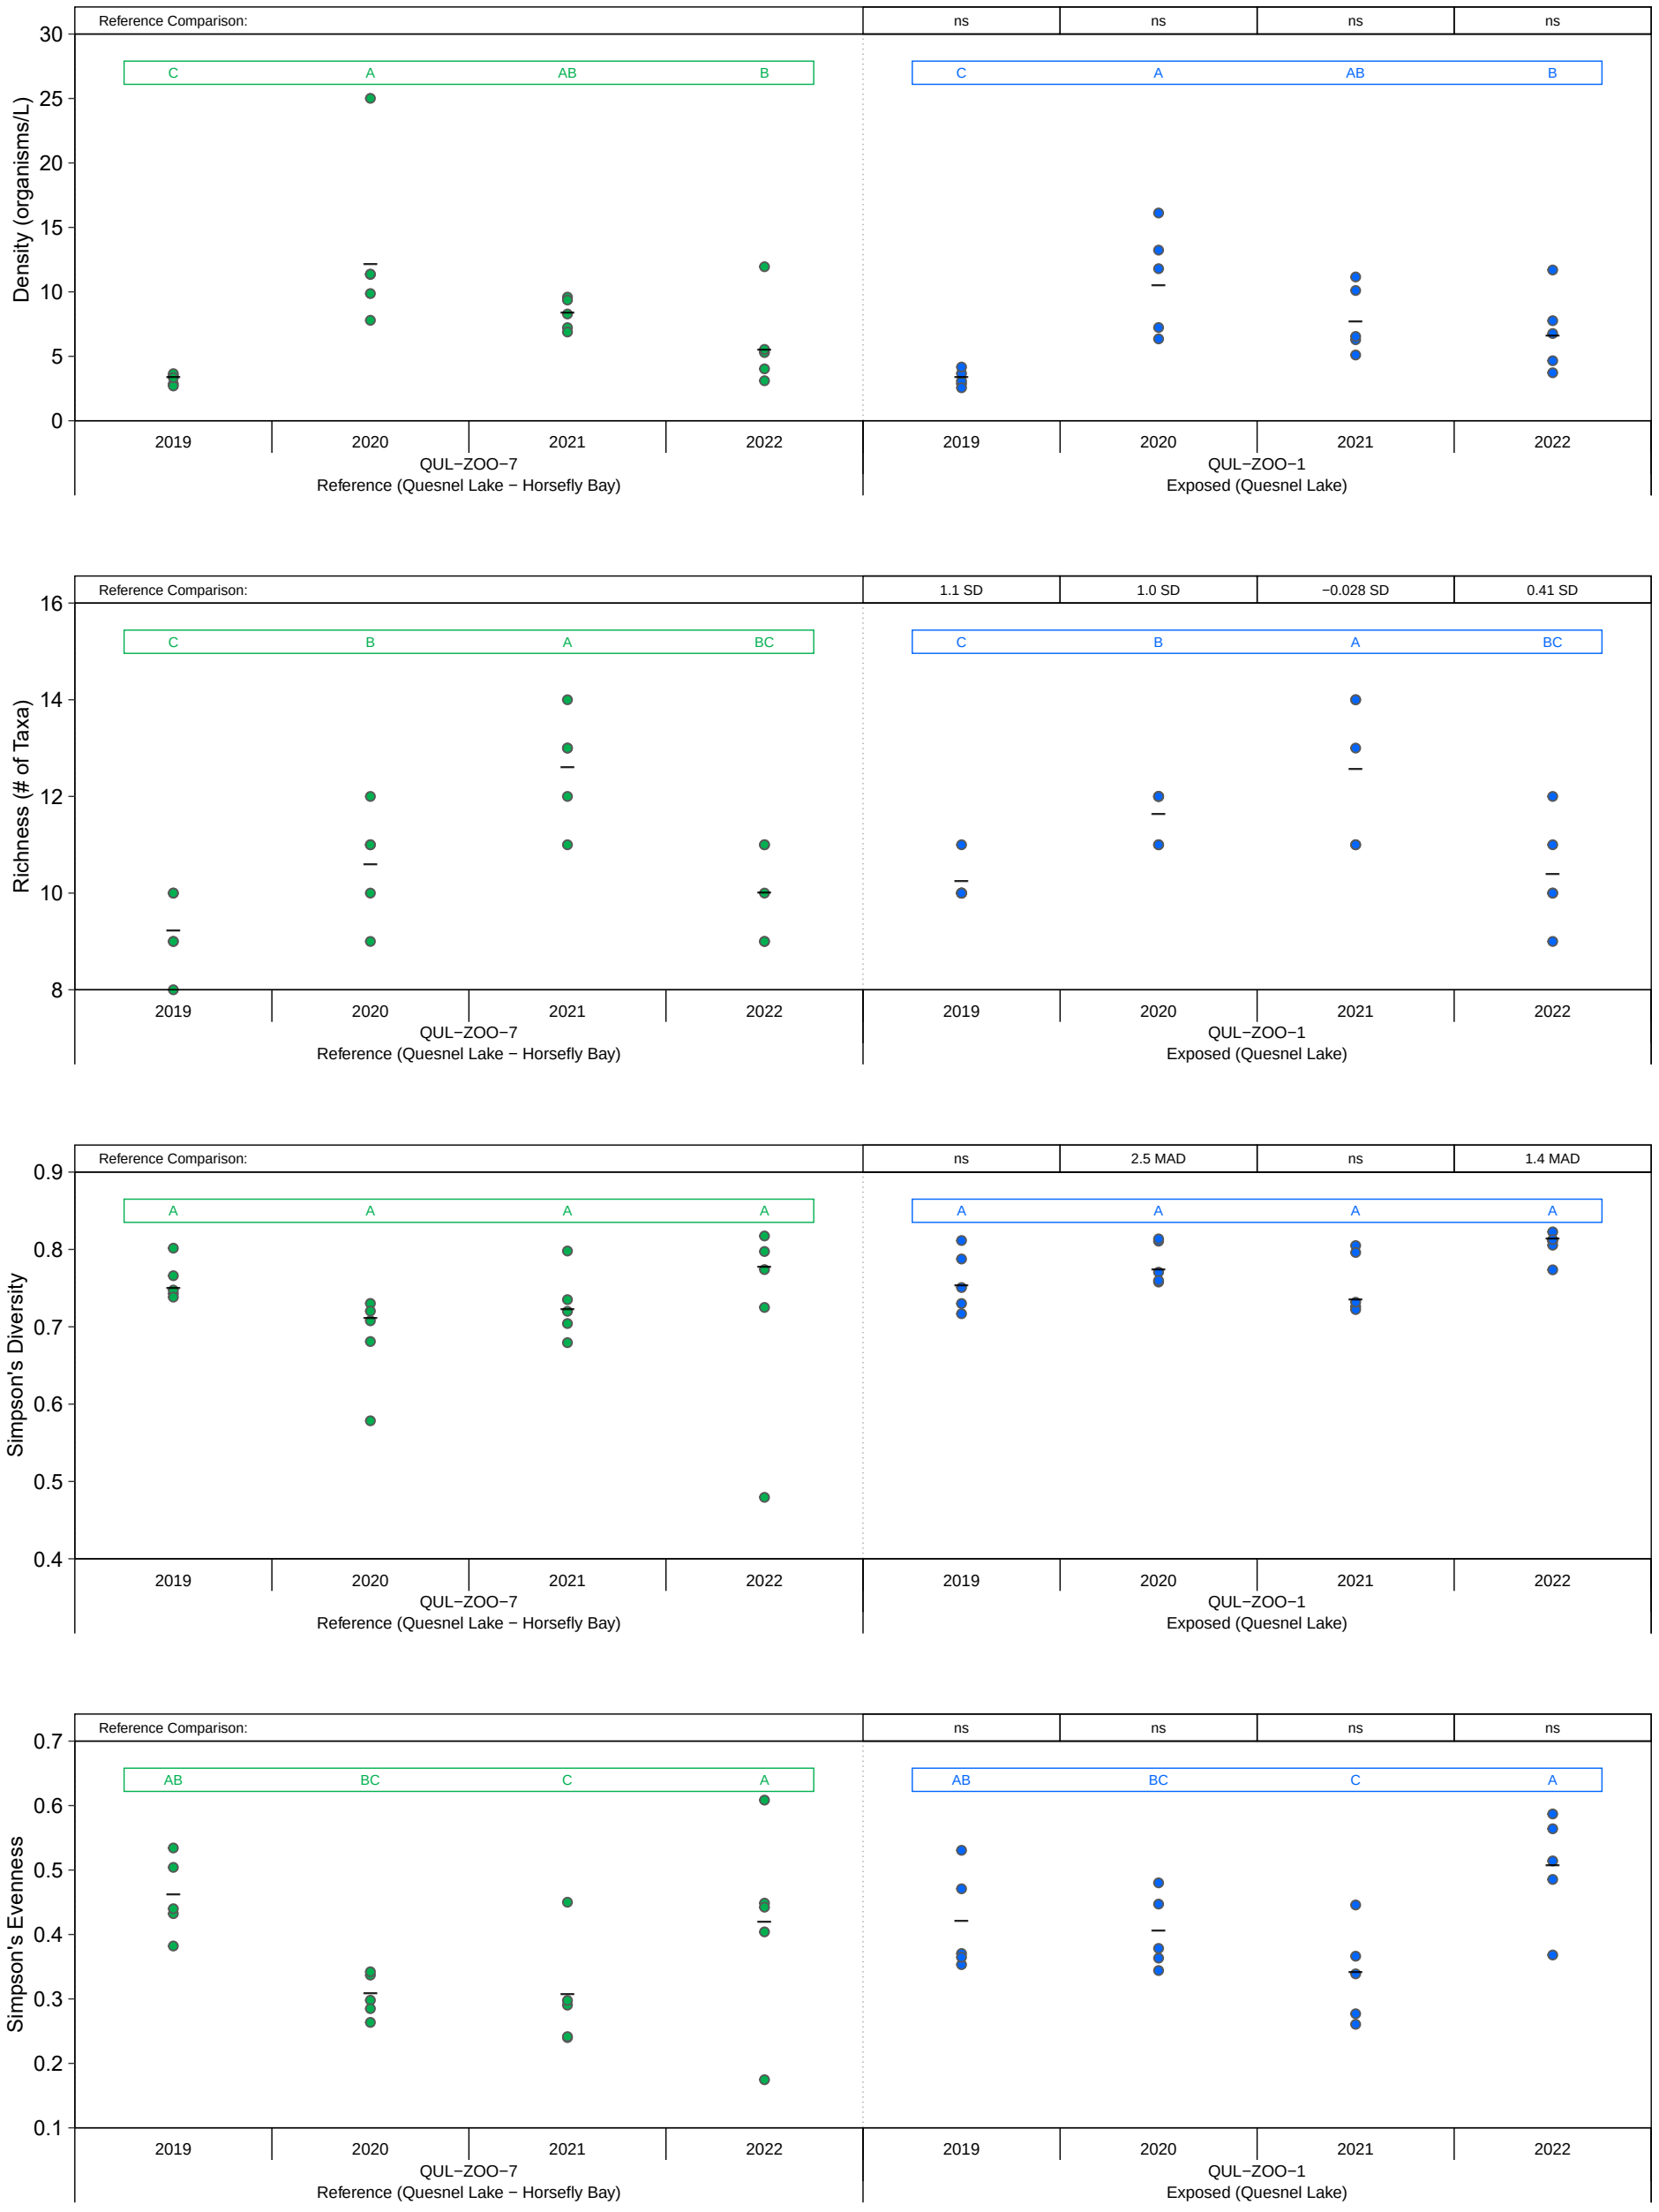

Figure 5.22: Zooplankton Community Endpoints for Quesnel Lake at QUL−ZOO−1 (Exposed) and QUL−ZOO−7 (Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, $\log_{10}$− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non −significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of zooplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated zooplankton results collected in June and August 2022, see Appendix Table C.3.7.

Magnitude of Difference (MOD) < -2.
Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available. "nc" = no comparison. "ns" = no significance. "nm" = Contrast MODs could not be calculated because the MAD = 0, organisms/L = organisms per litre, mg/L = milligrams per litre.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log $_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Remediated Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

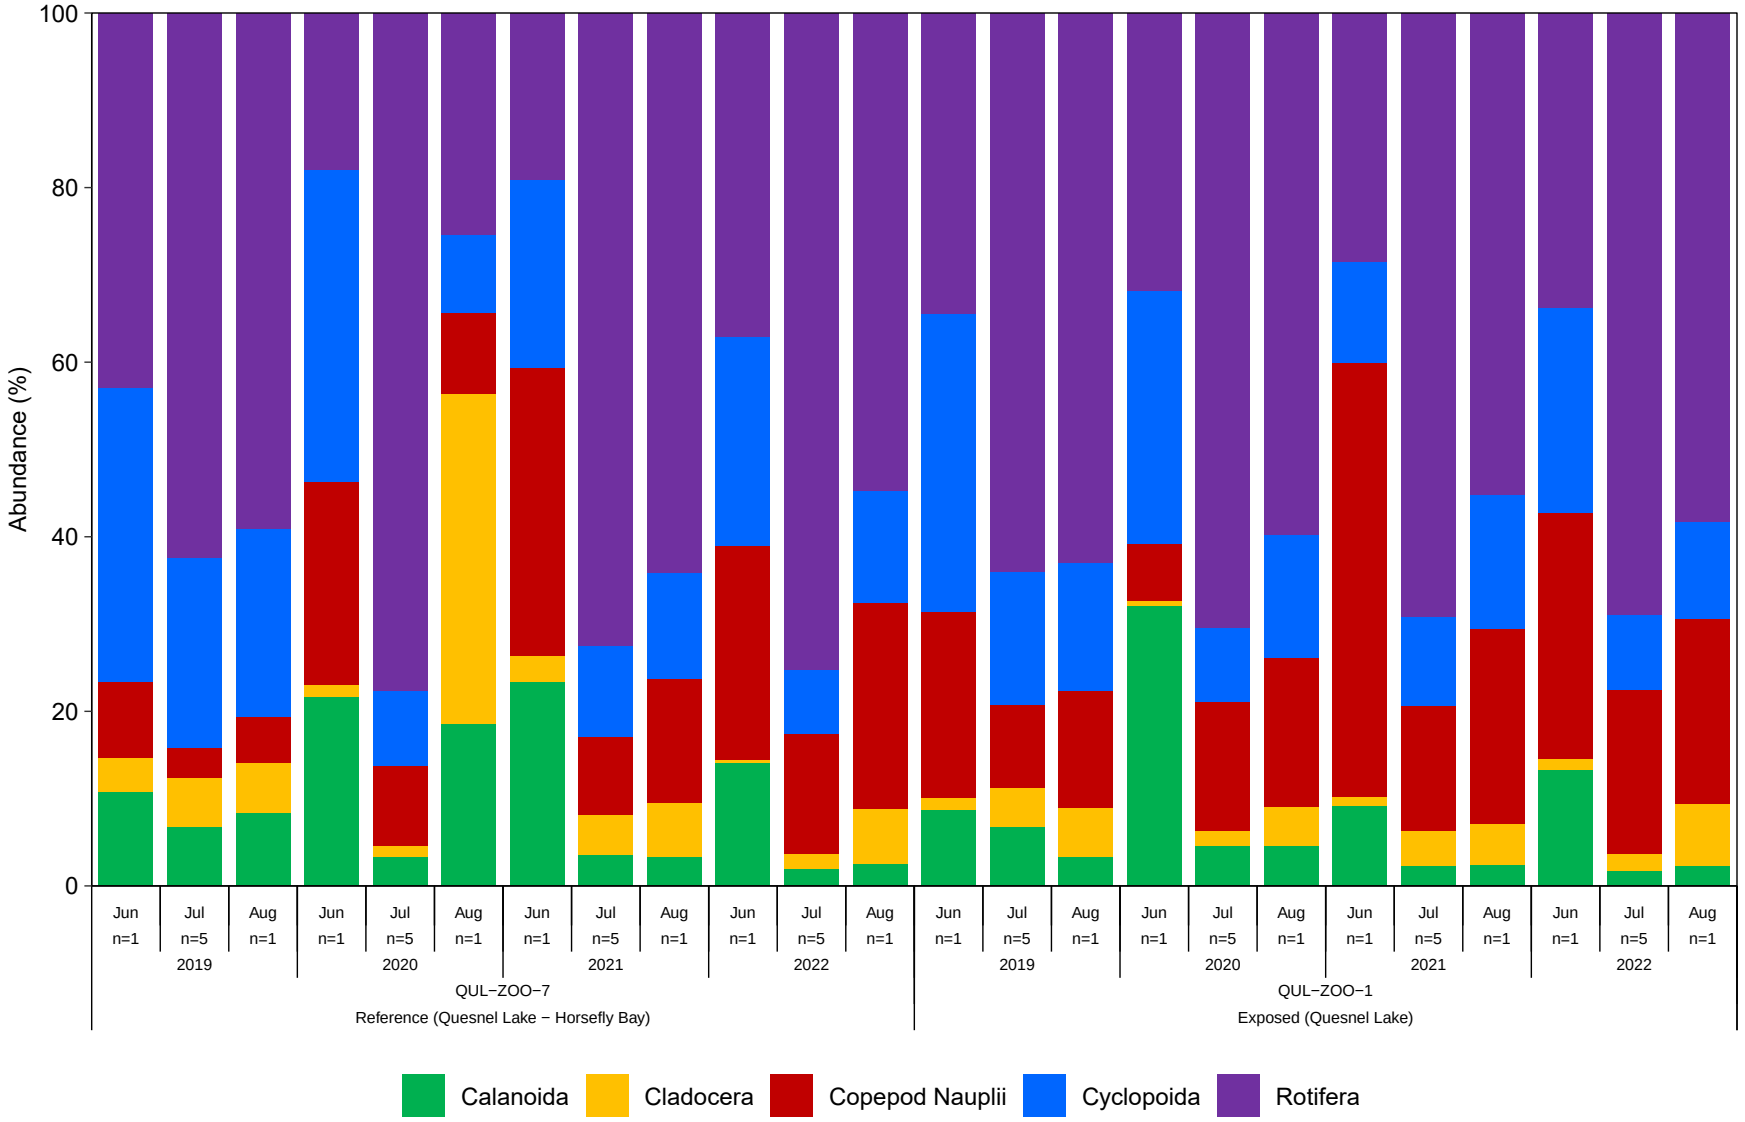

Figure 5.23: Relative Mean Densities of Major Zooplankton Community Taxonomic Groups for Quesnel Lake at QUL−ZOO−1 (Exposed) and QUL−ZOO−7 (Reference) Areas, 2019 to 2022

Overall, zooplankton communities were very similar at the exposed and reference areas of Quesnel Lake in 2022, as all community metrics were statistically similar at both areas with the exceptions of higher taxon richness, higher Simpson's Diversity, and higher relative density and density of Copepod Nauplii relative to reference. While there was variability in community metrics when comparing 2019 to 2022 data, the changes (i.e., direction and relative magnitude) were generally the same at both QUL-ZOO-1 and QUL-ZOO-7, suggesting that changes in the zooplankton community were largely driven by environmental conditions common between both areas (e.g., water temperatures and nutrient concentrations). The similarity of zooplankton communities between the exposed and reference areas for most endpoints and temporal stability of those endpoints that differed between the areas (i.e., Copepod Nauplii) from 2019 to 2022 are suggestive of a lack of mine-related influence on the zooplankton community of Quesnel Lake.

5.2.3.2.2 Productivity

Zooplankton total biomass (dw) in 2022 was highest in July and June at QUL-ZOO-1 and QUL-ZOO-7, respectively, and lowest in August at both areas (Appendix Figure E.2.10, Appendix Table C.3.7). Mean total zooplankton biomass (dw) was consistently similar between QUL-ZOO-1 and QUL-ZOO-7 from July 2019 to 2022 (Figure 5.24, Table 5.18; Appendix Tables C.3.7 and C.3.8). The similar temporal changes in zooplankton biomass at both areas (i.e., significantly higher in 2020 than in 2019, 2021, and 2022 at both areas) was likely driven by natural variability in environmental parameters similar between the two areas (e.g., water temperature, nutrient availability, and phytoplankton community; Appendix Figures A.1.5, C.1.5, Appendix Table C.1.5). The consistent similarity in zooplankton productivity between exposed and reference areas throughout this period is indicative of a healthy lentic system and sufficient food for fish (Jeppesen et al. 2011).

5.2.4 Zooplankton Tissue Quality

Zooplankton tissue quality monitoring in 2022 was completed three times (June, July, and August) in exposed and reference areas of Quesnel Lake (Figure 3.3, Table 3.6) and replicated results from July (n=5) were statistically contrasted (see Section 3.4.3). A review of the 2022 zooplankton tissue data quality (Appendix B) indicated that these data can be used with a high level of confidence for interpretation (see Section 5.1.4 for details). A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

As indicated in Section 3.4.3, data interpretation was focused on primary and secondary analytes (Table 2.4) with a significantly positive expose-reference difference (i.e., analytes with exposed

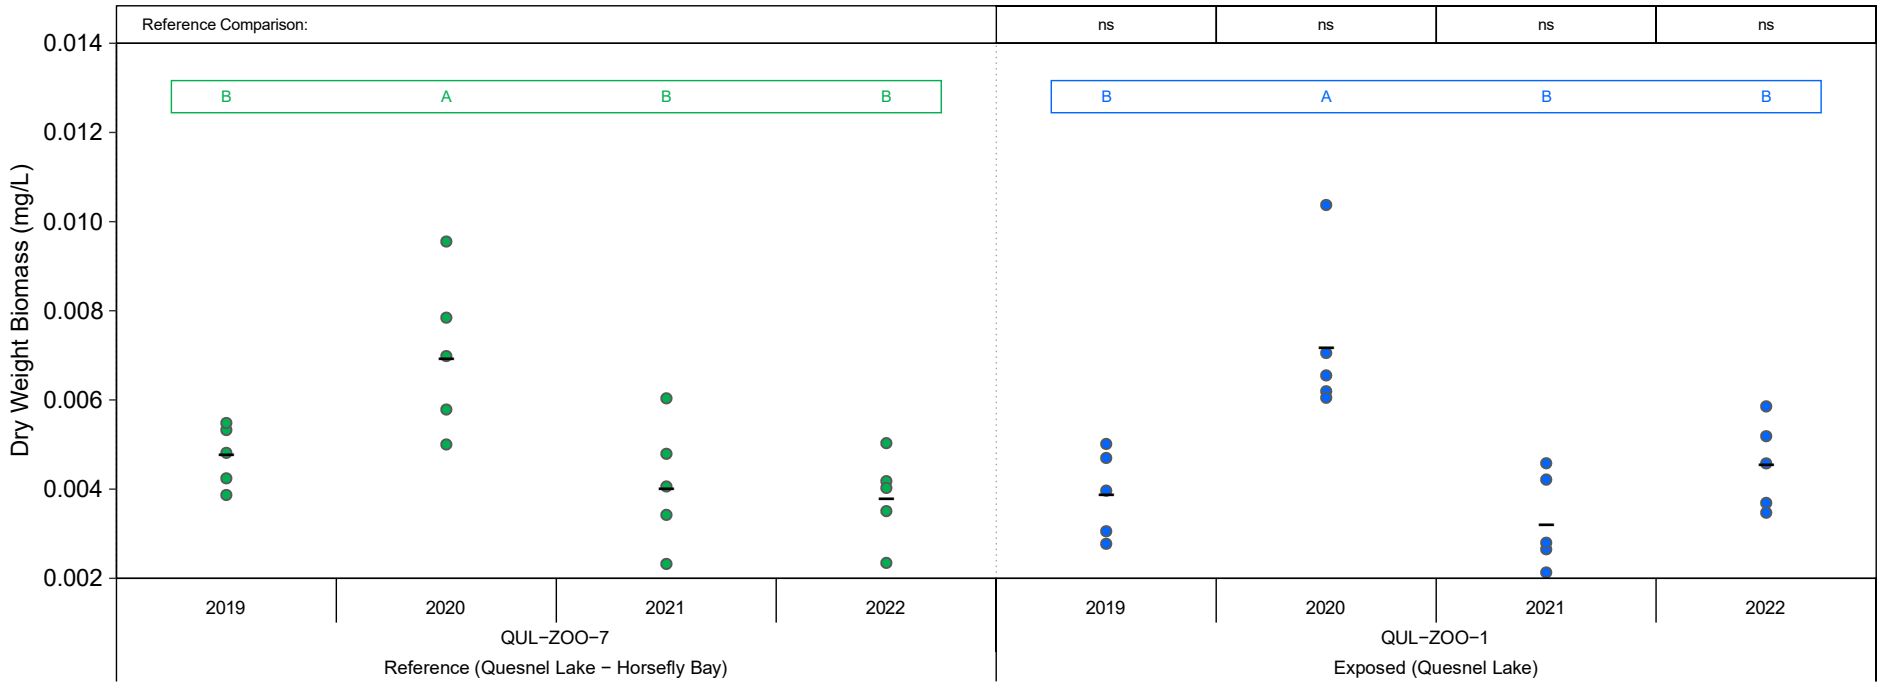

Figure 5.24: Zooplankton Biomass (Total Dry Weight) for Quesnel Lake at QUL−ZOO−1 (Exposed) and QUL−ZOO−7 (Reference) Areas in July, 2019 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, o r median depending o n if analysis was conducted o n untransformed, $\log_{10}$−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box o f the same colour d o not differ significantly within a n area. A number above the plot indicates significant exposed vs. reference posthoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons are expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. For plots of zooplankton results prior to 2019, see Minnow 2019a, 2020a, 2021a. For unreplicated zooplankton results collected in June and August 2022, see Appendix Table C.3.7.

concentrations significantly higher than reference) in 2022 (if the analysis *Area×Year* interaction was significant) or in all monitoring years (if the *Area×Year* interaction was not significant[56]). Zooplankton tissue from the exposed area of Quesnel Lake had concentrations of primary or secondary analytes that were similar to or lower than reference in 2022 or in all monitoring years. This has been true in each of the monitoring years evaluated statistically since 2019 (Appendix Table E.3.3). Thus, results indicate that zooplankton tissue quality in Quesnel Lake from 2019 to 2022 was unimpacted by the breach and potential effluent exposure.

Post-breach (2015 to 2022) surface water quality trends in exposed areas of Quesnel Lake also showed temporal stability for most analytes, with some exceptions. Specifically, total manganese, total phosphorus, and total and dissolved selenium, and dissolved barium, molybdenum and sodium were the only primary or secondary analytes that showed significant increasing trends from 2015 to 2022 in surface water from QUL-18 (near QUL-ZOO-1) and/or QUL-2a exposed water quality monitoring stations (Figure 3.3; Appendix Table E.3.4). Significant increasing trends in dissolved selenium and dissolved molybdenum were identified at both exposed stations (QUL-18 and QUL-2a), whereas an increasing trend was identified at only one of the two stations for the remaining analytes (QUL-18 [total manganese] or QUL-2a [total phosphorous and selenium, dissolved barium and sodium]; Appendix Figures C.1.5 to C.1.8, Appendix Tables C.1.5, E.3.4).

Although no BCWQG exists for dissolved selenium, total selenium concentrations at QUL-18 and QUL-2a remained approximately 10 times lower than the BCWQG for total selenium (2 µg/L; BCMOECCS 2021b) from 2015 to 2022 (Appendix Figure C.1.8). In addition, zooplankton selenium concentrations did not differ significantly between the exposed and reference areas in 2019 to 2022, as indicated above (Appendix Table E.3.2). Zooplankton selenium concentrations at both QUL-ZOO-1 (exposed) and QUL-ZOO-7 (reference) in 2022 were below the BC interim tissue guideline (4 mg/kg dw; Appendix Table C.4.2). Concentrations at QUL-ZOO-1 (exposed) were also below the guideline in 2019 to 2021, while results from 2015 to 2017 exceeded the guidelines (Appendix Figure C.4.2). Concentrations of selenium in zooplankton tissue at reference (QUL-ZOO-7 and QUL-ZOO-8) exceeded the BC interim tissue guideline in 2015 to 2017, 2019, and 2021, indicating that selenium concentrations in zooplankton tissue were naturally higher than the guideline in some areas of Quesnel Lake (Appendix Figure C.4.2, Appendix Table C.4.2). Of the remaining water quality analytes identified as increasing since 2015 at the exposed area(s), BCWQG exist only for total manganese (which remained well below the BCWQG from 2015 to 2022)

[56] If no significant change was detected in the exposed-reference difference among years (i.e., the *Area* x *Year* interaction was not significant), then data from 2019 to 2022 were combined for the analyses.

and phosphorus, but not for dissolved barium, molybdenum, or sodium (BCMOECCS 2021a,b; Figures C.1.5 to C.1.8). A measurable increase of these analytes in zooplankton tissue concentrations was not observed since 2019, indicating no sustained impact of the increased aqueous concentrations of these analytes on zooplankton tissue quality (Appendix Figure C.4.2). The evaluation of potential changes to plankton productivity associated with increased phosphorus concentrations is addressed in Sections 5.2.3.1.2 and 5.2.3.2.2.

To evaluate the potential impact of copper concentrations on aquatic life in Quesnel Lake, dissolved concentrations were compared to the relevant BLM-based BCWQG to calculate GEFs for dissolved copper (refer to Section 3.8.3.3 for details). The copper GEFs in surface water did not change significantly from 2015 to 2022 at any of the routine water quality monitoring stations (Appendix Figure C.1.7, Appendix Table E.3.4). The GEFs observed in 2022 for Quesnel Lake exposed (QUL-18 and QUL-2a) were typically within the range of previous years and results remained within the range of copper GEFs reported for the reference (QUL-12), which suggests there is likely little risk to aquatic life in the near term (Appendix Figure C.1.7)

5.2.5 Benthic Invertebrate Community

Benthic invertebrate community monitoring in 2022 was completed at the exposed deep near-field area of Quesnel Lake (QUL-PNF; Figure 3.2, Table 3.7). A comparable deep reference area located at Horsefly Bay (QUL-PREF1) was monitored from 2014 to 2021 (Minnow 2022a). Data for this area were displayed and incorporated in the interpretation to provide context for the temporal evaluation of QUL-PNF results where applicable (see Section 3.5.3 for details). A review of the 2022 benthic invertebrate community data quality (Appendix B) indicated excellent sampling sorting, efficiency, subsampling precision and accuracy, and taxonomic identification accuracy achieved the laboratory DQO, indicating the data were of excellent quality.

The mean benthic invertebrate density at QUL-PNF in 2022 (995 organisms/m^2) was unchanged since 2016 (i.e., temporally stable from 2016 to 2022; range = 590 organisms/m^2 in 2016 to 1,899 organisms/m^2 in 2019), but higher than densities reported in 2014 and 2015 (Figure 5.25, Table 5.19; Appendix Tables C.5.1, C.5.2, E.4.1). Density in 2022 at QUL-PNF remained much lower than the densities reported for the reference area (QUL-PREF1) in 2014 to 2021, but the difference relative to reference has steadily decreased (Figure 5.25, Table 5.19; Appendix Tables C.5.1 and C.5.2). Taxon richness in 2022 (mean = 6.2 taxa) was similar to all previous years (2014 to 2021; range = 2.2 to 8.2 taxa), indicating temporal stability since the initiation of monitoring in this area. Of the years when comparison to reference was possible, taxon richness was similar to reference in 2014 and 2019 but lower than reference in the remaining years (including the most recent sampling event in 2021; Figure 5.25, Table 5.16; Appendix Table E.4.1). Simpson's Evenness at QUL-PNF in 2022 was significantly lower than

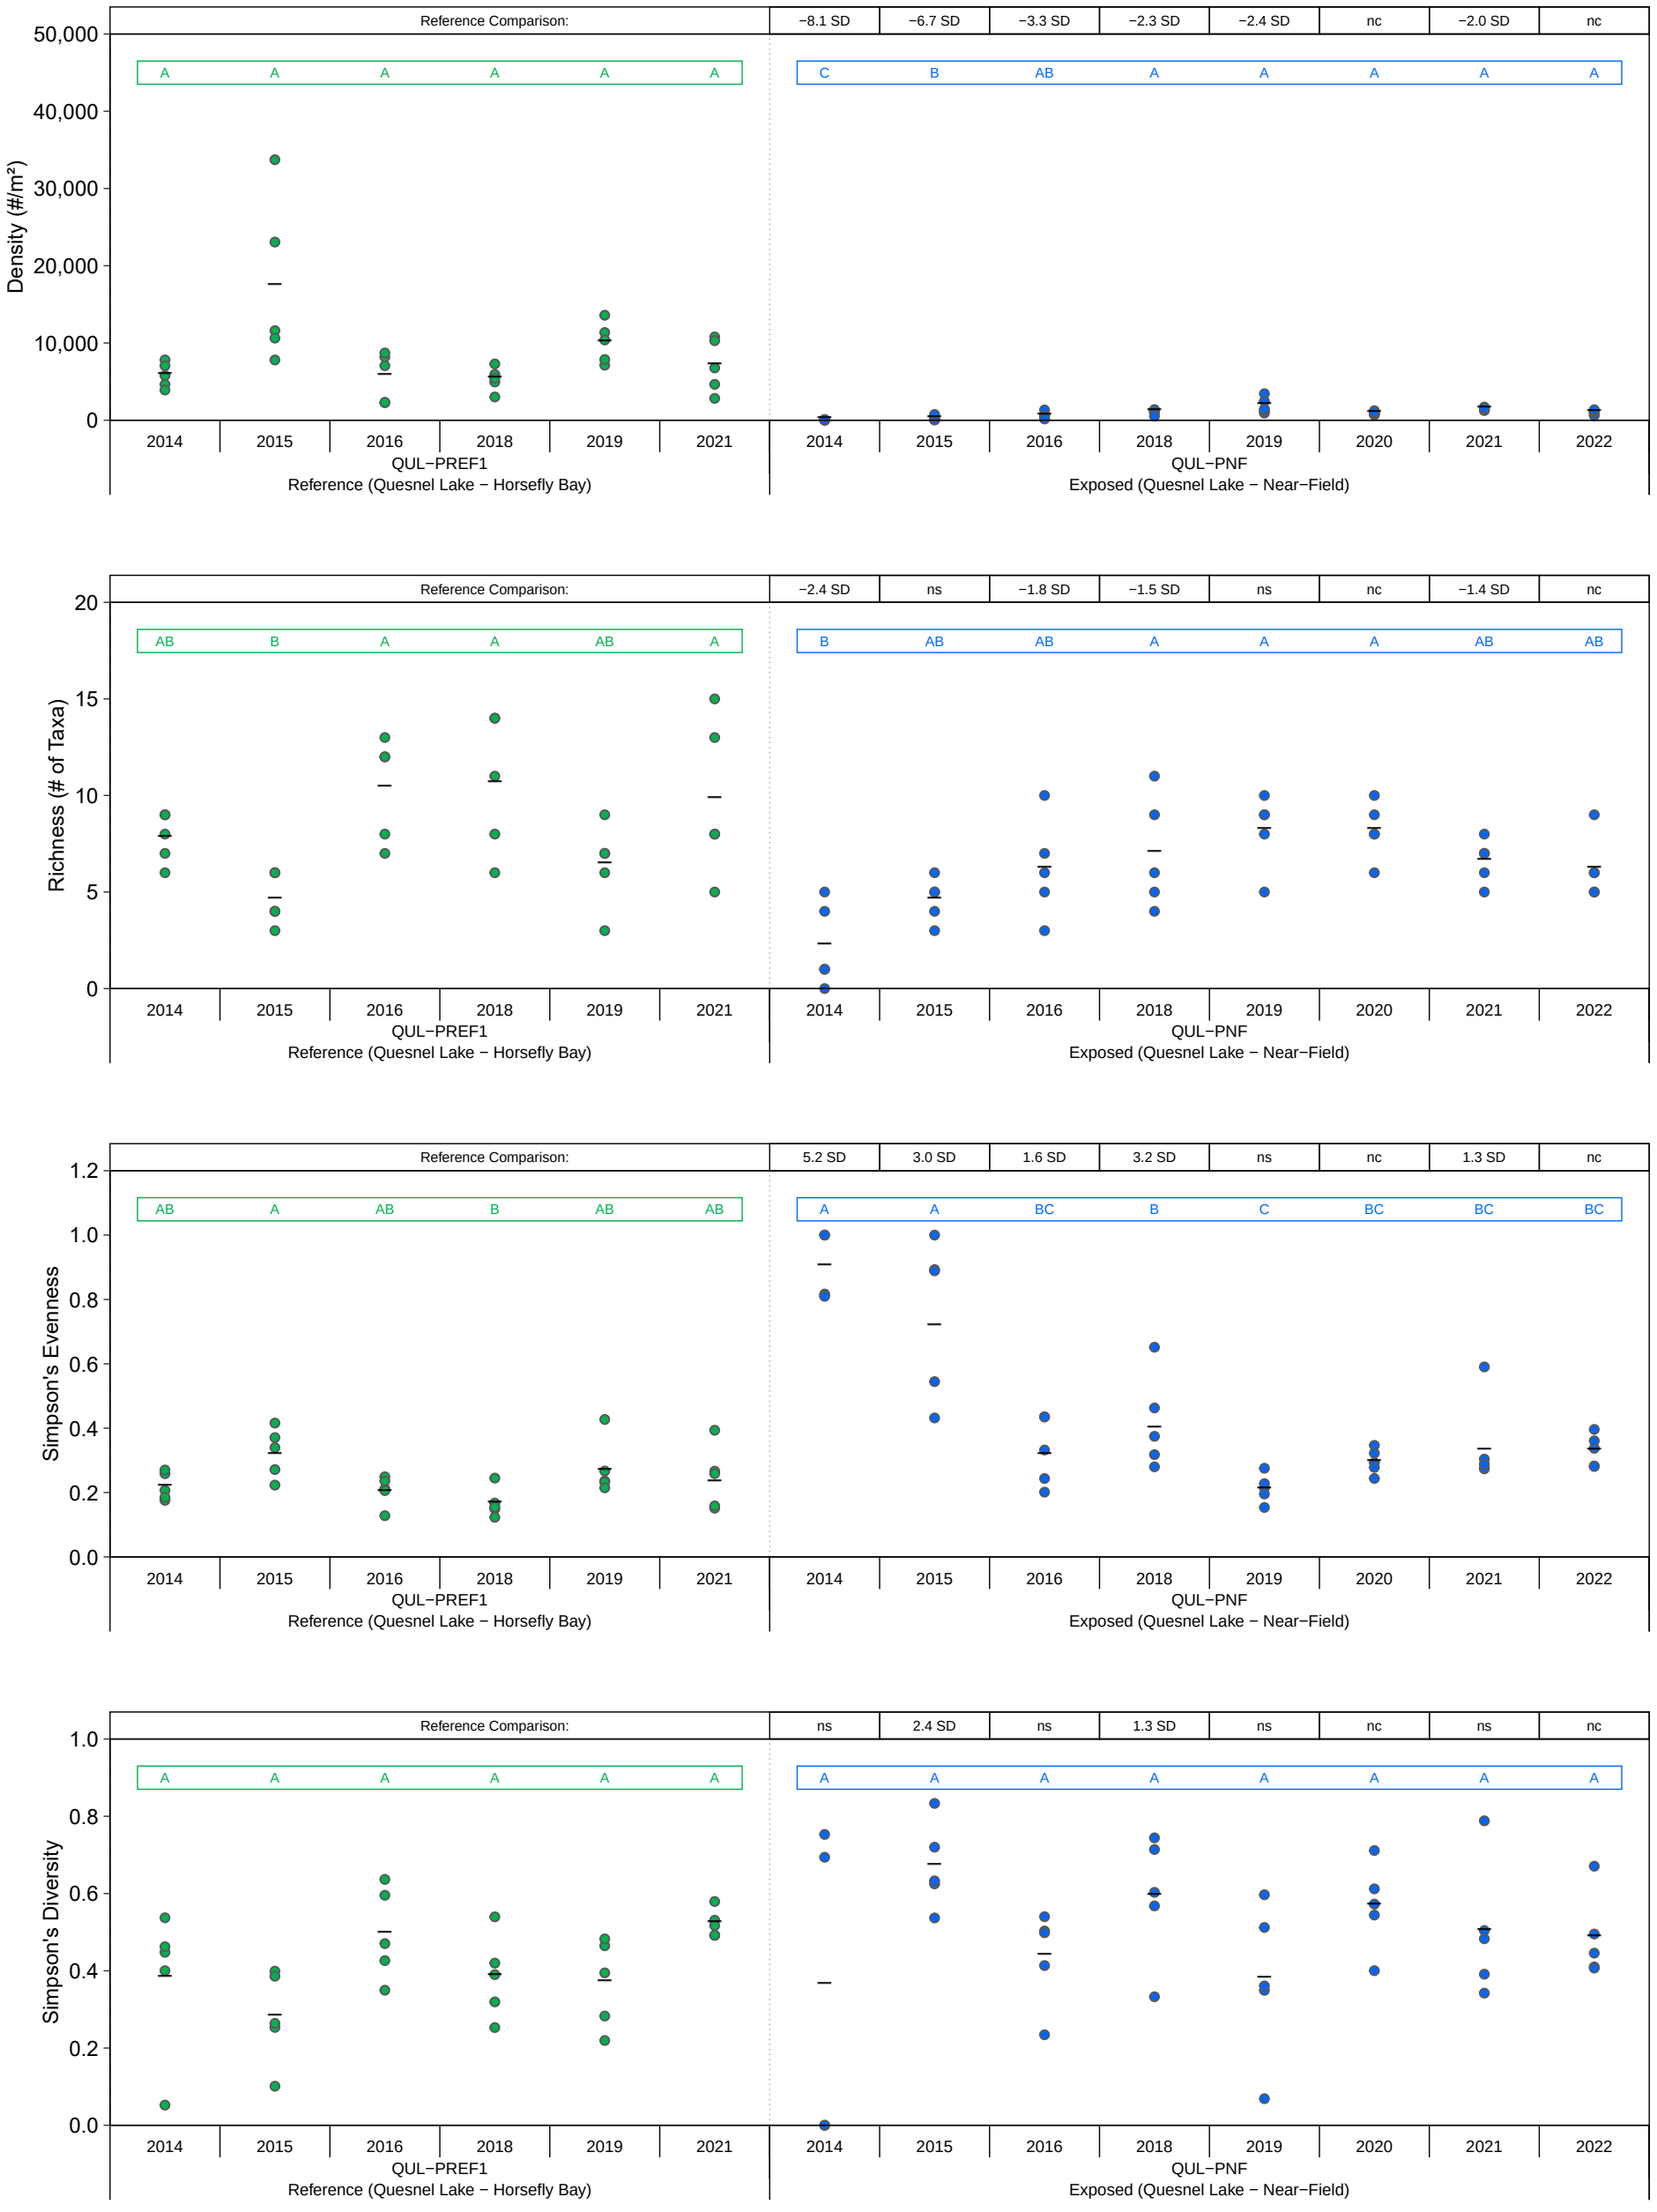

Figure 5.25: Benthic Invertebrate Community Endpoints for Quesnel Lake at QUL−PNF (Exposed) and QUL−PREF1 (Reference) Deep Areas, 2014 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log_{10}−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0.

Table 5.19: Results of Statistical Comparisons of Benthic Invertebrate Community Endpoints for Quesnel Lake at QUL-PNF (Exposed) and QUL-PREF1 (Reference) Deep Areas, 2014 to 2022

Magnitude of Difference (MOD) < -2

Magnitude of Difference (MOD) > 2

Notes: "-" = no data available, "nc" = no comparison, "ns" = no significance, "nm" = Contrast MODs could not be calculated because the MAD=0, "MAD" = Median Absolute Deviation. No data available for QUL-PREF1 in 2020 or 2022, as area was not sampled.

[a] MCT = Measures of Central Tendency. Mean, geometric mean, or median depending on if analysis was conducted on untransformed, $\log_{10}$-transformed, or rank-transformed data.

[b] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled Median Absolute Deviation.

2014 and 2015 and temporally stable since 2016, while Simpson's Diversity showed no change between 2014 and 2022 (Figure 5.25, Table 5.16; Appendix Table E.4.1). Simpson's Evenness at QUL-PNF has remained higher than reference except in 2019, and Diversity has been similar to reference except in 2015 and 2018 when it was higher than reference (for years when comparison to reference is possible; Figure 5.25, Table 5.16; Appendix Table E.4.1).

The benthic invertebrate community at QUL-PNF in 2022 was dominated by Chironomidae, which has been observed in this area since 2014 (mean range = 46 to 91%; Figure 5.26; Appendix Figures E.4.2 and E.4.3, Appendix Table C.5.2). The relative densities of the major taxonomic groups (including Chironomidae) have shown temporal stability since 2014, except for a temporary increase in EPT proportions in 2019 (Appendix Figure E.4.2, Appendix Table E.4.1). Densities of Chironomidae at QUL-PNF have been temporally stable since 2016 and were significantly higher in 2018 to 2022 compared to 2014 and 2015. This was consistent with the stability in total organism density observed since 2016 and the significantly higher density in these monitoring years (2018 to 2022 compared to 2014 and 2015; Table 5.16; Appendix Figure E.4.2, Appendix Table E.4.1). Compared to reference, densities and relative densities (%) of EPT (taxon known to be sensitive to habitat disturbances and water pollution; Lenat 1988, Herman and Nejadhashemi 2015) and Arachnida have been similar to reference in all years. Chironomidae (%) has been similar to reference since 2018 (and in 2014), while Oligochaeta (%) was lower than reference in 2015, 2016, and 2021 (for years when comparison to reference is possible). Since 2014, densities of EPT and Arachnida have been similar to reference, while densities of Chironomidae and Oligochaeta have been lower than reference (Appendix Figure E.4.2, Appendix Table E.4.1)

Multivariate analysis (CA) was used to further evaluate temporal changes in community composition from 2014 to 2022 at QUL-PNF. The first two axes of the CA explained a total of 41.1% of the community variation at QUL-PNF (24.4% and 16.7% for CA Axis 1 and 2, respectively; Appendix Table E.4.2, Appendix Figure E.4.4). Evaluation of temporal changes in community composition indicated that the community QUL-PNF in 2022 only differed significantly from 2014 along CA Axis 1, and 2016 along CA Axis 2 (Appendix Figure E.4.4, Appendix Table E.4.2). The similarity of the benthic community composition in most monitoring years as determined by CA (except for the difference of 2016 relative to all other years along CA Axis 1) is indicative of minimal temporal changes in community composition at this area over time. This was consistent with the temporal stability observed in the proportion of major taxonomic groups over time (Appendix Figure E.4.2). Evaluation of spatial differences indicated that the community composition at QUL-PNF differed significantly from reference along CA Axis 1 in each comparable year (i.e., each year with paired reference and exposed results since 2014; Appendix Figure E.4.4, Appendix Tables E.4.1 to E.4.3). This difference was consistent with the

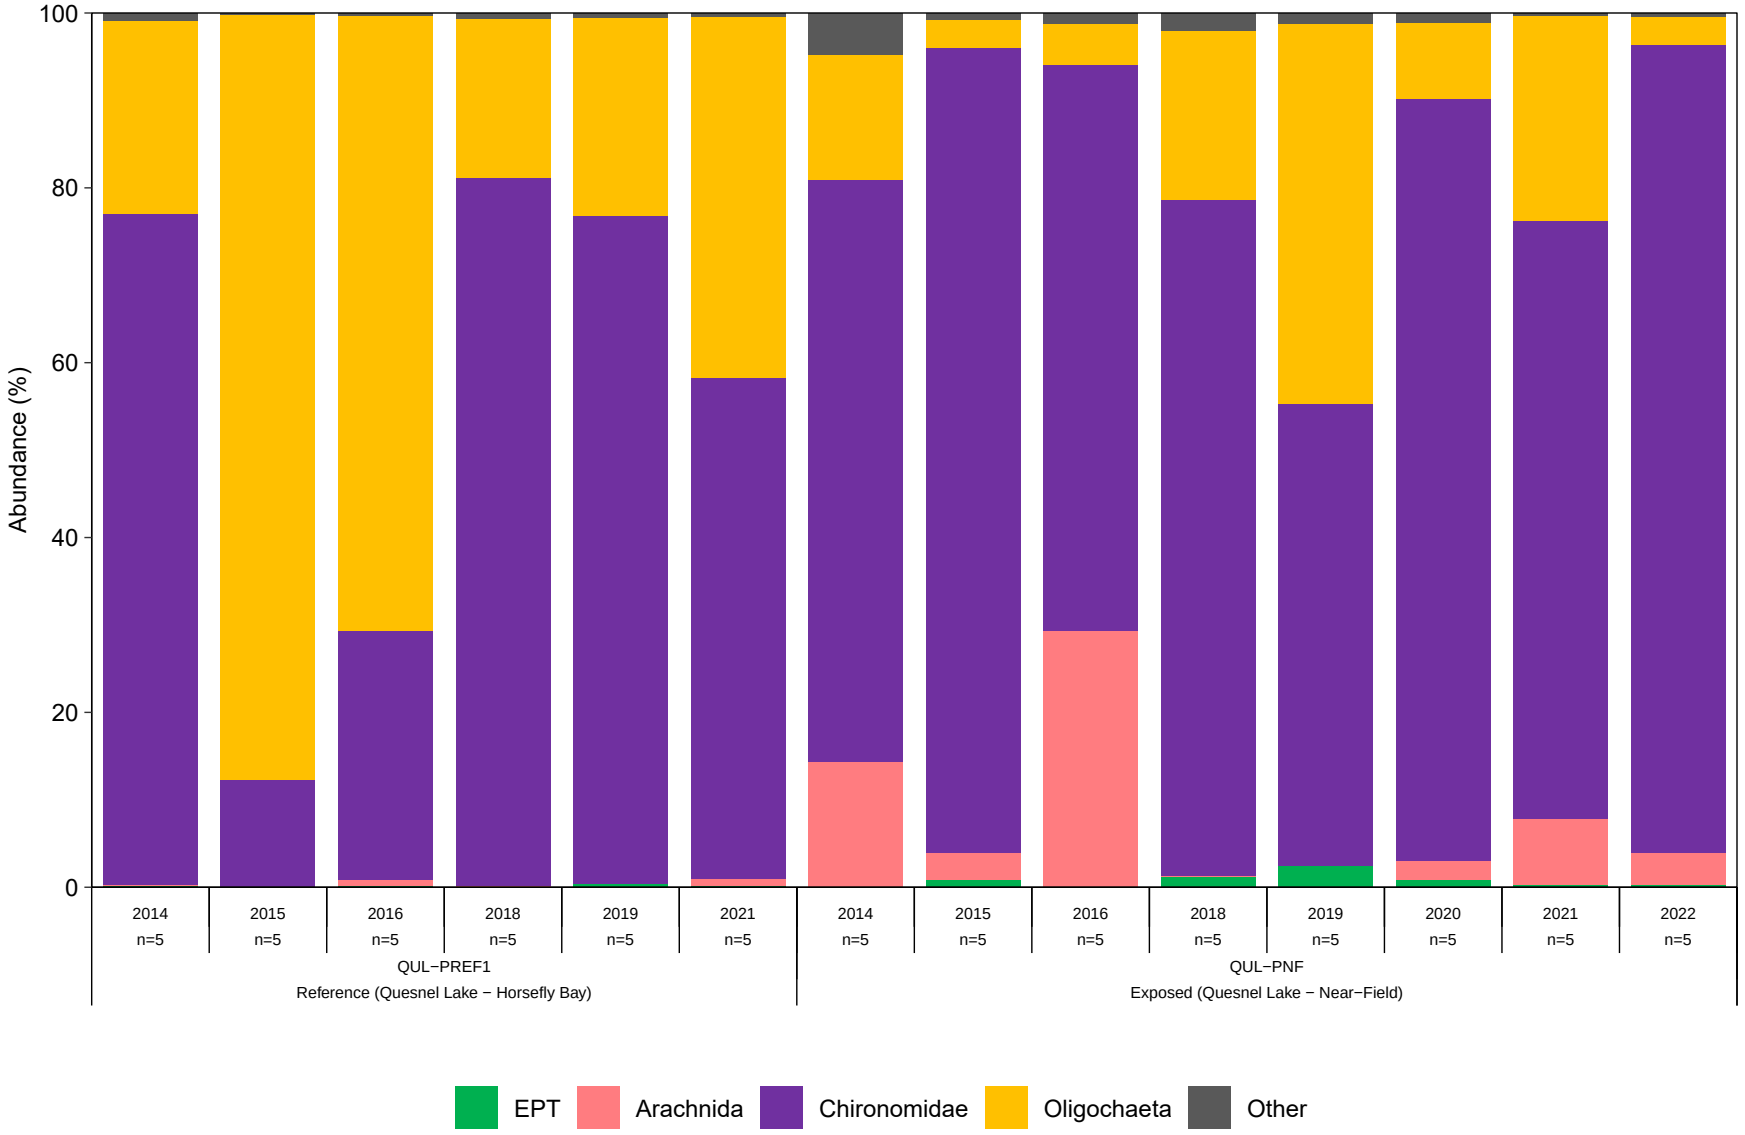

Figure 5.26: Relative Mean Densities of Major Benthic Invertebrate Community Taxonomic Groups for Quesnel Lake at QUL-PNF (Exposed) and QUL-PREF1 (Reference) Deep Areas, 2014 to 2022

continued differences in community composition at QUL-PNF relative to reference; primarily the lower relative density of Oligochaeta. Like other metrics discussed previously, these CA results suggested some recovery of the benthic invertebrate community at QUL-PNF since the initial breach event in 2014, but that no substantial change in community from 2016 to 2021.

Benthic invertebrate community endpoints of total density, Chironomidae density, Oligochaeta density and relative density (%), and CA Axis 1 were negatively correlated with percent fines and the sediment concentration of all analytes of interest (arsenic, copper, iron, and manganese), and positively correlated with TOC and with lower concentrations of several metals as reflected by PCA Axis-1 (Appendix Figure E.1.3, E.4.5, Appendix Tables E.1.7, E.1.8, E.4.4). Richness was positively correlated with TOC and negatively correlated with the concentration of copper, whereas Evenness was negatively correlated with TOC and PCA Axis-1, and positively correlated with all analytes of interest (Appendix Figure E.4.5, Appendix Table E.4.4). Tailings-impacted sediments from the breach characteristically contained a higher proportion of fines, lower TOC content, and elevated concentrations of metals such as copper, the latter of which occurred at concentrations above the upper WSQG at QUL-PNF areas following the breach (see Section 5.2.1.1). Therefore, correlation analysis indicated that the physical and chemical characteristics of sediment at QUL-PNF, including finer particle size, lower TOC content, and elevation in concentrations of metals such as copper, were related to lower total density, richness, Chironomidae density, and Oligochaeta density and relative density compared to the reference area over time. The positive correlation between Chironomidae density, total density (which is dominated by Chironomidae) and TOC content is consistent with the documented intolerance of chironomids (*Chironomus tentans*) to sediments with TOC below 1% (Suedel et al. 1993), and poor survival in sediments with TOC below 0.5% (Suedel and Rodgers 1994). Mean TOC content at QUL-PNF in 2022 was 0.614 ± 0.111% (see Section 5.2.1.1; Table 5.13). Specific conductance and water temperature were negatively correlated with total density, Chironomidae density, and Oligochaeta density and abundance but the incremental differences between the exposed and reference areas for these measures were minor (Appendix Figure E.4.5, Appendix Table E.4.4). Similarly, dissolved oxygen was positively correlated with taxon richness and temperature was also negatively correlated with richness, Oligochaeta (%), and CA Axis 1, but these measures were minor (Appendix Figure E.4.5, Appendix Table E.4.4). Therefore, no adverse effects to the benthic invertebrate community were likely associated with differences of these parameters at QUL-PNF area over time.

Overall, temporal analysis of the benthic invertebrate community at the deep near-field area of Quesnel Lake has indicated some recovery since the initial breach event in 2014, but that no substantial change in community features has occurred from 2016 to 2022. The differences in

benthic invertebrate community structure between the exposed and reference areas that were apparent in previous years appeared related to a greater proportion of fines, lower proportion of TOC, and higher metal concentrations in sediment at the exposed areas than at the reference area; sediment properties which were consistent with the presence of breach-impacted sediments at this deep exposed near-field area.

5.2.6 Fish Community, Catchability, and Population

Total fish catches and CPUE associated with fish sampling completed in Quesnel Lake and Quesnel River in fall 2022 are summarized in Appendix Tables C.6.12 to C.6.14. The supporting *in situ* water quality measurements and habitat data recorded during fish efforts are summarized in Appendix Figure A.1.6 and Appendix Table A.1.5.

Comparisons of CPUE for hoop netting efforts in exposed and reference areas in Quesnel Lake in 2022 indicated that catchability of kokanee (*Oncorhynchus nerka)* and largescale sucker (*Catostomus macrocheilus*) were 75.5-fold and 44.9-fold higher, respectively, in the exposed fishing area near Hazeltine Creek relative to the reference fishing area Grain Creek (Appendix Table C.6.12). Rainbow trout, longnose sucker, and redside shiner were caught at the reference area but not at the exposed area near Hazeltine Creek in 2022 and were also the only species that had higher CPUE at reference area compared to exposed area (Appendix Table C.6.12). Catchability of northern pikeminnow and peamouth chub were higher in the exposed fishing area relative to the reference fishing area in 2022, which agreed with the findings from 2021 (Minnow 2022a).

Comparisons of CPUE for gill net sets in Quesnel Lake in 2022 indicated that catchability of all fish species except for kokanee and rainbow trout was lower at the exposed area near Cedar Point than at the reference area in the East Arm of Quesnel Lake (Appendix Table C.6.13). Lake trout catchability in 2022 was lower at both the reference (mean CPUE = 0.00061) and exposed (mean CPUE = 0.000058) areas of Quesnel Lake compared to 2021 (Appendix Table C.6.13). Though catchability declined between 2021 and 2022, the CPUE in 2022 was within historic range (range = 0.000033 to 0.00053 in the exposed area and range = 0.00061 to 0.14 in the reference area between 2019 and 2021; Appendix Table C.6.13; Minnow 2020a, 2021a, 2022a). The CPUE for rainbow trout in 2022 at the Quesnel River sampling area was 1.5-fold lower than 2021, 1.1-fold higher than 2020, and 2.5-fold higher than 2019 (Appendix Table C.6.14; Minnow 2020a, 2021a, 2022a).

5.2.7 Fish Tissue Quality

Fish tissue quality in 2022 was evaluated at exposed and unexposed (reference) areas of Quesnel Lake and Quesnel River (Figure 3.6, Table 3.8). In Quesnel Lake, fish tissue quality was

evaluated from northern pikeminnow and peamouth chub collected near Hazeltine Creek and lake trout collected near Cedar Point, with areas in the East Arm (lake trout) and near Grain Creek (northern pikeminnow and peamouth chub) of Quesnel Lake serving as reference. In Quesnel River, fish tissue quality was evaluated from rainbow trout (Figure 3.6, Table 3.8). A review of the 2022 fish tissue data quality (Appendix B) indicated that these data can be used with a high level of confidence for interpretation (see Section 5.1.6 for details).

5.2.7.1 Comparison to Guidelines and Thresholds

Mean selenium concentrations of fish muscle samples from Quesnel Lake and Quesnel River in 2022 were consistently below consumption guidelines for the protection of human health, as was the case from 2015 to 2021 (Table 5.20; Appendix Tables C.7.5 to C.7.11; CFIA 2015; BCMOE 2014). Mean mercury concentrations in 2022 were also below the human health guideline (0.5 mg/kg ww) in fish muscle from Quesnel Lake and Quesnel River, although two lake trout individuals from each of the exposed (near Cedar Point) and reference (East Arm) areas of Quesnel Lake did exceed this threshold (Table 5.20; Appendix Table C.7.5, C.7.6, C.7.9 to C.7.11; CFIA 2015; BCMOE 2014). Given the longevity of lake trout as well as their trophic position in Quesnel Lake, it is not unexpected to see some large individuals with natural muscle tissue concentrations in exceedance of the human health guideline. In fact, it has been typical that a proportion of lake trout individuals from the reference area exceed this threshold, with results from 2021, 2020, 2019, and 2018 that exceeded the guideline by 63%, 63%, 50%, and 13% respectively (Table 5.20).

Mean selenium concentrations in fish muscle or whole-body samples from Quesnel Lake and Quesnel River were below the guideline for the protection of aquatic life in 2022 (4 mg/kg dw; BCMOE 2014), except for peamouth chub from the exposed area (Table 5.21; Appendix Tables C.7.5 to C.7.11). The mean selenium concentration in muscle of peamouth chub from the exposed area of Quesnel Lake in 2022 was higher than the guideline for the protection of aquatic life (mean = 4.3 mg/kg dw; range = 4.06 to 5.88 mg/kg dw), with 63% of samples exceeding the guideline (Table 5.21; Appendix Table C.7.9). The rate of guideline exceedances in peamouth chub muscle samples from the exposed area in 2022 (63%) has increased relative to all prior years (38% in 2021, 13% in 2018 and 2015). The rate of guideline exceedances in 2022 for rainbow trout muscle from Quesnel River (13%) and northern pikeminnow whole-body from the Quesnel Lake exposed area (25%) were greater than 2021 but were within the historic range (Table 5.21). Selenium concentrations in peamouth chub muscle and northern pikeminnow whole-body from the reference area of Quesnel Lake were below the guideline for the protection of aquatic life in all years, as were selenium concentrations in lake trout muscle from both the exposed and reference areas (Table 5.21).

Table 5.20: Fish Muscle Mercury and Selenium Concentrations from Quesnel Lake (Exposed and Reference) and Quesnel River (Exposed) Relative to Human Health Consumption Guidelines, 2015 to 2022

Waterbody or Area		Species	Year/Season	Sample Size	Mercury		Selenium

Indicates mean mercury concentration greater than Health Canada's Human Health guideline for muscle tissue in fish (0.5 mg/kg dw; CFIA 2015).
Indicates mean selenium concentration greater than the BCMOE Human Health guideline for moderate fish consumption (14.5 mg/kg dw; BCMOE 2014).
Indicates mean selenium concentration greater than the BCMOE Human Health guideline for high fish consumption (7.3 mg/kg dw; BCMOE 2014).

Notes: mg/kg ww = milligrams per kilogram wet weight, mg/kg dw = milligrams per kilogram dry weight, BCMOE = British Columbia Ministry of Environment, > = greater than, % = percent, guidelines for the protection of human health were applied to edible fish tissues only (i.e., muscle) not whole body tissue results (e.g., northern pikeminnow results for 2016 to 2022).

Table 5.21: Fish Muscle Selenium Concentrations from Quesnel Lake (Exposed and Reference) and Quesnel River (Exposed) Relative to the British Columbia Guideline for the Protection of Aquatic Life, 2015 to 2022

Indicates mean selenium concentration greater than the BCMOE guideline for muscle tissue or whole body in fish (4 mg/kg dw; BCMOE 2014).

Notes: mg/kg dw = milligrams per kilogram dry weight; BCMOE = British Columbia Ministry of Environment; > = greater than; % = percent. The guideline for the protection of aquatic life was applied to fish muscle and whole body tissue concentrations.

As indicated previously (Section 5.1.6.1), embryo toxicity is the primary mechanism of selenium-associated effects to egg laying vertebrates, the most selenium-sensitive organisms, and analysis of ovary tissue is recommended for assessing the effects of selenium on fish (e.g., Luoma and Presser 2009; Janz et al. 2010; DeForest et al. 2012; Janz 2012). Selenium analysis was completed on 19 ovary samples from Quesnel Lake and five samples from the Quesnel River in 2022. Seven peamouth chub ovary samples were collected from the exposed area of Quesnel Lake in 2022. Of these, six (86%) had selenium concentrations that exceeded the threshold for the protection of aquatic life (11 mg/kg dw[57]; BCMOE 2014), and three (43%) also exceeded the threshold for reproductive effects (Table 5.22). The rate of the guideline/threshold exceedances in these exposed peamouth chub ovary tissues was higher in 2022 than in prior years, with only a single sample previously reaching a concentration above the threshold for reproductive effects (*n*=1 [25%] in 2018; Table 5.22). It should be noted that 50% of the peamouth chub ovary samples from the reference area in 2022 were also above the threshold for the protection of aquatic life (range = 12.7 to 14.8 mg/kg dw; Appendix Table C.7.9). This suggests natural elevation of selenium in peamouth chub ovaries but was the first year that this occurred (Table 5.22). Mean selenium concentrations 80% of ovary samples from rainbow trout in Quesnel River in 2022 exceeded the guideline for the protection of aquatic life, which was within the range of previous years (range = 50 to 100%; Table 5.22; Appendix Table C.7.11)

5.2.7.2 Spatial and Temporal Comparisons

Data from Quesnel Lake and Quesnel River collected between 2015 to 2022 (Table 3.9) were compared spatially (exposed vs. reference) and temporally (annual change; see Section 3.7.3.2). These comparisons included up to 36 elements[58], four species (lake trout, northern pikeminnow, peamouth chub, and rainbow trout), and up to four tissues per species (whole-body, muscle, liver, ovary, and kidney; Appendix Figures E.6.9 to E.6.17, Appendix Tables E.6.9 to E.6.17). For Quesnel River rainbow trout (which do not have an associated reference area), temporal comparisons within this exposed area were evaluated (Appendix Figures E.7.18 to E.7.21, Appendix Tables E.7.18 to E.7.21).

Age and morphological measures (fork length and body weight) of lake trout, northern pikeminnow, and peamouth chub from Quesnel Lake, and rainbow trout from Quesnel River between 2015 and 2022 are summarized in Table 5.23 (see Appendix Tables C.6.15 to C.6.18 for detailed 2022 data). Statistical comparisons exhibited a significant *Area*×*Year* interaction for

[57] This guideline includes a two-fold uncertainty factor (BCMOE 2014).

[58] Silver and titanium were added to fish tissue analyses in 2020.

Table 5.22: Fish Ovary Selenium Concentrations from Quesnel Lake (Exposed and Reference) and Quesnel River (Exposed) Relative to the British Columbia Guideline for the Protection of Aquatic Life, 2015 to 2022[a]

Indicates mean selenium concentration greater than the BCMOE guideline for ovary tissue in fish (11 mg/kg dw; BCMOE 2014).

Indicates mean selenium concentration greater than DeForest et al. (2012) threshold for ovary tissue in fish (20 mg/kg dw) and the BCMOE guideline.

Notes: mg/kg dw = milligrams per kilogram dry weight, > = greater than, BCMOE = British Columbia Ministry of Environment, % = percent.

[a] No female lake trout were collected from the Quesnel Lake East Arm (reference) in 2021, therefore results for lake trout from this area are not displayed in 2021.

Note: - = no data / not calculated.

[a] Sample size is n = 9 for age estimate.

one or more of the physical measures for each species monitored in 2022[59]. Exposed peamouth chub sampled did not differ from those from the reference area in 2022 but were significantly longer and heavier than reference in 2020 and 2021 (Table 5.24; Appendix Table E.6.10). Relative to prior years, peamouth chub length at the exposed area in 2022 was not significantly different from any other year in the time series (2016 to 2021), while weight was significantly greater than in 2018 (Appendix Table E.6.10). Northern pikeminnow age and length at the exposed area were significantly greater relative to those at the reference area in 2022, but there was no significant difference in weight (Table 5.24). Relative to previous years at the exposed area, northern pikeminnow in 2022 were significantly older than 2021, 2019, and 2018, but had mean length and weight measures in 2022 that were higher than in 2018 (Table 5.24; Appendix Table E.6.11). Exposed lake trout were of similar length and weight to those from the reference area in 2022 but were consistently younger than reference lake trout from 2015 to 2022 (Table 5.24; Appendix Table E.6.16). Measures of length, weight, and age of Quesnel River rainbow trout did not differ temporally from 2015 to 2022 (Appendix Table E.6.20).

As indicated in Section 3.7.3, data interpretation was focused on primary and secondary analytes (Table 2.4) with a significant positive expose-reference difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2022 (if the analysis *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant[60]). For most metals, there was little to no evidence of increasing metal concentrations at exposed relative to reference areas over time in Quesnel Lake (Appendix Figures E.6.9 to E.6.17, Appendix Tables E.6.9 to E.6.17) or over time in Quesnel River (Appendix Figures E.6.18 to E.6.21, Appendix Tables E.6.18 to E.6.21). The primary analytes arsenic, copper, iron, and selenium and 14 secondary analytes (barium, cadmium, calcium, manganese, mercury, molybdenum, phosphorus, sodium, strontium, tin, titanium, uranium, vanadium, and zinc) met the criteria for inclusion in data interpretation outlined above for Quesnel Lake data (Table 5.24). None of these primary and secondary analytes showed higher concentrations in zooplankton from the exposed area relative to the reference area of Quesnel Lake (Appendix Table E.3.3; see Section 5.2.4 for details).

[59] Results of the two-way ANOVA for age, fork length, and body size may differ among tissue types for the same species in the same area due to sub-sampling (i.e., the number of females sampled for ovary tissue may be a subset of the total samples) or differences in data availability across years for the different tissue types (e.g., peamouth chub kidney and ovary data were collected from 2018 to 2022 compared to 2016 to 2022 for peamouth chub muscle and liver tissue). For all species sampled for tissue in 2022, discussion of age and body size is focused on results of two-way ANOVA for muscle tissues.

[60] If no significant change was detected in the exposed:reference ratio among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

Table 5.24: Summary of Statistical Contrasts of Exposed - Reference Relative Differences of Fish Tissue Primary and Secondary Analyte Concentrations for Quesnel Lake (Exposed and Reference), 2015 to 2022[a]

Contrast is significant (α = 0.05) and magnitude of difference is positive

Contrast is significant (α = 0.05) and magnitude of difference is negative

Notes: "-" = no data available for analysis (i.e., no data was collected for the given time period); "LRL" = majority of data were <LRL and could not be analysed; "ns" = not significant; "ww" = wet weight; Exp = exposed; Ref = reference; ANOVA = Analysis of Variance; MLE = Maximum Likelihood Estimation. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Data were analysed in units of mg/kg dry weight except mercury which was analysed in units of mg/kg wet weight. Age, fork length, and body weight results are those that are associated with muscle tissue analyses for peamouth chub and lake trout, and whole body tissue analyses for northern pikeminnow. No female lake trout were collected from the Quesnel Lake reference area in 2021, so 2021 was excluded from the analysis of lake trout ovary tissues.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Table E.6.9 to E.6.21). This table only presents results for primary and secondary analytes that had a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types in one or more species.

[b] Magnitude of difference (MOD) calculated on backtransformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted})\times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[c] Magnitude of difference (MOD) calculated on backtransformed least-squares means as (Exp-Ref)/Ref x 100%.

[d] Organ in which the specific primary analyte is known to accumulate (references in Appendix Table E.6.22).

[e] MOD is inflated because data for one of the groups in the comparison were entirely < LRL, leading to an underestimate of the mean for the <LRL result and a consequent increase in MOD between the two groups.

Contrast is significant (α = 0.05) and magnitude of difference is positive

Contrast is significant (α = 0.05) and magnitude of difference is negative

Notes: "-" = no data available for analysis (i.e., no data was collected for the given time period); "LRL" = majority of data were <LRL and could not be analysed; "ns" = not significant; "ww" = wet weight; Exp = exposed; Ref = reference; ANOVA = Analysis of Variance; MLE = Maximum Likelihood Estimation. Merged cells across years indicate that the Area × Time term was not significant, therefore MOD is for all years combined. Data were analysed in units of mg/kg dry weight except mercury which was analysed in units of mg/kg wet weight. Age, fork length, and body weight results are those that are associated with muscle tissue analyses for peamouth chub and lake trout, and whole body tissue analyses for northern pikeminnow. No female lake trout were collected from the Quesnel Lake reference area in 2021, so 2021 was excluded from the analysis of lake trout ovary tissues.

[a] Statistical approaches included ANOVA, ANCOVA, and MLE and for each case depended on data suitability (see complete statistical results in Appendix Table E.6.9 to E.6.21). This table only presents results for primary and secondary analytes that had a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types in one or more species.

[b] Magnitude of difference (MOD) calculated on backtransformed least-squares means for the observed time period as $(Exp_{observed} - Exp_{predicted})/(Exp_{predicted})\times 100\%$ where $Exp_{predicted} = Ref_{observed} + (Exp_{baseline} - Ref_{baseline})$.

[c] Magnitude of difference (MOD) calculated on backtransformed least-squares means as (Exp-Ref)/Ref x 100%.

[d] Organ in which the specific primary analyte is known to accumulate (references in Appendix Table E.6.22).

[e] MOD is inflated because data for one of the groups in the comparison were entirely < LRL, leading to an underestimate of the mean for the <LRL result and a consequent increase in MOD between the two groups.

Concentrations of the primary analytes arsenic, copper, iron, and selenium in the majority fish tissues from the exposed areas of Quesnel Lake were either: 1) statistically similar to reference, 2) significantly lower than reference in 2022, or 3) lacked a significant *Area×Year* interaction in the analyses (Figure 5.27, Table 5.24; Appendix Tables E.6.9 to E.6.17). The absence of a significant *Area×Year* interaction indicates that the ratio of exposed:reference concentrations did not differ among years (i.e., the geometric mean concentrations at the exposed area were trending the same as the geometric mean concentrations at the reference area). Therefore, for most fish tissues sampled from Quesnel Lake there is no evidence that concentrations of these primary analytes are increasing over time due to mine-related influence. Arsenic concentrations in northern pikeminnow whole-body tissue and copper concentrations in lake trout ovary in 2022 were both significantly higher in tissues from the exposed area relative to the reference and had a significant *Area×Year* interaction, indicating a temporal change in the ratio of exposed:reference concentrations (Figure 5.27, Table 5.24; Appendix Tables E.6.9 and E.6.11). However, in both cases the exposed:reference ratio in 2022 was similar to the baseline year (2016 for northern pikeminnow and 2015 for lake trout) indicating that the analyte concentrations in the exposed fish have not increased over time, relative to reference (Figure 5.27, Appendix Tables E.6.9 and E.6.11). It should be noted that the temporal comparison of lake trout analyte concentrations between exposed and reference sites were often challenged by low sample sizes, which is dependent on the proportion of the total sample (n=8) that were female (Appendix Tables C.7.5, C.7.6, E.6.9).

It is important to note that for peamouth chub no significant *Area×Year* interaction was reported for selenium concentrations in each of the tissues (muscle liver, ovary, and kidney) indicating temporal stability in these concentrations, relative to reference (Figure 5.27, Table 5.24; Appendix Tables E.6.10, E.6.12, E.6.13, E.6.15). This was despite the higher rate of guideline/threshold exceedances identified in muscle and ovary in 2022 relative to prior years (see Section 5.2.7.1) and was owing to the similar temporal variability in the selenium concentrations of tissues from exposed and reference peamouth chub. The similarity of temporal variability in exposed and reference peamouth chub tissues suggests that this variability was related to natural factors influencing both the exposed and reference areas in a similar manner. Since data are not available for these tissues from before the breach, definitive conclusions as to the potential factors influencing tissue selenium concentrations cannot be made (e.g., due to mine-exposure or due to inherent differences between the areas). Despite the fact that selenium concentrations were consistently elevated in all tissues of peamouth chub since 2016, relative to reference, there is no evidence that selenium concentrations in fish tissues from Quesnel Lake are increasing over time due to mine exposure.

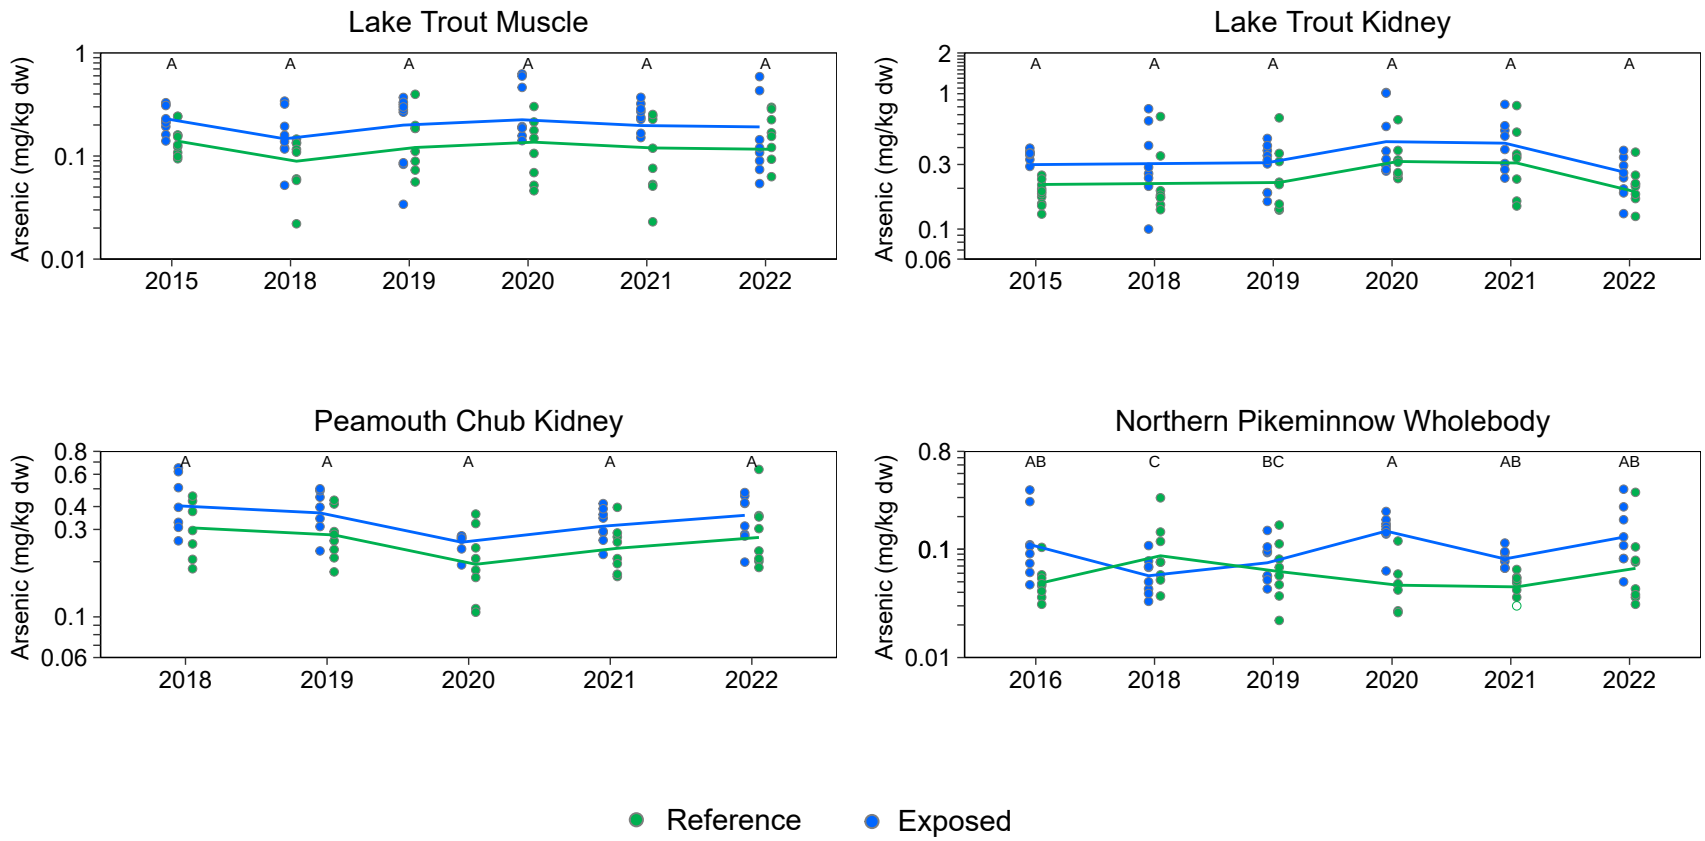

Figure 5.27: Fish Tissue Primary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Quesnel Lake (Exposed and Reference), 2015 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. Plots are only included for primary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given species and tissue type. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. No female lake trout were collected from the Quesnel Lake reference area in 2021, so 2021 was excluded fron analyses.

Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. No female lake trout were collected from the Quesnel Lake reference area in 2021, so 2021 was excluded fron analyses.

The secondary analytes, barium, cadmium, calcium, manganese, mercury, molybdenum, phosphorus, sodium, strontium, tin, titanium, uranium, vanadium, and zinc had significant interaction terms for one or more tissue types in one or more of the Quesnel Lake species (peamouth chub, northern pikeminnow, and lake trout) and/or were elevated in fish caught in the exposed area relative to the reference area in 2022 (Figure 5.28, Table 5.24; Appendix Tables E.6.9 to E.6.17). For most secondary analyte-tissue combinations for each of the three species, this difference was not indicative of an increase in concentrations over time due to mine influence. This is because the significant positive exposed-reference differences in 2022 were either not significantly different from prior years, or the *Area×Year* interaction and significant positive exposed-reference difference in 2022 was only reported in one tissue type in one species. For simplicity, only those secondary analyte-tissue combinations with a significant positive exposed-reference difference in 2022 or in all years (if the *Area×Year* interaction was not significant) in more than one tissue type within a species are discussed further (i.e., sodium, strontium, titanium, and uranium were not discussed further).

For most of the secondary analytes identified for further discussion (barium, cadmium, calcium, manganese, mercury, molybdenum, phosphorus, tin, vanadium, and zinc), there was no evidence of concentrations of these analytes increasing over time. This based on secondary analyte concentrations in the majority fish tissues from the exposed areas of Quesnel Lake were either: 1) statistically similar to reference, 2) significantly lower than reference in 2022 (if the *Area×Year* interaction in the analyses was significant), or 3) lacked a significant *Area×Year* interaction in the analyses (Figure 5.28, Table 5.24; Appendix Tables E.6.9 to E.6.17). As outlined above, the absence of a significant *Area×Year* interaction indicates that the ratio of exposed:reference concentrations did not differ among years. For instance, cadmium, molybdenum, and vanadium concentrations that were significantly higher in exposed tissues compared to reference were also temporally stable (i.e., lacked a significant *Area×Year* interaction; Table 5.24). For several secondary analytes (barium, calcium, manganese, mercury, phosphorus, tin, and zinc), some tissue types exhibited both a significant *Area×Year* interaction (i.e., a significant change in the ratio of exposed:reference concentrations over time) and higher exposed concentrations relative to reference in 2022. However, for most of these secondary analyte-tissue combinations, the analyte concentrations in exposed tissues in 2022 were similar to the baseline year, relative to reference, indicating no evidence of a mine-related temporal increase in analyte concentrations (Figure 5.28, Table 5.24; Appendix Tables E.6.9 to E.6.17). Some of these secondary analyte-tissue combinations showed increases in the exposed:reference ratio in 2022 compared to the baseline year. However, each occurred in a single tissue type within each species, and some were influenced by a high prevalence of data with results reported below the detection limit. This suggests that the observed increases may not be indicative of a persistent mine-related

Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. No female lake trout were collected from the Quesnel Lake reference area in 2021, so 2021 was excluded fron analyses.

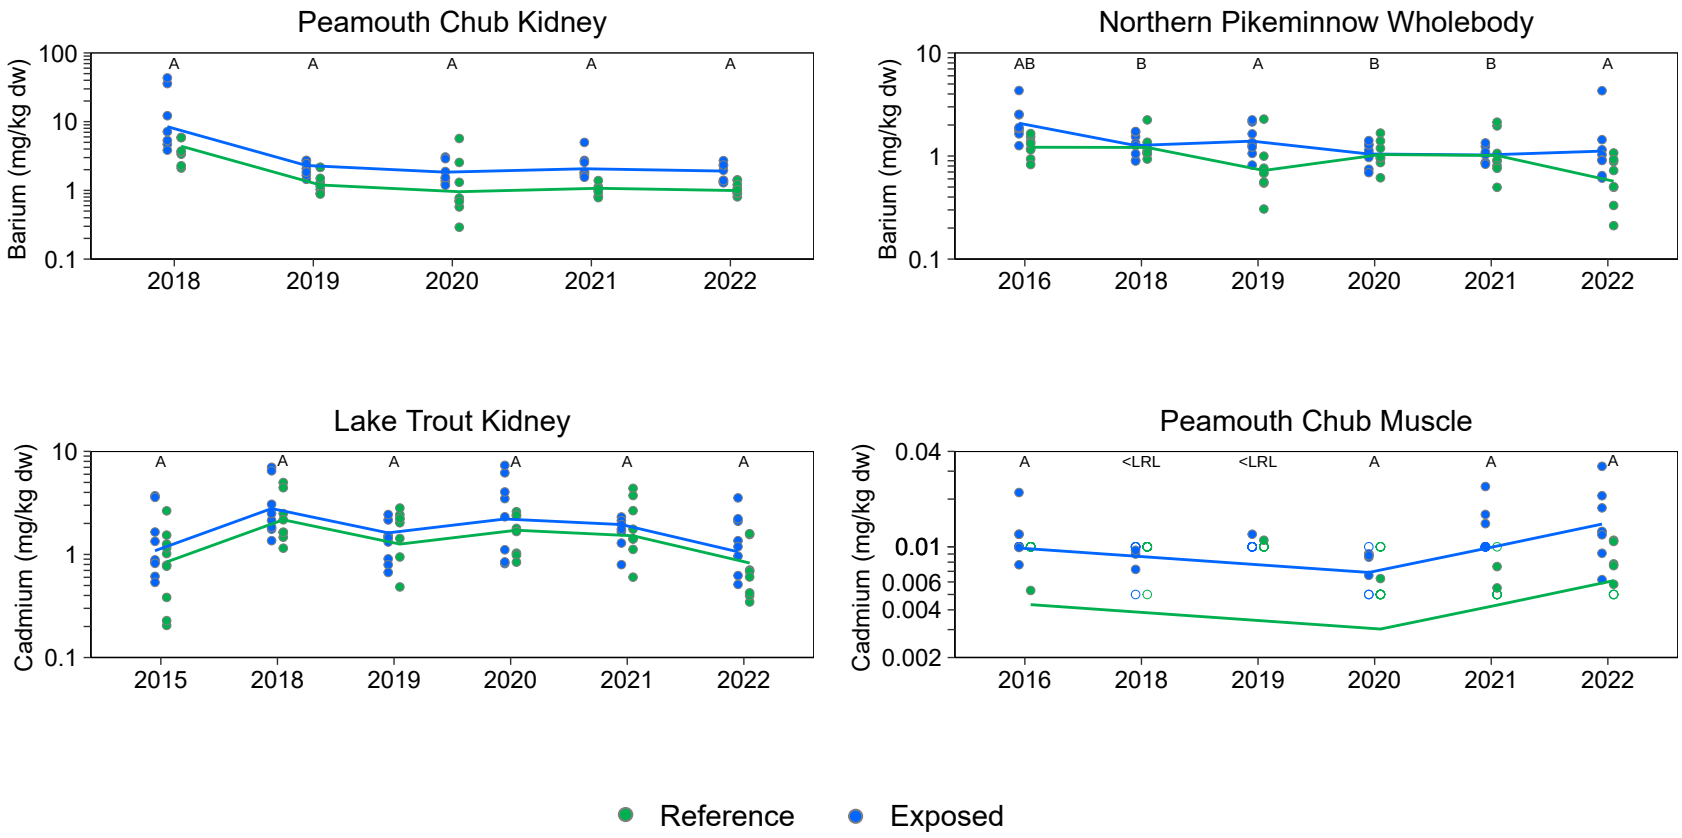

Figure 5.28: Fish Tissue Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Quesnel Lake (Exposed and Reference), 2015 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. Plots are only included for secondary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given species and tissue type. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. No female lake trout were collected from the Quesnel Lake reference area in 2021, so 2021 was excluded fron analyses.

influence which might affect all tissues within a given species. The secondary analyte-tissue combinations that showed increases in the exposed:reference ratio in 2022 compared to the baseline year are detailed below.

Barium concentrations in lake trout muscle from the exposed area were significantly higher in 2022 than in 2018 and 2019, relative to reference (Figure 5.28, Table 5.24; Appendix Table E.6.16). However, the results of temporal comparisons for barium were influenced by a relatively high frequency of results below the LRL, particularly at the reference area in 2021 and 2022. Calcium concentrations in lake trout kidney from the exposed area in 2022 were similar to 2018 but significantly higher than all other prior years (including baseline), relative to reference (Figure 5.28, Table 5.24; Appendix Table E.6.14).

Manganese concentrations in the muscle of peamouth chub and lake trout from the exposed area were significantly higher in 2022, relative to reference, than in the baseline year (Figure 5.28; Appendix Tables E.6.10, E.6.16). Specifically, manganese concentrations in peamouth chub muscle from the exposed area in 2022 was significantly higher than in 2016 and 2022, relative to reference, and 2022 was the first year where exposed area concentrations were significantly greater than reference (Figure 5.28, Table 5.24; Appendix Table E.6.10). Manganese concentrations in lake trout muscle from the exposed area in 2022 were significantly higher than in 2015 to 2019 but were similar to 2020 to 2021, relative to reference. The higher manganese concentrations in exposed lake trout muscle from 2020 to 2022 compared to 2015 to 2019, relative to reference, appears to be related (at least in part) to a steady decline in manganese concentrations at the reference site since 2018 (Figure 5.28, Table 5.24; Appendix Table E.6.16).

Phosphorus concentrations in lake trout kidney from the exposed area of Quesnel Lake were significantly higher in 2022 compared to all prior years (2015 to 2021), relative to reference. This appears to be related to both a slight increase in the phosphorus concentrations in lake trout muscle from the exposed area combined with a slight decrease in the reference results from 2020 to 2022 (Figure 5.28, Table 5.24; Appendix Table E.6.14).

Tin concentrations in peamouth chub liver and lake trout muscle from the exposed area were higher in 2022, relative to reference, than in the baseline year. For peamouth chub liver specifically, tin concentrations in the exposed tissues in 2022 were higher than in baseline (2016) but similar to or lower than the following years (2018 and 2020; when sufficient detectable data were available for analyses), relative to reference (Figure 5.28, Table 5.24; Appendix Table E.6.12). Tin concentrations in exposed lake trout muscle were higher in 2022 than in 2021,

relative to reference, which was the first year where there were sufficient detectable data for statistical comparisons (Figure 5.28, Table 5.24; Appendix Table E.6.16). Similar to barium, the results of temporal comparisons for tin were often influenced by results below the LRL, particularly for lake trout muscle results prior to and including 2021 (Figure 5.28, Table 5.24). In some of the comparisons for tin, the magnitude of the exposed-reference difference was inflated because data for one of the groups in the comparison were entirely less than the LRL, which was the case for one or more years of data for both peamouth chub liver and lake trout muscle (Table 5.24; Appendix Tables E.6.12, E.6.16).

Although there is no corresponding reference area for Quesnel River to assess *Area×Year* interaction, concentrations of three secondary analytes in rainbow trout tissues were significantly higher in 2022 compared to the baseline year (2015). Specifically, concentrations of phosphorus in muscle, sodium in kidney, and barium in liver were significantly higher than the baseline in more than one year (including 2022), sodium in kidney has been consistently elevated each year since baseline (including 2022), and sodium in ovary and barium in muscle were higher in 2022 only compared to baseline (Appendix Figures E.6.18 to E.6.21, Appendix Tables E.6.18 to E.6.21). Phosphorus concentrations in rainbow trout muscle were 18% and 34% higher in 2021 and 2022, respectively, relative to baseline (Appendix Table E.6.20). Sodium concentrations in rainbow trout kidney in 2022 were 93% greater than baseline, and sodium has shown consistently higher concentrations in lake trout kidney since 2017 relative to baseline (range = 82 to 189% higher than baseline; Appendix Table E.6.19). However, sodium concentrations in rainbow trout muscle were the lowest concentration reported post-baseline except for 2018 (Appendix Table E.6.19). Sodium concentrations in ovary in 2022 were also higher than baseline (by 163%; Appendix Table E.6.21). Barium was significantly elevated in both muscle (410% greater than baseline) and liver (503% greater than baseline) tissue of rainbow trout in 2022, relative to baseline. Barium concentrations in muscle were the highest observed since baseline, while those in liver were similar to those in 2018 to 2020 (Appendix Tables E.6.18 and E.6.20). Considering these analytes, the consistency among tissue types reflected in the increased concentrations of barium (in muscle and liver) and sodium (in ovary and kidney) infers a potential consistent influence on analyte concentrations in these exposed tissues. However, throughout the monitoring period (2015 to 2022) only kidney concentrations of sodium have consistently been significantly higher than the baseline year (2015) results. The increases in barium and sodium were not reflected in other rainbow trout tissues nor in the tissues of other fish species in Quesnel Lake, therefore may be reflective of natural variability of these analytes within the area.

5.2.8 Summary

Sediment monitoring in 2022 continued to indicate a breach influence on sediment chemistry at both the deep and shallow areas of Quesnel Lake. Sediment collected from the deep near-field area of Quesnel Lake was characterized by concentrations of several analytes (arsenic, copper, iron, and manganese) that were greater than reference concentrations and WSQG, and TOC content lower than reference, consistent with previous post-breach results. Copper was the most substantially elevated analyte, with mean concentrations 4.2 times the upper WSQG in 2022. Mean iron and manganese concentrations were also greater than reference and upper WSQG, although to a lesser degree, and mean concentrations of arsenic were greater than reference and the lower WSQG. Temporal stability of these analytes in the deep near-field area sediments was demonstrated by arsenic, copper, and iron concentrations in 2022 that were similar to those reported in 2014, and manganese concentrations and TOC content in 2022 similar to 2015. Sediments from the shallow near-field area in 2022 had a very high sand content (92.8%), and were characterized by concentrations of arsenic, copper, iron, manganese, and silver that were greater than reference concentrations and WSQG. Copper was the most substantially elevated analyte, with mean concentrations 5.7 times the upper WSQG. Mean iron and manganese concentrations were also greater than reference and the upper WSQG (to a lesser extent than copper), while mean concentrations of arsenic and silver were greater than reference and lower WSQG. Concentrations, arsenic, copper, iron, manganese, and silver and TOC content were temporally stable, relative to reference, with concentrations in 2022 remaining similar to 2014 values for each of these analytes (compared to reference).

Sediment toxicity testing of *H. azteca* using sediments from the shallow near-field area of Quesnel Lake (QUL-LNF1) in 2022 resulted in a moderate survival response (44 to 45% mortality) and a high growth response (76 to 79% reduction). However, concentrations of dissolved copper in overlying waters of the toxicity test vessels were highly dissimilar from those documented in field-collected water from these sites, which is consistent with previous years of monitoring. Dissolved copper concentrations in the toxicity test vessels in 2022 were an average of 97-times greater than in field-collected water, which is similar to 2020 and 2021 (74- and 114-times greater, respectively) and lower than 2019 (174-times). This strongly suggests copper mobilization in the test setup that has either not occurred *in situ* or has attenuated over time *in situ*. Under these conditions, the observed mortality and growth response are consistent with dissolved copper concentrations in overlying water, particularly given that *H. azteca* have been documented to derive little nutrition from sediment and to respond primarily to contaminants in overlying water. Significant regression relationships evaluating results from 2014 to 2022 inferred lower *H. azteca* growth and survival at higher overlying water dissolved copper concentrations and higher sediment copper concentrations. This further corroborates the observation that

toxicity responses of *H. azteca* are consistent with dissolved copper concentrations in the overlying test waters of these shallow sediments. Overall, the toxicity test results from the shallow near-field area cannot be reliably extrapolated to the field but suggest potential copper mobilization in this area with disturbance.

Phytoplankton community and productivity monitoring in Quesnel Lake in 2022 indicated that phytoplankton productivity (in terms of chlorophyll-a concentrations) was similar at the exposed and reference monitoring areas, as was also observed in previous years (2019 to 2021). These results characterize both the exposed and reference areas of Quesnel Lake as mesotrophic in 2022, which is a change from the classification of ultraoligotrophic in 2016 to 2018 and as oligotrophic in 2019 to 2021; a change likely owing in part to a switch from surface grab (2018 and earlier) to depth-integrated sampling methods (2019 onwards). The plankton community of the exposed area of Quesnel Lake in July 2022 was characterized by density higher than reference, taxon richness lower than reference, and Simpson's Evenness and Diversity indices similar to reference. Total density has consistently been higher at the exposed area compared to the reference area since 2019. Simpson's Diversity and Evenness at the exposed area have shown some temporal variability but have been either similar to or higher than reference in each year since 2019. Taxon richness at the exposed area in 2022 was lower than in previous years (2019 to 2021) reflecting a decrease from conditions that were similar to reference from 2019 to 2021, to lower than reference in 2022. This decrease in taxon richness was attributable to the absence of relatively rare phytoplankton taxa at QUL-ZOO-1 in July 2022, and appeared to be a temporary change based on the results of samples collected in August 2022 which included some of these relatively rare taxa. Continued monitoring will help to further understand whether the decrease in taxon richness in 2022 is part of a longer-term change or was a single variable result. The community composition at the exposed area has been similar to reference in terms of the relative densities of Diatoms, Cyanobacteria, and Chlorophytes from 2019 to 2022. The relative densities of Chrysophytes, Cryptomonads, and Dinoflagellates at the exposed area differed from reference in 2022 but showed temporal stability either within the exposed area or temporal stability in the difference relative to reference from 2019 to 2022. The similarity of the phytoplankton community at the exposed and reference areas of Quesnel Lake for most endpoints, and the temporal stability throughout the study period for most endpoints that differed between the areas (excluding taxon richness), are suggestive of a lack of mine-related influence on the phytoplankton community of Quesnel Lake.

Zooplankton community and productivity monitoring in Quesnel Lake in 2022 indicated that total biomass of zooplankton (dw) at the exposed area was similar to reference, which is consistent with prior years. The zooplankton community at the exposed area of Quesnel Lake in 2022 was characterized by total density and Simpson's Evenness that were similar to reference, and taxon

richness and Simpson's Diversity that were higher than reference. While there was temporal variability in these metrics at the exposed area from 2019 to 2022, the changes (i.e., direction and relative magnitude) were generally the same as those observed at the reference area, and metrics at the exposed area were largely similar to or greater than reference over this period. The community composition at the exposed area has been similar to reference in terms of the densities and relative densities of most zooplankton taxa (Calanoida, Cladocera, and Rotifera) from 2019 to 2022, with two exceptions, indicating that the communities at the exposed and reference areas were largely similar. The two exceptions were lower density and relative density of Cyclopoida in 2019, and consistently higher density and relative density of Copepod Nauplii in 2019 to 2022 at the exposed area compared to reference. The similarity of zooplankton communities between the exposed and reference areas for most endpoints and temporal stability of those endpoints that differed between the areas (i.e., Copepod Nauplii) from 2019 to 2022 are suggestive of a lack of mine-related influence on the zooplankton community of Quesnel Lake.

Zooplankton tissue quality monitoring in Quesnel Lake in 2022 indicated that concentrations of primary and secondary analytes in tissues from the exposed area were similar to or lower than reference, and also temporally stable from 2019 to 2022. The lack of temporal and spatial differences in zooplankton tissue quality results in 2022 was supported by trend analyses of surface water quality data which indicated temporal stability (from 2015 to 2022) for most analytes, except for increasing trends at one or both exposed monitoring stations for total manganese, total phosphorus, total and dissolved selenium, and dissolved barium, molybdenum, and sodium. A measurable increase in concentrations of these analytes in zooplankton tissue was not observed since 2019, indicating no sustained impact of the increased aqueous concentrations of these analytes on zooplankton tissue quality. In addition, aqueous total selenium and manganese concentrations remained well below the BCWQG from 2015 to 2022. Despite the identified increasing trend in aqueous selenium concentrations, zooplankton tissue selenium concentrations were below the BC interim guideline for aquatic life at the exposed area in 2022 (similar to 2019 to 2021), and tissue selenium concentrations at the exposed area were similar to reference from 2019 to 2022. As such, monitoring results indicate that zooplankton tissue quality in 2019 to 2022 was unimpacted by the breach and potential effluent exposure.

Benthic invertebrate community monitoring in the deep-near field area of Quesnel Lake in 2022 documented a community with total density and Simpson's Evenness that were unchanged since 2016, taxon richness that was similar to all years since 2014, and Simpson's Diversity that was unchanged since 2014. Total density at the deep near-field area in 2022 remained much lower than the densities reported for the reference area in previous years (2014 to 2021), but the difference relative to reference has steadily decreased. These results indicate some recovery of the benthic invertebrate community at the exposed areas from the initial breach event in 2014,

but no substantial change in community structure since 2016 at the deep near-field exposed area of Quesnel Lake. This lack of significant recovery is consistent with the stability of sediment TOC content and concentrations of arsenic, copper, iron, and manganese in these sediments since at least 2016. Chironomidae, which are the dominant taxa at the deep near-field area, are intolerant to sediments with organic content (TOC) of less than 1% (Suedel et al. 1993) and the TOC content of near-field area sediments (mean = 0.614%) remains well below this level. The community composition has shown temporal stability since 2014, and in 2022 continued to be characterized by Chironomidae dominance. Several characteristics of the benthic invertebrate community at the deep near-field area were related to sediment characteristics, including lower total density, richness, Chironomidae density, and Oligochaeta density and relative density associated with greater proportion of fines, lower proportion of TOC, and higher metal concentrations in sediment. These sediment properties are consistent with the presence of breach-impacted sediments at the deep near-field area.

The catchability of lake trout at the exposed area of Quesnel Lake in 2022 was lower than at the reference area, while catchability of peamouth chub and northern pikeminnow in 2022 were both higher at the exposed area relative to reference. The catchability of rainbow trout from the Quesnel River in 2022 was higher than in previous years. Fish tissue quality in 2022 was evaluated in up to four tissues (muscle, liver, kidney, and ovary) in four species (lake trout, northern pikeminnow, peamouth chub, and rainbow trout). Mean mercury and selenium concentrations in fish muscle tissue from Quesnel Lake and Quesnel River in 2022 were below the guidelines for the protection of human health (i.e., indicating that fish are safe for moderate human consumption). This was consistent with prior monitoring years except 2020 and 2021 when the mean mercury concentrations in muscle of reference lake trout exceeded the consumption guideline. Mean selenium concentrations in fish muscle or whole-body samples from Quesnel Lake and Quesnel River in 2022 were below the guideline for the protection of aquatic life except for peamouth chub from the exposed area which exceeded the guideline at a higher rate in 2022 (63%) than in previous years (2015 to 2021). Mean selenium concentrations in ovary tissue (the tissue most valuable in the assessment of potential selenium-associated effects on fish) from lake trout in 2022 were below the tissue specific guideline for the protection of aquatic life but exceeded the guideline in rainbow trout and peamouth chub. In rainbow trout ovary tissue, selenium concentrations in 2022 exceeded the guideline in 50% of samples which was within the range of previous years. In peamouth chub ovary tissue, selenium concentrations in the majority of exposed (86%) and reference (50%) samples in 2022 exceeded the tissue specific guideline for the protection of aquatic life, with 43% of exposed samples also exceeding the threshold for reproductive effects. The rate of the guideline/threshold exceedances in exposed peamouth chub ovary tissue was higher in 2022 than in prior years. Despite this,

selenium concentrations in peamouth chub tissues (muscle liver, ovary, and kidney) and in northern pikeminnow whole-body samples (also a small home-range species) have been temporally stable from 2016 to 2022, relative to reference. The absence of pre-breach data precludes drawing definitive conclusions about the potential factors influencing tissue selenium concentrations (e.g., due to mine-exposure or due to inherent differences between the areas). However, results from 2016 to 2022 indicated there is no evidence that selenium concentrations in fish tissues from Quesnel Lake are increasing over time due to mine exposure. Evidence of a persistent mine influence was not detected for most analytes assessed in fish tissue from Quesnel Lake and Quesnel River in 2022. All primary analytes (arsenic, copper, iron, and selenium), and the secondary analytes barium, cadmium, calcium, manganese, mercury, molybdenum, phosphorus, sodium, strontium, tin, titanium, uranium, vanadium, and zinc were elevated relative to reference in 2022 in at least one tissue type in at least one species. However, the results for most these analytes were inconsistent among tissues and species, and/or were temporally stable, and/or the results were not supported by zooplankton tissue quality results, indicating that the weight of evidence does not support a pattern of increasing analyte concentrations over time due to mine-exposure.

6 RESULTS – CREEK HABITAT

6.1 Hazeltine Creek

6.1.1 Sediment Quality

Creek sediment quality monitoring in 2022 targeted one area in upper (HAC-U) and one in lower (HAC-D) Hazeltine Creek, with areas in upper (EDC-U) and lower (EDC-D) Edney Creek serving as reference sites, respectively (Figure 4.1, Table 4.1). A review of the 2022 sediment data quality (Appendix B) indicated that the data met the established DQOs and can be used with a high level of confidence for interpretation (see Section 5.1.1 for details).

6.1.1.1 Upper Hazeltine Creek

Sediments collected from upper Hazeltine Creek (HAC-U) in 2022 were composed primarily of silt and clay particles (mean = 71.1% and 16.1%, respectively) and were higher in silt content than the reference sediments from EDC-U, which were composed predominantly of sand and silt (mean = 55.1% and 35.7%, respectively; Table 6.1; Appendix Tables D.2.1 to D.2.7). Sediments collected at HAC-U in 2022 (mean = 71.1% silt) had the highest silt content observed since 2018 (following the completion of remediation; Table 6.1). Silt content of sediments from HAC-U has been fairly consistent from 2019 to 2022 (53.2 to 71.1%) but higher than previous years (30.0 to 30.5% in 2014 and 2018), while sand (11.2 to 32.0%) and clay content (13.4 to 21.0%) have been more variable from 2019 to 2022 (Table 6.1; Appendix Tables D.2.6 to D.2.7). The presence of fine sediments in these erosional sampling areas has been limited in some years, and this limited availability of fine sediments has necessitated opportunistic sampling (as described in Section 4.1.1; Minnow 2019a, 2020a, 2021a, 2022a). Therefore, variability in particle size is likely related to variability among years in the presence of similarly fine sediments in these erosional habitats.

Total nitrogen content in HAC-U sediment (mean = 0.765%) was higher than the corresponding reference site (mean = 0.283%) in 2022 and was also higher than prior monitoring years (mean range = <0.020 to 0.656% in 2014 to 2021; Table 6.1). The mean TOC of sediments from HAC-U (mean = 6.74%) was similar to reference (EDC-U mean = 6.01%) in 2022 and was significantly higher at HAC-U in 2022 than in 2018 and 2020 at this area, relative to reference (Appendix Figure F.1.1, Appendix Tables F.1.1 and F.1.2). The mean TOC content of sediments from HAC-U has been similar to reference in each year except 2018 and 2020, when TOC content of HAC-U sediments was significantly lower than reference (Appendix Table F.1.2). The observed variability in both TOC and total nitrogen among years is likely primarily associated with differences in sediment texture. For instance, the significantly lower TOC content of HAC-U

Table 6.1: Summary of Sediment Quality Results for Upper Hazeltine Creek (HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 2014 to 2022

Notes: "-" = no data, ***Bold/ Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (< 5th percentile value for pH). Pre-breach values that were reported as < the laboratory reporting limit were not used for screening.

[a] British Columbia Working Sediment Guidelines (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b).

[b] For calculation of pre-breach 95th percentile values see Appendix Table D.2.2, for calculation of reference 95th percentile values see Appendix Table D.2.3. The 5th percentile is reported for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

sediments observed in 2018 and 2020, compared to reference, was associated with the highest sand content of these sediments (excluding 2014; mean = 32.0 to 38.5% sand; Table 6.1; Appendix Table F.1.2). As indicated above, the observed variability in sediment texture is likely associated with the variable availability of similarly fine sediments among years in these erosional habitats; variability which may stabilize as sediment accumulation continues to occur in this remediated system.

Mean concentrations of 14 out of 34 elements in the HAC-U sediment (<63 µm fraction) collected in 2022 exceeded both pre-breach[61] and reference upper 95th percentile values. Among these elements, copper and selenium were the only Analytes of Interest with mean sediment concentrations that also exceeded WSQG in 2022 (Figure 6.1, Table 6.1; Appendix Table D.2.7). Specifically, the mean copper concentration of HAC-U sediments in 2022 exceeded the upper WSQG by 2.0 times (Table 6.1; Appendix Table D.2.7). Mean copper concentrations in reference (EDC-U) sediments were naturally elevated above the lower WSQG in previous years (2018, 2019, 2021; Table 6.1; Appendix Table D.2.3), demonstrating that copper is naturally elevated in stream habitats in the vicinity of the Mount Polley Mine. The mean selenium concentration in HAC-U sediments in 2022 exceeded the lower WSQG by 2.0 times (Figure 6.1, Table 6.1; Appendix Table D.2.7). Although the mean selenium concentration in HAC-U sediments previously exceeded the reference 95th percentile and the lower WSQG (in 2019 and 2021), 2022 represented the first year that the mean concentration also exceeded the pre-breach 95th percentile value (for HAC-U; Table 6.1; Appendix Figure F.1.1, Appendix Table D.2.7).

Mean copper concentrations in HAC-U sediments have been significantly higher than reference sediments from 2018 to 2022, and mean selenium concentrations have been significantly higher than reference sediments from 2019 to 2022 (Figure 6.1; Appendix Table F.1.2). The mean copper and selenium concentrations in HAC-U sediments were significantly higher in 2022 than previously observed (2018 to 2021), relative to reference (Figure 6.1; Appendix Table F.1.1). However, this change for both analytes was driven by a decrease in copper and selenium concentrations at the reference area (EDC-U), which were significantly lower in 2022 compared to all prior years except 2020 (which was similar to 2022; Appendix Table F.1.2). Evaluation of temporal changes within HAC-U only (i.e., not relative to reference) indicated that copper

[61] TOC and metal concentrations reported for pre-breach sediments were based predominantly on bulk sediment, but were reported for the <63 µm fraction of sediments collected post-breach. This difference in the fraction of sediment evaluated (i.e., bulk sediments for pre-breach and <63 µm fraction for post-breach) should be considered when making comparisons of TOC and metals concentrations between the two time periods. Formal statistical temporal comparisons were conducted using data from between 2018 to 2022 which reported TOC and metal concentrations in the <63 µm fraction of sediments (see Sections 4.1.2 and 4.1.3.2).

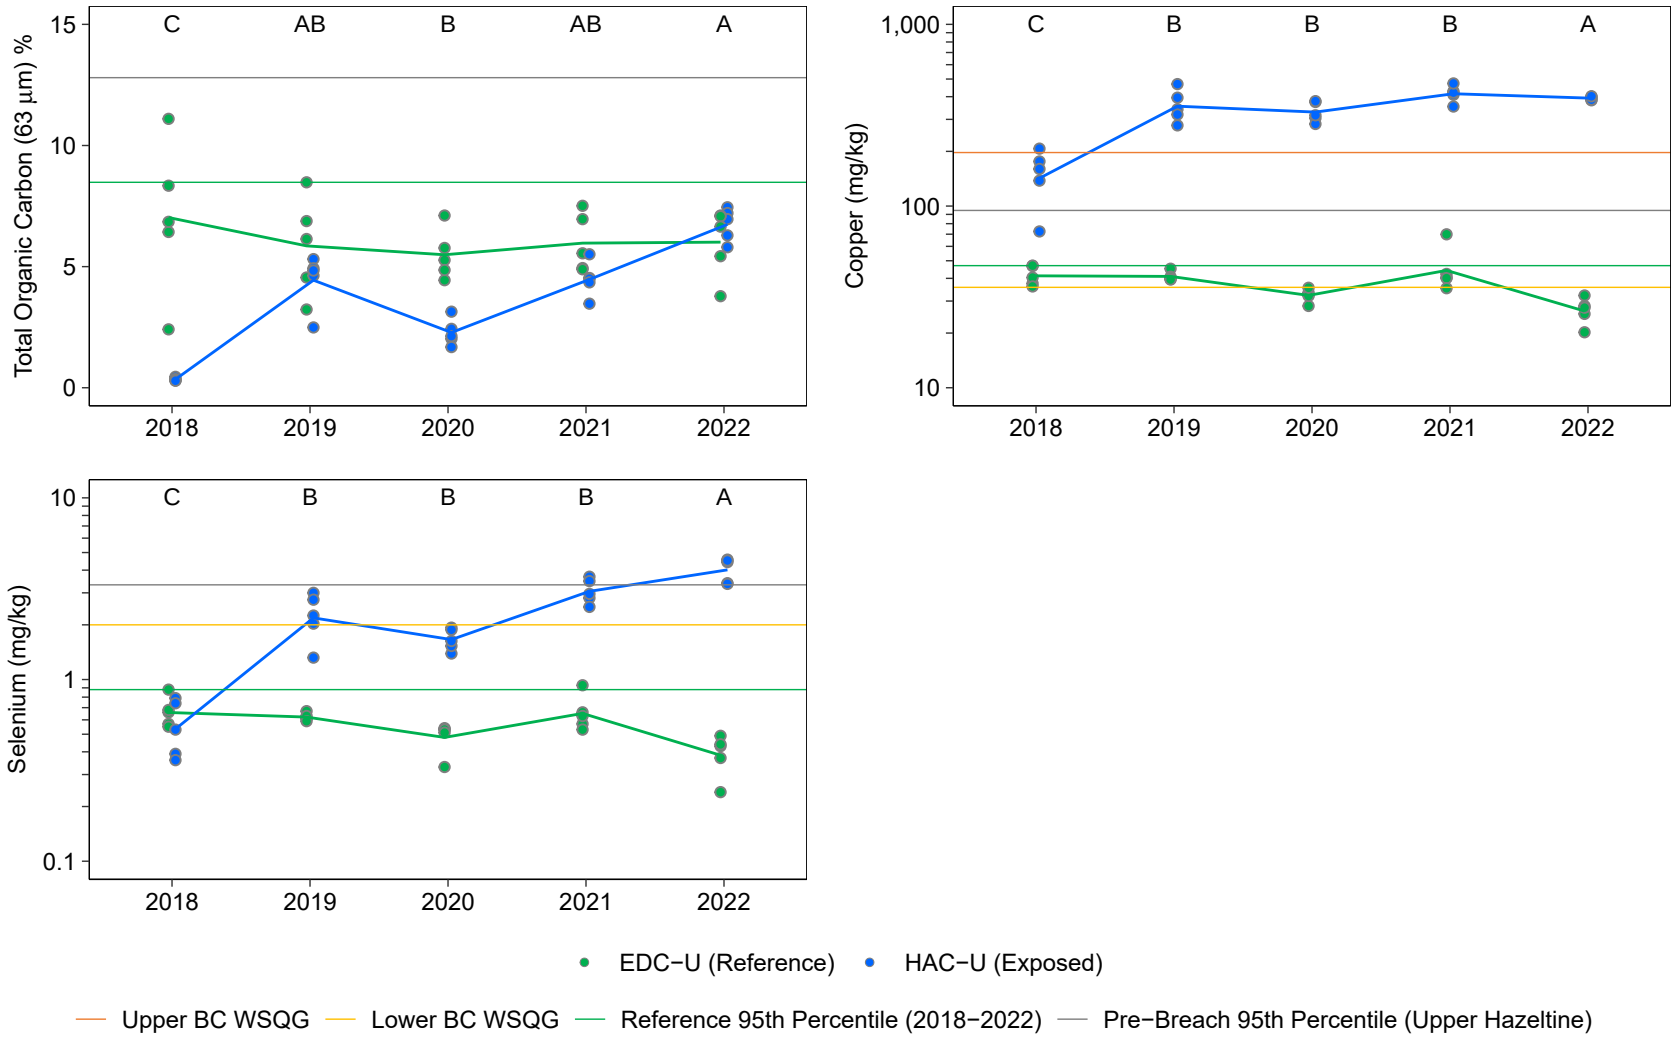

Figure 6.1: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for Upper Hazeltine Creek (HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 2018 to 2022

Notes: Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least −squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have differences in concentrations (Exposed − Reference) that do not differ significantly (p−value < 0.05) among years.

concentrations in HAC-U sediments have been temporally stable since 2019 (Appendix Table F.1.2). Selenium concentrations evaluated within HAC-U sediments only (not relative to reference) were similar in 2022 and 2021 and significantly higher in 2022 than the preceding years (2018 to 2020), with the greatest differences occurring relative to 2020 and 2018 (Appendix Table F.1.2). The significantly higher selenium concentrations in HAC-U sediments observed in 2022 (compared to 2018 and 2020) coincided with significantly lower TOC content of sediments in those years (2018 and 2020) compared to 2022 (Appendix Table F.1.2) and higher sand content (mean = 38.5 and 32.0% in 2018 and 2020, respectively; mean = 12.7% in 2022; Table 6.1). This suggests that the increase in selenium concentrations at HAC-U in 2022 was associated with temporal changes in the physical characteristics (i.e., TOC and sand content) that are driven by the necessity for opportunistic sampling due to limited availability of fine sediments in some monitoring years.

Copper and selenium concentrations in Hazeltine Creek sediment have demonstrated significant positive correlations with TOC, sulphur, and total nitrogen (Appendix Figure F.1.3; Appendix Table F.1.5). These relationships further support the observation that the slight (but not significant) changes in copper concentrations and the significant increase in selenium concentrations over time in upper Hazeltine Creek sediments are associated with temporal variability in the physical and chemical characteristics of the sampled sediment (i.e., significantly higher TOC content in 2022 compared to 2018 and 2020; Appendix Table F.1.2).

6.1.1.2 Lower Hazeltine Creek

Sediments collected from lower Hazeltine Creek (HAC-D) in 2022 were composed primarily of silt and sand particles (mean = 48.6% and 42.4%, respectively). Sediments from HAC-D in 2022 were higher in silt and lower in sand content than the reference sediments from EDC-D, which were composed predominantly of sand and silt (mean = 58.3% and 34.2%, respectively; Table 6.2; Appendix Tables D.2.8 and D.2.9). The particle size of sediments collected at HAC-D has shown some temporal variability, with sediments collected in 2022 having similar silt content to those from 2019 and 2021, but higher than in 2018 and 2020 (Table 6.2). The presence of fine sediment in the erosional areas has been limited in some years and was therefore sampled opportunistically (as described in Section 4.1.1; Minnow 2019a, 2020, 2021a, 2022a). As such, some of the variability in particle size is likely related to the ability to locate similarly fine sediment among areas and years. The TOC and total nitrogen content of HAC-D sediments in 2022 (mean = 1.68% and 0.152%, respectively) were the highest observed since 2018 (following initial remediation), though they remained lower than values observed at the reference area (EDC-D) in 2022 (mean = 3.63% and 0.170%, respectively; Table 6.2; Appendix

Table 6.2: Summary of Sediment Quality Results for Lower Hazeltine Creek (HAC-D; Exposed) and Lower Edney Creek (EDC-D; Reference), 2014 to 2022

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: "-" = no data, ***Bold/ Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (< 5th percentile value for pH). Pre-breach values that were reported as < the laboratory reporting limit were not used for screening.

[a] British Columbia Working Sediment Guidelines (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b).

[b] For calculation of pre-breach 95th percentile values see Appendix Table D.2.4, for calculation of reference 95th percentile values see Appendix Table D.2.5. The 5th percentile is reported for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Value is > Lower BC Working Sediment Quality Guideline.

Value is > Upper BC Working Sediment Quality Guideline.

Notes: "-" = no data, ***Bold/ Italics*** - Exposed value is > both reference and pre-breach 95th percentile values; reference value is > reference 95th percentile value (< 5th percentile value for pH). Pre-breach values that were reported as < the laboratory reporting limit were not used for screening.

[a] British Columbia Working Sediment Guidelines (BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b).

[b] For calculation of pre-breach 95th percentile values see Appendix Table D.2.4, for calculation of reference 95th percentile values see Appendix Table D.2.5. The 5th percentile is reported for pH.

[c] Total sulphur measured in bulk sediment, not the <63 µm fraction.

Tables D.2.8 and D.2.9). Sediments from HAC-D had significantly lower TOC content than reference sediments from 2018 to 2022 and TOC content was also temporally stable over this period, relative to reference (Figure 6.2; Appendix Tables F.1.3 and F.1.4).

The mean concentration of 16 out of 34 elements in the sediments (<63 µm fraction) collected in 2022 at HAC-D exceeded both pre-breach and reference upper 95th percentile values (Table 6.2). Among these elements, copper and iron were the only Analytes of Interest with mean sediment concentrations that also exceeded the WSQG in 2022 (Figure 6.2, Table 6.2; Appendix Table D.2.9). Specifically, the mean iron concentration of HAC-D sediments in 2022 exceeded the lower WSQG by 2.1 times, while the mean copper concentration exceeded the upper WSQG by 1.7 times (Table 6.2). However, mean sediment iron concentrations were naturally elevated above the lower WSQG in reference sediments (EDC-D) in each monitoring year (2018 to 2022; Figure 6.2, Table 6.2) indicating that iron is somewhat naturally elevated in stream habitats in the vicinity of the Mount Polley Mine.

Mean copper and iron concentrations in HAC-D sediments have been significantly higher than reference sediments from 2018 to 2022, except iron concentrations in 2019 that were similar to reference (Appendix Table F.1.4). The mean copper concentrations in HAC-D sediments in 2022 were similar to 2018 and 2021, but higher than 2019 and 2020, relative to reference (Figure 6.2; Appendix Table F.1.3). Mean iron concentrations in HAC-D sediments in 2022 were similar to the previous two years (2020 and 2021), higher than in 2019, and lower than in 2018, relative to reference (Figure 6.2; Appendix Table F.1.3). The similar (copper) or lower (iron) Analyte of Interest concentrations in HAC-D sediments in 2022 compared to 2018 indicates these analyte concentrations do not appear to be increasing over time, relative to reference (Figure 6.2).

Copper and iron concentrations in Hazeltine Creek sediment have demonstrated significant correlations with TOC, sulphur, and total nitrogen (Appendix Figure F.1.3, Appendix Table F.1.5). For copper, these relationships were positive and for iron these relationships were negative. These relationships suggest that the changes in copper and iron concentrations over time in lower Hazeltine Creek sediments are associated with temporal variability in the physical and chemical characteristics of the sampled sediment (Appendix Figure F.1.3, Appendix Table F.1.5).

6.1.2 Periphyton Community and Productivity

Periphyton community and productivity monitoring in 2022 was completed in remediated (exposed) areas of upper Hazeltine Creek (HAC-R1, HAC-U) with upper Edney Creek (EDC-U) serving as reference (Figure 4.2, Table 4.2). Post-breach periphyton productivity (chlorophyll-a) results from upper Hazeltine Creek were compared to those collected during baseline (1995, 1996) and pre-breach (2011; Table 4.2). Periphyton productivity monitoring

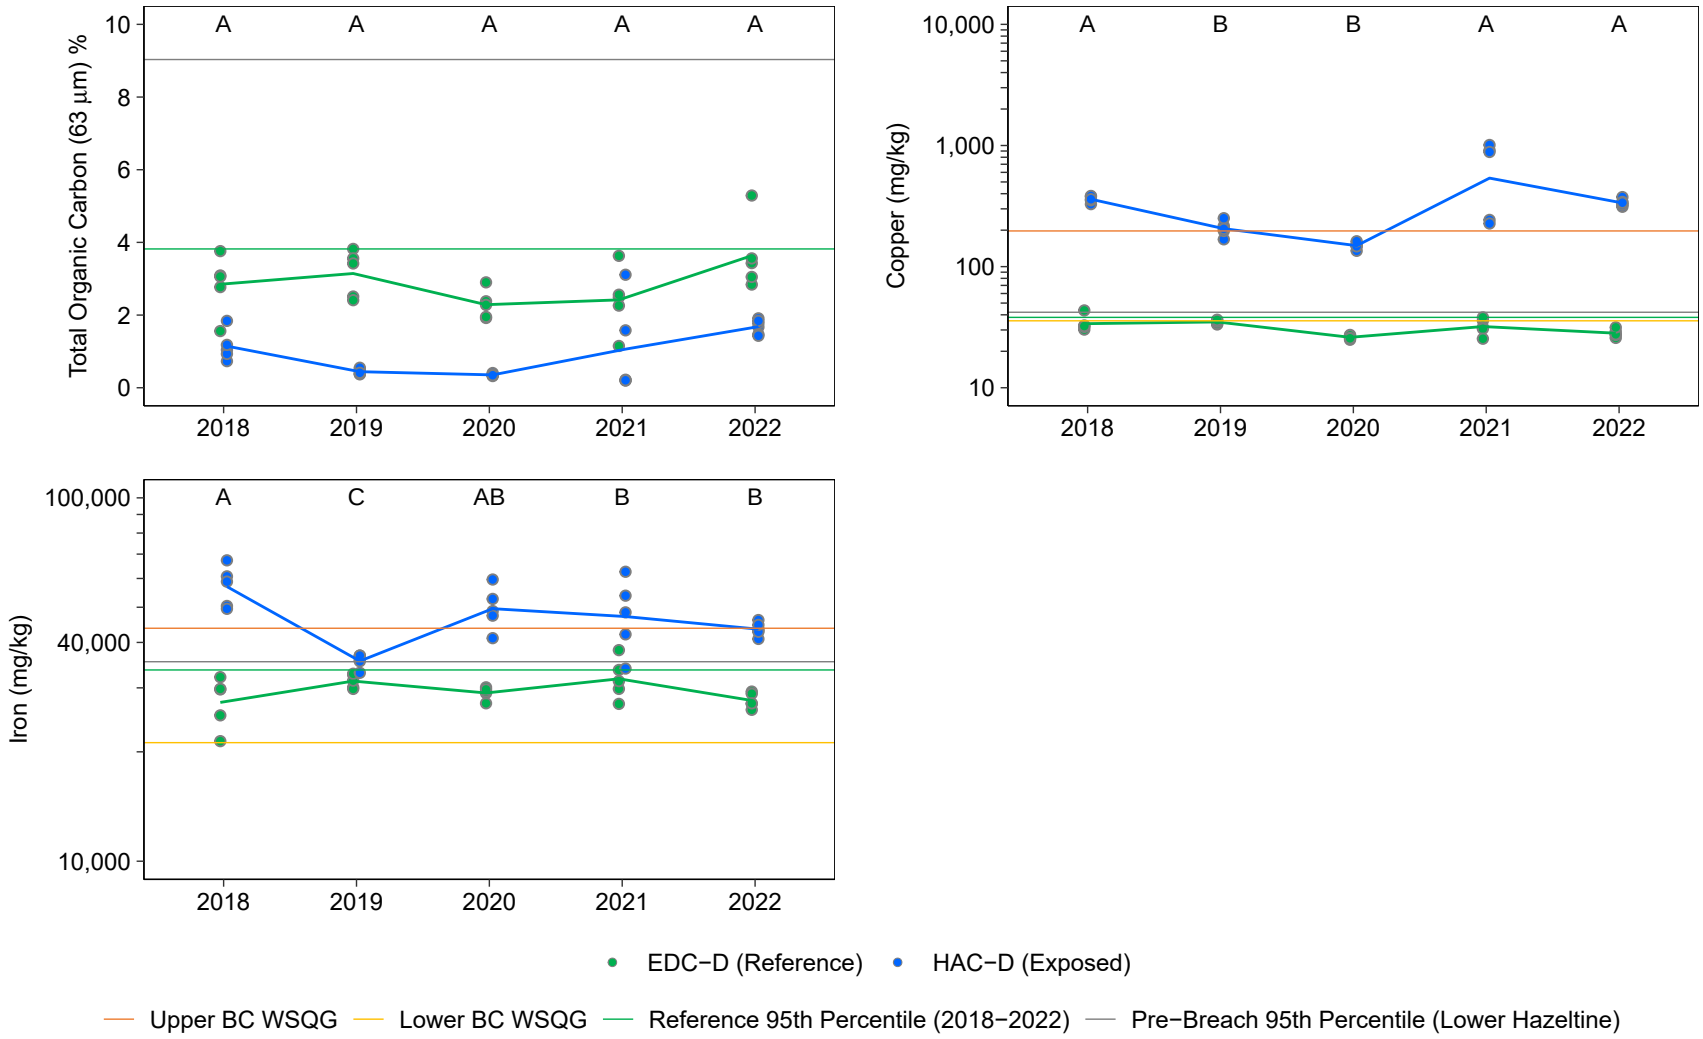

Figure 6.2: Sediment Analyte of Interest Concentrations (<63 µm Fraction) for Lower Hazeltine Creek (HAC-D; Exposed) and Lower Edney Creek (EDC-D; Reference), 2018 to 2022

Notes: Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Individual samples are plotted and lines join the least −squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have differences in concentrations (Exposed − Reference) that do not differ significantly (p−value < 0.05) among years.

(excluding community monitoring) was also completed in upper Hazeltine Creek (HAC-R3) with an area of Frypan Creek (FPC-R3) serving as reference (Figures 4.2 and 4.3, Table 4.2). Periphyton productivity monitoring at HAC-R3 and FPC-R3 was completed for the purpose of assessing fish habitat and data from this monitoring in 2022 were tabulated in the current report to meet CEMP requirements but were interpreted in a separate report (Minnow 2023). A review of the 2022 periphyton productivity and community data (Appendix B) indicated that the data met the established DQOs. Specifically, the community data were characterized by high subsampling agreement and data precision and accuracy checks, and the productivity data were characterized by appropriate LRLs, and negligible analyte concentrations in MB samples (Appendix B). Overall, the 2022 periphyton community and productivity data can be used with a high level of confidence in the derivation of conclusions. A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

6.1.2.1 Area Characteristics

During sampling in upper Hazeltine Creek and upper Edney Creek (i.e., reference), careful attention was paid to matching sampling habitats both year-to-year, and between the paired exposed and reference sampling areas. However, matching habitats characteristics of sampling areas was difficult in 2022 and in prior years (2018 to 2021; Minnow 2019a, 2020a, 2021a, 2022a) due a combination of factors. In 2022, matching habitat variables in upper Hazeltine Creek to those in upper Edney Creek was challenging due to supplemental pumping of water from Polley Lake to Hazeltine Creek that increased water depth and velocity in Hazeltine Creek (see Section 4.2.1 for details). This was consistent with challenges encountered in previous monitoring years due to the supplemental pumping (2018 to 2021) which were exacerbated in some years by extreme climate events in the area (i.e., drought conditions in summer 2021; Minnow 2022a). As such, the variability in water depth and velocity among years and between the exposed and reference areas were considered when interpreting temporal changes, and these physical habitat variables are summarized below.

Examination of the physical habitat characteristics of the upper Hazeltine Creek areas (HAC-R1 and HAC-U) indicated that mean water depth and velocity was similar between the two exposed areas within a year (controllable by sample station selection) but was variable among years (Table 6.3). Water depth and velocity differed between the upper Hazeltine Creek areas and reference area in most years (Table 6.3). In 2022, mean water depth at HAC-R1 and HAC-U was approximately three times greater than the mean water depth measured at EDC-U, and mean water velocity at HAC-U was approximately two times greater than the mean water velocity measured at EDC-U and HAC-R1 (Table 6.3; Appendix Table A.2.3). Substrate size,

[a] The displayed median substrate size represents the median (50 th percentile) of 100 pebble measures recorded for each sampling area. See Appendix Table A.2.5 for pebble count data.

[b] Canopy cover includes dense and partially open cover.

[c] Water quality results are from a single grab water sample collected within a week of biological sampling at a given area. The date of sample collection is shown.

[d] Seasonal range indicates the range of water quality parameters reported from routine water quality sampling. This included data from approximately 3 months preceding/concurrent with periphyton sampling (2018 to 2022: late April to late July [n = 4 for HAC-U from 2018 to 2020, n = 11 for HAC-R1 in 2018, n=4 for HAC-R1 in 2019 and 2020]; 2021 and 2022: late April to early August [n = 4 for HAC-R1 and HAC-U]). Routine water quality data from station HAC-13 was used for HAC-R1, and data from station HAC-05a was used for HAC-U (see Figure 4.2). Water quality is not monitored routinely near EDC-U or HAC-R3. See Appendix Tables D.1.3 and D.1.4 for 2022 results, and Minnow (2019a, 2020a, 2021a, 2022a) for 2018, 2019, 2020, and 2021 results, respectively.

which is controlled for during sampling, was similar between areas and among years (Table 6.3; Appendix Table A.2.5).

Remediation work following the breach was completed at HAC-R1 and HAC-U in 2016 and 2017, respectively (Table 4.2; see Section 4.2), and the regeneration of riparian vegetation at these remediated areas is a long-term process. Although the riparian vegetation in these upper Hazeltine Creek areas has shown substantial growth since the completion of remediation works, canopy cover over the creek channel remained absent in 2022, which was consistent with all previous sampling years (2018 to 2021; Table 6.3). Canopy coverage in 2022 remained a key difference between the remediated areas of Hazeltine Creek and the Edney Creek reference area (0% canopy coverage at HAC-R1 and HAC-U versus 80% canopy coverage at EDC-U; Table 6.3; Appendix A.2.2).

6.1.2.2 Community

In 2022, the periphyton community at HAC-R1 was similar to the reference area (EDC-U) in terms of mean density, total taxon richness, and Simpson's Evenness and Diversity. The periphyton community at HAC-U in 2022 had lower mean density and higher total richness at HAC-U compared to reference, and Simpson's Evenness and Diversity that were similar to reference (Figure 6.3, Table 6.4). Diatom richness at both HAC-R1 and HAC-U in 2022 was significantly higher than reference (Figure 6.3, Table 6.4).

The periphyton communities of the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) in 2022 were similar to each other in terms of all primary metrics (density, total taxon richness, Simpson's Evenness and Diversity, and Diatom richness; Table 6.4). Temporally, the periphyton communities of HAC-R1 and HAC-U have also been consistently similar to each other from 2018 to 2022 in terms of the primary metrics, with a few exceptions. These exceptions included significantly higher density in 2019, lower total richness in 2018, and higher Simpson's Evenness and Diversity in 2021 at HAC-U compared to HAC-R1 (Figure 6.3; Table 6.4). The similarity in periphyton communities at the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) in 2022, and for most metrics in prior years, indicates that recovery of the periphyton community in these two areas has been similar.

Mean periphyton densities at the upper Hazeltine Creek areas (HAC-R1 and HAC-U) have been similar to the reference area (EDC-U) from 2018 to 2022, except in 2022 when density at HAC-U was significantly lower than reference (Figure 6.3, Table 6.4; Appendix Tables D.3.1 and D.3.2). The lower mean periphyton density at HAC-U than reference in 2022 was due to a significant temporal increase in periphyton density at the reference area (significantly higher in 2022 than in 2019 to 2021), rather than a decrease in density at HAC-U (Figure 6.3, Table 6.4). Periphyton densities at HAC-U have remained temporally stable from 2018 to 2022 (Figure 6.3,

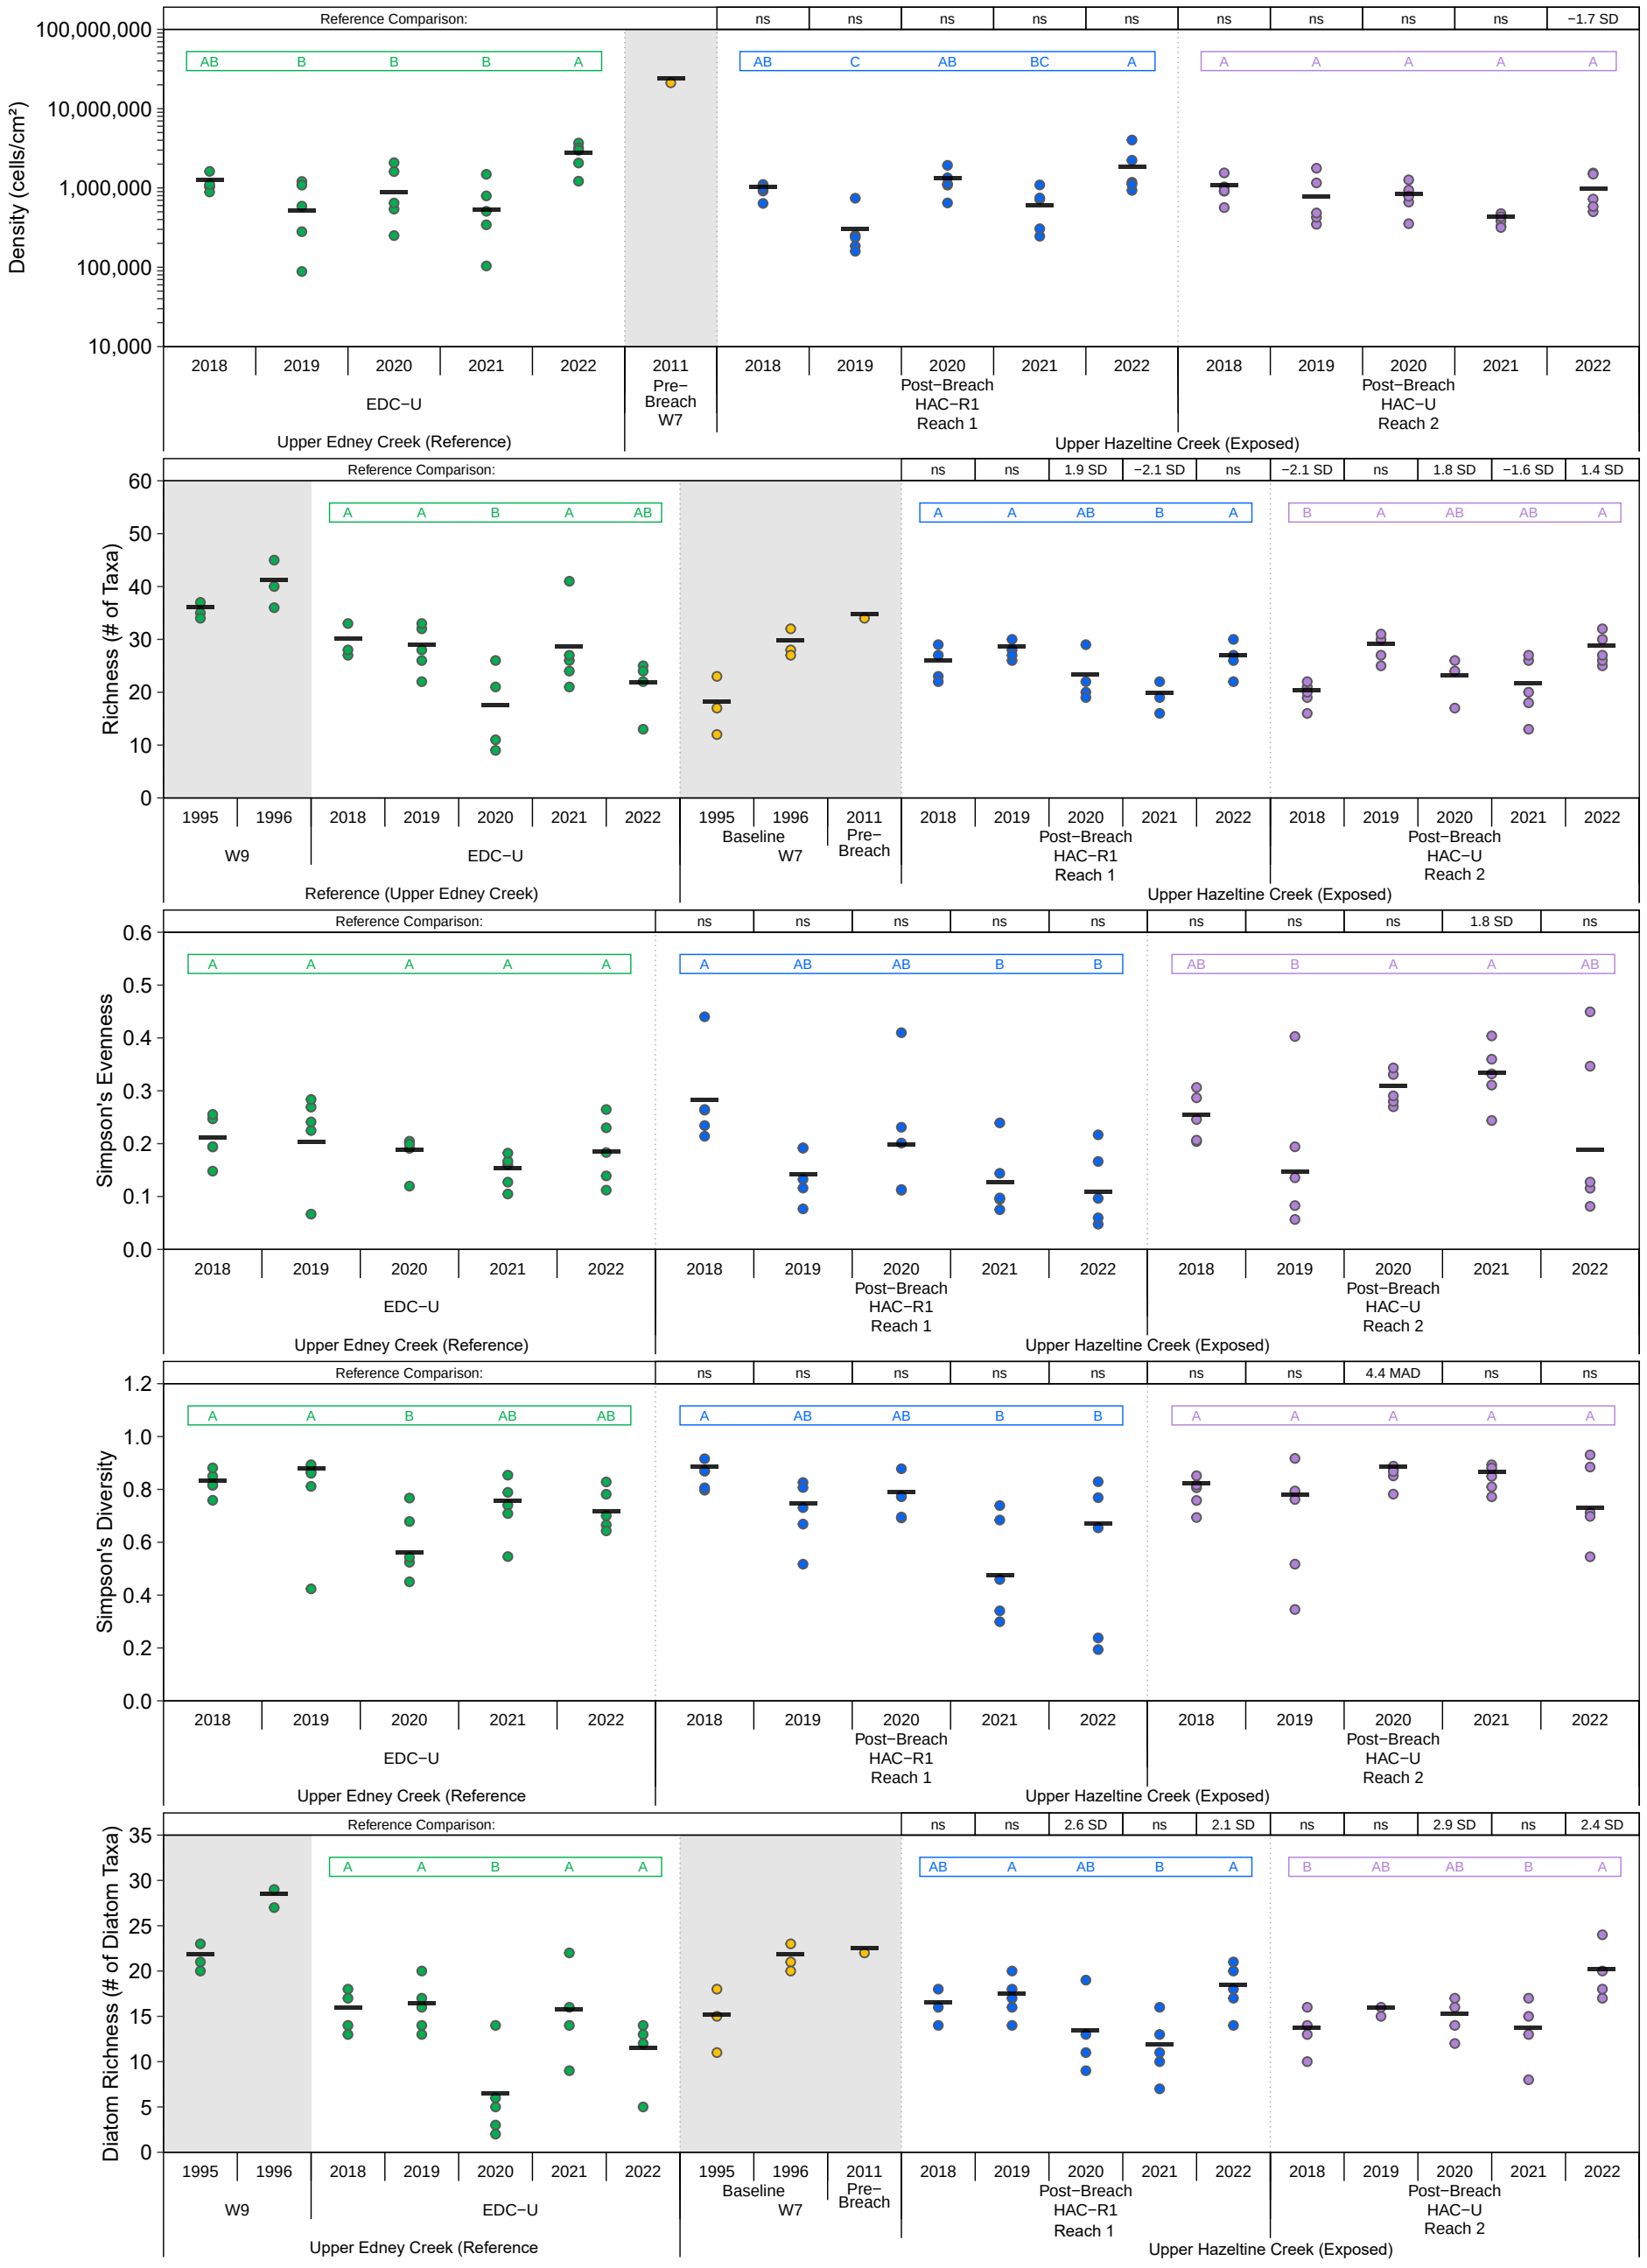

Figure 6.3: Periphyton Community Endpoints for Upper Hazeltine Creek (HAC−R1, HAC−U; Exposed) and Upper Edney Creek (EDC−U; Reference), 1995 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0. Grey shading indicates semi− quantitative data that were not included in statistical comparisons but are shown for visual comparison only.

Table 6.4: Results of Statistical Comparisons of Periphyton Community Endpoints for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 2018 to 2022

Table 6.4). Temporal changes in periphyton density at HAC-R1 from 2018 to 2022 were similar to those observed at the reference area, resulting in consistently similar densities at HAC-R1 and the reference area over this period (Figure 6.3, Table 6.4). The similarity in the temporal changes at HAC-R1 relative to the reference area indicates that the changes were likely related to natural variability in physical and chemical factors (e.g., light exposure, water temperature, nutrient availability).

Temporal comparisons of total taxon richness from 2018 to 2022 demonstrated variability at HAC-R1 and HAC-U when compared to the reference area. Total richness at both exposed areas was similar to or higher than reference in most years, except at HAC-U in 2018 and at both areas in 2021, when total richness was significantly lower than reference (Figure 6.3, Table 6.4). Despite this variability relative to reference, total richness within each of the exposed areas has been largely temporally stable, with total richness in 2022 similar to or higher than in prior years (2018 to 2021; Figure 6.3, Table 6.4; Appendix Tables D.3.1 and D.3.2). Total taxon richness of the periphyton community is generally used as a relative measure for assessment of stream health in that differences in number of taxa are interpreted as improvement (increasing taxon richness) or degradation (decreasing taxon richness; Amblard 1990). Despite the temporal variability in total richness at the exposed areas relative to reference, the similar (at HAC-R1) or significantly higher (at HAC-U) mean total richness in 2022, relative to reference, is a positive indicator of good periphyton community health in upper Hazeltine Creek. Similar to total taxon richness, Diatom taxon richness is used as a metric for determining relative stream health (Barbour et al. 1999). Diatom richness at both exposed areas (HAC-R1 and HAC-U) has been similar to or significantly higher than reference (EDC-U) from 2018 to 2022 (Figure 6.3, Table 6.4; Appendix Tables D.3.1 and D.3.2). This is a further positive indicator of good periphyton community health in the areas of upper Hazeltine Creek.

Temporal comparisons indicated that Simpson's Evenness and Diversity at the exposed areas were not significantly different from the reference area from 2018 to 2022 except for higher Simpson's Evenness (2021) and Diversity (2020), which were significantly higher at HAC-U (Figure 6.3, Table 6.4). There have been no significant differences in Simpson's Evenness or Diversity among monitoring years (2018 to 2022) at HAC-U indicating temporal stability within this area. In the past two years (2021 and 2022) at HAC-R1, Simpson's Evenness and Diversity were significantly lower compared to 2018 (Figure 6.3, Table 6.4), but did not differ relative to reference over time. The consistent similarity between both exposed (HAC-R1 and HAC-U) and reference (EDC-U) areas further indicates good periphyton community health within upper Hazeltine Creek.

In 2022, periphyton communities of upper Hazeltine Creek and the reference area were dominated by Cyanobacteria (blue-green algae; Figure 6.4). The remainder of the periphyton community at HAC-R1 and HAC-U in 2022 was primarily composed of Diatoms, Phaeophytes, and Chlorophytes (Figure 6.4). The periphyton community at HAC-R1 in 2022 had relative densities (%) of most taxa that were similar relative to reference area, except for significantly higher relative densities of Phaeophytes (brown algae) that were absent from the reference area in 2022 (Appendix Figure F.2.1, Appendix Tables D.3.1, D.3.2, and F.2.1). The periphyton community at HAC-U in 2022 had significantly higher relative densities of Phaeophytes and Diatoms than the reference area, and significantly lower relative densities of Cyanobacteria. In addition, Rhodophytes (red algae) were not observed at either exposed area in 2022 despite being present at the reference area (EDC-U). The periphyton communities of HAC-R1 and HAC-U in 2022 were similar to each other in terms of the relative densities of the most dominant taxa except for a significantly higher mean relative density of Chlorophytes at HAC-U compared to HAC-R1 (Figure 6.4; Appendix Figure F.2.1, Appendix Table F.2.1). Evaluations of the dominant taxa in 2022 (i.e., Cyanobacteria, Diatoms, and Chlorophytes) based on density were largely similar to those based on relative densities, except that the density of Diatoms at HAC-U was not significantly different than the reference area (but relative density was significantly higher; Appendix Figures F.2.1, F.2.2, Appendix Table F.2.1).

Temporal evaluation of periphyton community composition has demonstrated relative densities of Diatoms and Chlorophytes at HAC-R1 and HAC-U that were similar to or significantly higher than reference from 2018 to 2022, except significantly lower relative densities of Chlorophytes at HAC-R1 in 2021 compared to reference. In contrast, the relative densities of Cyanobacteria at HAC-R1 and HAC-U from 2018 to 2022 were similar to or lower than reference (Appendix Figure F.2.1, Appendix Table F.2.1). The significantly lower relative densities of Cyanobacteria, and higher relative densities of Diatoms at HAC-R1 and HAC-U, relative to reference, are indicative of healthy periphyton communities (Pandey et al. 2018; Xue et al. 2019). Within HAC-R1 and HAC-U, the relative densities of Cyanobacteria have been similar from 2019 to 2022, as have the relative densities of Diatoms at HAC-U. The relative densities of Diatoms and Chlorophytes at HAC-R1 in 2022 were similar to both 2019 and 2020, while relative densities of Chlorophytes at HAC-U in 2022 were similar to all prior years (2018 to 2021; Appendix Figure F.2.1, Appendix Table F.2.1). The relative densities of less prevalent taxa have been similar to reference since 2018 for Chrysophytes and Dinoflagellates, while the relative densities of Phaeophytes were consistently higher than reference (due to a near absence at the reference area in all years). Rhodophytes were consistently absent from the upper Hazeltine Creek areas but present at the reference area (Appendix Figure F.2.1, Appendix Tables D.3.1, D.3.2

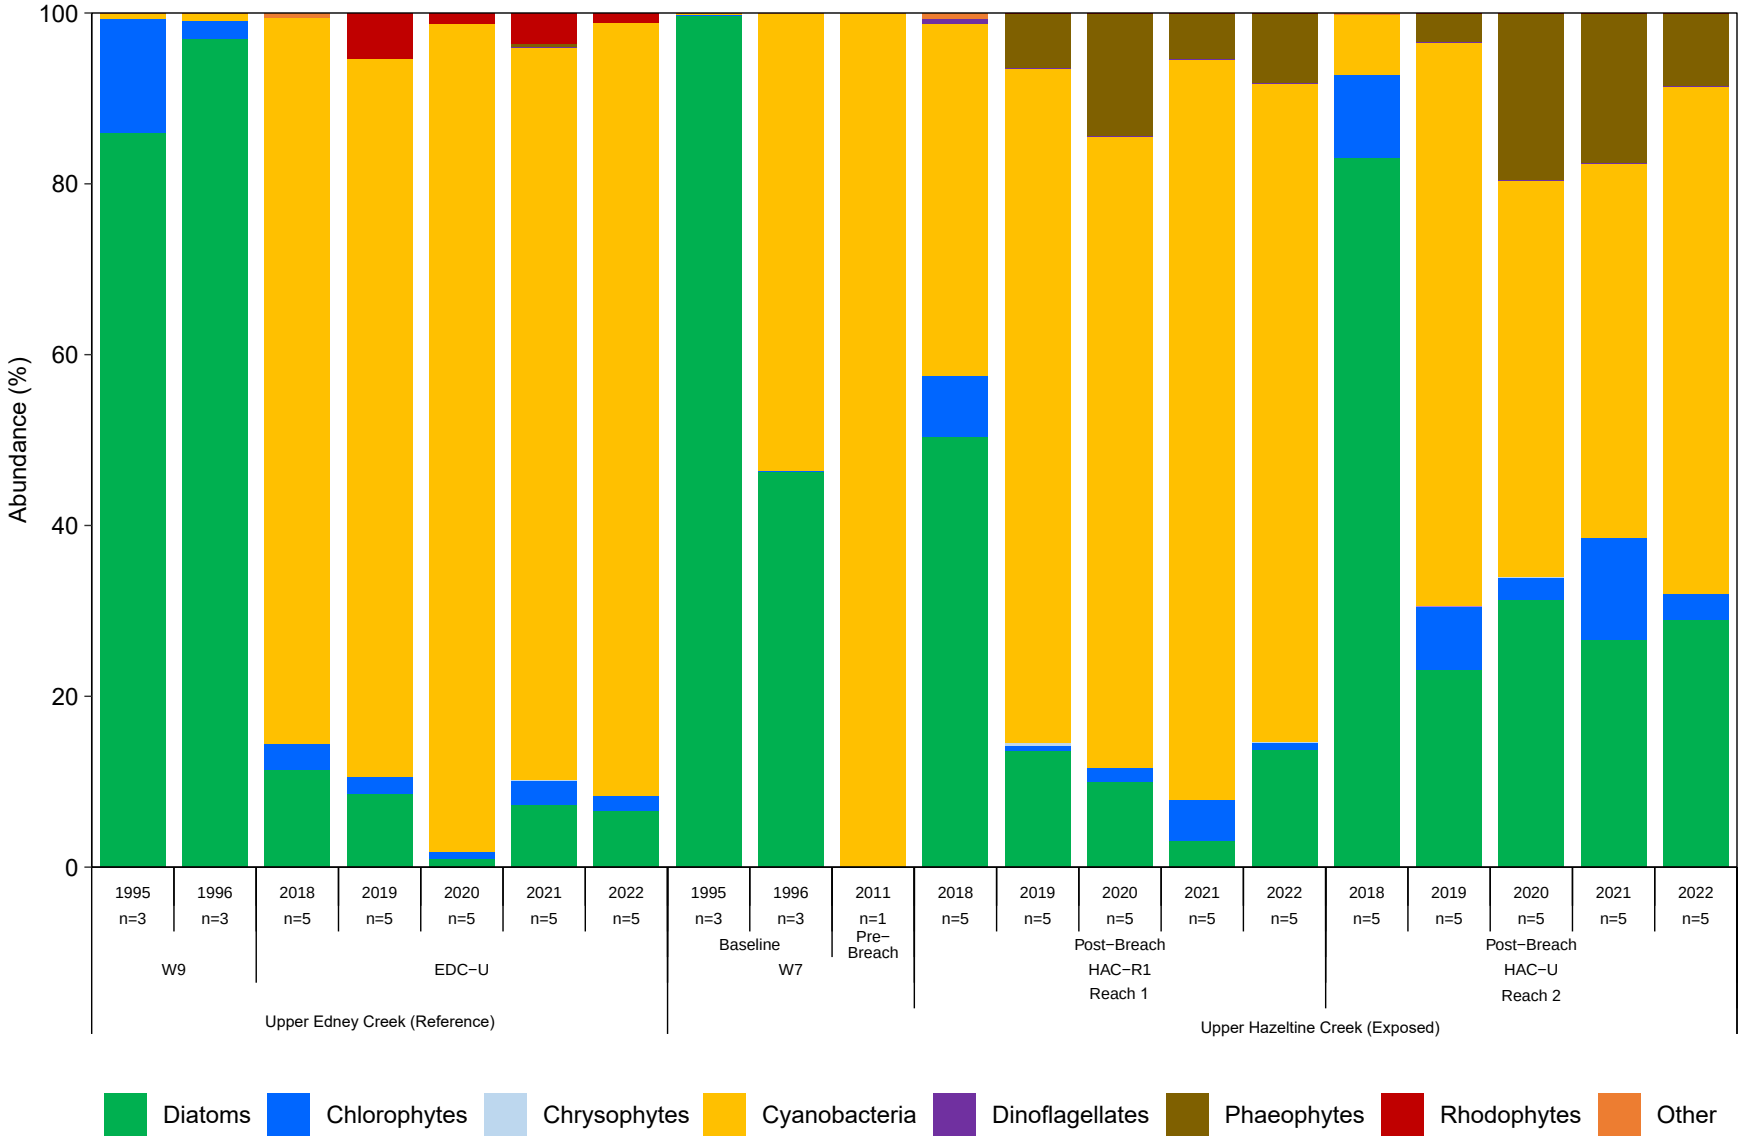

Figure 6.4: Relative Mean Densities of Major Periphyton Community Taxonomic Groups for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 1995 to 2022

Notes: The sampling area W7 (2011) is the pre-breach equivalent of the post-breach sampling areas HAC-R1 and HAC-U (2018 to 2022). In 2018 and earlier, Chrysophytes, Phaeophytes, and Rhodophytes are grouped into the 'Other' category. Periphyton data were classified as "Other" taxa in laboratory results issued in 2018 but the taxonomic groups contained in this category were unknown (i.e., unknown taxonomic idenification of these organisms), but suspected to include Phaeophytes, Chrysophytes, and Rhodophytes. See Minnow 2019a for detailed laboratory results for 2018. Periphyton taxonomy results have not been reported in an "Other" category by the laboratory since 2018. See report Section 4.2.3.1 for details.

and F.2.1). The relative temporal stability of the dominant taxa within the exposed areas and/or relative to reference, and the similar or lower relative densities of Cyanobacteria and the similar or higher relative densities of Diatoms compared to reference are indicative of relatively stable periphyton communities at the upper Hazeltine Creek areas.

Overall, the periphyton community of upper Hazeltine Creek (HAC-R1 and HAC-U) in 2022 had total taxon richness and Simpson's Evenness and Diversity that were similar or higher than the reference area, and higher Diatom richness than reference. Periphyton density at HAC-R1 was similar to reference in 2022 and all prior years. At HAC-U, periphyton density in 2022 was lower than reference but has been temporally stable from 2018 to 2022 within HAC-U. The periphyton communities at the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) were similar in 2022 in terms of density, total richness, Simpson's Evenness and Diversity, and Diatom richness, indicating similar recovery of the periphyton community in these two areas. The community composition at HAC-R1 (as measured by relative densities of dominant taxa) was similar to the reference area in 2022 for most groups (except Phaeophytes [brown algae] that were absent from the reference area). At HAC-U, the community composition in 2022 differed from the reference area in terms of higher relative densities of Diatoms and Phaeophytes, and lower relative densities of Cyanobacteria than the reference area. The higher and lower proportions of Diatoms and Cyanobacteria, respectively, relative to reference, are indicative of healthy periphyton communities. The similarity (or exceedance) of the periphyton community metrics (density, total richness, Simpson's Evenness and Diversity, Diatom richness) in upper Hazeltine Creek compared to the reference area in most years and/or temporal stability of these metrics are indicative of relatively stable periphyton communities at the upper Hazeltine Creek areas. Combined with the relative temporal stability of the dominant taxa within the exposed areas and/or relative to reference, and the similarity in community endpoints between the two areas (HAC-R1 and HAC-U), these are indicative of the health and robustness of the periphyton community in both areas of upper Hazeltine Creek.

6.1.2.3 Productivity

Mean periphyton chlorophyll-a (mass per unit area; mg/m²) in upper Hazeltine Creek (HAC-R1 and HAC-U) in 2022 was below the BCWQG of 100 mg/m² (BCMOECCS 2021b) but means at both areas were above a threshold indicative of moderately enriched streams (21 mg/m²; Biggs 1996; Figure 6.5; Appendix Tables D.3.2 and D.3.3). Two of the replicate samples from HAC-R1 in 2022 had chlorophyll-a (mg/m²) that exceeded the BCWQG, but samples from this area in 2022 showed a high degree of variability (mean = 87.4 ± 37.1 mg/m²; Figure 6.5; Appendix Table D.3.2). Periphyton chlorophyll-a (mg/m²) in 2022 at HAC-U was similar to the reference area (EDC-U), while the mean at HAC-R1 was significantly higher

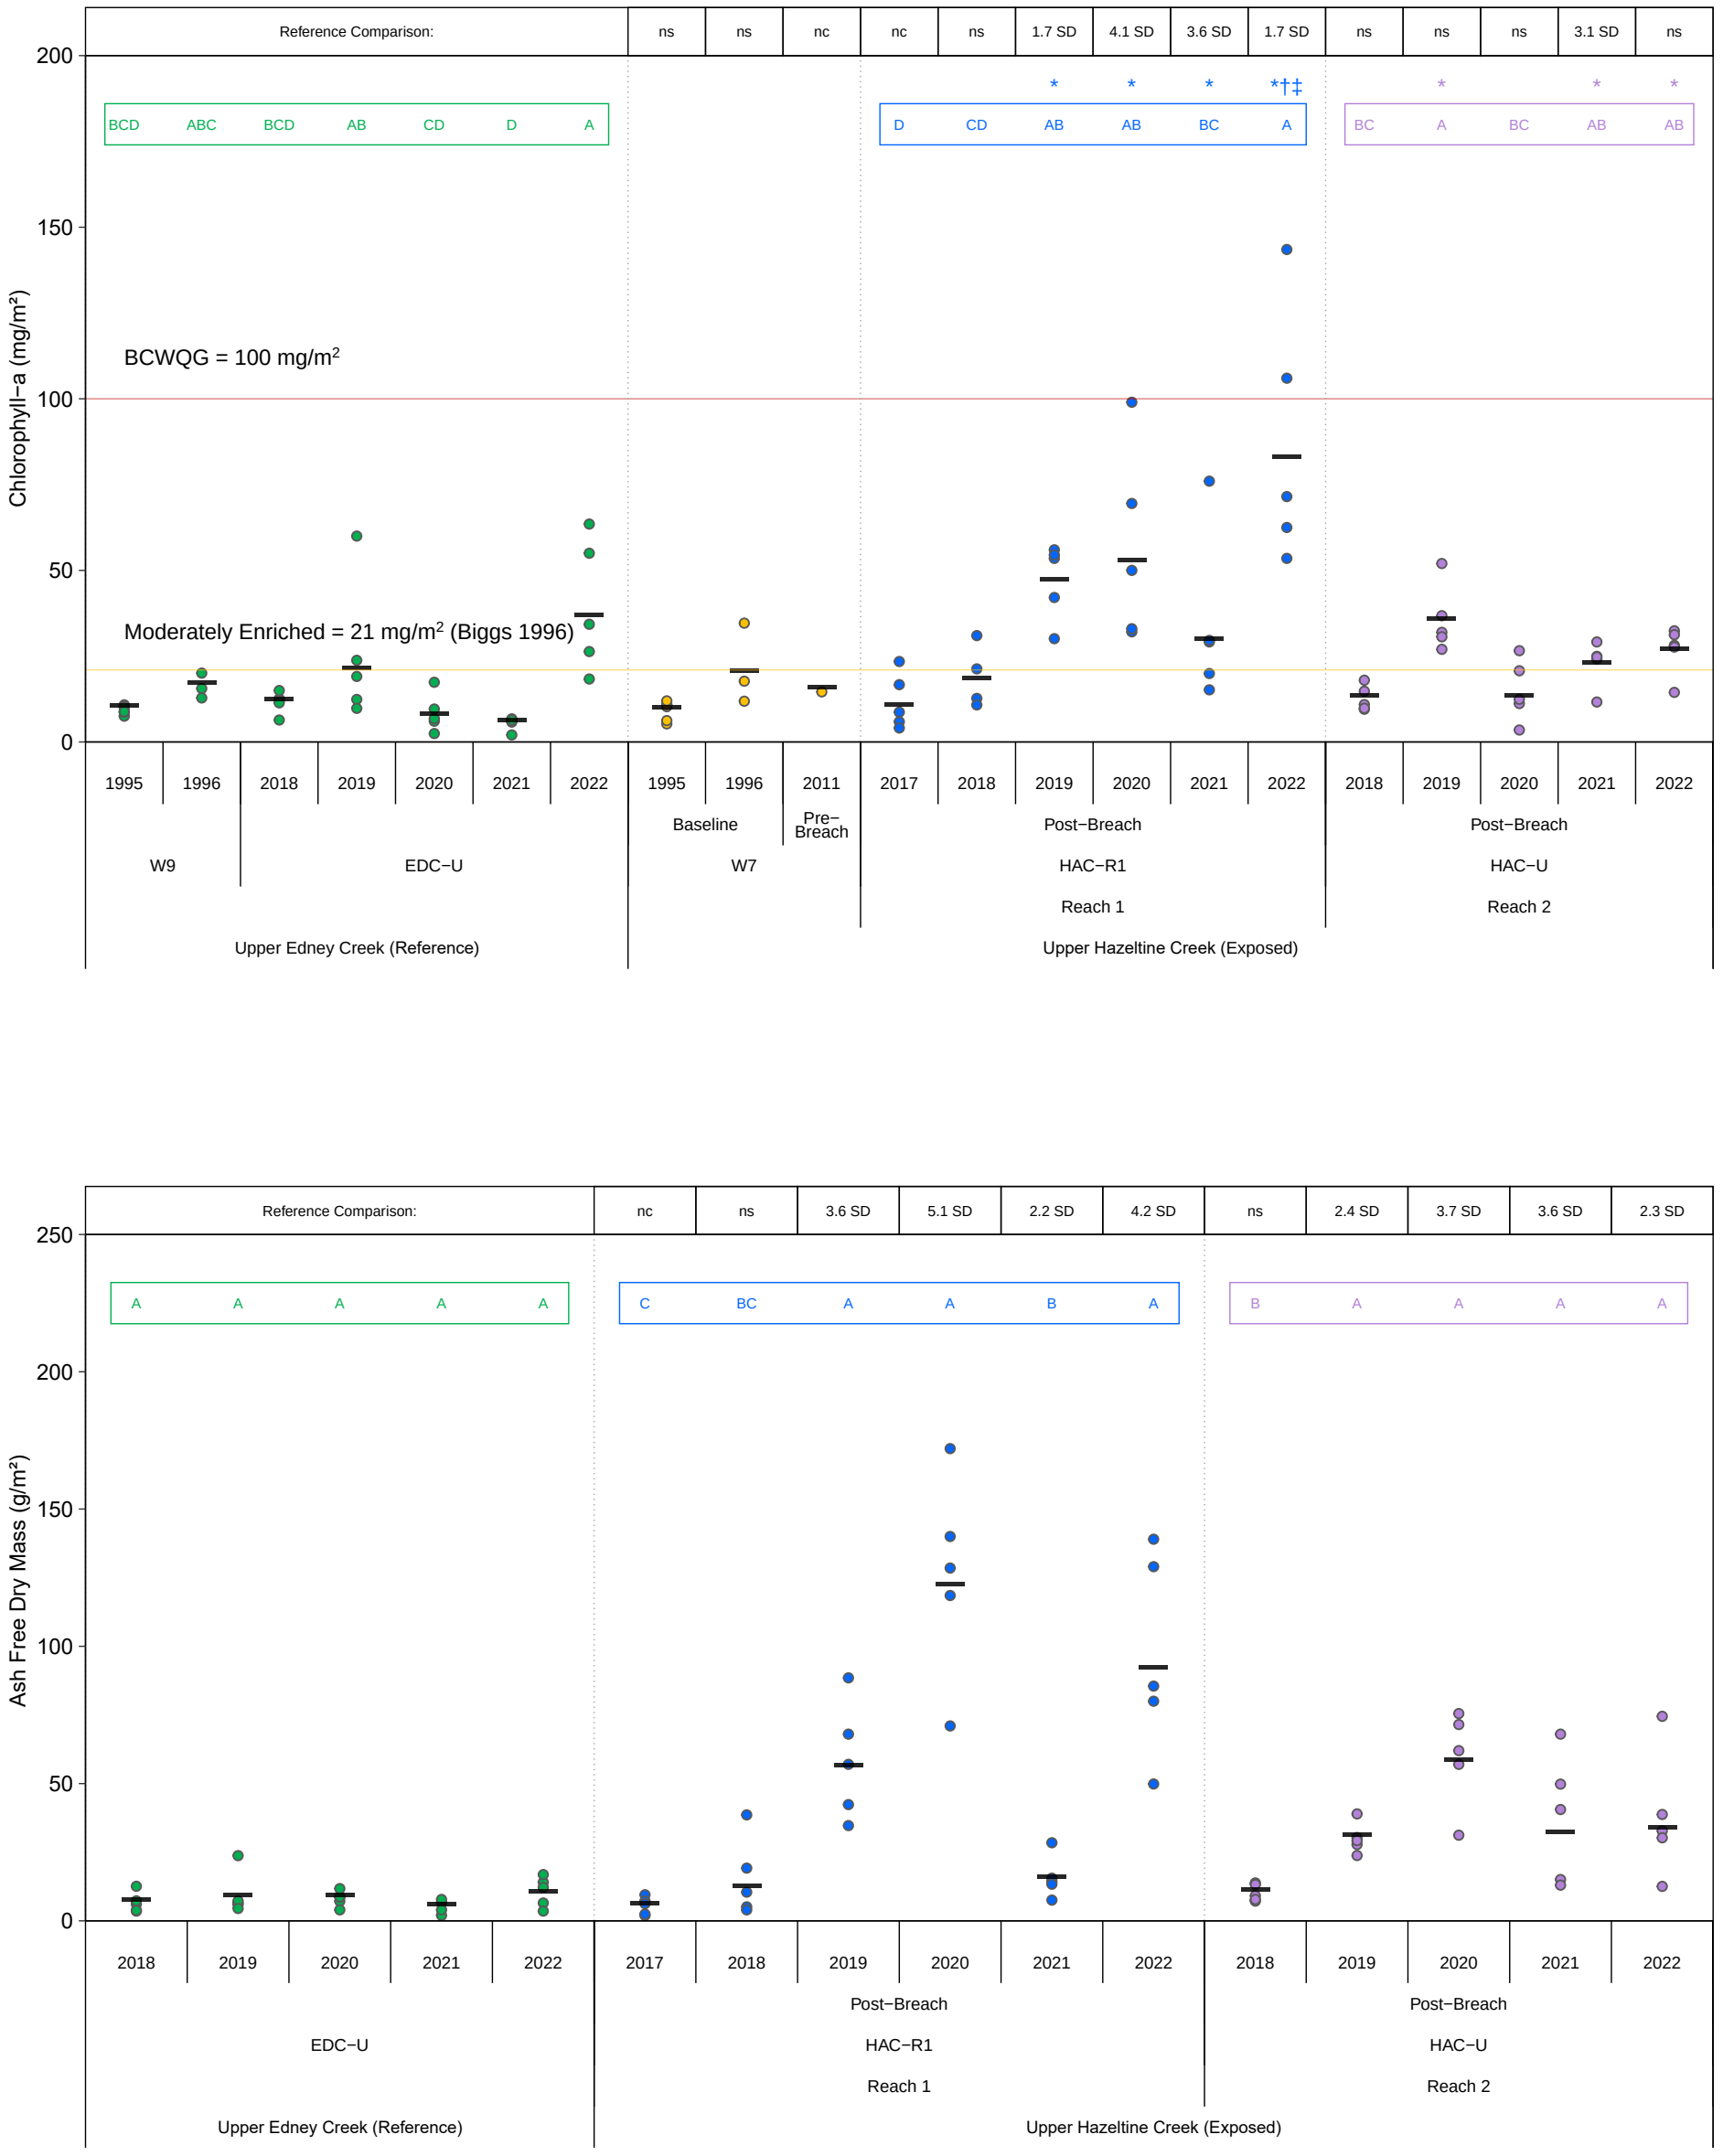

Figure 6.5: Periphyton Productivity Endpoints for Upper Hazeltine Creek (HAC−R1, HAC−U; Exposed) and Upper Edney Creek (EDC−U; Reference), 1995 to 2022

Notes: Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. For statistical contrasts of Chlorophyll−a data, the analyses compared post−breach (2017 to 2022) to baseline (1995 and 1996) to pre−breach conditions (2011) at W7. The sampling area W7 (2011) is the pre−breach equivalent of the post−breach sampling areas HAC−R1 and HAC−U (2017 to 2022). Significant differences between HAC−R1 or HAC−U post−breach (2017 to 2022) results compared to baseline (1995 and 1996) or pre−breach (2011) results for W7 are indicated as follows: an * indicates significant differences to W7 in 1995, a † indicates significant differences to W7 in 1996, and a ‡ indicates significant differences to W7 in 2011. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0.

than reference (Figure 6.5; Appendix Table F.2.2). The higher chlorophyll-a (mg/m²) at HAC-R1 in 2022 compared to reference (EDC-U) may be related, at least in part, to elevated water temperatures and increased exposure to sunlight from lack of canopy cover at the upper Hazeltine Creek areas (Table 6.3; Schnurr and Allen 2015).

From 2019 to 2022, chlorophyll-a (mg/m²) at HAC-R1 was significantly higher than reference. The magnitude of this difference was the same in 2019 and 2022 (1.7 SD) indicating that productivity at HAC-R1 has not increased progressively over time, relative to reference (Figure 6.5; Appendix Table F.2.2). Conversely, mean chlorophyll-a at HAC-U was similar to reference from 2018 to 2022, except for 2021, when chlorophyll-a was higher at HAC-U compared to reference (Figure 6.5; Appendix Table F.2.2). This was likely a result of chlorophyll-a (mg/m²) at the reference area in 2021 that was lower than other monitoring years (2019 and 2022; Figure 6.5; Appendix Tables D.3.2, D.3.3 and F.2.2). Except for 2021, chlorophyll-a in upper Hazeltine Creek generally followed similar temporal patterns as the reference area (EDC-U; Figure 6.5), suggesting that temporal changes may be related to natural variability in physical and chemical factors (e.g., temperature and nutrient availability). Chlorophyll-a (mg/m²) at HAC-U in 2022 was significantly higher than 1995 but similar to the 1996 baseline, pre-breach (2011), and prior post-breach years (2018 to 2021; Figure 6.5; Appendix Table F.2.2). Conversely, chlorophyll-a at HAC-R1 in 2022 was significantly higher than baseline (1995, 1996), pre-breach (2011), and most post-breach years (2017, 2018 and 2021; Appendix Table F.2.2). Chlorophyll-a at HAC-R1 was significantly higher than at HAC-U in 2020 and 2022 (Appendix Table F.2.2). *In situ* measures of dissolved oxygen recorded in upper Hazeltine Creek indicate that dissolved oxygen concentrations measured during periphyton sampling, and in the year preceding sampling, were consistently higher than the short-term BCWQG but occasionally lower than the long-term BCWQG by a maximum of 7% in August (Appendix Tables D.1.2 to D.1.4). These results indicate that dissolved oxygen concentrations largely remain above the long-term BCWQG despite increased periphyton growth in upper Hazeltine Creek.

Productivity measured as AFDM at HAC-R1 and HAC-U in 2022 was significantly higher than the reference area (EDC-U), which was consistent with the chlorophyll-a results for HAC-R1 but not the chlorophyll-a results for HAC-U in 2022 (Figure 6.5; Appendix Tables D.3.2, D.3.3 and F.2.2). Mean AFDM at HAC-R1 and HAC-U increased significantly between 2018 and 2019, and has remained stable since 2019, except at HAC-R1 in 2021 when drought conditions occurred in the area (Figure 6.5). Mean AFDM in upper Hazeltine Creek (HAC-R1 and HAC-U) has been significantly higher than reference (EDC-U) since 2019, suggesting recovery to stable periphyton biomass conditions. The significantly higher periphyton AFDM in areas of upper Hazeltine Creek compared to reference may be related, at least in part, to the elevated water temperature and increased exposure to sunlight from lack of canopy cover (Table 6.3; Schnurr and Allen 2015).

Like chlorophyll-a (mg/m²), AFDM at HAC-R1 was significantly higher than at HAC-U in 2020 and 2022 (Appendix Table F.2.2).

Overall, the chlorophyll-a and AFDM results indicated that productivity was significantly higher in upper Hazeltine Creek than in the reference area in 2022 but mean chlorophyll-a (mg/m²) at all areas remained below the BCWQG. Greater periphyton productivity at the remediated (exposed) areas relative to reference was likely related, at least in part, to greater exposure to direct sunlight due to the absence of canopy cover at these areas. The lack of cover in the remediated areas also drives higher water temperatures in upper Hazeltine Creek, which although mitigated to some extent by supplemental pumping from below the thermocline in Polley Lake (see Section 6.1.2), could also contribute to higher productivity. Both chlorophyll-a and AFDM at HAC-R1 in 2022 were significantly higher than at HAC-U, indicating this area had greater periphyton productivity. Periphyton productivity in upper Hazeltine Creek increased following remediation efforts and has remained temporally stable since 2019 except at HAC-R1 where AFDM decreased in 2021, potentially due to the drought conditions during this year. Despite the increased productivity following remediation efforts, water quality monitoring indicates that dissolved oxygen concentrations largely remain above the long-term BCWQG in upper Hazeltine Creek. The recovery of periphyton productivity in upper Hazeltine Creek since completion of remediation indicates there are appropriate environmental conditions (e.g., nutrients, sunlight, lack of turbidity, adequate water quality) to support periphyton growth in this area.

6.1.3 Benthic Invertebrate Community and Productivity

Benthic invertebrate community and productivity monitoring in 2022 was completed in exposed (remediated) areas of upper Hazeltine Creek (HAC-R1, HAC-U) with an area of upper Edney Creek (EDC-U) [62] serving as reference (Figure 4.2, Table 4.3). Post-breach benthic invertebrate community results from upper Hazeltine Creek were compared to those collected in 2007 (from UHC) to evaluate changes relative to pre-breach conditions (Table 4.3). Benthic invertebrate community and productivity monitoring was also completed in upper Hazeltine Creek (HAC-R3) with an area of Frypan Creek (FPC-R3) serving as reference (Figures 4.2 and 4.3, Table 4.3). The monitoring at HAC-R3 and FPC-R3 in 2022 was completed for the purpose of assessing fish habitat, and these data were tabulated in the current report to meet CEMP requirements (Appendix Tables D.4.1 to D.4.4) but were interpreted in a separate report (Minnow 2023). A review of the 2022 benthic invertebrate community data quality (Appendix B) indicated these data were of excellent quality (see Section 5.2.5 for details).

[62] Upper Edney Creek (EDC-U; reference) was not sampled in 2020 due to habitat differences relative to upper Hazeltine Creek (Minnow 2021a). As such, temporal data interpretation for reference does not refer to 2020.

A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

6.1.3.1 Area Characteristics

The challenges associated with matching sampling habitats between the paired exposed and reference sampling areas outlined for periphyton monitoring (see Section 6.1.2.1) also applied to benthic invertebrate community and productivity monitoring in 2022 (Table 6.5; Appendix Table A.2.3). Briefly, supplemental pumping of water from Polley Lake to Hazeltine Creek in 2022 increased water depth and velocity in Hazeltine Creek (see Section 4.2.1 for details), which presented challenges for matching habitat variables in the upper Edney Creek reference area to those in upper Hazeltine Creek. This was consistent with challenges encountered in previous monitoring years due to the supplemental pumping (2018 to 2021; Minnow 2019a, 2020a, 2021a, 2022a) which were exacerbated in some years by extreme climate events in the area (i.e., drought conditions in summer 2021; Minnow 2022a). For instance, mean water velocity at the reference area was highly dissimilar to upper Hazeltine Creek in 2018 and 2021 due to local drought conditions (0 to 0.002 m/s), and the reference area was not sampled in 2020 due to obvious habitat differences relative to the upper Hazeltine Creek areas (Table 6.5; Minnow 2021a). In 2022, water velocity at the exposed areas (mean = 0.371 to 0.448 m/s) was similar to the reference area (mean = 0.339 m/s) but water depth at the exposed areas (mean = 28.8 to 28.9 cm) was approximately 2.4 times that in the reference area (mean = 12.0 cm; Table 6.5). In consideration of the temporal variability in water depth and velocity, data interpretation focused on the following comparisons for the upper Hazeltine Creek areas in the post-breach period: 1) comparisons to reference conditions at upper Edney Creek (EDC-U) in post-breach years (2018 to 2022), 2) comparisons to pre-breach conditions (UHC in 2007), and 3) temporal changes within the exposed areas (HAC-R1, HAC-U) from 2018 to 2022.

Evaluation of water quality collected routinely in upper Hazeltine Creek (at HAC-13 and HAC-05a; Figure 4.2) indicated that concentrations of total and dissolved metals exceeded the long-term BCWQG in samples collected during the year preceding sampling (i.e., September 2021 to August 2022). Specifically, at HAC-13 (which is located closest to the HAC-R1 sampling area), dissolved aluminum and copper exceeded the long-term BCWQG in 17 % and 75% of samples, respectively (Appendix Figures D.1.1 and D.1.2, Appendix Table D.1.3). At HAC-05a (which is located closest to the HAC-U sampling area), the long-term BCWQG was exceeded by total chromium (8% of samples) and total selenium (42% of samples), and dissolved aluminum (17% of samples) and dissolved copper (75% of samples; Appendix Figures D.1.1 and D.1.2, Appendix Table D.1.3). No analyte concentrations exceeded the short-term BCWQG in samples

Table 6.5: **Physical and Chemical Characteristics for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 2018 to 2022**

[c] Water quality results are from a single grab water sample collected within a week of biological sampling at a given area. The date of sample collection is shown.

[d] Seasonal range indicates the range of water quality parameters reported from routine water quality sampling. This included data from approximately 3 months preceding/concurrent with benthic invertebrate community sampling (2018 to 2022: late April to late July [n = 4 for HAC-U from 2018 to 2022, n = 11 for HAC-R1 in 2018, n=4 for HAC-R1 in 2019 and 2022]; 2021 and 2022: late April to early August [n = 4 for HAC-R1 and HAC-U]) . Routine water quality data from station HAC-13 was used for HAC-R1, and data from station HAC-05a was used for HAC-U (see Figure 4.2). Water quality is not monitored routinely near EDC-U or HAC-R3. See Appendix Tables D.1.3 and D.1.4 for 2022 results, and Minnow (2019a, 2020a, 2021a, 2022a) for 2018, 2019, 2020, and 2021 results, respectively.

collected from these exposed areas (Appendix Tables D.1.3 and D.1.4). Water quality is not routinely monitored at the upper Edney Creek reference area (EDC-U), but the single sample collected concurrently with biological monitoring (in August 2022) demonstrated analyte concentrations that were all below the BCWQG (Appendix Table D.1.2).

6.1.3.2 Community

The benthic invertebrate communities at HAC-U and HAC-R1 in 2022 were similar to reference (EDC-U) in terms of mean density, taxon richness, and Simpson's Evenness and Diversity except for significantly higher density at HAC-R1 (44,467 organisms/m^2) compared to reference (22,389 organisms/m^2; Figure 6.6, Table 6.6; Appendix Tables D.4.5 and D.4.6). Densities at HAC-R1 and HAC-U (33,747 organisms/m^2) in 2022 were also similar to pre-breach conditions (39,228 organisms/m^2), as were Simpson's Evenness and Diversity (Figure 6.6, Table 6.6). Mean taxon richness at HAC-R1 in 2022 (29 taxa) was significantly lower than pre-breach (44 taxa) while taxon richness at HAC-U in 2022 (32 taxa) was similar to pre-breach (Figure 6.6, Table 6.6). Overall, the benthic invertebrate community at HAC-R1 and HAC-U in 2022 was similar to both reference and pre-breach in terms of most primary metrics (density, richness, Simpson's Evenness and Diversity), except higher density than reference (but similar to pre-breach) at HAC-R1 and lower taxon richness than pre-breach (but similar to reference) at HAC-R1. These results indicate the benthic invertebrate community of Upper Hazeltine Creek has largely recovered to reference and/or pre-breach conditions when primary metrics (density, richness, Simpson's Evenness and Diversity) are considered.

The benthic invertebrate communities of the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) in 2022 were similar to each other in terms of all primary metrics (density, taxon richness, and Simpson's Evenness and Diversity; Table 6.6). Temporally, the benthic invertebrate communities of these two areas have also been consistently similar to each other from 2018 to 2022 in terms of the primary metrics with few exceptions. These exceptions included significantly lower taxon richness in 2021, and significantly higher Simpson's Diversity in 2020 at HAC-U compared to HAC-R1 (Figure 6.6; Table 6.4). The similarity in benthic invertebrate communities at the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) in 2022 and most prior years indicates that recovery of the benthic invertebrate community in these two areas has been largely similar when primary metrics are considered.

Mean benthic invertebrate densities at HAC-U and HAC-R1 have been significantly higher than the reference area (EDC-U) from 2018 to 2022 with one exception: density at HAC-U in 2022 was similar to reference (Figure 6.6, Table 6.6; Appendix Tables D.4.5 and D.4.6). The benthic invertebrate densities at HAC-R1 and HAC-U from 2018 to 2022 were similar to pre-breach densities with the exception of HAC-R1 in 2021, when density was significantly lower

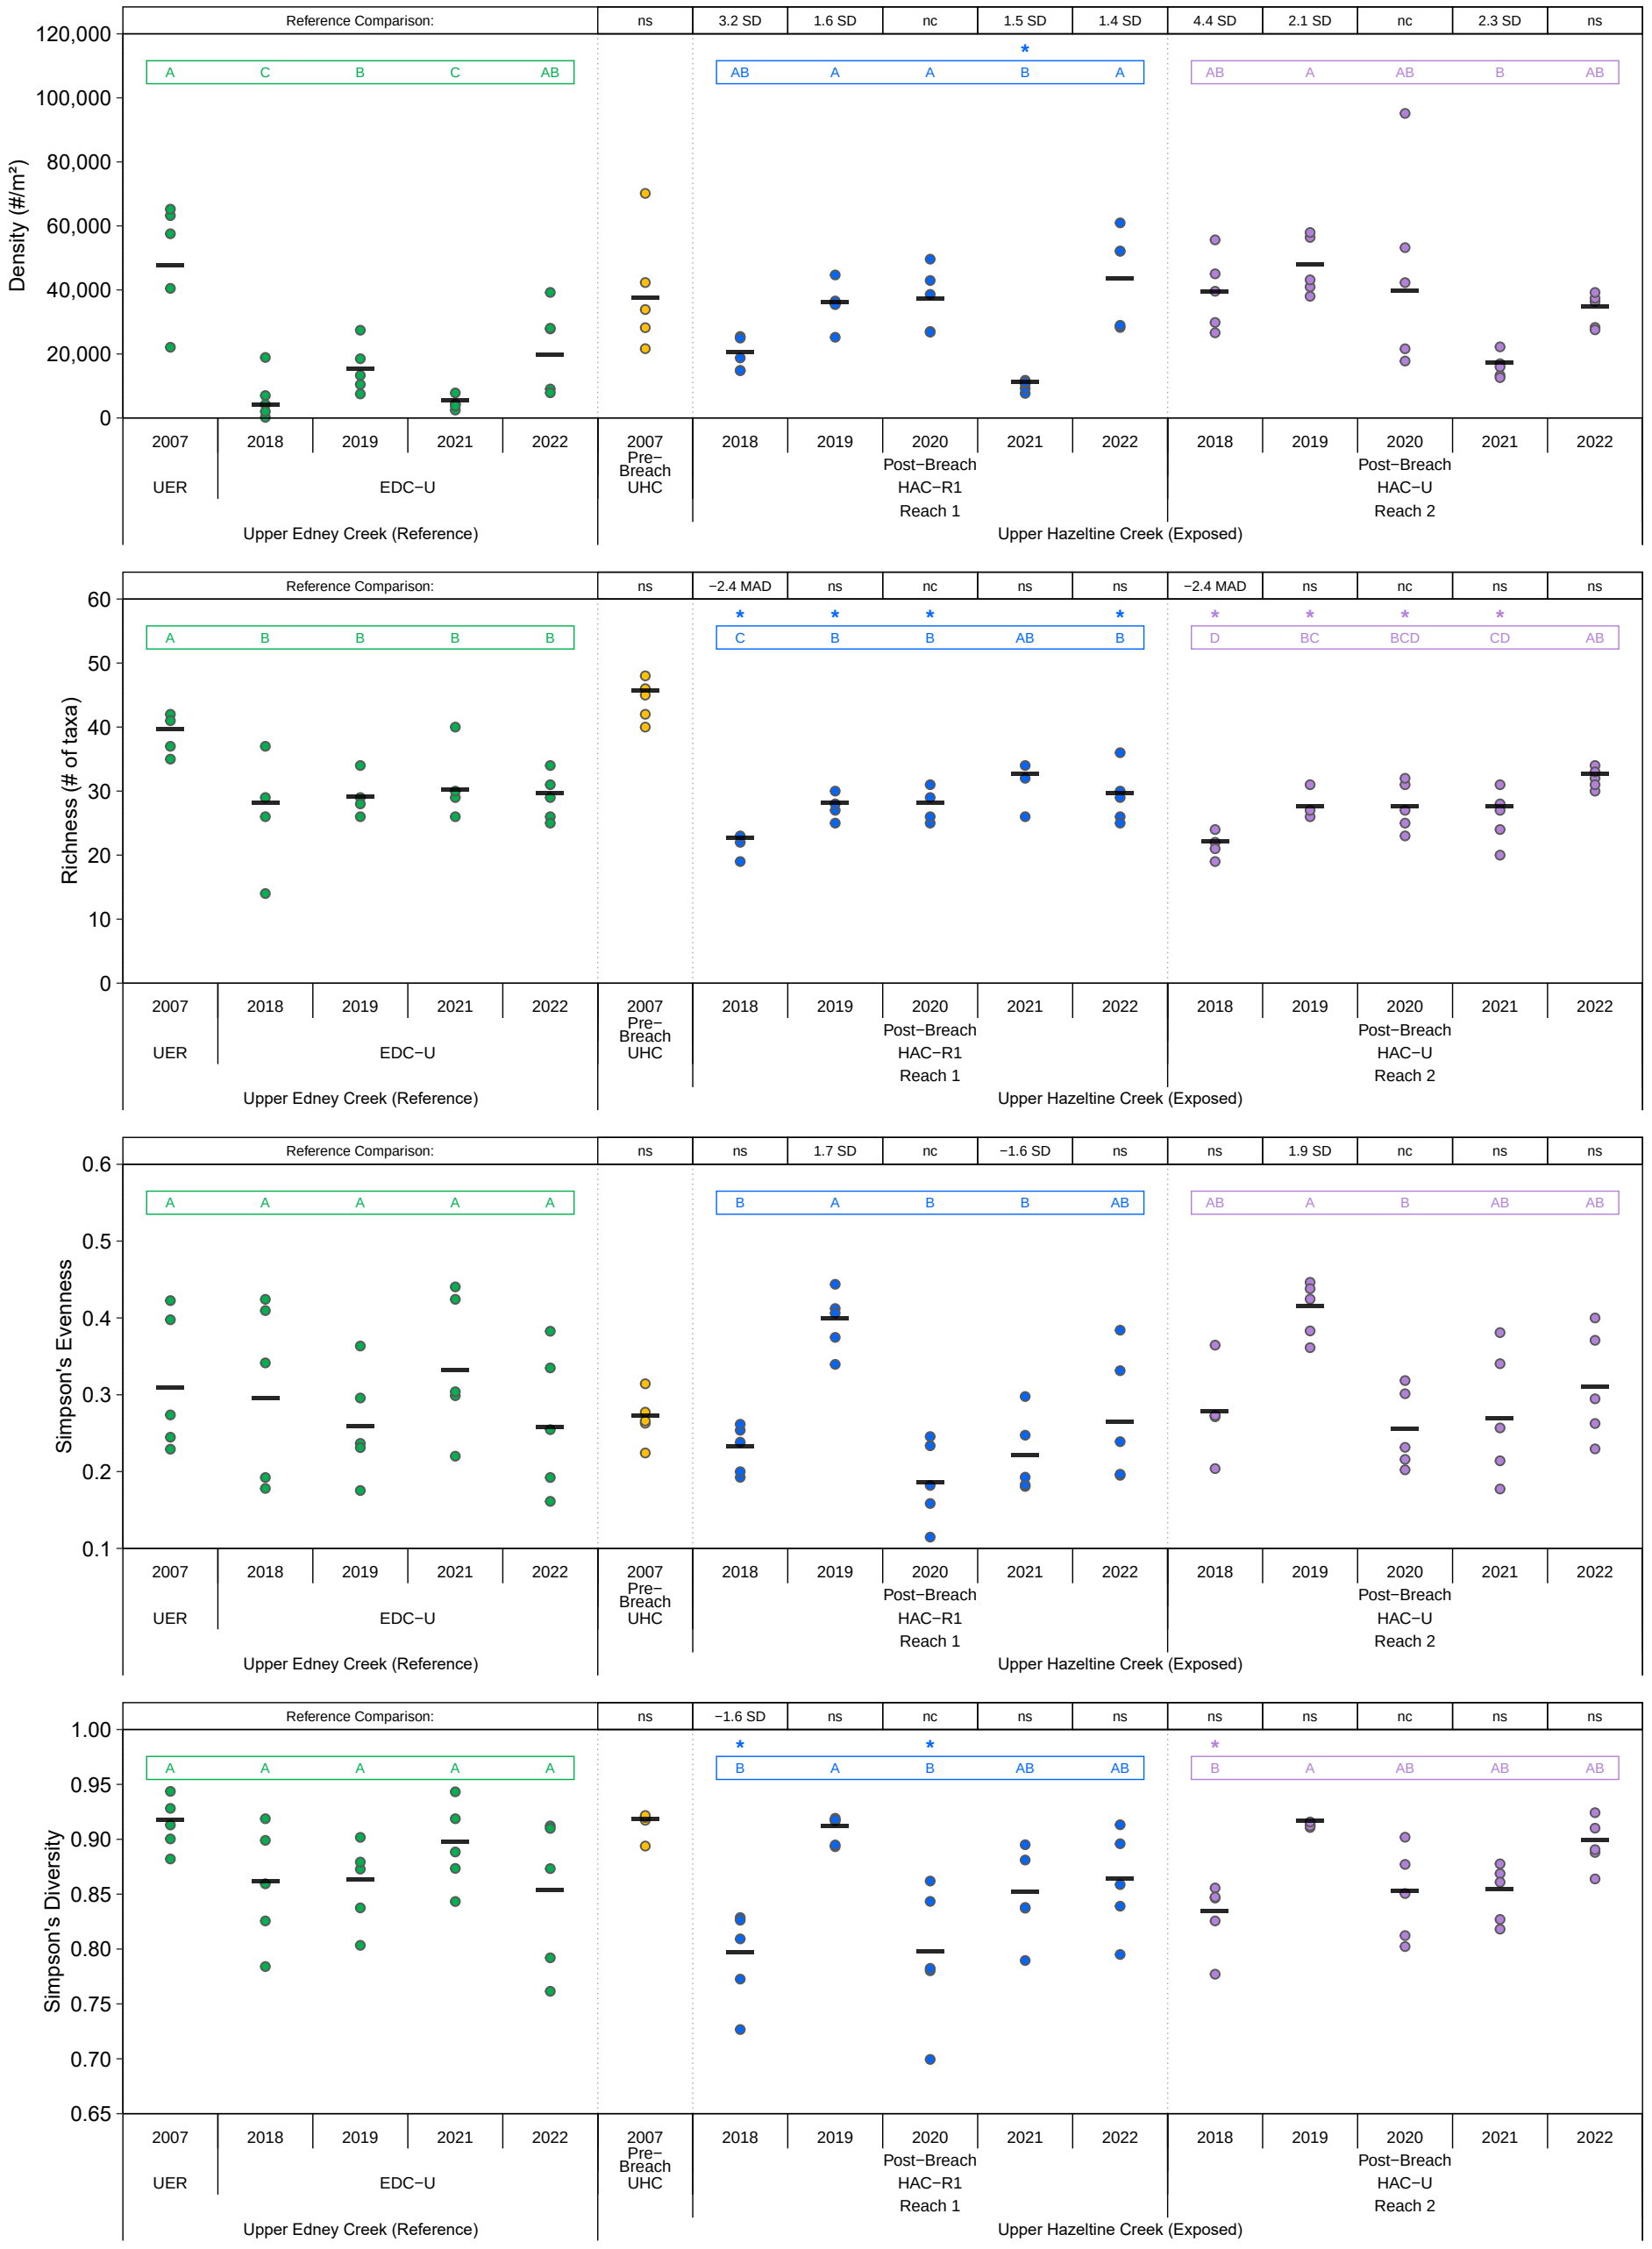

Figure 6.6: Benthic Invertebrate Community Endpoints for Upper Hazeltine Creek (HAC−R1, HAC−U; Exposed) and Upper Edney Creek (EDC−U; Reference), 2007 to 2022

Notes: Reference area EDC−U was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC−R1 and HAC−U. See Section 4.3 for details. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log10− transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. Data from 2007 were used in the analyses to compare post−breach (2018 to 2022) to pre−breach conditions (2007). Post−breach data from HAC−R1 and HAC−U were compared to pre−breach data from UHC, and post−breach data from EDC−U was compared to pre−breach data from UER. An * indicates a significant difference between HAC−R1 or HAC−U and UHC in 2007. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post −hoc comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0.

P-value < 0.1.
Magnitude of Difference (MOD) < -2.
Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available, nc = no comparison, ns = no significance, nm = Contrast MODs could not be calculated because the Median Absolute Deviation (MAD) = 0. Reference area EDC-U was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC-R1 and HAC-U. See Section 4.3 for details.

[a] Data from 2007 were used in the analyses to compare post-breach (2018 to 2022) to pre-breach conditions (2007). Post-breach data from HAC-R1 and HAC-U was compared to pre-breach data from UHC, and post-breach data from EDC-U was compared to pre-breach data from UER.

[b] Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log_{10}-transformed, or rank-transformed data.

[c] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

[d] Pairwise contrasts against of post-breach (2018 to 2022) data from HAC-R1 and HAC-U against pre-breach (2007) data from UHC are indicated with in Figure 6.9.

[e] Spatial pairwise contrasts between HAC-R1 and HAC-U in 2007 not calculated because UHC in 2007 represents baseline for both HAC-R1 and HAC-U.

Table 6.6: Results of Statistical Comparisons of Benthic Invertebrate Community Endpoints for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 2007 to 2022

P-value < 0.1.
Magnitude of Difference (MOD) < -2.
Magnitude of Difference (MOD) > 2.

Notes: "-" = no data available, nc = no comparison, ns = no significance, nm = Contrast MODs could not be calculated because the Median Absolute Deviation (MAD) = 0. Reference area EDC-U was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC-R1 and HAC-U. See Section 4.3 for details.

[a] Data from 2007 were used in the analyses to compare post-breach (2018 to 2022) to pre-breach conditions (2007). Post-breach data from HAC-R1 and HAC-U was compared to pre-breach data from UHC, and post-breach data from EDC-U was compared to pre-breach data from UER.

[b] Mean, geometric mean, or median depending on if analysis was conducted on untransformed, log_{10}-transformed, or rank-transformed data.

[c] Magnitude of difference (MOD) calculated for two-way ANOVA as (Exposed Mean - Reference Mean)/SD (or [Mean - Baseline Mean]/SD for temporal comparisons) on the transformed scale, where SD was the pooled standard deviation of the model residuals. MOD calculated for Kruskal-Wallis (i.e., rank-transformed data) as (Exposed Median - Reference Median)/MAD, where MAD was the pooled median absolute deviation.

[d] Pairwise contrasts against of post-breach (2018 to 2022) data from HAC-R1 and HAC-U against pre-breach (2007) data from UHC are indicated with in Figure 6.9.

[e] Spatial pairwise contrasts between HAC-R1 and HAC-U in 2007 not calculated because UHC in 2007 represents baseline for both HAC-R1 and HAC-U.

than pre-breach (Figure 6.6, Table 6.6). The significantly lower total density at HAC-R1 in 2021 was driven by significantly lower Chironomidae densities that occurred at both HAC-R1 and HAC-U in 2021 compared to all other post-breach monitoring years (Appendix Figure F.3.1, Appendix Table F.3.1). Within both HAC-R1 and the reference area (EDC-U), benthic invertebrate densities at each area in 2021 were similar to 2018, but significantly lower than all remaining monitoring years within each area (Figure 6.6, Table 6.6). These similar year-over-year changes at HAC-R1 and the reference area suggest that the decreased benthic invertebrate densities at HAC-R1 in 2021 compared to pre-breach were likely related to environmental conditions that similarly affected HAC-R1 and the reference area (EDC-U); namely the drought-like conditions that occurred in 2018 and 2021 (Minnow 2022a). Density at HAC-U has been temporally stable from 2018 to 2022 except that density in 2021 was significantly lower than in 2019 (Figure 6.6, Table 6.6). The temporal evaluation indicates that recovery of benthic invertebrate densities at HAC-R1 and HAC-U to pre-breach and/or reference conditions has been consistently observed since 2018.

Taxon richness at HAC-R1 and HAC-U was similar to reference from 2019 to 2022, but significantly lower than pre-breach from 2018 to 2022, except in 2021 at HAC-R1 and in 2022 at HAC-U when richness was similar to pre-breach values (Figure 6.6, Table 6.6). Simpson's Diversity at HAC-R1 and HAC-U was similar to reference and to pre-breach from 2019 to 2022 except in 2020 at HAC-R1 when Simpson's Diversity was lower than pre-breach (Figure 6.6, Table 6.6). Simpson's Evenness showed more temporal variability relative to reference but was similar to pre-breach from 2018 to 2022 in both exposed areas (HAC-R1 and HAC-U; Figure 6.6, Table 6.6). Simpson's Evenness and Diversity indices at both HAC-R1 and HAC-U in 2022 were temporally similar to prior post-breach monitoring years (i.e., 2018 to 2021; Figure 6.6, Table 6.6). The similarities of taxon richness and Simpson's Evenness and Diversity at HAC-R1 and HAC-U in 2022 to pre-breach and/or reference (EDC-U) conditions indicate that both upper Hazeltine Creek areas support a diverse benthic invertebrate community similar to that of reference and pre-breach conditions. The continued lower taxon richness at HAC-R1 in 2022 relative to pre-breach, but not reference, indicates that some recovery in community structure at this area is ongoing relative to pre-breach conditions.

Chironomidae was the most abundant taxon present at the upper Hazeltine Creek areas in 2022 (Figure 6.7). The mean relative densities of Chironomidae at HAC-R1 (62%) and HAC-U (36%) in 2022 were significantly higher than pre-breach (22%) and the reference area (EDC-U; 19%; Figure 6.7; Appendix Figure F.3.1, Appendix Table F.3.1). This contrasted with 2021 when the relative densities of Chironomidae at both HAC-R1 and HAC-U were similar to pre-breach and significantly lower than reference; a change that was owing to a significant increase in both relative density and density of Chironomidae at both areas between 2021

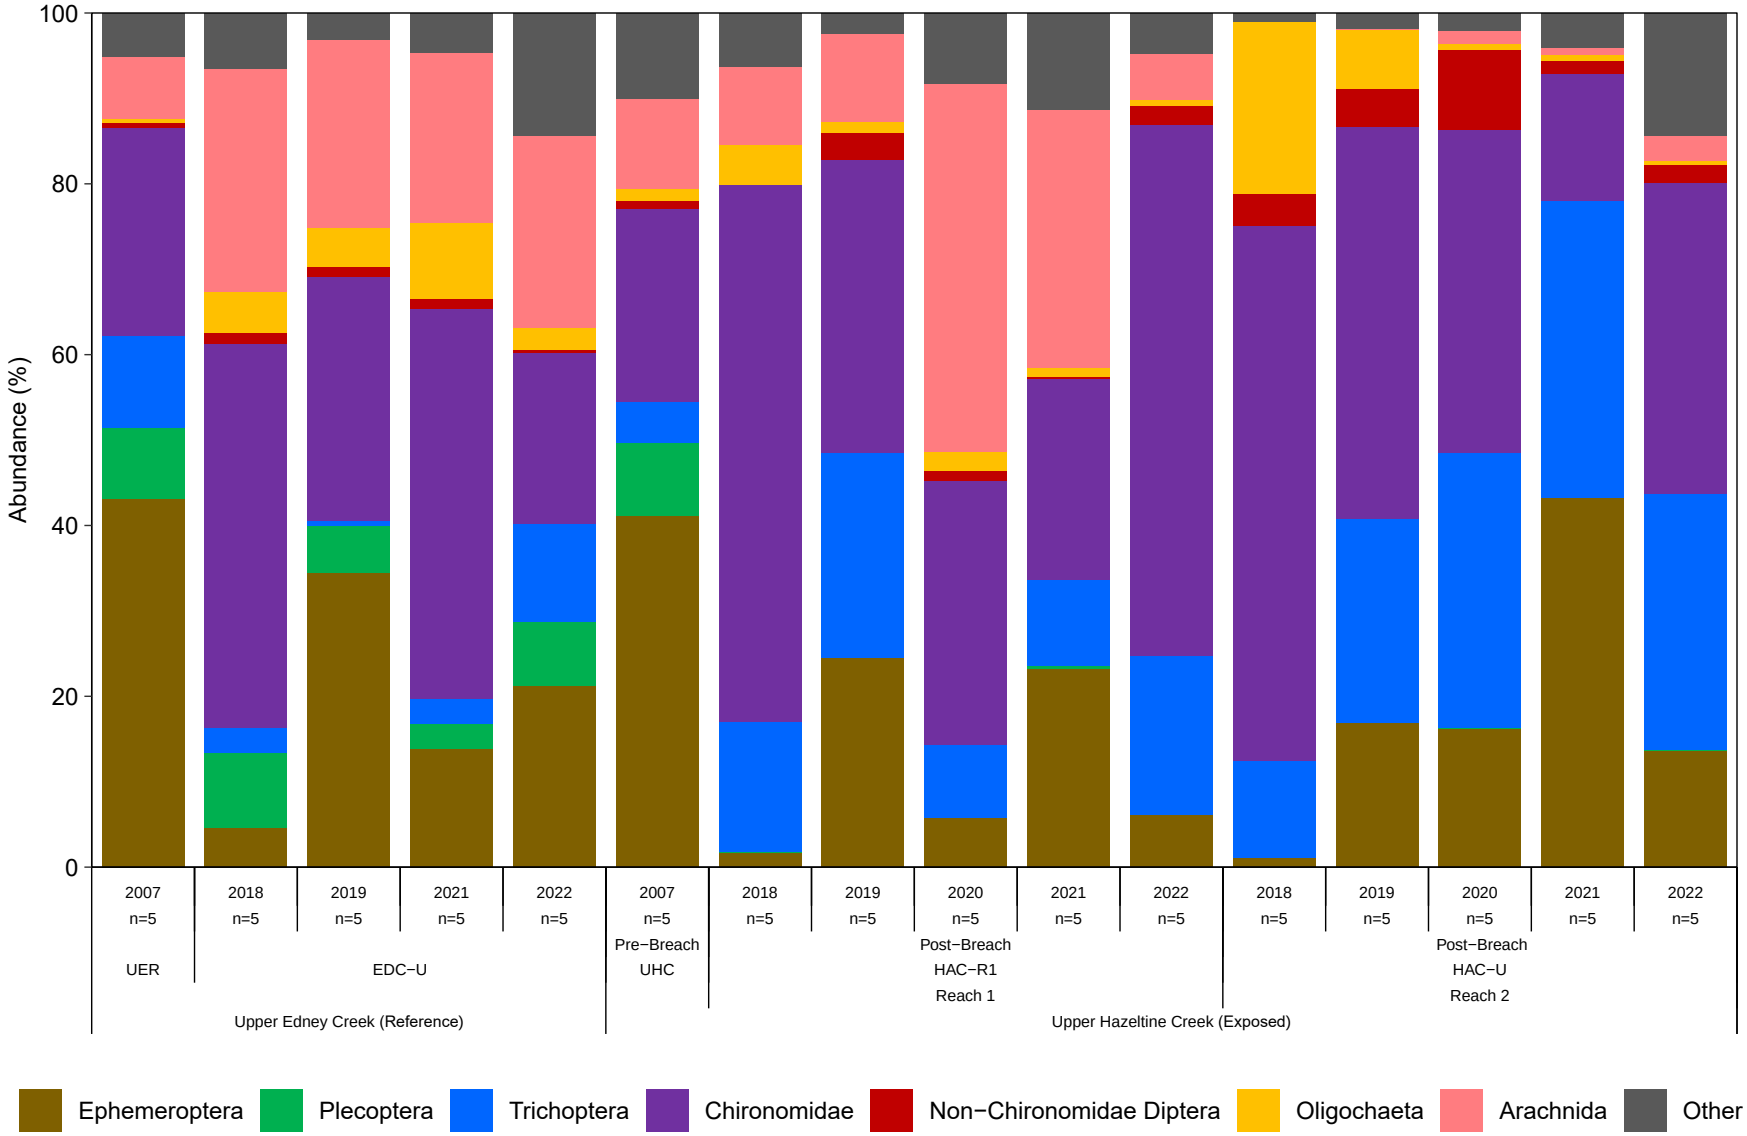

Figure 6.7: Relative Mean Densities of Major Benthic Invertebrate Community Taxonomic Groups for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 2007 to 2022

and 2022 (Appendix Figures F.3.1 and F.3.2, Appendix Tables F.3.1). For both HAC-R1 and HAC-U, the increase in Chironomidae density between 2021 and 2022 reflected a return to densities that were similar to prior years (2018 to 2020) and was the primary driver of the temporal changes in total density observed between 2021 and 2022 at HAC-R1 (Appendix Figure F.3.1, Appendix Table F.3.1). For relative densities of Chironomidae, the significant increase between 2021 and 2022 reflected a return to 2018 conditions at HAC-R1 (i.e., significantly higher than 2019 to 2021) and a return to conditions similar to 2019 and 2020 at HAC-U (i.e., significantly higher than 2021; Appendix Figure F.3.1, Appendix Tables D.4.5, D.4.6, F.3.1). The relative density of Chironomidae in 2022 at HAC-R1 was significantly higher compared to HAC-U and showed a higher magnitude of difference to both reference and pre-breach. Chironomidae are tolerant of environmental stress (Mandaville 2002) and are generally expected to be present in greater proportion with increasing environmental disturbance (Barbour 1999). The significantly higher relative densities of Chironomidae in 2022 at HAC-R1 and HAC-U compared to reference and pre-breach indicate that the community in these areas have not yet fully recovered to pre-breach and reference conditions. In addition, the higher relative density and the greater magnitude of difference compared to reference for Chironomidae at HAC-R1 in 2022 compared to HAC-U suggest that the recovery of the benthic invertebrate community at HAC-R1 may be less advanced than at HAC-U.

The relative density of EPT at HAC-R1 in 2022 (25%) was significantly lower than pre-breach (55%) and the reference area (EDC-U; 43%), while the mean relative density of EPT at HAC-U (43%) was similar to pre-breach and the reference area in 2022 (Appendix Figures F.3.1, Appendix Table F.3.1). The lower relative density of EPT at HAC-R1 in 2022 contrasts with 2021 when EPT relative density at HAC-R1 was higher than reference. This temporal change in the relative density of EPT at HAC-R1 (from higher to lower than reference between 2021 and 2022) was driven by the significant increase in density of Chironomidae between 2021 and 2022, as evidenced by densities of EPT at HAC-R1 and HAC-U in 2022 that were similar to all prior years (i.e., a decrease in EPT density did not occur in 2022; Appendix Figures F.3.1 and F.3.2, Appendix Table F.3.1). Furthermore, the densities of EPT at HAC-R1 and HAC-U in 2022 were similar to both pre-breach and reference conditions, which suggests recovery of these taxa that are sensitive indicators of environmental disturbances (Lenat 1988, Herman and Nejadhashemi 2015). At HAC-R1 however, the relative density of EPT has remained significantly lower than pre-breach in all years except 2019, indicating that the proportion of the community that these sensitive taxa occupy has not yet recovered to pre-breach conditions (owing to a higher relative contribution of Chironomidae and/or Arachnida; Appendix Figures F.3.1 and F.3.2, Appendix Table F.3.1).

Within the EPT group, there were significant differences between areas and among years in the densities and relative densities of the individual Ephemeroptera, Plecoptera, and Trichoptera taxa. Most notably, the taxa Plecoptera (stoneflies), which were present pre-breach (8%) and at the reference area (EDC-U; 10%) in 2022, were not present at the upper Hazeltine Creek areas for all post-breach monitoring years including 2022 (Figure 6.7; Appendix Figure F.3.1, Appendix Table F.3.1). Plecoptera have narrow ecological requirements and are vulnerable to water pollution, habitat fragmentation, and alteration of water courses and their banks (Mandaville 2002). The lack of Plecoptera at the upper Hazeltine Creek areas since initiation of monitoring in 2018, suggest habitat conditions in these remediated areas are currently better suited for the colonization of Ephemeroptera and Trichoptera than Plecoptera for the EPT taxa.

The relative densities of Ephemeroptera (mayflies) at HAC-R1 (6%) and HAC-U (14%) in 2022 were significantly lower (-7.3 SD and -3.4 SD, respectively) than the reference area (EDC-U; 21%), and lower than pre-breach (41%; Figure 6.7; Appendix Table F.3.1). The lower relative density of Ephemeroptera at HAC-R1 and HAC-U in 2022 (compared to reference and pre-breach) contrasts with 2021 when relative densities at both areas were higher than reference and at HAC-U were similar to pre-breach (Appendix Figure F.3.1, Appendix Table F. 3.1). This temporal change in Ephemeroptera relative density was driven by the significant increase in Chironomidae density between 2021 and 2022 (similar to the temporal change observed for EPT), as evidenced by Ephemeroptera densities at HAC-R1 and HAC-U in 2022 that were similar to those in 2019 to 2021 (i.e., a decrease in Ephemeroptera density did not occur in 2022; Appendix Figures F.3.1 and F.3.2, Appendix Table F.3.1). Similar to most previous post-breach monitoring years (2018, 2020 2021), the mean density of Ephemeroptera at HAC-R1 in 2022 was still significantly lower (-2.2 SD) than pre-breach but significantly higher than in 2018. The mean density of Ephemeroptera at HAC-U has been consistently similar to pre-breach since 2019 (Appendix Tables D.4.6 and F.3.1). In comparison, the relative densities of Ephemeroptera at both HAC-R1 and HAC-U have been consistently lower than pre-breach since 2018 at both areas, except in 2021 at HAC-U when the relative density was similar to pre-breach (Figure 6.7; Appendix Figures F.3.1 and F.3.2, Appendix Table F.3.1). Further investigation of Ephemeroptera showed that the most abundant families (Leptophlebiidae and Baetidae) at HAC-R1 and HAC-U in 2022 are relatively intolerant to water pollution, whereas the most abundant family at the reference area (EDC-U; Heptageniidae) have a higher tolerance to water pollution (Mandaville 2002; Appendix G). The occurrence of Ephemeroptera families at the exposed areas that are less pollutant tolerant than those at the reference area suggests the significantly lower proportion of Ephemeroptera at the exposed areas

(compared to reference and pre-breach) is likely related to physical habitat conditions rather than chemical conditions (i.e., water chemistry).

The other notable change within EPT was the significantly higher relative density of Trichoptera (caddisflies) at both areas of upper Hazeltine Creek compared to pre-breach (in 2018, 2019, and 2022 at HAC-R1; in 2018 to 2022 at HAC-R1) and compared to the reference area in each year (2018 to 2022; Appendix Figure F.3.1, Appendix Table F.3.1). Examination of the relative density of EPT at both areas of upper Hazeltine Creek showed that Trichoptera was the dominant taxa in 2022 (i.e., greatest contributor to EPT relative density), while Ephemeroptera was the dominant taxa in 2021 (Figure 6.7; Appendix Table F.3.1, Appendix Figures F.3.1 and F.3.2). The density and relative density of Trichoptera in 2022 were similar to prior years (2019 to 2021) at both HAC-R1 and HAC-U, indicating temporal stability within each area (Appendix Figure F.3.1, Appendix Table F.3.1). The relative density of Trichoptera at HAC-U (29%) was significantly higher compared to HAC-R1 (18%) in 2022 and showed a higher magnitude of difference in 2022 to both reference and pre-breach. This higher relative density of Trichoptera at HAC-U (29%) in 2022 positively contributed to the higher relative density of EPT observed at HAC-U compared to HAC-R1 in 2022, discussed above (Appendix Figures F.3.1 and F.3.2, Appendix Table F.3.1). The significantly higher mean relative density of Trichoptera at both areas of upper Hazeltine Creek, compared to pre-breach and reference conditions, suggests that the remediated habitat is well suited to specific families within this group. Specifically, net-spinning caddisflies of the family Hydropsychidae composed greater than 74% and 83% of the mean relative density of Trichoptera at HAC-R1 and HAC-U, respectively in 2022. This is similar to results observed since 2018 and much higher than those observed during pre-breach conditions (46%; Appendix G; Minnow 2019a, 2020a, 2021a). A higher relative density of Hydropsychidae has been correlated with habitat disturbance in small streams (Houghton 2004), therefore the significantly higher mean relative density of this group at both areas of upper Hazeltine Creek in 2022 (since 2018 at HAC-R1 and 2019 at HAC-U) was consistent with early recovery of the benthic invertebrate community at this area.

For the remaining taxon evaluated (Arachnida, non-Chironomidae Diptera, and Oligochaeta), only Arachnida had relative densities in 2022 that differed from pre-breach. Specifically, Arachnida relative densities at HAC-U in 2022 were significantly lower than pre-breach, which is consistent with all prior years (2018 to 2022) while the relative densities of Arachnida at HAC-R1 have been similar to or significantly higher than pre-breach from 2018 to 2022 (Figure 6.7; Appendix Figure F.3.1, Appendix Table F.3.1). Reach 1 of Hazeltine Creek (where HAC-R1 is located) was characterized as having more pool habitat and lower water velocities than Reach 2 (where HAC-U is located; Minnow 2021a) and in 2022 periphyton productivity was greater at HAC-R1 compared to HAC-U (See Section 6.1.2.3). Arachnida mainly

inhabit aquatic vegetation (Schatz and Behan-Pelletier 2008), therefore the similar or higher relative densities of Arachnida at HAC-R1 compared to pre-breach was likely reflective of the recovery of aquatic vegetation in this remediated area.

Comparison of the community composition of HAC-R1 and HAC-U in 2022 based on the dominant taxa indicated that the densities and relative densities of most taxa were similar in 2022 between the two exposed areas with three exceptions. These exceptions are noted and discussed above and included significantly higher relative densities of Chironomidae and lower relative densities of EPT and Trichoptera at HAC-R1 compared to HAC-U in 2022 (Appendix Figure F.3.1, Appendix Table F.3.1). As indicated above, these differences in community composition suggest that benthic invertebrate community recovery is more advanced at HAC-U than at HAC-R1.

Correlation analysis indicated that some of differences in benthic invertebrate community metrics at the upper Hazeltine Creek areas (from 2018 to 2022) were related to water velocity, which is modified by the augmentation of water flows in Hazeltine Creek for the purposes of maintaining fish habitat (as outlined in Section 6.1.3.1; Minnow 2023). For instance, Simpson's Evenness and Diversity, the mean density and mean relative density of Ephemeroptera, Trichoptera, EPT and non-Chironomidae Diptera were positively correlated with mean water velocity, whereas the mean relative density of Arachnida was negatively correlated with mean water velocity. Specific conductance, which is reflective of water quality constituent concentrations, was positively correlated with Simpson's Evenness, and density and relative density of Chironomidae and Oligochaeta and negatively correlated with richness and density and density of Arachnida (Appendix Figure F.3.3, Appendix Table F.3.2). The correlations with specific conductance were driven by the highest values that were observed in 2018 and 2019 (immediately after remediation), with lower specific conductance results observed in 2020 onwards (Appendix Figure F.3.3). Of the benthic invertebrate endpoints correlated with specific conductance, taxon richness, Chironomidae density and relative, and Arachnida relative density were the only endpoints in 2022 that differed significantly from pre-breach. Taxon richness was also positively correlated with temperature (with a stronger relationship than observed with specific conductance) suggesting the influence of multiple factors on taxon richness. The significant positive correlation between density and relative density of Chironomidae and specific conductance is consistent with the tolerance of this taxon (Mandaville 2002). However, as indicated above, the occurrence of Ephemeroptera families at the exposed areas that are less pollutant tolerant than those at the reference area suggests the chemical conditions (i.e., water chemistry) of the exposed areas are not limiting for benthic invertebrate community recovery. This is further supported by the absence of significant correlations between Ephemeroptera or EPT and specific conductance. Density of Ephemeroptera and relative density of EPT were negatively, and mean relative density of

Chironomidae was positively correlated, respectively, with substrate size (Appendix Figure F.3.3, Appendix Table F.3.2)

Overall, benthic invertebrate community at both areas of Upper Hazeltine Creek in 2022 was characterized by density, richness, and Simpson's Evenness and Diversity that were similar between the two areas (HAC-R1 and HAC-U) and that were similar to reference and/or pre-breach conditions. Compared specifically to pre-breach, taxon richness at HAC-R1 in 2022 remained significantly decreased but was similar to reference conditions. These results indicate the benthic invertebrate community at these upper Hazeltine Creek areas have largely recovered to reference and/or pre-breach conditions when primary metrics (density, richness, Simpson's Evenness and Diversity) are considered. Chironomidae was the most abundant taxon at both upper Hazeltine Creek areas and was present in proportions at both areas in 2022 that were significantly higher than reference and pre-breach conditions. However, Chironomidae densities at HAC-R1 or HAC-U were only slightly higher than, or similar, respectively, to pre-breach conditions. Although lower relative density of EPT was shown at HAC-R1, but not HAC-U, compared to pre-breach and reference conditions, mean densities of EPT at both areas were similar to each other, pre-breach, and reference conditions. Notable differences in EPT at both upper Hazeltine Creek areas, compared to reference and pre-breach, were the lack of Plecoptera and the higher relative density of Trichoptera, which were dominated by a family of net-spinning caddisflies (Hydropsychidae). The occurrence of Ephemeroptera families at the exposed areas that are less pollutant tolerant than those at the reference area suggests the chemical conditions (i.e., water chemistry) of the exposed areas are not limiting for benthic invertebrate community recovery. Comparison of community composition between the two upper Hazeltine Creek areas suggested that benthic invertebrate community recovery is more advanced in Reach 2 (at HAC-U) than in Reach 1 (at HAC-R1). In summary, these results indicate both areas of upper Hazeltine Creek have recovered substantially since remediation to a condition that is similar to reference and/or pre-breach conditions based on primary metrics, but with some remaining differences in community composition compared to reference and pre-breach.

6.1.3.3 Productivity

Mean total dry biomass of benthic invertebrates at HAC-R1 and HAC-U was similar between the two upper Hazeltine Creek areas in 2022 and was also similar to prior years within each area (2019 to 2021; Figure 6.8; Appendix Table F.3.1). Similar to previous monitoring years, HAC-R1 and HAC-U had significantly higher (2.0 and 3.6 SD, respectively) dry biomass of benthic invertebrates in 2022 than the reference area (EDC-U; Figure 6.8), which at HAC-R1 was corroborated by significantly higher benthic invertebrate density than reference

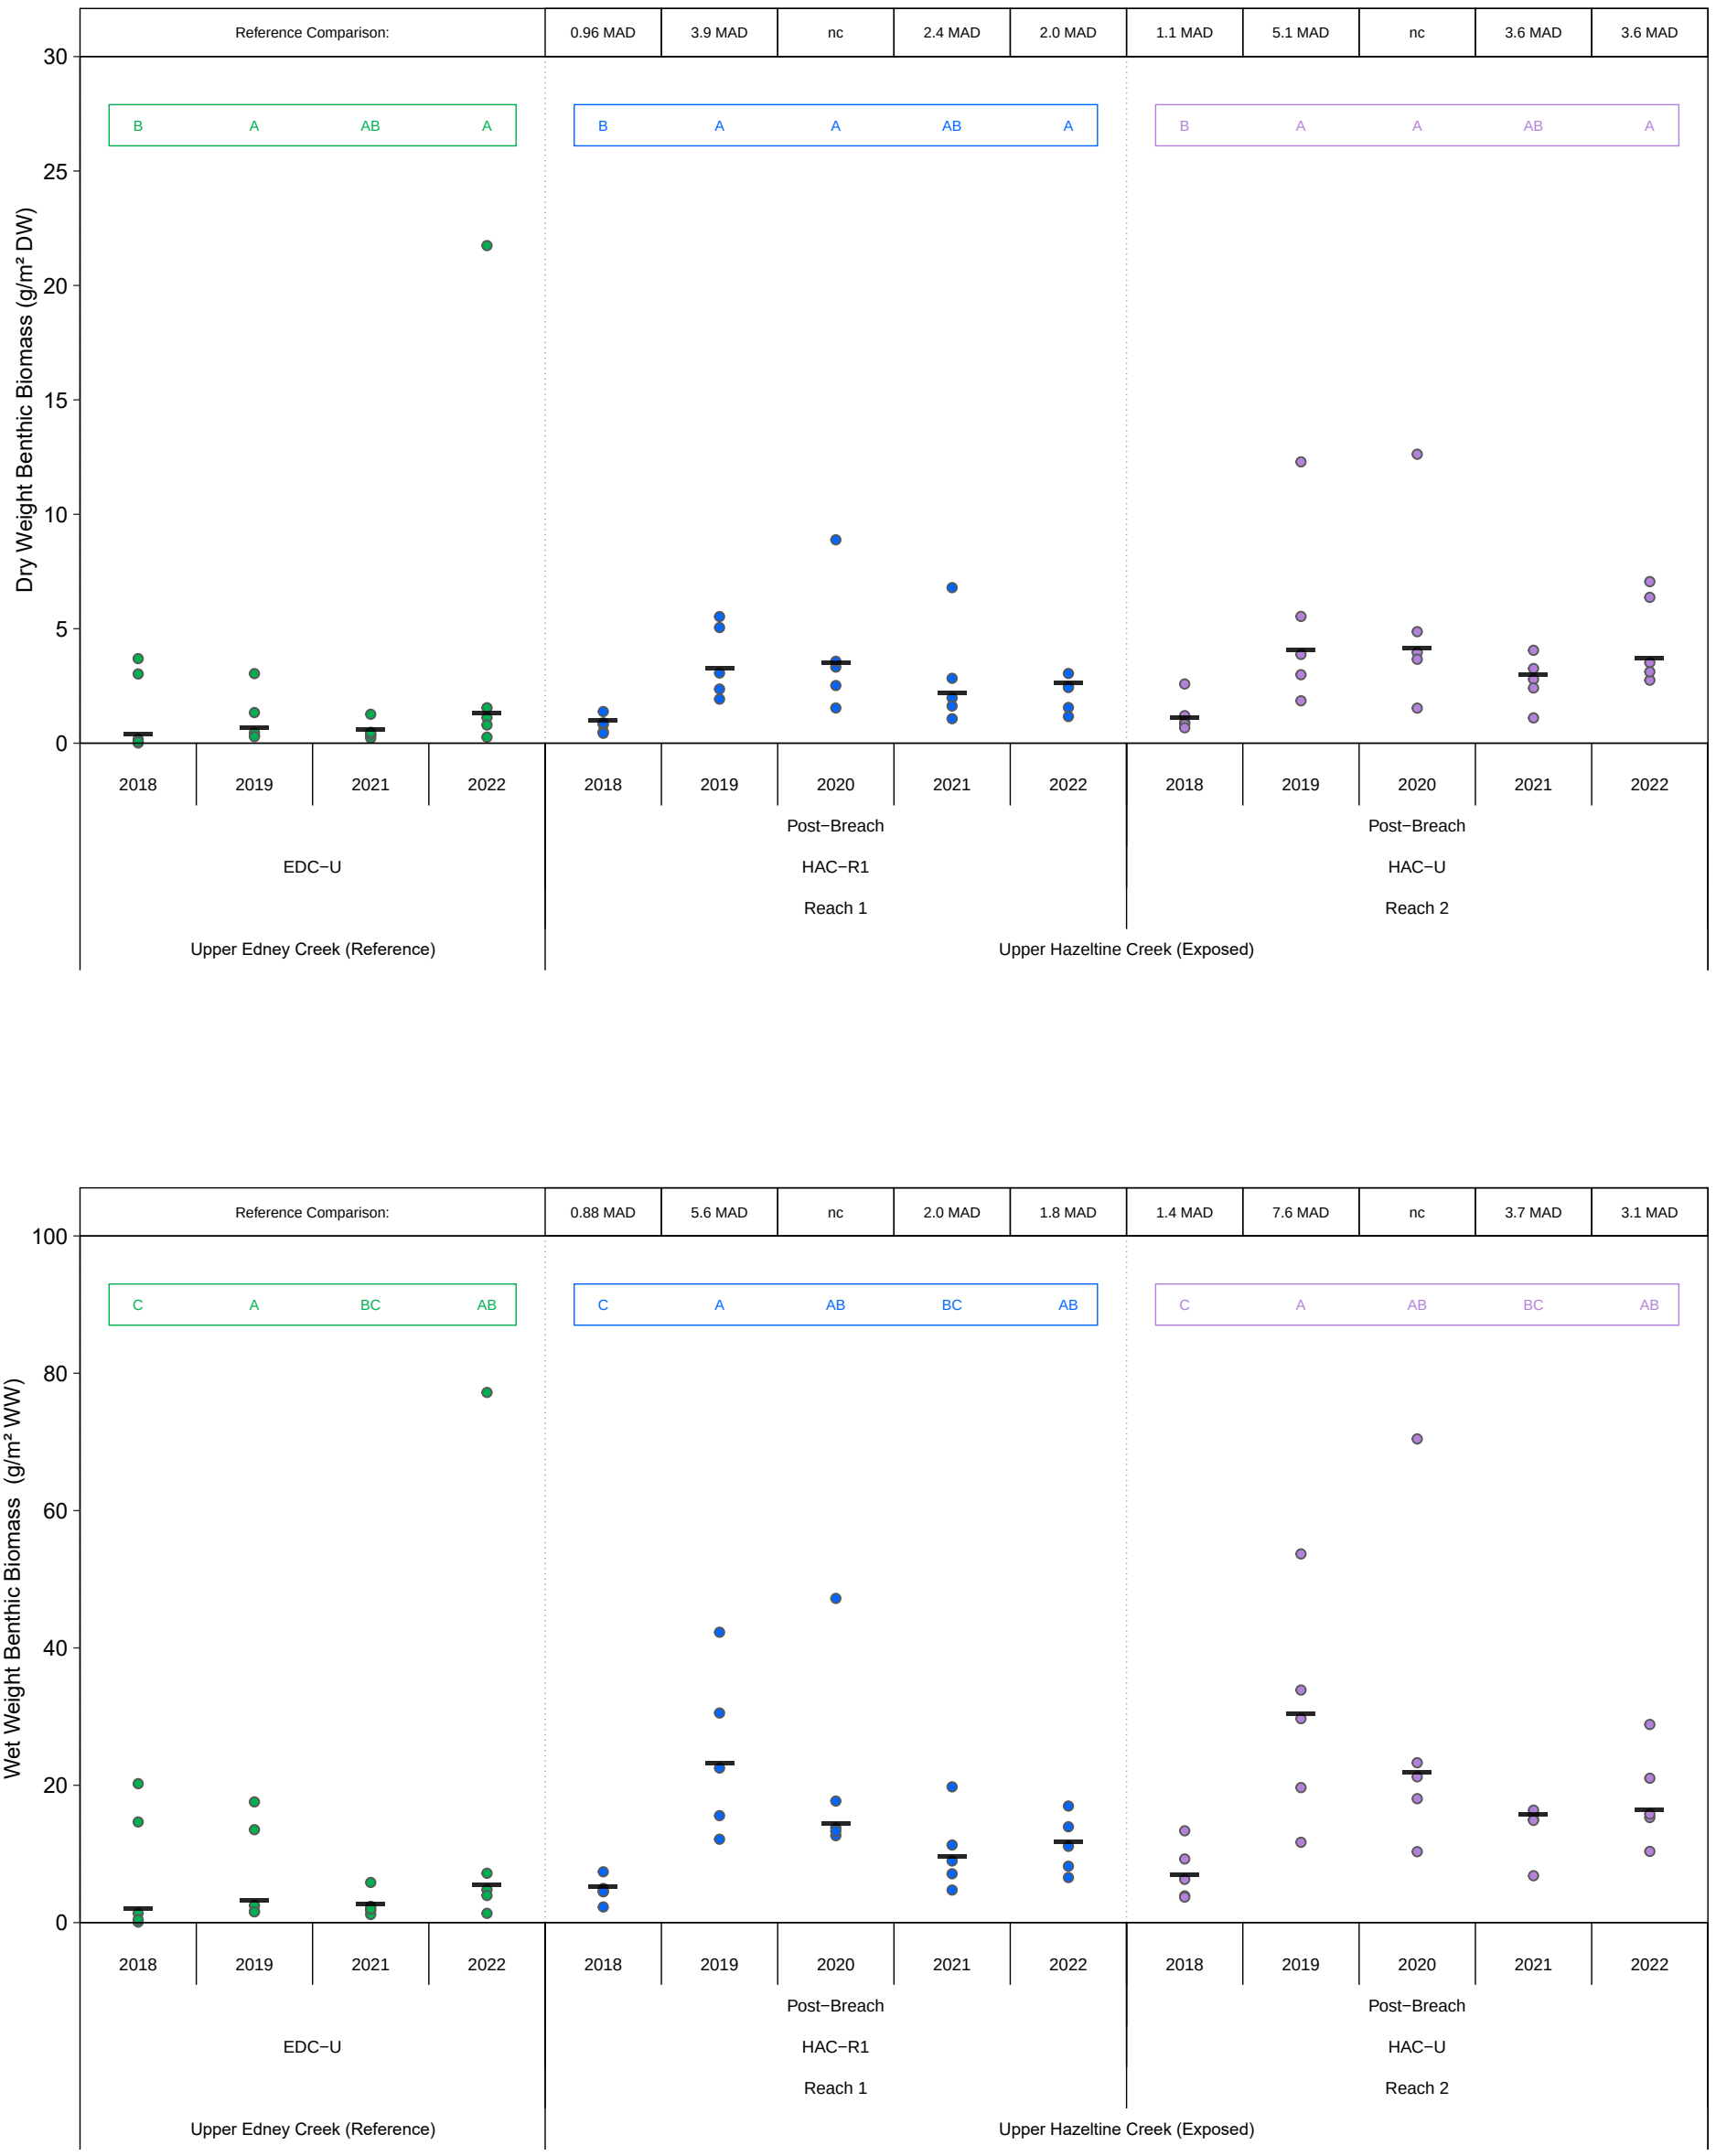

Figure 6.8: Benthic Invertebrate Biomass for Upper Hazeltine Creek (HAC−R1, HAC−U; Exposed) and Upper Edney Creek (EDC−U; Reference), 2018 to 2022

Notes: Reference area EDC−U was not sampled in 2020 due to habitat differences (in water depth and flow) relative to the remediated areas HAC−R1 and HAC−U. See Section 4.3 for details. Black bars represent measures of central tendency (mean, geometric mean, or median depending on if analysis was conducted on untransformed, log_{10}−transformed or rank−transformed data). Coloured letters represent significant (p−value <0.1) post−hoc comparisons within areas over time; years that share a letter of the same colour (e.g., A, B) within a box of the same colour do not differ significantly within an area. A number above the plot indicates significant exposed vs. reference post−hoc comparisons within a given year. The magnitude of difference (MOD) for these significant post−hoc comparisons is expressed in units of standard deviation (SD) or median absolute deviations (MAD; if the data were rank−transformed prior to analysis) relative to reference. 'nc' indicates no comparisons were possible; 'ns' indicates a non−significant contrast; 'nm' indicates that the MOD could not be calculated because MAD = 0.

(Figure 6.6; Appendix Table F.3.1). Benthic invertebrate dry weight biomass was positively correlated with mean water velocity (Appendix Figure F.3.3, Appendix Table F.3.2). The consistently higher benthic invertebrate dry biomass at the remediated areas relative to reference indicates benthic invertebrate productivity that has recovered to (and exceeded) reference conditions.

6.1.4 Periphyton and Benthic Invertebrate Tissue Quality

6.1.4.1 Overview

Periphyton and benthic invertebrate tissue samples were collected from remediated (exposed) areas of upper Hazeltine Creek (HAC-R1 and HAC-U) with upper Edney Creek (EDC-U) serving as reference, and at lower Hazeltine Creek (HAC-D) with an unimpacted area of lower Edney Creek (EDC-D) serving as reference (Figure 4.2; Table 4.4). A review of the 2022 periphyton and benthic invertebrate tissue quality data (Appendix B) indicated that the data largely met the established DQOs. Specifically, the data were characterized by appropriate detectability, negligible analyte concentrations in MB samples, low laboratory and field sampling precision, and excellent laboratory accuracy. The low laboratory and field precision were a result of sample heterogeneity (e.g., taxonomic variability in composite-taxa samples or natural variability within a single taxon); however, the collection of replicated samples (n = 8 per area in accordance with the CEMP; MPMC 2019) helped to characterize this variability. Overall, the tissue quality data can be used with a high level of confidence for interpretation, although the occurrence of some natural heterogeneity in analyte results were considered during data interpretation. A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

As indicated in Section 4.4.3.2, data interpretation was focused on primary and secondary analytes (Table 2.4) with a significant positive exposed-reference difference (i.e., analytes with concentrations that were significantly higher in tissues from the remediated [exposed] area compared to those from the reference area) in 2022 (if the analysis *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant[63]) for at least one tissue type (periphyton, caddisfly, or composite-taxa benthic invertebrate) in at least one area. Data interpretations were further focused by integrating the results of water quality monitoring (i.e., bioconcentration) and trophic transfer factors (TTFs) of benthic invertebrate tissue analyte concentrations. Specifically, water quality data (and BCFs) for the analytes selected for data interpretation were examined to determine whether the

[63] If no significant change was detected in the exposed:reference ratio among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

significantly higher analyte concentrations in exposed tissues (relative to reference) were related to water chemistry. The TTFs for the analytes selected for data interpretation were also evaluated to determine if these analytes were bioaccumulating in the aquatic biota in Hazeltine Creek. Combined, these approaches were used to identify analytes for which concentrations in biota and TTFs at the exposed areas have increased at a rate that differs from reference and that may represent a potential risk to aquatic biota. This interpretive approach was completed separately for upper and lower Hazeltine Creek areas because the results for these areas differed slightly. Results for composite-taxa benthic invertebrate tissue samples are referred to as composite-taxa for the remainder of this section.

6.1.4.2 Upper Hazeltine Creek

For most metals evaluated, there was no evidence of increasing concentrations in periphyton and/or benthic invertebrate tissues at the exposed areas relative to the reference area over time (Appendix Figures F.4.1 to F.4.6, Appendix Tables D.5.1 to D.5.6, F.4.1 to F.4.10). The primary analytes arsenic, copper, iron, and selenium, and nine secondary analytes (barium, calcium, nickel, phosphorus, sodium, strontium, titanium, uranium, and vanadium) met the criteria for inclusion in data interpretation outlined above (i.e., were significantly higher for at least one exposed area of upper Hazeltine Creek relative to reference in 2022 or in all years; Table 6.7). Of these analytes, only titanium did not show a significant *Area×Year* interaction for at least one tissue type for at least one upper Hazeltine Creek area (Table 6.7).

MPMC implements routine water quality monitoring in upper Hazeltine Creek at HAC-13 (a station within the sampling area of HAC-R1) and at HAC-05a (a station downstream of HAC-U; Figure 4.2). Results from these routine water quality monitoring stations indicated that aqueous concentrations of two primary or secondary analytes (copper and selenium) exceeded the BCWQG during the year preceding sampling (i.e., September 2021 to August 2022). Specifically, the chronic BCWQG for dissolved copper, which is based on the BLM (BCMOECCS 2019b,c, 2021b) was exceeded in 75% of the samples collected from both station HAC-13 (HAC-R1) and station HAC-05a (HAC-U; Appendix Tables D.1.3 and D.1.4). The chronic BCWQG for total selenium (0.002 mg/L; BCMOECCS 2021b) was exceeded in 42% of the samples collected from station HAC-05a (HAC-U); selenium did not exceed the BCWQG at station HAC-13 (HAC-R1; Appendix Tables D.1.3 and D.1.4).

Of the four primary and nine secondary analytes identified for inclusion in data interpretation, mean dissolved aqueous concentrations of copper and selenium were elevated at HAC-R1 and

Indicates significantly higher tissue concentration at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

(↑) = Indicates significantly higher tissue concentration relative to pre-breach in 2010 (α = 0.05).
(↓) = Indicates significantly lower tissue concentration relative to pre-breach in 2010 (α = 0.05).
(ns) = no significant different in analyte concentration relative to pre-breach in 2010 (α = 0.05).
Notes: "-" = no statistical comparison could be made because data were not available or all results below Laboratory Reporting Limit (LRL), refer to Appendix Tables F.4.1 to F.4.10 and F.4.17 to F.4.21 for statistical analyses results and magnitude of difference calculations. Data were analysed in units of mg/kg dry weight.

[a] Results are shown for primary and secondary analytes that had a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types (periphyton, caddisfly, or composite benthic invertebrate) in at least one area. Years that share a letter (e.g., A,B,C) had ratios of analyte concentrations (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

Table 6.7: Summary of Statistical Contrasts of Exposed - Reference Relative Differences of Primary and Secondary Analyte Concentrations in Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D; Exposed), and Lower Edney Creek (EDC-D; Reference), 2015 to 2022 [a]

Notes: "-" = no statistical comparison could be made because data were not available or all results below Laboratory Reporting Limit (LRL), refer to Appendix Tables F.4.1 to F.4.10 and F.4.17 to F.4.21 for statistical analyses results and magnitude of difference calculations. Data were analysed in units of mg/kg dry weight.

[a] Results are shown for primary and secondary analytes that had a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types (periphyton, caddisfly, or composite benthic invertebrate) in at least one area. Years that share a letter (e.g., A,B,C) had ratios of analyte concentrations (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

HAC-U relative to reference, as were the secondary analytes calcium, sodium, strontium, and uranium (Table 6.8)[64]. Despite elevated dissolved aqueous concentrations of copper and selenium relative to reference, periphyton BCFs for these primary analytes in upper Hazeltine Creek were generally lower than reference in 2022, as expected[65], and similar to results from 2021 (Minnow 2022a). The BCF for copper was 4.4 times greater than reference at HAC-U and 1.2 times greater than reference at HAC-R1 for composite-taxa tissues, and not elevated for caddisfly tissues. The BCF for selenium was slightly (< 2 times) greater than reference for caddisfly at both HAC-R1 and HAC-U and not elevated in composite-taxa tissues (Table 6.8; Appendix Tables D.5.1 to D.5.6). The BCFs were at least 2.0 times greater than reference for arsenic, iron, barium, calcium, nickel, phosphorus, strontium, titanium, and vanadium in at least one tissue type for at least one area of upper Hazeltine Creek (Table 6.8).

Concentrations of copper in most tissue types from upper Hazeltine Creek were consistently elevated relative to the reference area (EDC-U) from 2018 to 2022, with the exception of caddisfly tissues at HAC-R1 (in 2022) and HAC-U (in 2020 and 2021), and periphyton tissues from HAC-R1 (in 2019 to 2021; Figures 6.9 and 6.10, Table 6.7; Appendix Figures F.4.1 to F.4.6, Appendix Tables F.4.1 to F.4.10). Specifically, copper concentrations in periphyton tissues from HAC-R1 were significantly higher than reference in 2018 and 2022 but similar to reference in the interim years (2019 to 2021), and at HAC-U have been consistently elevated relative to reference from 2018 to 2022 (Figures 6.9 and 6.10, Table 6.7). Copper concentrations in periphyton tissues from both areas (HAC-R1 and HAC-U) in 2022 were similar to those in 2018, relative to reference, indicating no temporal increase has occurred (Figures 6.9 and 6.10, Table 6.7). Concentrations of copper in caddisfly tissue samples in 2022 at HAC-R1 were similar to reference but at HAC-U were significantly higher than reference. However, the magnitude of these differences relative to reference in 2022 were significantly lower than in 2018, 2019 and 2021 at HAC-R1, and lower than in 2018 and 2019 (but not different from 2021 and higher than 2020) at HAC-U (Table 6.7). Most notable, concentrations of copper in composite-taxa tissues from HAC-U have steadily increased since 2020 and were significantly higher in 2022 compared to all previous monitoring years, relative to reference (Figure 6.10, Table 6.7). In contrast, the concentrations of copper in composite-taxa tissues from HAC-R1 have varied among previous monitoring years and in 2022 exposed:reference ratios were significantly lower than 2018 (Figure 6.9, Table 6.7). Copper concentrations in composite-taxa tissue for both areas of upper Hazeltine Creek in 2022

[64] Elevated analytes were identified as those with mean concentrations at the exposed station that were at least twice the mean concentration at the reference station.

[65] Both BCFs and trophic TTFs are generally expected to decrease with increasing concentration. Increased BCFs and TTFs with increasing concentrations can be suggestive of enhanced bioavailability or reduced ability of organisms to regulate metals.

Table 6.8: Summary of Primary and Secondary Analytes Concentrations in Water, Periphyton, Composite-Taxa, and Caddisfly Tissues, BCFs and TTFs for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D; Exposed), and Lower Edney Creek (EDC-D; Reference), 2022

Dissolved concentration at exposed area exceeded reference area by less than 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 2-times.
Dissolved concentration at exposed area exceeded reference area by at least than 5-times.
Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05).
Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05).
BCF for exposed area exceeded reference area by less than 2-times.
BCF for exposed area exceeded reference area by at least 2-times.
BCF for exposed area exceeded reference area by at least 10-times.
Mean TTF exceeds 1.
Mean TTF at exposed area exceeds 1 and the corresponding reference area TTF for a given year.
Mean TTF at exposed area exceeds 1, the corresponding reference area TTF for a given year, and mean TTFs for all previous years (pre-breach and 2017 when applicable).

BOLD = mean tissue selenium value exceeds long-term benthic invertebrate tissue guideline for selenium (4 mg/kg dw; BCMOE 2014).

BOLD/ITALICS = Indicates dissolved water value greater than the long-term average British Columbia Water Quality Guideline (BCMOECCS 2021a,b).

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., those with a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = no data for dissolved water concentration/ BCF was not calculated for analytes due to no data for dissolved water concentration. "na" = not applicable. Summary statistics reported to 3 significant figures for display purposes.

[a] Monitoring stations included W10, HAC-13, HAC-05a, and HAC-08 for corresponding tissue sampling stations EDC-D, HAC-R1, HAC-U, and HAC-D, respectively (refer to Appendix Tables D.1.3, D.1.4, D.1.6, and D.1.7). For EDC-U routine water quality data were not available, so BCFs were calculated using spot water quality samples taken during tissue collection.

[b] Sample sizes for water quality monitoring are 1, 3, 8, 8, and 8 for EDC-U (EDC-U spot water quality monitoring), EDC-D (W10), HAC-R1 (HAC-13), HAC-U (HAC-05a), and HAC-D (HAC-08).

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOECCS 2021a,b) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2022 and the time of sampling in August 2022 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a).

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L), if the dissolved water concentration was reported as below the Laboratory Reporting Limit (LRL), then the LRL was substituted for the BCF calculation.

[f] Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

Table 6.8: Summary of Primary and Secondary Analytes Concentrations in Water, Periphyton, Composite-Taxa, and Caddisfly Tissues, BCFs and TTFs for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D; Exposed), and Lower Edney Creek (EDC-D; Reference), 2022

Dissolved concentration at exposed area exceeded reference area by less than 2-times.

Dissolved concentration at exposed area exceeded reference area by at least 2-times.

Dissolved concentration at exposed area exceeded reference area by at least than 5-times.

Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05).

BCF for exposed area exceeded reference area by less than 2-times.

BCF for exposed area exceeded reference area by at least 2-times.

BCF for exposed area exceeded reference area by at least 10-times.

Mean TTF exceeds 1.

Mean TTF at exposed area exceeds 1 and the corresponding reference area TTF for a given year.

Mean TTF at exposed area exceeds 1, the corresponding reference area TTF for a given year, and mean TTFs for all previous years (pre-breach and 2017 when applicable).

BOLD = mean tissue selenium value exceeds long-term benthic invertebrate tissue guideline for selenium (4 mg/kg dw; BCMOE 2014).

BOLD/ITALICS = Indicates dissolved water value greater than the long-term average British Columbia Water Quality Guideline (BCMOECCS 2021a,b).

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., those with a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = no data for dissolved water concentration/ BCF was not calculated for analytes due to no data for dissolved water concentration. "na" = not applicable. Summary statistics reported to 3 significant figures for display purposes.

[a] Monitoring stations included W10, HAC-13, HAC-05a, and HAC-08 for corresponding tissue sampling stations EDC-D, HAC-R1, HAC-U, and HAC-D, respectively (refer to Appendix Tables D.1.3, D.1.4, D.1.6, and D.1.7). For EDC-U routine water quality data were not available, so BCFs were calculated using spot water quality samples taken during tissue collection.

[b] Sample sizes for water quality monitoring are 1, 3, 8, 8, and 8 for EDC-U (EDC-U spot water quality monitoring), EDC-D (W10), HAC-R1 (HAC-13), HAC-U (HAC-05a), and HAC-D (HAC-08).

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOECCS 2021a,b) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2022 and the time of sampling in August 2022 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a).

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L), if the dissolved water concentration was reported as below the Laboratory Reporting Limit (LRL), then the LRL was substituted for the BCF calculation.

[f] Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

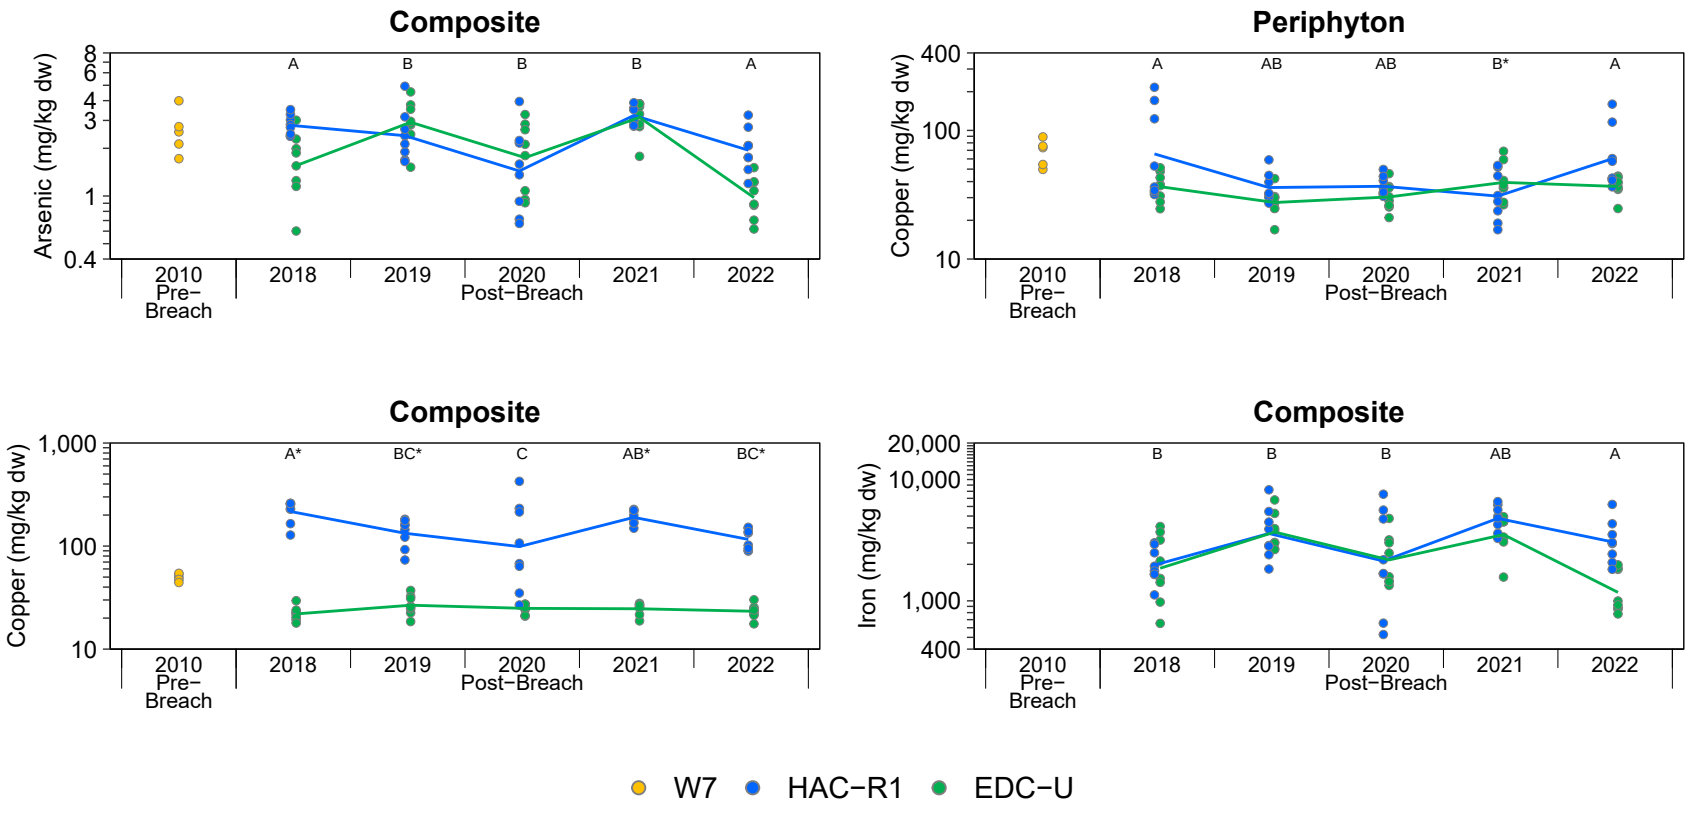

Figure 6.9: Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Upper Hazeltine Creek (HAC-R1; Exposed) and Upper Edney Creek (EDC-U; Reference), 2010 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. W7 (2010) is the pre-breach equivalent of HAC-R1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Plots are only included for primary and secondary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given tissue type. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. Letters with a * designate years where the exposed site is different than pre-breach conditions, as determined using a one-way temporal ANOVA.

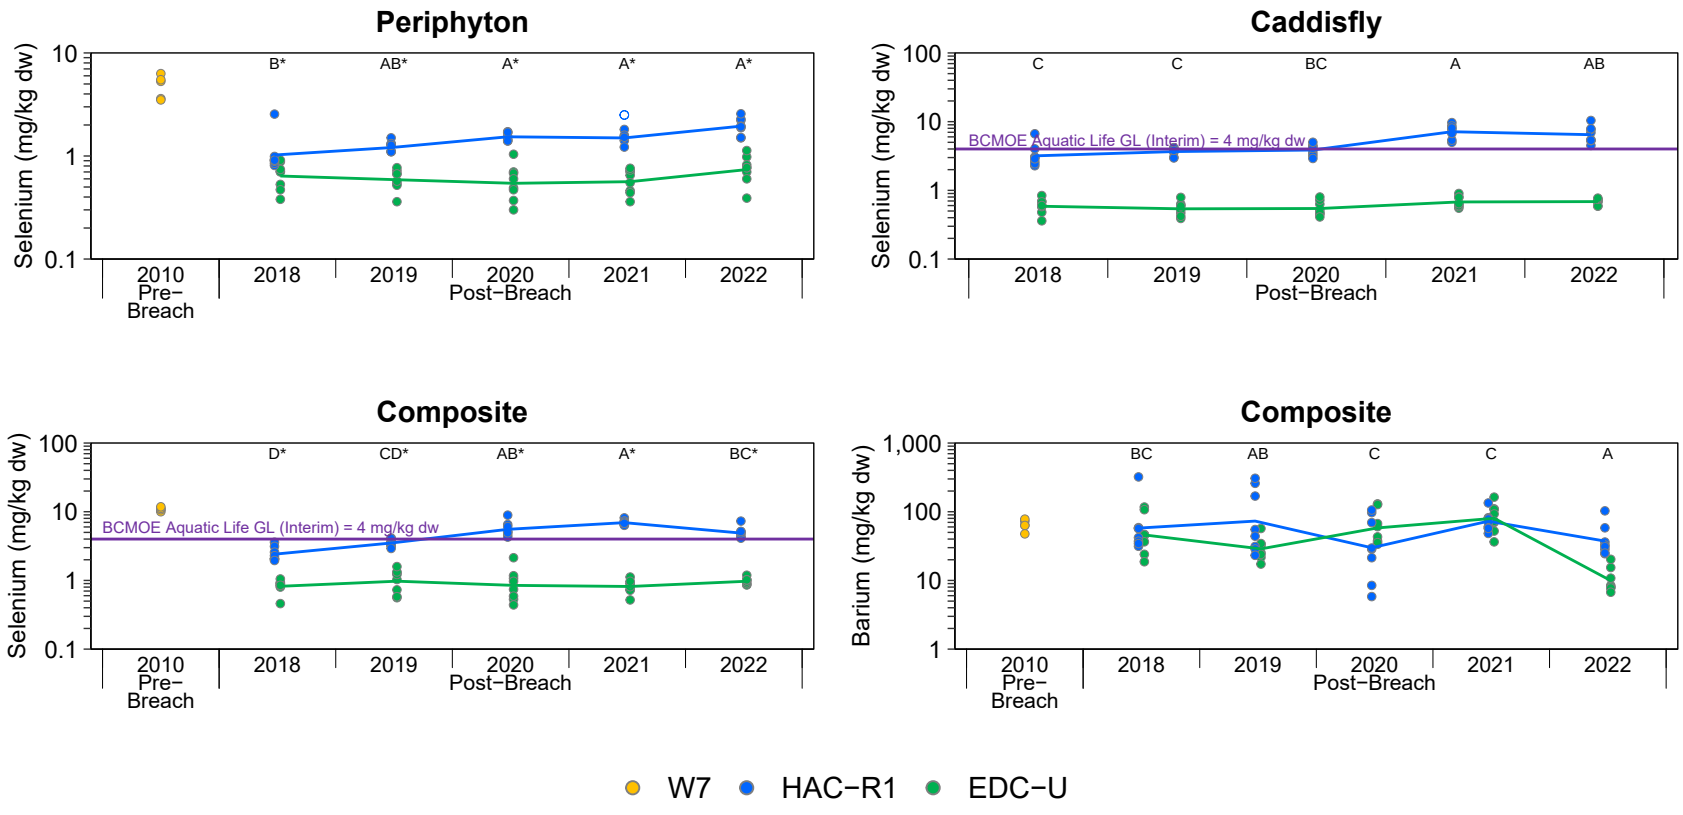

Figure 6.9: Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Upper Hazeltine Creek (HAC-R1; Exposed) and Upper Edney Creek (EDC-U; Reference), 2010 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. W7 (2010) is the pre-breach equivalent of HAC-R1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. Letters with a * designate years where the exposed site is different than pre-breach conditions, as determined using a one-way temporal ANOVA.

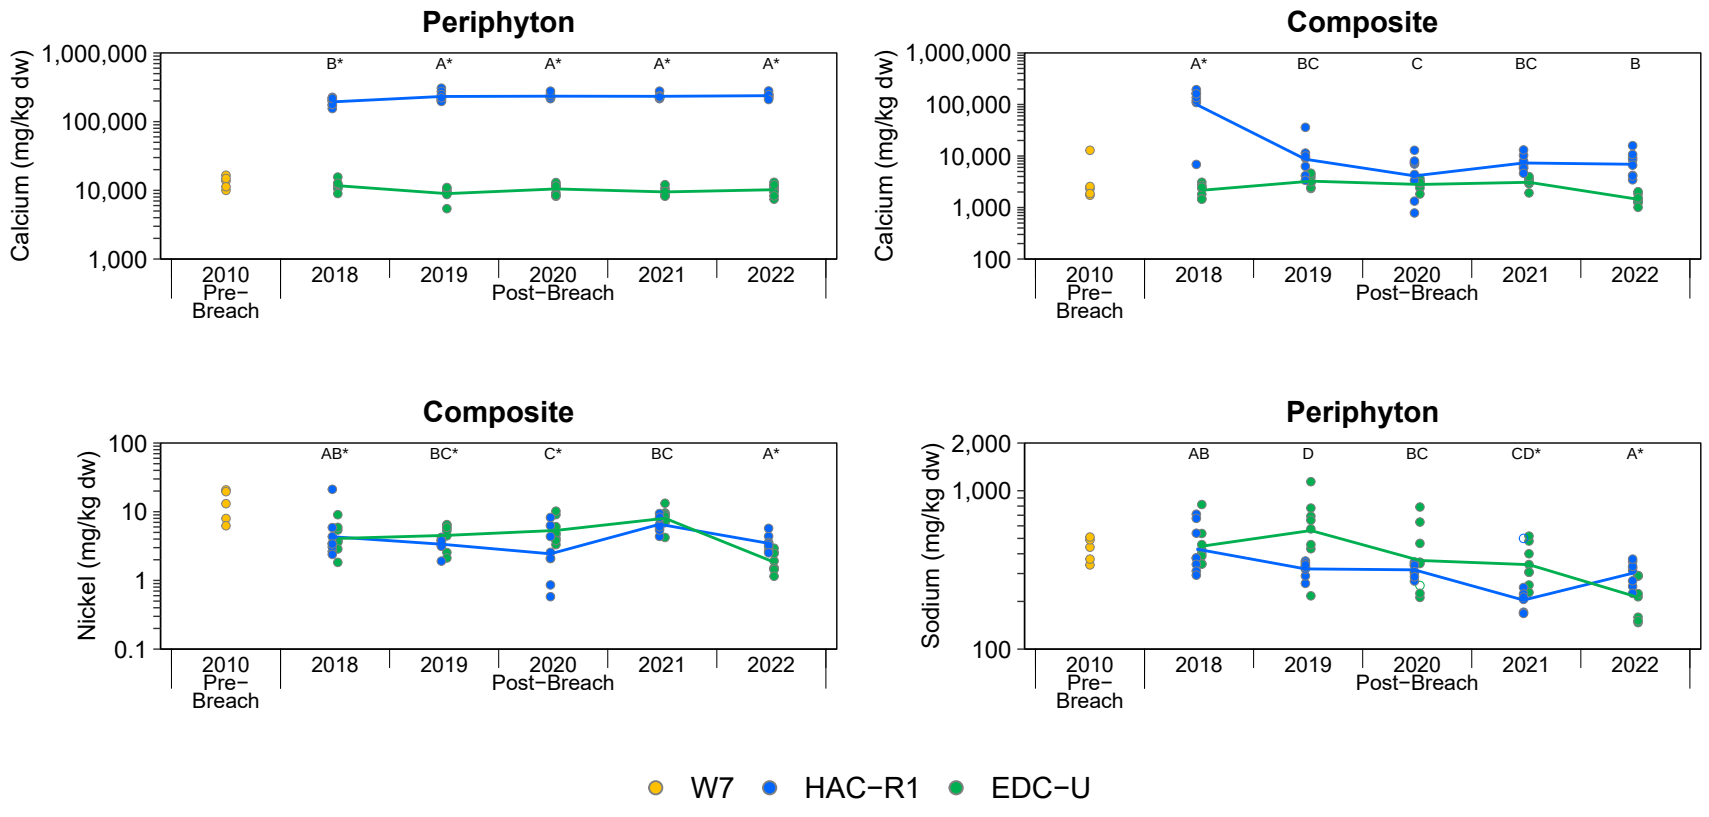

Figure 6.9: Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Upper Hazeltine Creek (HAC-R1; Exposed) and Upper Edney Creek (EDC-U; Reference), 2010 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. W7 (2010) is the pre-breach equivalent of HAC-R1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Plots are only included for primary and secondary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given tissue type. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Figure 6.10: Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Upper Hazeltine Creek (HAC-U; Exposed) and Upper Edney Creek (EDC-U; Reference), 2010 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. W7 (2010) is the pre-breach equivalent of HAC-U. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Plots are only included for primary and secondary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given tissue type. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two −way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. Letters with a * designate years where the exposed site is different than pre-breach conditions, as determined using a one-way temporal ANOVA.

were significantly higher than pre-breach, which was consistent with all previous monitoring years (Figures 6.9 and 6.10, Table 6.7; Appendix Figures F.4.1 to F.4.6, Appendix Tables F.4.1 to F.4.10). Copper TTFs in caddisfly tissues in 2022 for both exposed areas were lower than reference, and significantly lower than 2018, 2019 and 2021 at HAC-R1, and only lower than 2019 at HAC-U (Table 6.9; Appendix Figures F.4.7 to F.4.10, Appendix Tables D.5.7 and D.5.8, F.4.11 to F.4.16). Composite-taxa TTFs for copper at HAC-R1 were consistently higher than reference from 2018 to 2022 but in 2022 were significantly lower than in 2021, relative to reference, which represented a decrease from higher than pre-breach in prior years (2018 to 2021) to similar to pre-breach in 2022 (Table 6.9; Appendix Figures F.4.7 to F.4.10). In contrast, composite-taxa TTFs for copper at HAC-U in 2022 were significantly higher than reference and pre-breach, and were significantly higher than all previous monitoring years, relative to reference (Table 6.9). In summary, copper concentrations in 2022 were elevated relative to reference in most tissue types, were higher than pre-breach in composite-taxa samples but not periphyton for both exposed areas, were similar or lower over time at HAC-R1 for all tissue types, and similar (periphyton and caddisfly tissues) or increased (composite-taxa tissues) over time at HAC-U. Results from 2021 showed little evidence of bioaccumulation of copper in benthic invertebrate tissues (Minnow 2022a). In contrast, results from 2022 for copper in composite-taxa tissues showed evidence of BCFs that were higher than reference and a significant temporal increase in TTFs at HAC-U between 2021 and 2022 (to TTFs that were higher than pre-breach), relative to reference. There is therefore some evidence of copper bioaccumulation in benthic invertebrate biota in 2022 in Reach 2 of upper Hazeltine Creek. However, this was limited to composite-taxa benthic invertebrate tissues from Reach 2 (HAC-U) and was not observed in caddisfly tissues from HAC-U nor in benthic invertebrate tissues (caddisfly or composite-taxa) from Reach 1 (HAC-R1), indicating a potentially localized increase.

Concentrations of selenium in all tissue types from upper Hazeltine Creek were consistently elevated relative to the reference area (EDC-U) from 2018 to 2022 (Figures 6.9 and 6.10, Table 6.7; Appendix Figures F.4.1 to F.4.6, Appendix Tables D.5.1 to D.5.6, F.4.1 to F.4.10). Selenium concentrations in periphyton tissues in 2022 were significantly higher at both exposed areas compared to 2018 but have been temporally stable since 2019 at HAC-R1, and temporally stable since 2020 at HAC-U, relative to reference (Figures 6.9 and 6.10, Table 6.7). In caddisfly tissue, concentrations of selenium in 2022 were similar to 2020 and 2021 but significantly higher than 2018 and 2019 at HAC-R1, and were significantly higher in 2022 than all prior years (2018 to 2021) at HAC-U. For composite-taxa tissue, concentrations of selenium in 2022 were lower than 2021, and similar to 2019 and 2020 but higher than 2018 at HAC-R1, and stable from 2020 to 2022 but higher than 2018 and 2019 at HAC-U (Figures 6.9 and 6.10, Table 6.7). Mean concentrations of selenium in caddisfly (6.69 mg/kg dw at HAC-R1 and 13.1 mg/kg dw

Indicates significantly higher tissue concentration at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

(↑) = Indicates significantly higher tissue concentration relative to pre-breach in 2010 (α = 0.05).
(↓) = Indicates significantly lower tissue concentration relative to pre-breach in 2010 (α = 0.05).
(ns) = no significant different in analyte concentration relative to pre-breach in 2010 (α = 0.05).

Notes: "-" = no statistical comparison could be made since data were not available or all results were below Laboratory Reporting Limit (LRL). Trophic Transfer Function (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated. Refer to Appendix Tables F.4.11 to F.4.16 and F.4.22 to F.4.24 for statistical analyses results and magnitude of difference calculations.

[a] Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., those with a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). Years that share a letter (e.g., A,B,C) had ratios of TTFs (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

at HAC-U) and composite-taxa (4.97 mg/kg dw at HAC-R1 and 6.67 mg/kg dw at HAC-U) tissue samples in 2022 were above the BC interim guideline (4 mg/kg dw; BCMOE 2014) in upper Hazeltine Creek. This is consistent with results from 2020 and 2021 (Figures 6.9 and 6.10) and suggests potential selenium-associated risks to aquatic life. Similar to previous monitoring years, selenium concentrations in periphyton and composite-taxa tissues[66] remained significantly lower than or similar to pre-breach tissue concentrations for both areas of upper Hazeltine Creek (Figures 6.9 and 6.10, Table 6.7; Appendix Figures F.4.1 to F.4.6, Appendix Tables D.5.1 to D.5.6, F.4.1 to F.4.10).

Evaluation of temporal changes in TTFs for selenium showed no significant change in the exposed:reference ratio over time and compared to pre-breach for most tissue types and areas, with one exception. The exception is TTFs for selenium in caddisfly tissue from HAC-U, which were significantly higher in 2022 compared to 2018 to 2020, relative to reference (Table 6.9; Appendix Figures F.4.7 to F.4.10, Appendix Tables D.5.7 and D.5.8, F.4.11 to F.4.16). The increased selenium TTFs for caddisfly tissue at HAC-U in 2022 corresponded with higher dissolved aqueous concentrations and BCFs than reference in 2022, and caddisfly tissue concentrations that were significantly higher than reference and higher than in prior years (2018 to 2021; Tables 6.8 and 6.9). Overall, the significantly higher concentrations of selenium in all tissue types from upper Hazeltine Creek relative to reference, higher TTFs relative to reference, and an increase in the exposed:reference ratio for most tissues since 2018 (except composite-taxa tissues at HAC-R1), suggests a mine-related influence on selenium concentrations in aquatic biota. Since 2021, a significant increase in selenium concentrations and associated TTFs occurred, relative to reference, for caddisfly tissue from Reach 2 (HAC-U) only. The presence of mean selenium concentrations above the guideline for protection of aquatic life indicates potential risks to aquatic biota; however, it is important to note that tissue selenium concentrations in 2022 remained similar to or significantly lower than pre-breach. For periphyton and composite-taxa benthic invertebrate tissue, the occurrence of BCFs for selenium below reference and TTFs results which show no temporal change indicate that the bioavailability and bioaccumulation of selenium in these tissues has not increased due to mine-exposure. However, there is some evidence of increased bioaccumulation of selenium in caddisfly tissues from Reach 2 (HAC-U) of upper Hazeltine Creek, based on increasing TTFs for this tissue over time.

The two other primary analytes (arsenic and iron) only had elevated tissue concentrations relative to reference for composite-taxa tissues (Table 6.7; Appendix Figures F.4.1 to F.4.6, Appendix Tables F.4.1 to F.4.10). Although the exposed:reference ratios for arsenic and iron in

[66] Caddisfly tissue results cannot be compared to pre-breach values because monitoring of this tissue type was initiated in 2018.

composite-taxa tissues from HAC-R1 and arsenic in composite-taxa tissues from HAC-U were significantly higher than previous monitoring years, these differences were due to a temporal decrease in analyte concentrations at the reference area (EDC-U) rather than an increased analyte concentrations at the exposed areas (Figures 6.9 and 6.10, Table 6.7). Composite-taxa tissue concentrations of arsenic in 2022 were similar to pre-breach concentrations at both areas of upper Hazeltine Creek (no pre-breach data exists for iron; Table 6.7; Appendix Tables F.4.7 and F.4.10). The TTFs for arsenic and iron in composite-taxa have been significantly higher than reference for all monitoring years, and for arsenic in composite-taxa tissue the TTFs for both HAC-R1 and HAC-U in 2022 were higher than pre-breach and similar to or higher than previous monitoring years (Table 6.9; Appendix Figures F.4.7 to F.4.10, Appendix Tables F.4.11 to F.4.16). Although composite-taxa tissues BCFs and TTFs were elevated relative to reference in 2022 (Tables 6.8 and 6.9), the absence of increased concentrations of arsenic and iron in composite-taxa tissue (outside of reference contrasts) indicate there is little evidence that either analyte is bioaccumulating in these tissues over time.

Concentrations and TTFs for the nine secondary analytes identified for data interpretation (barium, calcium, nickel, phosphorus, sodium, strontium, titanium, uranium, and vanadium) varied among tissue types (Figures 6.9 and 6.10, Table 6.7; Appendix Figures F.4.1 to F.4.6, Appendix Tables D.5.1 to D.5.8, F.4.1 to F.4.10). Most notable in 2022 was that concentrations of all secondary analytes in caddisfly tissues from HAC-R1 were similar to or lower than reference (Table 6.7). Furthermore, in contrast to 2021 when concentrations of molybdenum and mercury were elevated relative to reference in most caddisfly and all composite tissues (Minnow 2022a), neither analyte was elevated relative to reference in 2022 in benthic invertebrate tissues. Benthic invertebrate tissue concentrations of both molybdenum and mercury were similar to or lower than previous monitoring years (Table 6.7; Appendix Tables F.4.5 to F.4.10), therefore TTFs for these analytes were not included in data interpretation. Periphyton tissues from both upper Hazeltine Creek areas had concentrations of calcium and strontium that were consistently higher than reference and higher than pre-breach in all years (2018 to 2022). Although the concentrations of calcium and strontium in periphyton tissues changed significantly over time, concentrations in 2022 for both analytes were either similar to or lower than previous monitoring years (relative to reference) for both exposed areas (Figures 6.9 and 6.10, Table 6.7; Appendix Figures F.4.1, F.4.2, Appendix Tables F.4.1 to F.4.4). Calcium and strontium in exposed composite-taxa tissues from HAC-R1 and caddisfly and composite-taxa tissues from HAC-U were higher than reference in 2022 (Figures 6.9 and 6.10; Appendix Figures F.4.4 and F.4.6). Composite-taxa tissue concentrations of calcium and strontium in 2022 at both exposed areas were significantly higher than reference. At HAC-R1, concentrations of both analytes were similar to pre-breach and lower than most previous monitoring years (except 2020),

relative to reference, whereas at HAC-U composite-taxa tissue concentrations of these analytes were higher than pre-breach and the concentration (relative to reference) was higher than all previous monitoring years (Figures 6.9 and 6.10, Table 6.7; Appendix Tables F.4.6, F.4.7, F.4.9, F.4.10). Caddisfly tissue concentrations of calcium and strontium in 2022 at HAC-U were also significantly higher than reference but were lower than those observed in 2018 and/or 2019 (Figure 6.10, Table 6.7; Appendix Table F.4.8). Periphyton (but not caddisfly or composite-taxa) tissue concentrations of sodium were significantly higher than reference in 2022 but similar to or lower than pre-breach concentrations for both areas (Figures 6.9 and 6.10, Table 6.7). Evaluation TTFs indicated that calcium, sodium and strontium were similar to or lower than reference in caddisfly or composite-taxa tissues from both exposed areas of upper Hazeltine Creek (Tables 6.9 and 6.10; Appendix Tables F.4.11 to F.4.16).

Composite-taxa tissues from HAC-R1 had concentrations of barium, nickel, titanium, uranium, and vanadium that were significantly higher than reference, but concentrations in 2022 were similar to or lower than pre-breach (where pre-breach data exist) or were temporally stable (Figure 6.9, Table 6.7). Tissues collected from HAC-U in 2022 had analyte concentrations that were higher than reference for uranium in caddisfly, and barium and phosphorous in composite-taxa tissues. However, composite-taxa tissue concentrations of barium were similar to pre-breach (no pre-breach data for phosphorus) and caddisfly tissue uranium concentrations in 2022 were similar to 2019, indicating no temporal increase (Figures 6.9 and 6.10, Table 6.7; Appendix Tables F.4.5 to F.4.10). The similarity (or lower) concentrations of these analytes in 2022 compared to pre-breach, lack of temporal increase relative to 2018/2019, and inconsistencies among tissue types and sampling areas, indicates there is no equivocal evidence that concentrations of these analytes are increased due to a mine-related influence.

6.1.4.3 Lower Hazeltine Creek

For most metals evaluated, there was no evidence of increasing concentrations in periphyton and/or benthic invertebrate tissues at the lower Hazeltine Creek area relative to the reference area over time (Appendix Figures F.4.11 to F.4.13, Appendix Tables D.5.2, D.5.4, D.5.6, D.5.9 to D.5.11, F.4.17 to F.4.21). The primary analytes copper and selenium and seven secondary analytes barium, cadmium, calcium, manganese, molybdenum, phosphorus, and strontium met the criteria for inclusion in data interpretation (i.e., were significantly higher for at the lower Hazeltine Creek exposed area relative to reference in 2022 or in all years; Table 6.7). Of these analytes, only cadmium did not show a significant (*Area×Year*) interaction for at least one tissue type in lower Hazeltine Creek.

MPMC routinely monitors water quality in lower Hazeltine Creek at Station HAC-08 (a station upstream of HAC-D; Figure 4.2). Results from this routine water quality monitoring station

indicated that aqueous concentrations of two primary or secondary analytes (copper and selenium) exceeded the BCWQG during the year preceding sampling (i.e., September 2021 to August 2022). Specifically, concentrations of dissolved copper consistently (100% of samples) exceeded the BLM-based chronic guideline and total selenium concentrations exceeded the chronic BCWQG in one sample (Appendix Table D.1.6). Of the two primary and seven secondary analytes identified for further investigation (above), only dissolved aqueous concentrations of copper, selenium and molybdenum were elevated at HAC-D relative to reference (Table 6.8)[67]. BCFs were slightly elevated (< 2 times higher than reference) for copper in periphyton tissues and not elevated in any tissues for selenium (Table 6.8). The BCFs for barium, cadmium, and manganese were also slightly elevated relative to reference (< 2 times), while BCFs for phosphorus and strontium were 2.0 and 5.2 times higher than reference, and the BCF for calcium in periphyton tissue was the most elevated (18 times higher than reference; Table 6.8). For the most part, BCFs were lower than those observed for upper Hazeltine Creek for the secondary analytes evaluated in 2022, except for calcium and phosphorus (Table 6.8).

Concentrations of copper in periphyton, caddisfly, and composite-taxa tissues from lower Hazeltine Creek were consistently elevated relative to the lower Edney creek reference area (EDC-D) in most sampling years, except for caddisfly tissue in 2018. In addition, copper concentrations in periphyton and caddisfly tissues were consistently higher than pre-breach in most sampling years, except 2018 for composite-taxa tissues (pre-breach data do not exist for caddisflies; Figure 6.11, Table 6.7; Appendix Figures F.4.11 to F.4.13, Appendix Tables D.5.2, D.5.4, D.5.6, D.5.9 to D.5.11, F.4.17 to F.4.21). However, the mean copper concentrations in each tissue type in 2022 were significantly lower than in 2021 and were similar to or lower than previous monitoring years, relative to reference (Figure 6.11, Table 6.7). Evaluation of temporal changes in TTFs for copper showed results different to those from upper Hazeltine Creek. The copper TTFs for caddisfly and composite taxa-tissues were similar to or lower than reference in all years, and for composite-taxa tissues were temporally stable and similar to or lower than pre-breach (Table 6.9; Appendix Tables D.5.7 and D.5.8, F.4.22 to F.4.24). Overall, although copper concentrations in periphyton and benthic invertebrate tissues were significantly higher than reference and pre-breach (where pre-breach data exist), the BCFs were only slightly higher (periphyton, by 1.7 times) or lower than reference (caddisfly and composite-taxa; Table 6.8), and the TTFs were similar to or lower than reference and pre-breach.

[67] Elevated analytes were identified as those with mean concentrations at the exposed station that were at least twice the mean concentration at the reference station.

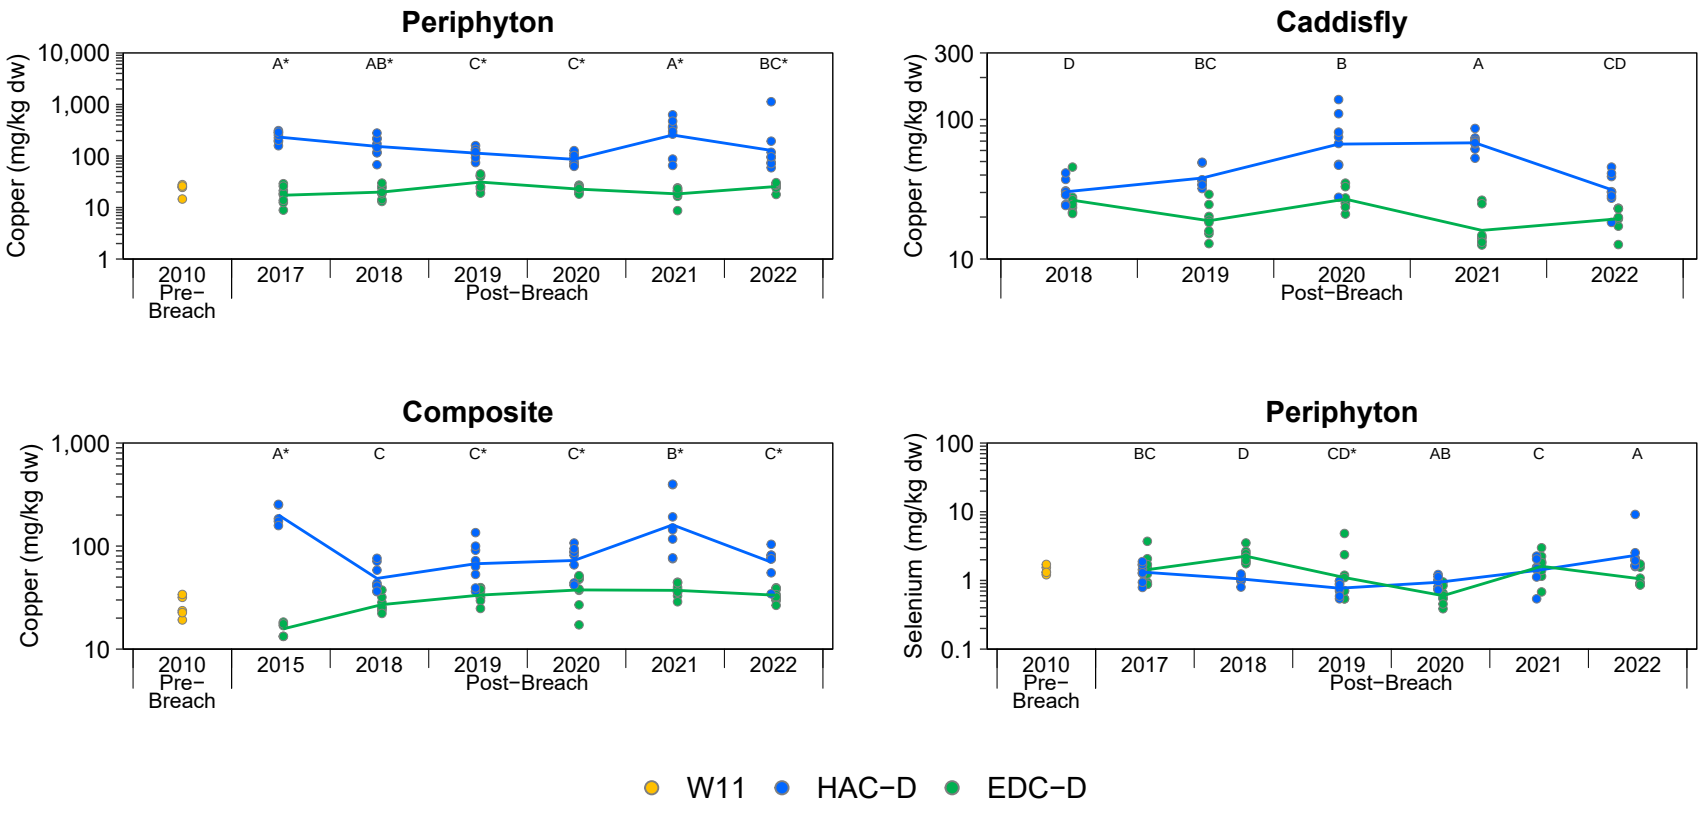

Figure 6.11: Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Lower Hazeltine Creek (HAC-D; Exposed) and Lower Edney Creek (EDC-D; Reference), 2010 to 2022

Notes: BCMOE = British Columbia Ministry of the Environment; GL = Guideline; dw = dry weight. W11 (2010) is the pre-breach equivalent of HAC-D. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Plots are only included for primary and secondary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given tissue type. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted. Letters with a * designate years where the exposed site is different than pre-breach conditions, as determined using a one-way temporal ANOVA.

These findings indicate there is no evidence of increasing tissue concentrations or bioavailability of copper over time in biota from lower Hazeltine Creek.

Selenium concentrations in periphyton, caddisfly and composite-taxa tissues from lower Hazeltine Creek were significantly higher compared to the reference area in 2022 (Figure 6.11, Table 6.7; Appendix Figures F.4.11 to F.4.13, Appendix Tables F.4.17 to F.4.21). Selenium concentrations in periphyton and caddisfly in 2022 were higher than most prior years (periphyton: 2017 to 2021 except 2020; caddisfly: 2018 to 2020). In composite-taxa tissues, selenium concentrations in 2022 were similar to most prior years but higher than in 2018 and 2019 (Figure 6.11, Table 6.7). Compared to pre-breach conditions, selenium concentrations in periphyton tissue were similar to or lower than pre-breach in all years. In contrast, selenium concentrations in composite-taxa were lower than pre-breach in 2015, 2019, similar to pre-breach in 2018 and 2020, and increased to higher than pre-breach in 2021 and 2022 (Figure 6.11, Table 6.7; Appendix Tables F.4.18 and F.4.21). Mean selenium concentrations in caddisfly (4.58 mg/kg dw) and composite-taxa (4.54 mg/kg dw) were slightly above the BC interim guideline (4 mg/kg dw; BCMOE 2014) in 2022, which is consistent with 2021 but differs from prior years (2015 to 2020) when mean concentrations were below the guideline (Figure 6.11, Table 6.8; Appendix Tables D.5.5, D.5.7, D.5.10, D.5.11). The elevation of mean selenium concentrations over the guideline, although slight, suggests potential selenium-associated risks to aquatic life. The TTFs for selenium were similar to reference in 2022 (caddisfly tissues) or were higher than reference but temporally stable (composite-taxa tissues), which indicate selenium is not accumulating in aquatic biota over time (Table 6.9; Appendix Tables D.5.7 and D.5.8, F.4.22 to F.4.24). Overall, BCFs were lower than reference for all tissue types (Table 6.8) and the TTFs indicate there is no evidence of increasing bioavailability of selenium over time in lower Hazeltine Creek (Table 6.9). However, selenium concentrations in all exposed tissues in 2022 were significantly elevated relative to reference and were significantly higher in 2022 compared to 2018 and 2019 (for all tissues), relative to reference. In benthic invertebrate tissues, selenium concentrations that were previously below the interim guideline and pre-breach concentrations (2015 and 2019) were higher than the guideline and pre-breach concentrations in 2021 and 2022. Therefore, there is some evidence of a temporal increase in tissue selenium concentrations in lower Hazeltine Creek, and the elevation of mean selenium concentrations over the guideline for protection of aquatic life, although slight, suggests potential selenium-associated risks to aquatic life.

Temporal changes in the seven secondary analytes identified for data interpretation (barium, cadmium, calcium, manganese, molybdenum, phosphorus, and strontium) differed between tissue types from lower Hazeltine Creek (Figure 6.11, Table 6.7; Appendix Figures F.4.11 to F.4.13, Appendix Tables F.4.17 to F.4.21). Most notable in 2022 was that concentrations of all secondary analytes in caddisfly tissues from lower Hazeltine Creek were

either similar to or lower than reference (Table 6.7; Appendix Table F.4.16). A similar result was observed for caddisfly tissues at HAC-R1 in 2022 (see Section 6.1.4.2). Periphyton tissue concentrations of cadmium, calcium, phosphorus, and strontium were significantly elevated relative to reference in 2022 (Figure 6.11, Table 6.7; Appendix Tables F.4.17 and F.4.18). Tissue concentrations of cadmium were similar to pre-breach in 2022, which is consistent with previous monitoring years, and concentrations were temporally stable from 2017 to 2022, relative to reference (Figure 6.11, Table 6.7). Periphyton tissue concentrations of calcium and strontium in 2022 were significantly higher than pre-breach, and while differences in concentration (relative to reference) have varied from 2017, these differences were significantly higher than most previous monitoring years (except 2020; Figure 6.11, Table 6.7). However, these changes in the concentrations of calcium and strontium (relative to reference) in 2022 were driven by both a decrease in tissue concentration at the reference area and an increase in tissue concentrations at HAC-D in 2022 (with the exposed:reference ratio in 2022 being significantly higher than previous years; Figure 6.11, Table 6.7). Periphyton tissue concentrations for phosphorus were higher than pre-breach, the difference between exposed and reference were significantly higher than all previous monitoring years from 2017 except 2021, and the concentration of phosphorus (for the first time since monitoring began in 2017) was higher than reference in exposed tissues (Figure 6.11, Table 6.7; Appendix Tables F.4.17 and F.4.18).

Composite-taxa tissues from lower Hazeltine Creek had concentrations of barium, calcium, manganese, molybdenum, and strontium that were significantly elevated relative to reference, but that were similar to or lower than pre-breach tissue concentrations in 2022 (Figure 6.11, Table 6.7). Concentrations of these analytes in composite-taxa tissues in 2022 were similar to or lower than in the first year of monitoring (2015), except for molybdenum which was similar to or lower than concentrations from 2018 to 2021, relative to reference (Figure 6.11, Table 6.7; Appendix Tables F.4.14, F.4.15). Therefore, there is no evidence of a temporal increase in the concentrations of these secondary analytes in composite-taxa tissues, relative to reference. Calcium and strontium were the only two secondary analytes that were also significantly higher than reference in 2022 in other tissue types (i.e., periphyton) and which also showed a temporal increase, relative to reference (see description above).

The TTFs for most of the secondary analytes discussed above (barium, calcium, manganese, molybdenum, and strontium) in caddisfly and composite-taxa tissues from lower Hazeltine Creek in 2022 were similar to or lower than reference (Table 6.9; Appendix Figures F.4.14 and F.4.15, Appendix Tables D.5.7, D.5.8, F.4.22 to F.4.24). For manganese and molybdenum in composite taxa tissues, the TTFs in 2022 were significantly higher than reference (Table 6.9). A significant increase in the exposed:reference ratio for composite-taxa TTFs has not been observed since 2019 for any of the five secondary analytes assessed (including manganese

and molybdenum), and the TTFs for these five secondary analytes in composite-taxa tissue were lower than or similar to pre-breach (Appendix Tables F.5.18 to F.5.20, Appendix Figures F.5.13 and F.5.14). In addition, manganese and molybdenum did not have BCFs higher than reference. Overall, the TTFs for barium, calcium, manganese, molybdenum, and strontium in benthic invertebrate tissues were either similar to or lower than reference, temporally stable since 2019 (for those analytes with TTFs higher than reference), and similar to or lower than pre-breach, indicating there is no evidence of increased bioaccumulation of these analytes in aquatic biota in lower Hazeltine Creek.

6.1.4.4 Tissue-Type Comparison

A comparison between benthic invertebrate (caddisfly and composite) tissue findings was completed to evaluate if results were consistent between the two tissue types. This qualitative comparison focused on analytes with a significant positive exposed-reference difference (i.e., analytes with concentrations that were significantly higher in tissues from the exposed area compared to those from the reference area) in 2022 or in all monitoring years for at least one tissue type in at least one area.

In upper Hazeltine Creek, selenium was the only primary analyte for which both benthic invertebrate tissue concentrations (caddisfly and composite-taxa) and TTFs in 2022 were higher at HAC-R1 and HAC-U than reference. However, for selenium only the TTFs in caddisfly tissues from HAC-U had a significant (*AreaxYear*) interaction which indicates there has been a significant increase in TTFs over time (Tables 6.9 and 6.10). For both areas of upper Hazeltine Creek, the TTFs for arsenic, iron, cadmium, manganese, nickel, phosphorus, uranium, and vanadium were elevated relative to reference in both caddisfly and composite-taxa tissues, however tissue concentrations for most of these analytes were not similarly elevated in both tissue types (Table 6.10; see Section 6.1.4.2 for detailed discussion of these results). Molybdenum and titanium were the only analytes for which tissue concentrations were similar to reference (for at least one area) and TTFs were elevated in caddisfly tissues but not composite-taxa tissues (Table 6.10). Barium was the only analyte for which only composite-taxa tissues had a higher concentration and TTFs for both exposed areas (Table 6.10). Overall, there were only a handful of instances when higher tissue concentrations or TTFs relative to reference occurred in caddisfly tissues from upper Hazeltine Creek that were undetected in composite-taxa samples (i.e., molybdenum and titanium TTFs at HAC-U, and uranium tissue concentrations at HAC-U; Table 6.10). In addition, there were also a few instances when significant temporal increases in the TTFs for analytes in caddisfly tissues occurred that were undetected in composite-taxa samples (i.e., no temporal change in analyte TTFs was detected in composite-taxa tissues): nickel at HAC-R1, and iron, selenium, and vanadium at HAC-U (Table 6.10).

Table 6.10: Summary Magnitude of Difference (MOD)[a] of Exposed - Reference Contrasts of Primary and Secondary Analyte Concentrations and Trophic Transfer Factors (TTFs) in Caddisfly and Composite-Taxa Benthic Invertebrate Tissue for Upper Hazeltine Creek (HAC-R1, HAC-U; Exposed), Upper Edney Creek (EDC-U; Reference), Lower Hazeltine Creek (HAC-D; Exposed), and Lower Edney Creek (EDC-D; Reference), 2022

Indicates significantly higher tissue concentration or TTF at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly higher tissue concentrations or TTF at exposed compared to reference area (α = 0.05), without a significant (Area x Year) interaction of the two-way ANOVA. Values represent the MOD exposed:reference, which did not change significantly among monitoring years.

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.7 (i.e., analytes that had a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = not enough data available for test or comparison, ns = no significant difference between exposed at reference area. TTF calculated as (benthic invertebrate tissue analyte concentration) / (periphyton tissue analyte concentration).

[a] Magnitude of difference (MOD) calculated on backtransformed least-squares means as (Exp-Ref)/Ref x 100%.

At lower Hazeltine Creek (HAC-D) in 2022, none of the secondary analytes had higher concentrations or TTFs relative to reference in caddisfly tissues, but copper and selenium (primary analytes) were significantly higher than reference (Table 6.10). Only selenium, manganese, and molybdenum had both elevated tissues concentrations and TTFs relative to reference in composite-taxa tissue, and of these analytes, only TTFs for manganese increased significantly over time (but not since 2019; Tables 6.9 and 6.10). Iron, nickel, titanium, uranium, and vanadium had elevated TTFs, however tissue concentrations of these analytes were not similarly elevated in 2022 (Table 6.10). For lower Hazeltine Creek, there were no instances when higher tissue concentrations or TTFs relative to reference occurred in caddisfly tissues from upper Hazeltine Creek that were undetected in composite-taxa samples from this area (Table 6.10).

When comparing the magnitude of the exposed:reference ratio of analyte concentrations and TTF results in 2022, the magnitude of most ratios was lower in caddisfly samples compared to composite samples (Table 6.10). However, differences in exposed:reference ratios for tissue concentrations were consistently higher in caddisfly tissues compared composite-taxa tissues for selenium for all three exposed areas, and for uranium at HAC-U (Table 6.10). Among all areas (HAC-R1, HAC-U, and HAC-D), there were only a few instances when higher tissue concentrations or TTFs relative to reference occurred in caddisfly tissues that were undetected in composite-taxa samples (these are outlined above). Combined, these results indicate that if sampling were limited to composite-taxa tissue samples only, potential changes in tissue concentrations and TTFs in caddisfly tissues would largely be detected by continued monitoring composite-taxa tissues, which is consistent with results reported in 2020 and 2021 (Minnow 2021a, 2022a).

6.1.5 Summary

Sediment quality monitoring completed in upper and lower Hazeltine Creek in 2022 continued to document the physical and chemical characteristics of sediments from this erosional habitat. Sediments were characterized by concentrations of several analytes that were greater than reference/pre-breach concentrations and WSQG values: copper and selenium in upper Hazeltine Creek, and copper and iron in lower Hazeltine Creek. In both upper and lower Hazeltine Creek in 2022, copper was the most substantially elevated analyte with concentrations 2.0 and 1.7 times higher than the upper WSQG, respectively, and higher than reference/pre-breach concentrations. The TOC content of sediments from upper Hazeltine Creek was significantly higher in 2022 than in 2018, relative to reference, as were the concentrations of copper and selenium. Mean concentrations of copper and selenium in upper Hazeltine Creek sediments were significantly higher in 2022 than previously observed (2018 to 2021), relative to reference. For both analytes, this change was driven by a significant decrease in sediment copper and

selenium concentrations at the reference area, with copper concentrations within upper Hazeltine Creek sediments (i.e., not evaluated relative to reference) showing temporal stability. Sediment selenium concentrations evaluated within upper Hazeltine Creek in 2022 (not relative to reference) were significantly higher than in preceding years (2018 to 2020) which was associated with higher TOC and lower sand content of these sediments. In lower Hazeltine Creek, the TOC content of lower Hazeltine Creek sediments has remained unchanged relative to reference from 2018 to 2022. Copper and iron concentrations in lower Hazeltine Creek sediments in 2022 were similar to or lower than those observed in 2018, relative to reference, indicating sediment concentrations of these analytes have not increased significantly over that period. The 2022 sediment quality monitoring results continue to indicate that results related to variable sediment physical characteristics (i.e., TOC and sand content) that are driven by the necessity for opportunistic sampling due to limited availability of fine sediments in some monitoring years. The variability in sediment physical characteristics may stabilize as sediment accumulation continues to occur in this remediated system.

Periphyton monitoring indicated that primary productivity of upper Hazeltine Creek, as assessed by mean chlorophyll-a (mass per unit area; mg/m^2), was below BCWQG but above the threshold indicative of moderate enrichment in lower Hazeltine Creek. Primary productivity as measured by both chlorophyll-a and AFDM at both upper Hazeltine Creek areas (HAC-R1, HAC-U) has been consistently similar to or significantly higher than reference from 2018, and higher than pre-breach since 2019 at HAC-R1 and since 2021 at HAC-U. Chlorophyll-a concentrations and AFDM at HAC-R1 in 2022 were significantly higher than at HAC-U, indicating this area had greater periphyton productivity. Despite the increased productivity following remediation, water quality monitoring indicates that dissolved oxygen concentrations largely remain above the long-term BCWQG in upper Hazeltine Creek. The periphyton community of upper Hazeltine Creek in 2022 was characterized by taxon richness, Simpson's Evenness and Diversity, and diatom richness that were similar to or higher than the reference area. Periphyton densities in 2022 at HAC-R1 and HAC-U were similar to and lower than reference, respectively, but were temporally stable at HAC-U despite being lower than reference in 2022. The periphyton communities at the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) were similar in 2022 in terms of all primary metrics (density, taxon richness, Simpson's Evenness and Diversity, and diatom richness) indicating similar recovery of the periphyton community in these two areas. Periphyton community composition at HAC-R1, but not HAC-U, was similar to reference in 2022. Community composition at HAC-U continued to differ from the reference area, with higher and lower relative densities of Diatoms and Cyanobacteria, respectively; differences which are indicative of healthy periphyton communities. The similarity (or exceedance) of the primary periphyton community metrics (density, richness, Simpson's Evenness, and Simpson's Diversity)

in upper Hazeltine Creek compared to the reference area in most years and/or temporal stability of these metrics are indicative of relatively stable periphyton communities at the remediated upper Hazeltine Creek areas and good periphyton community health.

The benthic invertebrate community of upper Hazeltine Creek in 2022 was characterized by total density, taxon richness, and Simpson's Evenness and Diversity that were similar between the two areas (HAC-R1 and HAC-U) and that were similar to reference and/or pre-breach conditions. Taxon richness at HAC-R1 in 2022 remained significantly lower than pre-breach conditions but was similar to reference conditions. These results indicate that the benthic invertebrate community at these areas of upper Hazeltine Creek have largely recovered to reference and/or pre-breach conditions when primary metrics (density, richness, Simpson's Evenness and Diversity) are considered. Key differences in the benthic community structure in 2022 at both areas of upper Hazeltine Creek, compared to pre-breach conditions, included higher relative densities of Chironomidae and Trichoptera, and lower relative densities of EPT (at HAC-R1 only), Arachnida (at HAC-U only), Ephemeroptera, and Plecoptera. Notable differences in EPT at both areas of upper Hazeltine Creek, compared to reference and pre-breach, were due to the lack of Plecoptera and the higher relative density of Trichoptera, which were dominated by a family of net-spinning caddisflies (Hydropsychidae) that are tolerant of habitat disturbances. The occurrence of Ephemeroptera families at the exposed areas that are less pollutant tolerant than those at the reference area suggests the chemical conditions (i.e., water chemistry) of the exposed areas are not limiting for benthic invertebrate community recovery. Comparison of community composition between the two upper Hazeltine Creek areas suggested greater recovery of the benthic invertebrate community in Reach 2 (at HAC-U) compared to Reach 1 (at HAC-R1), based on lower and higher relative densities of Chironomidae and Trichoptera at HAC-U compared to HAC-R1, respectively. Benthic invertebrate total dry weight biomass at both upper Hazeltine Creek areas in 2022 was unchanged since 2019 and was either similar to or higher than reference in each year from 2018 to 2022. In summary, these results indicate that both areas of upper Hazeltine Creek have recovered substantially since remediation to a condition that is similar to reference and/or pre-breach conditions based on primary metrics, but with some remaining differences in community composition compared to reference and pre-breach.

Periphyton and benthic invertebrate tissue quality monitoring in upper and lower Hazeltine Creek indicated that the primary analytes arsenic, copper, iron, and selenium had higher tissue concentrations compared to reference in 2022 for which the exposed-reference difference also increased significantly over time. There is some evidence of increased bioavailability and trophic transfer of copper in benthic invertebrate tissues in upper Hazeltine Creek, since BCFs and TTFs were elevated relative to reference and TTFs for composite-taxa tissues from HAC-U increased in 2022 to higher than pre-breach conditions. However, this was limited to composite-taxa benthic

invertebrate tissues from Reach 2 (HAC-U) and was not observed in caddisfly tissues from HAC-U nor in benthic invertebrate tissues (caddisfly or composite-taxa) from Reach 1 (HAC-R1) of upper Hazeltine Creek, indicating a potentially localized increase. In contrast, there is no evidence of increasing tissue concentrations or bioavailability and trophic transfer of copper over time in biota from lower Hazeltine Creek. For selenium, BCFs were lower than reference in periphyton tissues and elevated in caddisfly, but not composite-taxa samples (upper Hazeltine Creek only) and TTFs were typically stable over time compared to reference (except for caddisflies in Reach 2 of upper Hazeltine Creek). These results indicate that the bioavailability and trophic transfer of selenium has not increased due to mine influence, except for increased trophic transfer in caddisflies from Reach 2 of upper Hazeltine Creek. Selenium concentrations in most tissues in Hazeltine Creek (upper and lower) have increased since 2018 compared to reference (except composite-taxa benthic invertebrate samples from lower Hazeltine Creek), suggesting a mine influence on tissue concentrations, if not bioavailability and trophic transfer of selenium. In upper Hazeltine Creek, tissue selenium concentrations in 2022 were similar to or lower than pre-breach results in comparable tissues, while those in composite-taxa benthic invertebrate samples from lower Hazeltine Creek in 2022 exceeded pre-breach results. Mean selenium concentrations in benthic invertebrates from upper and lower Hazeltine Creek were above the BC interim guideline for aquatic life, suggesting potential selenium-associated risks to aquatic life. In composite-taxa benthic invertebrate samples from upper Hazeltine Creek, arsenic and iron concentrations in tissues from Reach 2 (HAC-U) and Reach 1 (HAC-R1), respectively, were higher in 2022 than previous monitoring years compared to reference, but this was owing to a temporal decrease at the reference area rather than an increase in tissues from upper Hazeltine Creek. Elevated concentrations of some secondary analytes in periphyton and/or benthic invertebrate tissues over time were also observed, relative to reference, but evidence was equivocal as to whether these observed increases in tissue concentrations were mine-related, and there was little or no evidence of increased metal bioavailability (based on assessment of BCFs and TTFs relative to reference and pre-breach). In comparison to 2021 when higher tissue concentrations and trophic transfer of mercury were identified compared to reference, mercury results in 2022 did not continue to demonstrate higher bioaccumulation in the aquatic biota compared to reference (as evidenced by tissue concentrations and TTFs similar to or lower than reference and/or prior years). Overall, periphyton and benthic invertebrate tissue quality data showed some evidence of moderately higher bioavailability and/or trophic transfer of selenium and copper in upper Hazeltine Creek, and selenium in lower Hazeltine Creek. Comparison of the two benthic invertebrate tissue types (caddisfly and composite-taxa) indicated that although some variability exists between the tissues, potential changes in analyte concentrations and TTFs in caddisfly tissues would largely be detected if sampling were limited to composite-taxa tissue samples only.

6.2 Edney Creek

6.2.1 Periphyton and Benthic Invertebrate Tissue Quality

Periphyton and benthic invertebrate tissue samples were collected from the remediated (exposed) section of lower Edney Creek (E1), with an upstream area of Edney Creek unaffected by the breach (EDC-D) serving as reference (Figure 4.2, Table 4.4). A review of the 2022 periphyton and benthic invertebrate tissue quality data (Appendix B) indicated that the data largely met the established DQOs, although laboratory and field precision were low (see Section 6.1.4.1 for details) and the heterogeneity in analyte results were considered during data interpretation. A review of 2022 supporting water data quality indicated these data can be used with a good level of confidence for interpretation (see Section 5.1.1 for details).

As indicated in Section 4.4.3.2, data interpretation was focused on primary and secondary analytes (Table 2.4) with a significant positive exposed-reference difference (i.e., analytes with concentrations that were significantly higher in tissues from the remediated [exposed] area compared to those from the reference area) in 2022 (if the analysis *Area*×*Year* interaction was significant) or in all monitoring years (if the *Area*×*Year* interaction was not significant[68]) for at least one tissue type (periphyton, caddisfly, or composite-taxa benthic invertebrate). Data interpretations were further focused by integrating the results of water quality monitoring (i.e., bioconcentration) and trophic transfer factors (TTFs) of benthic invertebrate tissue analyte concentrations as detailed in Section 6.1.4.1. Combined, these approaches were used to identify analytes for which concentrations in biota and TTFs at the exposed areas have increased at a rate that differs from reference and that may represent a potential risk to aquatic biota. Results for composite-taxa benthic invertebrate tissue samples are referred to as composite-taxa for the remainder of this section.

For most metals evaluated, there was no evidence of increasing metal concentrations in periphyton and/or benthic invertebrate tissues from the exposed (E1) relative to the reference (EDC-D) area over time (Appendix Figures F.4.16 to F.4.18, Appendix Tables D.5.2, D.5.4, D.5.6, D.5.9 to D.5.11, F.4.25 to F.4.27). The primary analyte copper and the nine secondary analytes cadmium, calcium, cobalt, silver, sodium, strontium, titanium, vanadium, and zinc met the criteria for inclusion in data interpretation (i.e., were significantly higher at the lower Edney Creek exposed area relative to reference in 2022 or in all years; Table 6.11). Of these analytes, only copper

[68] If no significant change was detected in the exposed:reference ratio among years (i.e., the *Area* x *Year* interaction was not significant), then data from all available years were combined for the analyses.

Table 6.11: Summary of Statistical Contrasts of Exposed - Reference Relative Differences of Primary and Secondary Analyte Concentrations in Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue for Lower Edney Creek (E1 [Exposed]; EDC-D [Reference]), 2019 to 2022 [a]

Analytes		Lower Edney Creek (E1; Exposed) / Lower Edney Creek (EDC-D; Reference)											
		Periphyton				Caddisfly				Composite-Taxa Benthic Invertebrate			
		2019	2020	2021	2022	2019	2020	2021	2022	2019	2020	2021	2022
Primary Analyte	Copper	A	A	A	A	C	B	B	A	B	AB	A	AB
Secondary Analyte	Cadmium	A	A	A	A	A	A	A	A	A	A	A	A
	Calcium	BC	B	A	C	B	B	B	A	A	A	A	A
	Cobalt	A	A	A	A	A	A	A	A	A	A	A	A
	Silver	AB	A	AB	B	B	B	AB	A	A	A	A	A

	Strontium	B	B	A	B	B	B	B	A	B	AB	A	A
	Titanium	BC	AB	A	C	A	A	A	A	A	A	A	A
	Vanadium	BC	A	AB	C	A	A	A	A	A	A	A	A
	Zinc	A	A	A	A	B	A	AB	A	A	A	A	A

Indicates significantly higher tissue concentration at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Notes: "-" = no statistical comparison could be made because data were not available or all were results below Laboratory Reporting Limit (LRL). Refer to Appendix Tables F.4.25 to F.4.27 for statistical analyses results and magnitude of difference calculations.

[a] Results are shown for primary and secondary analytes that had a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types (periphyton, caddisfly, or composite benthic invertebrate) in at least one area. Years that share a letter (e.g., A,B,C) had ratios of analyte concentrations (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

calcium, silver, strontium, and zinc had a significant (*Area×Year*) interaction and significant positive exposed-reference difference for at least one tissue type in 2022 (Table 6.11; Appendix Tables F.4.25 to F.4.27).

MPMC implements routine water quality monitoring in lower Edney Creek at Station EDC-01a, a station within sampling area E1 (Figure 4.2). Results from this routine water quality monitoring station indicated that aqueous concentrations of dissolved copper exceeded the BLM-based chronic BCWQG in 75% of samples in the year preceding sampling (i.e., September 2021 to August 2022). Of the one primary analyte (copper) and the nine secondary analytes identified above for further evaluation (above), only dissolved aqueous concentrations of copper exceeded the reference concentrations by more than two times, while the cadmium, calcium, sodium, strontium, and vanadium were slightly (< 2 times) higher than the reference area (EDC-U; Table 6.12)[69]. Overall, this indicates very similar water quality between the exposed and reference areas, except for elevated dissolved copper concentrations, which was consistent with little to no upstream mine-related influence in lower Edney Creek. Mean BCFs were slightly (less than two-times) higher than reference for calcium, sodium, strontium, and vanadium and slightly greater than two-times reference for copper and cadmium for at least one tissue type (Table 6.12).

Copper concentrations in all three tissue types (periphyton, caddisfly, and composite-taxa) were significantly higher at the exposed area in 2022 relative to reference (Table 6.11; Appendix Tables D.5.9, F.4.25). Concentrations of copper in exposed periphyton tissues were consistently higher than the reference area (from 2019 to 2022), but the difference relative to reference was temporally stable (i.e., *AreaxYear* interaction was not significant; Figure 6.12, Table 6.11; Appendix Table F.4.25). Copper concentrations in exposed caddisfly tissues were higher than reference from 2020 to 2022 and were significantly higher in 2022 than in all prior years (2019 to 2021), relative to reference (Figure 6.12, Table 6.11; Appendix Tables D.5.4, D.5.10, F.4.26). For exposed composite-taxa tissues, copper concentrations were higher than reference in 2021 and 2022, but concentrations in 2022 were similar to all previous monitoring years (2019 to 2021) indicating temporal stability (Figure 6.12, Table 6.11; Appendix Tables D.5.6, D.5.11, F.4.27). Despite concentrations of copper in caddisfly and composite-taxa tissue in 2022 that were significantly higher than reference, TTFs for copper in both tissues from the exposed area were lower than reference in all years (Table 6.13; Appendix Figures F.4.19, F.4.20, Appendix Tables D.5.7, D.5.8, F.4.28, F.4.29). The elevated concentrations of copper in exposed caddisfly and composite-taxa tissues compared to reference in 2022, but lower TTFs in

[69] Elevated analytes were identified as those with mean concentrations at the exposed station that were at least twice the mean concentration at the reference station.

Table 6.12: Summary of Primary and Secondary Analytes Concentrations in Water, Periphyton, Composite-Taxa, and Caddisfly Tissues, BCFs and TTFs for Lower Edney Creek (E1 [Exposed]; EDC-D [Reference]), 2022

Analytes		Component	Metric	Units	n	Area	
						Reference	Breach-exposed
						Lower Edney Creek

Dissolved concentration at exposed area exceeded reference area by less than 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 2-times.
Dissolved concentration at exposed area exceeded reference area by at least than 5-times.
Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05).
Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05).
BCF for exposed area exceeded reference area by less than 2-times.
BCF for exposed area exceeded reference area by at least 2-times.
BCF for exposed area exceeded reference area by at least 10-times.
Mean TTF exceeds 1.
Mean TTF at exposed area exceeds 1 and the corresponding reference area TTF for a given year.

BOLD = mean tissue selenium value exceeds long-term benthic invertebrate tissue guideline for selenium (4 mg/kg dw; BCMOE 2014).

BOLD/ITALICS = Indicates dissolved water value greater than the long-term average British Columbia Water Quality Guideline (BCMOECCS 2021a,b).

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.11 (i.e., those with a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = Dissolved water concentration not data available or BCF/TTF was not calculated for analytes because no data available for calculation or one or more result used in the calculation was below the Laboratory Reporting Limit (LRL); "na" = not applicable; summary statistics reported to 3 significant figures for display purposes.

[a] Monitoring stations included EDC-01 and W10 for corresponding tissue sampling stations E1 and EDC-D, respectively (refer to Appendix Tables D.1.7 and D.1.8).

[b] Sample size for water quality monitoring is n=12 for EDC-01a (E1) and n=6 for EDC-D (W10).

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOECCS 2021a,b) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2022 and the time of sampling in August 2022 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a). See Appendix Tables D.1.7 to D.1.8 for raw data used in the calculation of mean values.

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L). If the reported dissolved water or tissue analyte concentration was below the LRL, the BCF was not calculated.

[f] Trophic Transfer Factor (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

Table 6.12: Summary of Primary and Secondary Analytes Concentrations in Water, Periphyton, Composite-Taxa, and Caddisfly Tissues, BCFs and TTFs for Lower Edney Creek (E1 [Exposed]; EDC-D [Reference]), 2022

Analytes		Component	Metric	Units	n	Area

Dissolved concentration at exposed area exceeded reference area by less than 2-times.
Dissolved concentration at exposed area exceeded reference area by at least 2-times.
Dissolved concentration at exposed area exceeded reference area by at least than 5-times.
Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05).
Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05).
BCF for exposed area exceeded reference area by less than 2-times.
BCF for exposed area exceeded reference area by at least 2-times.
BCF for exposed area exceeded reference area by at least 10-times.
Mean TTF exceeds 1.
Mean TTF at exposed area exceeds 1 and the corresponding reference area TTF for a given year.

BOLD = mean tissue selenium value exceeds long-term benthic invertebrate tissue guideline for selenium (4 mg/kg dw; BCMOE 2014).

BOLD/ITALICS = Indicates dissolved water value greater than the long-term average British Columbia Water Quality Guideline (BCMOECCS 2021a,b).

Notes: Results are shown for primary and secondary analytes that are presented in Table 6.11 (i.e., those with a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). "-" = Dissolved water concentration not data available or BCF/TTF was not calculated for analytes because no data available for calculation or one or more result used in the calculation was below the Laboratory Reporting Limit (LRL); "na" = not applicable; summary statistics reported to 3 significant figures for display purposes.

[a] Monitoring stations included EDC-01 and W10 for corresponding tissue sampling stations E1 and EDC-D, respectively (refer to Appendix Tables D.1.7 and D.1.8).

[b] Sample size for water quality monitoring is n=12 for EDC-01a (E1) and n=6 for EDC-D (W10).

[c] Guidelines were derived from the British Columbia Water Quality Guidelines for the protection of aquatic life (BCMOECCS 2021a,b) outlined in Table D.1.1.

[d] Means were calculated for routine water quality stations using data collected between January 1, 2022 and the time of sampling in August 2022 in order to be consistent with means calculated during previous years (Minnow 2016d, 2017c, 2018c, 2019, 2020a, 2021a, 2022a). See Appendix Tables D.1.7 to D.1.8 for raw data used in the calculation of mean values.

[e] Bioconcentration Factor (BCF) = Mean Tissue Concentration (mg/kg dw) / Mean Dissolved Water Concentration (mg/L). If the reported dissolved water or tissue analyte concentration was below the LRL, the BCF was not calculated.

[f] Trophic Transfer Factor (TTF) = Benthic Invertebrate Tissue Concentration / Periphyton Tissue Concentration. If the reported analyte concentrations for either periphyton or benthic invertebrate tissue were below the LRL, the TTF was not calculated.

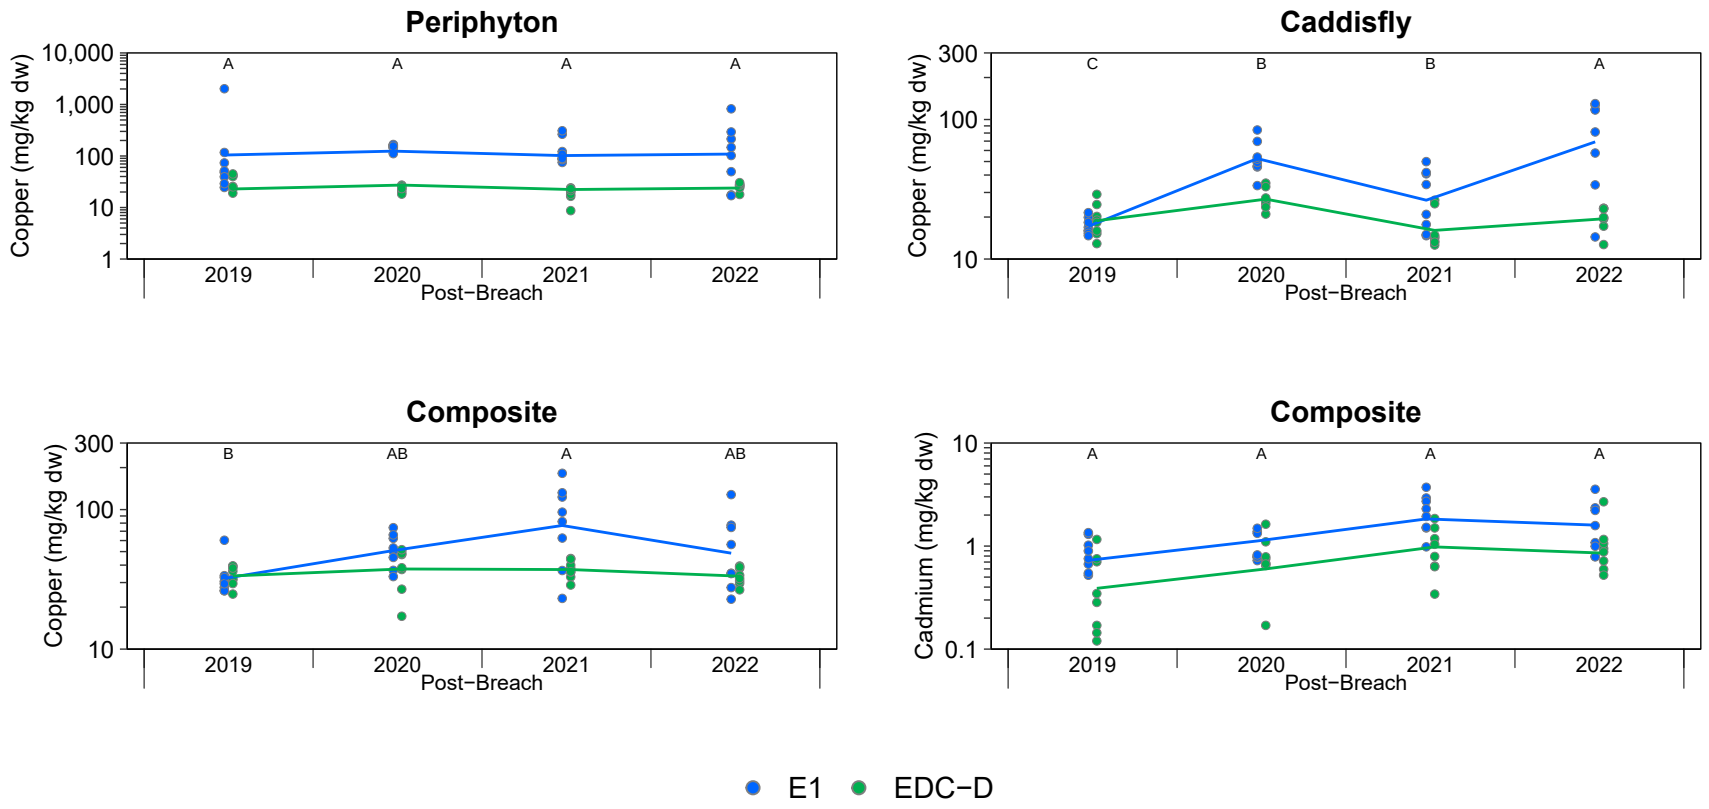

Figure 6.12: Periphyton, Caddisfly, and Composite-Taxa Benthic Invertebrate Tissue Primary and Secondary Analyte Concentrations with a Significant Positive Exposed - Reference Difference for Lower Edney Creek (E1 [Exposed]; EDC-D [Reference]), 2019 to 2022

Notes: Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL and the open symbol represents one or more values reported below the LRL. Plots are only included for primary and secondary analytes that had either a significant Area × Time interaction term and were higher at exposed than reference areas in 2022 or had no significant interaction but had a higher exposed magnitude of difference across all years for a given tissue type. Individual samples are plotted and lines join the least−squares estimated mean values for years included in the statistical analysis (i.e., not <LRL). Statistical analyses were conducted using a two−way ANOVA with factors Area and Year. The models were fit using Maximum Likelihood Estimation with an assumed log−normal distribution. Years that share a letter (e.g., A,B,C) have ratios of concentrations (Exposed:Reference) that do not differ significantly (p−value < 0.05) among years. Letter A was assigned to the year with the highest ratio of concentrations (Exposed:Reference). Only years with samples from both reference and exposed areas are plotted.

Table 6.13: Summary of Statistical Contrasts of Exposed - Reference Relative Differences in Trophic Transfer Factors of Primary and Secondary Analytes in Caddisfly and Composite-Taxa Benthic Invertebrate Tissue for Lower Edney Creek (E1 [Exposed]; EDC-D [Reference]), 2019 to 2022[a]

Analytes		Lower Edney Creek (E1; Exposed) / Lower Edney Creek (EDC-U; Reference)							
		Caddisfly				Composite-Taxa Benthic Invertebrate			
		2019	2020	2021	2022	2019	2020	2021	2022
Primary Analyte	Copper	A	A	A	A	A	A	A	A
Secondary Analyte	Cadmium	B	AB	A	A	A	A	A	A
	Calcium	B	B	C	A	B	B	C	A
	Cobalt	B	B	AB	A	A	A	A	A
	Silver	B	B	AB	A	A	B	AB	A
	Sodium	AB	AB	B	A	A	A	B	A
	Strontium	B	BC	C	A	B	AB	B	A
	Titanium	B	B	B	A	A	A	A	A
	Vanadium	B	B	B	A	A	A	A	A
	Zinc	B	A	A	A	A	A	A	A

Indicates significantly higher tissue concentration at exposed compared to reference area, and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was not significant (α = 0.05; i.e., the difference between exposed and reference did not change significantly among years).

Indicates significantly higher tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Indicates significantly lower tissue concentration at exposed compared to reference area (α = 0.05), and the interaction (Area x Year) term of the two-way ANOVA was significant (α = 0.05; i.e., the difference between exposed and reference changed significantly among years).

Notes: "-" = no statistical comparison could be made because data were not available or all were results below Laboratory Reporting Limit (LRL). Refer to Appendix Tables F.4.7, F.5.10, and F.5.11 for statistical analyses results and magnitude of difference calculations.

[a] Results are shown for primary and secondary analytes that are presented in Table 6.11 (i.e., those with a significant positive exposed - reference difference in 2022 or in all monitoring years for one or more tissue types [periphyton, caddisfly, or composite benthic invertebrate] in at least one area). Years that share a letter (e.g., A,B,C) had ratios of TTFs (Exposed:Reference) that did not differ significantly among years. Letters are assigned such that A is assigned to the year with the highest ratio of concentrations (Exposed:Reference).

all years, indicated there is no evidence of increased copper bioaccumulation in aquatic biota in lower Edney Creek. However, the significant increase in exposed caddisfly copper concentrations in 2020 and again in 2022, relative to reference, is consistent with the recent completion of final remediation works in this area (in the summer of 2020 and 2021).

Evaluation of the nine secondary analytes identified for data interpretation (cadmium, calcium, cobalt, silver, sodium, strontium, titanium, vanadium, and zinc) indicated that concentrations of these analytes in exposed periphyton tissues in 2022 were similar to or lower than reference (Table 6.11). This contrasts with 2021 when barium, calcium, strontium, titanium, and vanadium were elevated in exposed periphyton tissues relative to reference (Minnow 2022a; Table 6.11; Appendix Figure F.4.16, Appendix Tables D.5.2, D.5.9, F.4.25). For caddisfly tissues, the secondary analytes calcium, silver, strontium, and zinc had concentrations in exposed tissues in 2022 that were significantly higher than reference (Figure 6.12, Table 6.11; Appendix Figure 4.17, Appendix Table F.4.26). Temporal evaluation of these analytes showed that caddisfly tissue concentrations of calcium and strontium from the exposed area in 2022 were significantly higher than all prior years (2019 to 2021), relative to reference. However, the BCFs for calcium and strontium in caddisflies in 2022 were only slightly (< 1.2 times) higher than reference which did not suggest increased bioaccumulation of either analyte in caddisfly tissues (Figure 6.12, Table 6.12). Evaluation of the TTFs for calcium and strontium in caddisflies is discussed below. The exposed caddisfly tissue concentrations of silver in 2022 were higher than 2019 and 2020, relative to reference, while exposed caddisfly concentrations of zinc in 2022 were higher than 2019 but similar to other monitoring years, relative to reference (2020 and 2021; Figure 6.12, Table 6.11). Composite-taxa tissue concentrations of cadmium, cobalt, sodium, titanium, and vanadium were significantly elevated at the exposed area relative to reference in all years (2019 to 2022) but were temporally stable over this period (Figure 6.12, Tables 6.11; Appendix Figure F.4.18, Appendix Table F.4.27). The lack of consistency between exposed caddisfly and composite-taxa results for calcium, silver, strontium, and zinc concentrations indicate there is no consistent evidence of a mine-related influence on benthic invertebrate concentrations of these analytes. Lastly, the mean concentrations of selenium in caddisfly and composite benthic invertebrate tissue samples at E1 (1.5 and 1.9 mg/kg dw, respectively) were well below the BC interim guideline (4 mg/kg dw; BCMOE 2014) and pre-breach concentrations (3.5 mg/kg dw) and were similar to EDC-D (1.5 and 1.8 mg/kg dw, respectively; Appendix Figures F.4.17, F.4.18, Appendix Tables D.5.4, D.5.6, D.5.10, D.5.11, F.4.26, F.4.27). These results are consistent with previous years (2019 to 2021) and indicate mine related activities are not affecting the selenium concentrations in lower Hazeltine Creek, and the risk to aquatic biota from selenium is low.

The four secondary analytes (calcium, silver, strontium, and zinc) identified as having significantly higher exposed tissue concentrations in caddisflies relative to reference in 2022 also had

significantly higher TTFs in exposed tissues compared to reference in 2022 (Table 6.13; Appendix Table 4.28; Appendix Figure F.4.19). The TTFs for zinc in exposed caddisfly tissues have been significantly higher than reference since 2020. The exposed caddisfly TTFs for calcium, silver, and strontium were significantly higher than reference in 2022, and were significantly higher in 2022 than in all prior years (2019 to 2021) for calcium and strontium, and higher in 2022 than in 2019 and 2020 for silver, relative to reference (Table 6.13; Appendix Figure F.4.19, Appendix Table F.4.28). The temporal increases in exposed caddisfly TTFs for calcium, silver, strontium, and zinc suggest there is some evidence of increased bioavailability and bioaccumulation of these analytes in caddisflies, however this is not supported by the composite-taxa TTF results. The exposed composite-taxa TTF for cadmium, cobalt, sodium, and titanium were significantly higher than reference in 2022, but the TTFs in 2022 for all these analytes were similar to those in 2019, indicating no temporal increase in TTFs has occurred from 2019 to 2022 (Table 6.13; Appendix Figure F.4.20, Appendix Table F.4.29). As indicated above for tissue concentrations, the lack of consistency between exposed caddisfly and composite-taxa TTFs for calcium, silver, strontium, and zinc indicate there is no consistent evidence of increased bioavailability of these analytes in benthic invertebrate tissues from lower Edney Creek.

Overall, tissue concentrations did not exceed the guideline for protection of aquatic life for selenium. The BCFs were lower than or similar to reference for most analytes evaluated (except copper, cadmium, calcium, sodium, strontium, and vanadium), and TTFs showed little evidence of increasing bioavailability for most analytes, with the exception of calcium, silver, strontium, and zinc in caddisfly tissues. Increased tissue concentrations and TTFs of calcium, silver, strontium, and zinc in exposed caddisfly tissues were not corroborated by composite-taxa benthic invertebrate tissue results. As such, periphyton and benthic invertebrate tissues in Edney Creek did not exhibit consistent changes over time in tissue concentrations or the bioavailability for most analytes, except for copper. Tissue concentrations of copper from the exposed area in 2022 were higher than reference in all tissues, and copper BCFs were elevated for periphyton and caddisfly tissues, but TTFs in exposed benthic invertebrate tissues were lower than reference in all years. The elevated concentrations of copper in exposed caddisfly and composite-taxa tissues compared to reference in 2022, but lower TTFs in all years, indicated there is no evidence of increased copper bioavailability in aquatic biota in lower Edney Creek. However, the significant increase in exposed caddisfly copper concentrations in 2020, and again in 2022, relative to reference, is consistent with the recent completion of final remediation works in this area (in the summer of 2020 and 2021).

6.2.2 Summary

Periphyton and benthic invertebrate tissue quality monitoring in lower Edney Creek in 2022 indicated that tissue concentrations of several primary and secondary analytes were significantly higher at the exposed area (E1) than reference. However, for most metals, there was no consistent evidence of increasing metal concentrations in periphyton and/or benthic invertebrate tissues from the exposed area relative to the reference area over time. Copper was an exception, with concentrations in all exposed area tissues (i.e., periphyton, caddisfly, and composite-taxa benthic invertebrates) that were higher than reference. Most analytes demonstrated a lack of consistency among tissue types in concentrations and TTFs (except copper), BCFs that were only slightly above reference (except copper and cadmium), and TTFs that did not demonstrate increased bioavailability. These results collectively indicate that the potential mine-influence on analyte concentrations in lower Edney Creek appears limited to increased copper concentrations in benthic invertebrate tissues. Copper concentrations in exposed caddisfly and composite-taxa tissues were higher than reference in 2022, but copper TTFs were lower than reference in all years, indicating there is no evidence of increased copper bioavailability in aquatic biota in lower Edney Creek. However, the significant increase in copper concentrations in exposed caddisfly tissues in 2020, and again in 2022, relative to reference, is consistent with the recent completion of final remediation works in this area (in the summer of 2020 and 2021). Mean concentrations of selenium in caddisfly and composite benthic invertebrate tissue samples were well below the BC interim guideline for aquatic life, indicating that no selenium-associated effects to aquatic life would be expected.

7 SUMMARY OF FINDINGS

This section provides an overall summary of the findings of sediment and aquatic biological monitoring completed under the Mount Polley CEMP from 2022, drawing on additional historic monitoring results for data interpretation as required. As identified in Section 2, this section considers multiple lines of evidence to identify well supported findings versus those that are not fully supported and/or those for which uncertainty exists. Throughout the following sub-sections, each monitoring component builds on evidence from others, typically over the line of evidence sequence from sediment quality to primary producer to secondary producer/benthic invertebrates to fish.

7.1 Polley Lake

7.1.1 Sediment Quality

Sediments were collected from the shallow area of Polley Lake (and reference) in 2022 to support the evaluation of sediment toxicity. Sediments from this area were characterized by concentrations of arsenic, copper, and iron greater than reference concentrations and WSQG. Copper was the most substantially elevated Analyte of Interest, with a mean concentration 3.4 times the upper WSQG. Copper was also the only Analyte of Interest to exceed the lower WSQG in reference sediments, which it exceeded by approximately 2.5 times. Arsenic, copper, and iron concentrations in shallow Polley Lake sediments in 2022 were similar to those reported in the previous sampling event (i.e., 2019), relative to reference, indicating temporal stability of these analyte concentrations. The TOC content of Polley Lake shallow sediments in 2022 was significantly lower than reference and did not change from 2019 to 2022, relative to reference. Overall, the 2022 sediment quality results from the shallow area of Polley Lake indicate temporal stability in the physical and chemical characteristics of these sediments since initiation of monitoring in 2019.

Sediment toxicity testing of the shallow area of Polley Lake (and reference) in 2022 indicated no unacceptable response to survival or growth of *H. azteca* relative to the reference area or the sand control. The survival and growth responses observed in 2022 were similar to those in 2019 when sampling was initiated. Conditions of the CEMP outlined that sediment toxicity testing of the shallow Polley Lake area must be continued "*unless MPMC can clearly show that copper concentrations in all Polley Lake shallow sediment samples are below the 95th percentile of the copper concentrations in the Bootjack Lake reference area shallow sediment samples.*" (BCMOECCS 2021c). This condition was not met in 2022 in Polley Lake shallow sediments, indicating that toxicity testing of these shallow sediments must be completed in three years (in 2025) in accordance with the CEMP conditions.

7.1.2 Aquatic Life

Phytoplankton community and productivity monitoring in Polley Lake in 2022 indicated that phytoplankton productivity (in terms of chlorophyll-a concentrations) was higher than reference, despite being significantly lower in 2021 and similar between the two lakes in 2019 and 2020. The chlorophyll-a results characterize Polley Lake as mesotrophic and reference (Bootjack Lake) as oligotrophic. While the trophic state of Polley Lake increased from oligotrophic to mesotrophic between 2021 and 2022, this represented a return to the same mesotrophic status observed in Polley Lake in 2019. The phytoplankton community in Polley Lake in 2022 was characterized by higher total density, lower taxon richness, higher Simpson's Diversity and Evenness, higher relative densities of Chlorophytes and Chrysophytes, and lower relative densities of Cyanobacteria compared to reference. Overall, result for most primary endpoints in Polley Lake were similar to or higher than reference in 2022 (density, Simpson's Diversity and Evenness), while those endpoints that were lower than reference (e.g., taxon richness) were temporally stable, suggesting there is no mine-related influence on the phytoplankton community of Polley Lake.

Zooplankton community and productivity monitoring in Polley Lake in 2022 indicated that total zooplankton biomass (dw) was similar to reference, which is consistent with prior years (2019 to 2021) when biomass was either similar to or higher than reference. The consistently similar or significantly higher total biomass of zooplankton in Polley Lake compared to the reference is indicative of a healthy lentic system, providing critical habitat for fish. The zooplankton community of Polley Lake in 2022 was characterized by total density, taxon richness, and Simpson's Diversity and Evenness that were similar to reference. From 2019 to 2022, the zooplankton community of Polley Lake differed from the reference area in terms of significantly higher and lower density in 2019 and 2021, respectively, lower taxon richness in 2020, and lower Simpson's Diversity and Evenness in 2019 and 2020. Community composition from 2019 to 2022 has consistently been characterized by higher relative densities of Copepod Nauplii and Cyclopoida, and lower relative densities of Rotifera compared to reference. The consistent differences in zooplankton community composition between Polley Lake and the reference area suggests that temporal changes community composition (which were similar in both areas over time) were likely driven by natural variability in environmental parameters (e.g., water temperature, nutrient availability, phytoplankton community).

Zooplankton tissue quality monitoring in Polley Lake in 2022 indicated that concentrations of primary and secondary analytes in tissues from Polley Lake were similar to or lower than reference except for sodium. Sodium concentrations were significantly greater than reference between 2019 and 2022 but demonstrated temporal stability relative to reference (i.e., did not

differ between 2019 and 2022). Concentrations of two primary analytes (arsenic and copper) and three secondary analytes (manganese, mercury, molybdenum) in zooplankton tissue from Polley Lake in 2022 were significantly lower, relative to reference, than in 2019 when replicated sampling was initiated. Concentrations of selenium in zooplankton tissue from Polley Lake were below the BC interim guideline for aquatic life in 2022, which contrasts with prior years when individual zooplankton tissue selenium results have exceeded the guideline (2016, 2017, 2019, and 2021). Selenium concentrations in zooplankton tissue from Polley Lake in 2022 were similar to reference and were significantly lower than in 2020 and 2021 (but not 2019), relative to reference. The temporal stability or decreases in primary and secondary analyte concentrations in zooplankton tissue from Polley Lake in 2022 compared to 2019 was supported by trend analyses of surface water quality data which similarly showed stable or decreasing concentrations for all aqueous primary and secondary analytes except copper and vanadium.

Fish community and population health assessments undertaken from 2019 to 2022 documented the influence of the temporary loss of Hazeltine Creek due to the breach (August 2014 to April 2018), which previously supported the majority of fish recruitment to Polley Lake. Rainbow trout CPUE in spring was higher in 2022 than in all previous years since 2016. Prior to 2022, spring CPUE progressively decreased from 2019 to 2021, and was also substantially lower in all three years than in 2016, consistent with loss of recruitment and natural mortality of older fish since the breach. As such, the spring CPUE in 2022 suggests that most of the remaining 2018 and a portion of the 2019 cohort has reached maturity which is further supported by spring spawning surveys conducted in Hazeltine Creek that documented the highest abundance of adults since 2019 (Minnow 2023). In the fall of 2022, when fishing was randomized in Polley Lake, CPUE was lower than 2019 to 2021. However it should be noted that temporal comparisons of CPUE are subject to variability resulting from several factors that can affect the success of netting efforts, which is true even when considering the randomized and standardized fish collection methods employed. The assessment of rainbow trout size distribution provides a more temporally comparable basis for evaluating population recovery in Polley Lake. Length frequency distributions for rainbow trout over time showed a proportional shift towards smaller and younger fish in 2019, a continued to shift towards a more balanced distribution among size classes with the survivorship of the 2018 and 2019 cohorts, and in 2022, a size class distribution more closely resembling 2016. The length frequency distribution in 2022 had greater resemblance to 2016 than the length frequency distributions from any of the other years (2018 to 2021), suggesting the population has returned to a pre-breach size class distribution. Condition of female rainbow trout in spring 2022 was similar to 2021 but lower than in all prior years (2016 to 2020) whereas growth rate in 2022 was similar to prior years but lower than in 2020. CPUE for longnose sucker in the spring has varied without evidence of a consistent

directional trend over time, but CPUE in the fall has progressively decreased from 2016 to 2022. As indicated above, there are several sources of variability that can affect temporal comparisons of CPUE. Length frequency distributions for longnose sucker in Polley Lake from 2016 to 2022 showed more smaller fish were caught in 2022 compared to 2016, as was the case in 2018, 2020, and 2021, suggesting ongoing recruitment success despite the decrease in CPUE since 2016. Condition of longnose sucker females in spring has varied since 2016 but in 2022 was similar to baseline (2016) and weight-at-age also varied, although growth rate in 2022 did not significantly differ from prior years.

Fish tissue quality, evaluated in four tissues (muscle, liver, kidney, and ovary) from rainbow trout and longnose sucker, indicated that mean mercury and selenium concentrations in muscle tissue in 2022 were below guidelines for the protection of human health based on moderate consumption (i.e., indicating that fish are safe for moderate human consumption). The mean selenium concentration in muscle of longnose sucker from Polley Lake in 2022 exceeded the guideline for the protection of human health based on high consumption, which was consistent with data from 2016 (except 2017 and 2021). However, the likelihood that longnose sucker would be consumed at a high rate (i.e., subsistence consumers) is low. Selenium concentrations in ovary tissue in 2022 (the tissue most valuable in the assessment of potential selenium-associated effects on fish) for both species were lower than the BCWQG for the protection of aquatic life in all individuals except one rainbow trout in 2022 and were below the threshold for reproductive effects in all fish. Selenium concentrations in muscle tissue of rainbow trout and longnose sucker were moderately greater than the guideline for aquatic life, which was consistent with data from 2015 to 2021. Overall, selenium concentrations in Polley Lake fish tissue have remained elevated relative to reference conditions since the uncontrolled runoff from 2006 to 2009 but the difference has not increased over the post breach period. In fact, selenium concentrations in rainbow trout muscle and ovary tissues were both significantly lower in 2022, relative to reference, than in 2017 to 2019. Additionally, selenium concentrations in longnose sucker ovary tissues were significantly lower in 2022, relative to reference, than in 2015 to 2020. This decrease in fish tissue selenium concentrations in Polley Lake corresponds with a decrease in the selenium concentrations in zooplankton tissue (i.e., dietary exposure) in 2022 compared to 2020 and 2021, and with a significant decrease in total and dissolved selenium concentrations in surface waters of Polley Lake from 2015 to 2022. Evidence of a persistent mine influence was not detected for most other analytes assessed in fish tissue in 2022. All primary analytes (arsenic, copper, iron, and selenium), and the secondary analytes cobalt, manganese, molybdenum, nickel, sodium, tin, vanadium, and zinc were elevated relative to reference in 2022 in at least one tissue type in one or both species. However, results for most these analytes (excluding selenium) were inconsistent among tissues and species, and/or were temporally stable or decreased relative to reference,

indicating that the weight of evidence does not support a pattern of increasing analyte concentrations over time due to mine-exposure.

7.1.3 Key Findings

Key findings of CEMP monitoring of Polley Lake in 2022 (Table 7.1) are:

- Arsenic, copper and iron in shallow Polley Lake sediments were elevated relative to guidelines and reference while TOC content was lower than reference. Copper concentrations in all shallow Polley Lake sediment samples in 2022 were greater than the reference 95th percentile value, indicating a continued requirement for sediment toxicity testing of these shallow sediments. Arsenic, copper, and iron concentrations and TOC content were temporally stable since initiation of monitoring in 2019.
- Toxicity testing of sediment collected from shallow areas of Polley Lake (using *Hyalella azteca*) indicated no unacceptable responses to survival or growth relative to both field reference and laboratory controls.
- Phytoplankton productivity (chlorophyll-a) in 2022 was slightly higher than reference and 2020 and 2021, but similar to 2019. Chlorophyll-a measures resulted in the classification of Polley Lake as mesotrophic in 2022, similar to 2019. Phytoplankton community composition differed from reference, but differences relative to reference were generally stable over time (2019 to 2022). Zooplankton productivity was similar to or higher than reference from 2019 to 2022 and although community composition differed from reference, the differences compared to reference were stable from 2019 to 2022.
- Zooplankton tissue quality was similar to or lower than reference except the secondary analyte sodium which was higher than reference, but stable from 2019 to 2022 (compared to reference). Concentrations of two primary analytes (arsenic and copper) and four secondary analytes (manganese, mercury, molybdenum, and selenium) were lower in 2022 than prior years, relative to reference. Selenium concentrations in 2022 were below the BC interim guideline for aquatic life (which is different from the prior years 2016, 2017, 2019 when selenium concentrations were higher than the guideline).
- The number of rainbow trout spawners (assessed in spring) was higher in 2022 than in 2016 to 2021 due to accessibility to Hazeltine Creek since 2018 and successful recruitment of YOY from 2019 onwards. In the spring of 2022 growth of female rainbow trout was similar to prior years but lower than 2020 and CPUE was higher than 2016 to 2021. Although fall rainbow trout CPUE in 2022 was lower than 2019 to 2021, the length frequency distribution resembled 2016, suggesting the population has returned to

Table 7.1: Summary of Mount Polley CEMP Results for Polley Lake, 2022[a]

Area		Sediment			Plankton			Fish	
		Basic Chemistry[b]	Toxicity[c] *Hyalella azteca* (14-day)		Productivity[d]	Community[d]	Zooplankton Tissue Quality[e]	Usage and Population Health	Tissue Quality[f]

Notes: "-" = not applicable / no data available, WSQG = British Columbia Working Sediment Quality Guidelines, BCWQG = British Columbia Water Quality Guideline, Chl-a = Chlorophyll-a, 95th = 95th Percentile (applicable to sediment quality evaluation), CPUE = catch-per-unit-effort, YOY = young-of-the-year, RB = rainbow trout, LSU = longnose sucker, M = muscle tissue, O = ovary tissue, K = kidney tissue, L = liver tissue, GL = guideline. Temporal changes presented as "relative to reference" refer to changes in the exposed-reference difference over time as evaluated using a 2-way Analysis of Variance. Analytes presented for zooplankton and fish tissue quality endpoints are primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2022 or in all monitoring years.

[a] Findings from 2022 are included at minimum. Additional years are displayed (as available) to support temporal comparisons.

[b] WSQG Lower = Lower BC Working Sediment Guideline; WSQG Upper = Upper BC Working Sediment Quality Guideline (BCMOECCS 2021a,b).

[c] Significant reductions in survival and growth are classed as high response (>50% reduction compared to control/reference); moderate response (20-50% reduction compared to control/reference, and significantly different than reference); low response (20-50% reduction compared to control/reference, and not significantly different than reference), and no unacceptable response (< 20% reduction compared to control/reference). Results relative to control or reference are shown in parentheses.

[d] Magnitude of significant differences are classed as highly (>5x SD), moderately (5x to 2x SD), and slightly (<2x SD) different, where SD is the pooled standard deviation.

[e] BCWQG = British Columbia Water Quality Guideline for the protection of aquatic life - interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

[f] Human Health guideline for Hg in muscle tissue of fish (0.5 mg/kg dw; CFIA 2015); Human Health guideline for Se in fish muscle (moderate consumption; 14.5 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in muscle tissue or whole body of fish (4 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in fish ovary tissue (11 mg/kg dw; BCMOE 2014).

a pre-breach size class distribution. For longnose sucker,CPUE in the spring has varied and CPUE in the fall has progressively decreased from 2016 to 2022. Length frequency distributions for longnose sucker in Polley Lake from 2016 to 2022 showed more smaller fish were caught in 2022 compared to 2016, which was similar to previous years and suggests ongoing recruitment success despite the decrease in CPUE since 2016.

- Mercury and selenium concentrations in fish muscle in 2022 were below applicable human health guidelines for moderate consumption, while selenium concentrations in 13% of rainbow trout and 63% of longnose sucker samples exceeded the human health guideline for high consumption. Selenium concentations in rainbow trout (50% of samples) and longnose sucker (100% of samples) muscle in 2022 were above the BCWQG for the protection of aquatic life, exceeded the BCWQG in 13% of rainbow trout ovaries, and were below the threshold for reproductive effects. Selenium concentrations in fish tissues have been stable over time or decreasing over time (relative to reference) which is consistent with the temporal decrease in zooplankton tissue selenium concentrations.

7.2 Quesnel Lake

7.2.1 Sediment Quality

Sediment monitoring in 2022 continued to indicate a breach influence on sediment chemistry at both the deep and shallow areas of Quesnel Lake. Sediment collected from the deep near-field area of Quesnel Lake was characterized by concentrations of several analytes (arsenic, copper, iron, and manganese) that were greater than reference concentrations and WSQG, and TOC content lower than reference, consistent with previous post-breach results. Copper was the most substantially elevated analyte, with mean concentrations 4.2 times the upper WSQG in 2022. Mean iron and manganese concentrations were also greater than reference and upper WSQG, although to a lesser degree, and mean concentrations of arsenic were greater than reference and the lower WSQG. Temporal stability of these analytes in the deep near-field area sediments was demonstrated by arsenic, copper, and iron concentrations in 2022 that were similar to those reported in 2014, and manganese concentrations and TOC content in 2022 similar to 2015. Sediments from the shallow near-field area in 2022 had a very high sand content (92.8%), and were characterized by concentrations of arsenic, copper, iron, manganese, and silver that were greater than reference concentrations and WSQG. Copper was the most substantially elevated analyte, with mean concentrations 5.7 times the upper WSQG. Mean iron and manganese concentrations were also greater than reference and the upper WSQG (to a lesser extent than copper), while mean concentrations of arsenic and silver were greater than reference and lower WSQG. Concentrations, arsenic, copper, iron, manganese, silver, and TOC were

temporally stable, relative to reference, with concentrations in 2022 remaining similar to 2014 values for each of these analytes (compared to reference).

Sediment toxicity testing of *H. azteca* using sediments from the shallow near-field area of Quesnel Lake (QUL-LNF1) in 2022 resulted in a moderate survival response (44 to 45% mortality) and a high growth response (76 to 79% reduction). However, concentrations of dissolved copper in overlying waters of the toxicity test vessels were highly dissimilar from those documented in field-collected water from these sites, which is consistent with previous years of monitoring. Dissolved copper concentrations in the toxicity test vessels in 2022 were an average of 97-times greater than in field-collected water, which is similar to 2020 and 2021 (74- and 114-times greater, respectively) and lower than 2019 (174-times). This strongly suggests copper mobilization in the test setup that has either not occurred *in situ* or has attenuated over time *in situ*. Under these conditions, the observed mortality and growth response are consistent with dissolved copper concentrations in overlying water, particularly given that *H. azteca* have been documented to derive little nutrition from sediment and to respond primarily to contaminants in overlying water. Significant regression relationships evaluating results from 2014 to 2022 inferred lower *H. azteca* growth and survival at higher overlying water dissolved copper concentrations and higher sediment copper concentrations. This further corroborates the observation that toxicity responses of *H. azteca* are consistent with dissolved copper concentrations in overlying test waters of these shallow sediments. Overall, the toxicity test results from the shallow near-field area cannot be reliably extrapolated to the field but suggests potential for copper mobilization in this area with disturbance.

7.2.2 Aquatic Life

Phytoplankton community and productivity monitoring in Quesnel Lake in 2022 indicated that phytoplankton productivity (in terms of chlorophyll-a concentrations) was similar at the exposed and reference monitoring areas, as also observed in previous years (2019 to 2021). These results characterize both the exposed and reference areas of Quesnel Lake as mesotrophic in 2022, which is a change from the classification of ultraoligotrophic in 2016 to 2018 and as oligotrophic in 2019 to 2021; a change likely owing in part to a switch from surface grab (2018 and earlier) to depth-integrated sampling methods (2019 onwards). The plankton community of the exposed area of Quesnel Lake in July 2022 was characterized by density higher than reference, taxon richness lower than reference, and Simpson's Evenness and Diversity indices similar to reference. Total density has consistently been higher at the exposed compared to the reference area since 2019. Simpson's Diversity and Evenness at the exposed area have shown some temporal variability but have been either similar to or higher than reference in each year since 2019. Taxon richness at the exposed area in 2022 was lower than in previous years

(2019 to 2021) reflecting a decrease from conditions that were similar to reference from 2019 to 2021, to lower than reference in 2022. This decrease in taxon richness was attributable to the absence of relatively rare phytoplankton taxa at QUL-ZOO-1 in July 2022, and appeared to be a temporary change based on the results of samples collected in August 2022 which included some of these relatively rare taxa. Continued monitoring will help to further understand whether the decrease in taxon richness in 2022 is part of a longer-term change or was a single variable result. The community composition at the exposed area has been similar to reference in terms of the relative densities of Diatoms, Cyanobacteria, and Chlorophytes from 2019 to 2022. The relative densities of Chrysophytes, Cryptomonads, and Dinoflagellates at the exposed area differed from reference in 2022 but showed temporal stability either within the exposed area or temporal stability in the difference relative to reference from 2019 to 2022. The similarity of the phytoplankton community at the exposed and reference areas of Quesnel Lake for most endpoints, and the temporal stability throughout the study period for most endpoints that differed between the areas (excluding taxon richness), are suggestive of a lack of mine-related influence on the phytoplankton community of Quesnel Lake.

Zooplankton community and productivity monitoring in Quesnel Lake in 2022 indicated that total biomass of zooplankton (dw) at the exposed area was similar to reference, which is consistent with prior years. The zooplankton community at the exposed area of Quesnel Lake in 2022 was characterized by total density and Simpson's Evenness that were similar to reference, and taxon richness and Simpson's Diversity that were higher than reference. While there was temporal variability in these metrics at the exposed area from 2019 to 2022, the changes (i.e., direction and relative magnitude) were generally the same as those observed at the reference area, and metrics at the exposed area were largely similar to or greater than reference over this period. The community composition at the exposed area has been similar to reference in terms of the densities and relative densities of most zooplankton taxa (Calanoida, Cladocera, and Rotifera) from 2019 to 2022, with two exceptions, indicating that the communities at the exposed and reference areas were largely similar. The two exceptions were lower density and relative density of Cyclopoida in 2019, and consistently higher density and relative density of Copepod Nauplii in 2019 to 2022 at the exposed area compared to reference. The similarity of zooplankton communities between the exposed and reference areas for most endpoints and temporal stability of those endpoints that differed between the areas (i.e., Copepod Nauplii) from 2019 to 2022 are suggestive of a lack of mine-related influence on the zooplankton community of Quesnel Lake.

Zooplankton tissue quality monitoring in Quesnel Lake in 2022 indicated that concentrations of primary and secondary analytes in tissues from the exposed area were similar to or lower than reference, and also temporally stable from 2019 to 2022. The lack of temporal and spatial differences in zooplankton tissue quality results in 2022 was supported by trend analyses of

surface water quality data which indicated temporal stability (from 2015 to 2022) for most analytes, except for increasing trends at one or both exposed monitoring stations for total manganese, total phosphorus, total and dissolved selenium, and dissolved barium, molybdenum, and sodium. A measurable increase in concentrations of these analytes in zooplankton tissue was not observed since 2019, indicating no sustained impact of the increased aqueous concentrations of these analytes on zooplankton tissue quality. In addition, aqueous total selenium and manganese concentrations remained well below the BCWQG from 2015 to 2022. Despite the identified increasing trend in aqueous selenium concentrations, zooplankton tissue selenium concentrations were below the BC interim guideline for aquatic life at the exposed area in 2022 (similar to 2019 to 2021), and tissue selenium concentrations at the exposed area were similar to reference from 2019 to 2022. As such, monitoring results indicate that zooplankton tissue quality in 2019 to 2022 was unimpacted by the breach and potential effluent exposure.

Benthic invertebrate community monitoring in the deep-near field area of Quesnel Lake in 2022 documented a community with total density and Simpson's Evenness that were unchanged since 2016, taxon richness that was similar to all years since 2014, and Simpson's Diversity that was unchanged since 2014. Total density at the deep near-field area in 2022 remained much lower than the densities reported for the reference area in previous years (2014 to 2021), but the difference relative to reference has steadily decreased. These results indicate some recovery of the benthic invertebrate community at the exposed areas from the initial breach event in 2014, but no substantial change in community features since 2016 at the deep near-field exposed area of Quesnel Lake. This lack of significant recovery is consistent with the stability of sediment TOC content and concentrations of arsenic, copper, iron, and manganese in these sediments since at least 2016. Chironomidae, which are the dominant taxa at the deep near-field area, are intolerant to sediments with organic content (TOC) of less than 1% (Suedel et al. 1993) and the TOC content of near-field area sediments (mean = 0.614%) remains well below this level. The community composition has shown temporal stability since 2014, and in 2022 continued to be characterized by Chironomidae dominance. Several characteristics of the benthic invertebrate community at the deep near-field area were related to sediment characteristics, including lower total density, richness, Chironomidae density, and Oligochaeta density and relative density associated with greater proportion of fines, lower proportion of TOC, and higher metal concentrations in sediment. These sediment properties are consistent with the presence of breach-impacted sediments at the deep near-field area.

The catchability of lake trout at the exposed area of Quesnel Lake in 2022 was lower than at the reference area, while catchability of peamouth chub and northern pikeminnow in 2022 were both higher at the exposed area relative to reference. The catchability of rainbow trout from the Quesnel River in 2022 was higher than in previous years. Fish tissue quality in 2022 was

evaluated in up to four tissues (muscle, liver, kidney, and ovary) in four species (lake trout, northern pikeminnow, peamouth chub, and rainbow trout). Mean mercury and selenium concentrations in fish muscle tissue from Quesnel Lake and Quesnel River in 2022 were below the guidelines for the protection of human health (i.e., indicating that fish are safe for moderate human consumption). This was consistent with prior monitoring years except 2020 and 2021 when the mean mercury concentrations in muscle of reference lake trout exceeded the consumption guideline. Mean selenium concentrations in fish muscle or whole-body samples from Quesnel Lake and Quesnel River in 2022 were below the guideline for the protection of aquatic life except for peamouth chub from the exposed area which exceeded the guideline at a higher rate in 2022 (63%) than in previous years (2015 to 2021). Mean selenium concentrations in ovary tissue (the tissue most valuable in the assessment of potential selenium-associated effects on fish) from lake trout in 2022 were below the tissue specific guideline for the protection of aquatic life but exceeded the guideline in rainbow trout and peamouth chub. In rainbow trout ovary tissue, selenium concentrations in 2022 exceeded the guideline in 50% of samples which was within the range of previous years. In peamouth chub ovary tissue, selenium concentrations in the majority of exposed (86%) and reference (50%) samples in 2022 exceeded the tissue specific guideline for the protection of aquatic life, with 43% of exposed samples also exceeding the threshold for reproductive effects. The rate of the guideline/threshold exceedances in exposed peamouth chub ovary tissue was higher in 2022 than in prior years. Despite this, selenium concentrations in peamouth chub tissues (muscle liver, ovary, and kidney) and in northern pikeminnow whole-body samples (also a small home-range species) have been temporally stable from 2016 to 2022, relative to reference. The absence of pre-breach data precludes drawing definitive conclusions about the potential factors influencing tissue selenium concentrations (e.g., due to mine-exposure or due to inherent differences between the areas). However, results from 2016 to 2022 indicated there is no evidence that selenium concentrations in fish tissues from Quesnel Lake are increasing over time due to mine exposure. Evidence of a persistent mine influence was not detected for most analytes assessed in fish tissue from Quesnel Lake and Quesnel River in 2022. All primary analytes (arsenic, copper, iron, and selenium), and the secondary analytes barium, cadmium, calcium, manganese, mercury, molybdenum, phosphorus, sodium, strontium, tin, titanium, uranium, vanadium, and zinc were elevated relative to reference in 2022 in at least one tissue type in at least one species. However, the results for most these analytes were inconsistent among tissues and species, and/or were temporally stable, and/or the results were not supported by zooplankton tissue quality results, indicating that the weight of evidence does not support a pattern of increasing analyte concentrations over time due to mine-exposure.

7.2.3 Key Findings

Key findings of CEMP monitoring of Quesnel Lake in 2022 (Table 7.2) are:

- Arsenic, copper, iron, and manganese remain the analytes most elevated in Quesnel Lake deep near-field sediments relative to guidelines. Concentrations of these analytes in 2022 were similar to 2014 except manganese which was similar to 2015 (compared to reference). Mean TOC concentration (0.614% in 2022) of the deep near-field sediments remains very low and has increased slightly since 2014, although not significantly since 2016, relative to reference. In shallow near-field sediments, arsenic, copper, iron, manganese, and silver concentrations remained greater than guidelines and reference, and concentrations of these analytes in 2022 were similar to 2014 (compared to reference). Mean TOC content (0.826% in 2022) of the shallow near-field area sediments remains lower than reference and temporally unchanged since initiation of sampling (2014)
- Toxicity testing of shallow exposed sediments (using *H. azteca*) indicated a moderate survival response (44 to 45% mortality) and a high growth response (76 to 79% reduction in growth) in 2022. Survival and growth in 2022 were similar to 2021 (46% mortality, 78 to 82% reduction), slightly lower than 2020 (39% mortality, 50 to 65% reduction) but higher than 2019 (100% mortality) However, concentrations of dissolved copper in overlying waters of the toxicity test vessels in 2022 were highly dissimilar (an average of 97-times greater) than in field-collected water from these sites, consistent with previous years of monitoring. This suggests that the sediment toxicity test results cannot be reliably extrapolated to the field, but suggests potential for copper mobilization in this area with disturbance.
- Plankton productivity was similar to reference based on chorophyll-a concentrations and zooplankton biomass in 2022. Chlorophyll-a measures resulted in the classification of Quesnel Lake as mesotrophic (at exposed and reference areas). Phytoplankton and zooplankton community condition and structure were similar to reference and/or temporally stable (excluding phytoplankton taxon richness). Phytoplankton taxon richness decreased between 2021 to 2022 to richness that was lower than reference in 2022; a change that was due to the absence of relatively rare taxa.
- Concentrations of primary and secondary analytes in zooplankton tissues were consistently similar to or lower than reference from 2019 to 2022. Selenium concentrations in all exposed samples from 2019 to 2022 were below the BCWQG for the protection of aquatic life.

Table 7.2: Summary of Mount Polley CEMP Results for Quesnel Lake, 2019 to 2022[a]

Area		Sediment			Plankton			Benthic Invertebrate	Fish	
		Basic Chemistry[b]	Toxicity[c] *Hyalella azteca* (14-day)		Productivity[d]	Community[d]	Zooplankton Tissue Quality[e]	Community[d]	Community and Catchability	Tissue Quality[f]

[d] Magnitude of significant differences are classed as highly (>5x SD), moderately (5x to 2x SD), and slightly (<2x SD) different, where SD is the pooled standard deviation.

[c] BCWQG = British Columbia Water Quality Guideline for the protection of aquatic life - interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

[e] Human Health guideline for Hg in muscle tissue of fish (0.5 mg/kg dw; CFIA 2015); Human Health guideline for Se in fish muscle (moderate consumption; 14.5 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in muscle tissue or whole body of fish (4 mg/kg dw; BCMOE 2014); Guideline for the protection of aquatic life: Se in fish ovary tissue (11 mg/kg dw; BCMOE 2014); Effects Threshold indicates mean selenium concentration greater than DeForest et al. (2012) threshold for ovary tissue in fish (20 mg/kg dw) and the BCMOE guideline.

- The benthic invertebrate community at the deep near-field area showed initial recovery in the years immediately after the breach (i.e., between 2014 and 2015). Since then, there has been no substantial change in community at this area (i.e., from 2016 to 2022), which is consistent with the stability of sediment quality and the limited increase in sediment TOC content over this period.
- Mercury and selenium concentrations in fish muscle were below human health guidelines in 2022 except in 25% of exposed and reference lake trout which exceeded the mercury guideline. Selenium concentrations in most fish muscle or whole-body tissues were below the BCWQG for the protection of aquatic life in 2022, except for exposed peamouth chub muscle (63%), northern pikeminnow (25%), and rainbow trout (13%) samples. Selenium concentrations in ovary tissues of exposed (86%) and reference (50%) peamouth chub and exposed rainbow trout (80%) samples were above the guideline for the protection of aquatic life, and above the threshold for reproductive effects for exposed peamouth chub (43%) samples. Despite the guideline/threshold exceedances for tissue selenium concentrations, there is no evidence that selenium concentrations in fish tissues from Quesnel Lake or Quesnel River are increasing over time due to mine exposure.

7.3 Hazeltine Creek

7.3.1 Sediment Quality

Sediment quality monitoring completed in upper and lower Hazeltine Creek in 2022 continued to document the physical and chemical characteristics of sediments from this erosional habitat. Sediments were characterized by concentrations of several analytes that were greater than reference/pre-breach concentrations and WSQG values: copper and selenium in upper Hazeltine Creek, and copper and iron in lower Hazeltine Creek. In both upper and lower Hazeltine Creek in 2022, copper was the most substantially elevated analyte with concentrations 2.0 and 1.7 times higher than the upper WSQG, respectively, and higher than reference/pre-breach concentrations. The TOC content of sediments from upper Hazeltine Creek was significantly higher in 2022 than in 2018, relative to reference, as were the concentrations of copper and selenium. Mean concentrations of copper and selenium in upper Hazeltine Creek sediments were significantly higher in 2022 than previously observed (2018 to 2021), relative to reference. For both analytes, this change was driven by a significant decrease in sediment copper and selenium concentrations at the reference area, with copper concentrations within upper Hazeltine Creek sediments (i.e., not evaluated relative to reference) showing temporal stability. Sediment selenium concentrations evaluated within upper Hazeltine Creek in 2022 (not relative to reference) were significantly higher than in preceding years (2018 to 2020) which was

associated with higher TOC and lower sand content of these sediments. In lower Hazeltine Creek, the TOC content of lower Hazeltine Creek sediments has remained unchanged relative to reference from 2018 to 2022. Copper and iron concentrations in lower Hazeltine Creek sediments in 2022 were similar to or lower than those observed in 2018, relative to reference, indicating sediment concentrations of these analytes have not increased significantly over that period. The 2022 sediment quality monitoring results continue to indicate that results related to variable sediment physical characteristics (i.e., TOC and sand content) that are driven by the necessity for opportunistic sampling due to limited availability of fine sediments in some monitoring years. The variability in sediment physical characteristics may stabilize as sediment accumulation continues to occur in this remediated system.

7.3.2 Aquatic Life

Periphyton monitoring indicated that primary productivity of upper Hazeltine Creek, as assessed by mean chlorophyll-a (mass per unit area; mg/m²), was below BCWQG but above the threshold indicative of moderate enrichment in lower Hazeltine Creek. Primary productivity as measured by both chlorophyll-a and AFDM at both upper Hazeltine Creek areas (HAC-R1, HAC-U) has been consistently similar to or significantly higher than reference from 2018, and higher than pre-breach since 2019 at HAC-R1 and since 2021 at HAC-U. Chlorophyll-a concentrations and AFDM at HAC-R1 in 2022 were significantly higher than at HAC-U, indicating this area had greater periphyton productivity. Despite the increased productivity following remediation, water quality monitoring indicates that dissolved oxygen concentrations largely remain above the long-term BCWQG in upper Hazeltine Creek. The periphyton community of upper Hazeltine Creek in 2022 was characterized by taxon richness, Simpson's Evenness and Diversity, and diatom richness that were similar to or higher than the reference area. Periphyton densities in 2022 at HAC-R1 and HAC-U were similar to and lower than reference, respectively, but were temporally stable at HAC-U despite being lower than reference in 2022. The periphyton communities at the two upper Hazeltine Creek areas (HAC-R1 and HAC-U) were similar in 2022 in terms of all primary metrics (density, taxon richness, Simpson's Evenness and Diversity, and diatom richness) indicating similar recovery of the periphyton community in these two areas. Periphyton community composition at HAC-R1, but not HAC-U, was similar to reference in 2022. Community composition at HAC-U continued to differ from the reference area, with higher and lower relative densities of Diatoms and Cyanobacteria, respectively; differences which are indicative of healthy periphyton communities. The similarity (or exceedance) of the primary periphyton community metrics (density, richness, Simpson's Evenness, and Simpson's Diversity) in upper Hazeltine Creek compared to the reference area in most years and/or temporal stability of these metrics are indicative of relatively stable periphyton communities at the remediated upper Hazeltine Creek areas and good periphyton community health.

The benthic invertebrate community of upper Hazeltine Creek in 2022 was characterized by total density, taxon richness, and Simpson's Evenness and Diversity that were similar between the two areas (HAC-R1 and HAC-U) and that were similar to reference and/or pre-breach conditions. Taxon richness at HAC-R1 in 2022 remained significantly lower than pre-breach conditions but was similar to reference conditions. These results indicate that the benthic invertebrate community at these areas of upper Hazeltine Creek have largely recovered to reference and/or pre-breach conditions when primary metrics (density, richness, Simpson's Evenness and Diversity) are considered. Key differences in the benthic community structure in 2022 at both areas of upper Hazeltine Creek, compared to pre-breach conditions, included higher relative densities of Chironomidae and Trichoptera, and lower relative densities of EPT (at HAC-R1 only), Arachnida (at HAC-U only), Ephemeroptera, and Plecoptera. Notable differences in EPT at both areas of upper Hazeltine Creek, compared to reference and pre-breach, were due to the lack of Plecoptera and the higher relative density of Trichoptera, which were dominated by a family of net-spinning caddisflies (Hydropsychidae) that are tolerant of habitat disturbances. The occurrence of Ephemeroptera families at the exposed areas that are less pollutant tolerant than those at the reference area suggests the chemical conditions (i.e., water chemistry) of the exposed areas are not limiting for benthic invertebrate community recovery. Comparison of community composition between the two upper Hazeltine Creek areas suggested greater recovery of the benthic invertebrate community in Reach 2 (at HAC-U) compared to Reach 1 (at HAC-R1), based on lower and higher relative densities of Chironomidae and Trichoptera at HAC-U compared to HAC-R1, respectively. Benthic invertebrate total dry weight biomass at both upper Hazeltine Creek areas in 2022 was unchanged since 2019 and was either similar to or higher than reference in each year from 2018 to 2022. In summary, these results indicate that both areas of upper Hazeltine Creek have recovered substantially since remediation to a condition that is similar to reference and/or pre-breach conditions based on primary metrics, but with some remaining differences in community composition compared to reference and pre-breach.

Periphyton and benthic invertebrate tissue quality monitoring in upper and lower Hazeltine Creek indicated that the primary analytes arsenic, copper, iron, and selenium had higher tissue concentrations compared to reference in 2022 for which the exposed-reference difference also increased significantly over time. There is some evidence of increased bioavailability and trophic transfer of copper in benthic invertebrate tissues in upper Hazeltine Creek, since BCFs and TTFs were elevated relative to reference and TTFs for composite-taxa tissues from HAC-U increased in 2022 to higher than pre-breach conditions. However, this was limited to composite-taxa benthic invertebrate tissues from Reach 2 (HAC-U) and was not observed in caddisfly tissues from HAC-U nor in benthic invertebrate tissues (caddisfly or composite-taxa) from Reach 1 (HAC-R1) of upper Hazeltine Creek, indicating a potentially localized increase. In contrast, there is no evidence of

increasing tissue concentrations or bioavailability and trophic transfer of copper over time in biota from lower Hazeltine Creek. For selenium, BCFs were lower than reference in periphyton tissues and elevated in caddisfly, but not composite-taxa samples (upper Hazeltine Creek only) and TTFs were typically stable over time compared to reference (except for caddisflies in Reach 2 of upper Hazeltine Creek). These results indicate that the bioavailability and trophic transfer of selenium has not increased due to mine influence, except for increased trophic transfer in caddisflies from Reach 2 of upper Hazeltine Creek. Selenium concentrations in most tissues in Hazeltine Creek (upper and lower) have increased since 2018 compared to reference (except composite-taxa benthic invertebrate samples from lower Hazeltine Creek), suggesting a mine influence on tissue concentrations, if not bioavailability and trophic transfer of selenium. In upper Hazeltine Creek, tissue selenium concentrations in 2022 were similar to or lower than pre-breach results in comparable tissues, while those in composite-taxa benthic invertebrate samples from lower Hazeltine Creek in 2022 exceeded pre-breach results. Mean selenium concentrations in benthic invertebrates from upper and lower Hazeltine Creek were above the BC interim guideline for aquatic life, suggesting potential selenium-associated risks to aquatic life. In composite-taxa benthic invertebrate samples from upper Hazeltine Creek, arsenic and iron concentrations in tissues from Reach 2 (HAC-U) and Reach 1 (HAC-R1), respectively, were higher in 2022 than previous monitoring years compared to reference, but this was owing to a temporal decrease at the reference area rather than an increase in tissues from upper Hazeltine Creek. Elevated concentrations of some secondary analytes in periphyton and/or benthic invertebrate tissues over time were also observed, relative to reference, but evidence was equivocal as to whether these observed increases in tissue concentrations were mine-related, and there was little or no evidence of increased metal bioavailability (based on assessment of BCFs and TTFs relative to reference and pre-breach). In comparison to 2021 when higher tissue concentrations and trophic transfer of mercury were identified compared to reference, mercury results in 2022 did not continue to demonstrate higher bioaccumulation in the aquatic biota compared to reference (as evidenced by tissue concentrations and TTFs similar to or lower than reference and/or prior years). Overall, periphyton and benthic invertebrate tissue quality data showed some evidence of moderately higher bioavailability and/or trophic transfer of selenium and copper in upper Hazeltine Creek, and selenium in lower Hazeltine Creek. Comparison of the two benthic invertebrate tissue types (caddisfly and composite-taxa) indicated that although some variability exists between the tissues, potential changes in analyte concentrations and TTFs in caddisfly tissues would largely be detected if sampling were limited to composite-taxa tissue samples only.

7.3.3 Key Findings

Key findings of CEMP monitoring of Hazeltine Creek from 2022 (Table 7.3) are:

Table 7.3: Summary of Mount Polley CEMP Results for Hazeltine Creek, 2022[a]

Area	Sediment	Periphyton		Benthic Invertebrate		Periphyton and Benthic Invertebrate Tissue Quality[d]
	Basic Chemistry[b]	Productivity[c]	Community[c]	Productivity[c]	Community[c]	
Reach 1 (HAC-R1)	-	Mean Chl-a < BCWQG and > moderately enriched stream threshold Chl-a > reference (slightly 1.7 SD) and baseline (1995, 1996) and pre-breach, > HAC-U (moderately 2.4 SD) AFDM > reference (moderate 4.2 SD) and HAC-U (slightly 1.9) Chl-a and AFDM in 2022 > 2017, 2018 and 2021, = 2019, 2020	Density = reference and HAC-U; Richness = reference and HAC-U Density in 2022 > 2021, 2019, = 2018 and 2020; Richness in 2022 > 2021, = 2018 to 2020	Dry biomass > reference (slightly 2.0 SD), = HAC-U; Dry biomass in 2022 = 2019 to 2021, > 2018	Density > reference (slightly 1.4 SD), = pre-breach and HAC-U; Richness = reference and HAC-U, < pre-breach (highly -5.4 SD) Density in 2022 = 2018 to 2020, >2021; Taxonomic richness in 2022 = 2019 to 2021, > 2018	Mean Se in caddisfly and BIC at HAC-U, HAC-R1, and HAC-D in 2022 > BCWQG Protection of Aquatic Life Se concentrations in 2022 > reference; Se concentrations in 2022 > 2018 (except HAC-D [BIC] = 2018), relative to reference; Se concentrations in 2022 ≤ pre-breach (except HAC-D [BIC] > pre-breach); Se BCFs in 2022 < reference, except HAC-R1 (Caddis) and HAC-U (Caddis) slightly > than reference; Se TTFs > reference but stable or decreasing over time except HAC-U (Caddis) in 2022 = 2021, > 2018 to 2020 Cu concentrations in 2022 > reference (except HAC-R1 [Caddis] < reference); Cu concentrations in 2022 ≤ 2018 (except HAC-U (BIC) > 2018 to 2021), relative to reference; Cu concentrations in 2022 > pre-breach (HAC-R1 and HAC-U [BIC], HAC-D [Peri, BIC]), = pre-breach (HAC-R1 and HAC-U [Peri]); Cu BCFs in 2022 = or slightly > reference (except HAC-U [BIC] > 2x reference); Cu TTFs in 2022 > reference at HAC-R1 (BIC) and HAC-U (BIC), ≤ 2018 (except HAC-U [BIC] and HAC-D [Caddis] > 2018), ≤ to pre-breach (except HAC-U [BIC] > pre-breach) Secondary analytes at HAC-R1, HAC-U and HAC-D showed some increases in concentration relative to reference and pre-breach but equivocal as to whether observed increases were mine-related and there was little or no evidence of increased metal bioavailability.
Upper (HAC-U)	Analytes of Interest = Cu, Se Cu > upper WSQG, and reference and pre-breach 95th percentile; Se > lower WSQG, and reference and pre-breach 95th percentile Cu in 2022 > 2018 to 2021, relative to reference; Se in 2022 > 2018 to 2021, relative to reference Cu and Se at reference in 2022 < 2018 to 2021, so temporal changes evaluated independent of reference: Cu in 2022 = 2019 to 2021, > 2018; Se in 2022 = 2021, > 2018 to 2020 TOC in 2022 = 2019 and 2021, > 2018 and 2020, relative to reference Temporal changes in metal concentrations associated with variability in sediment texture and physical characteristics among years	Chl-a < BCWQG and > moderately enriched stream threshold and baseline (1995) Chl-a = reference, = pre-breach, > baseline (1995); AFDM > reference (moderate 2.3 SD) Chl-a in 2022 = 2018 to 2021; AFDM in 2022 = 2019 to 2021, > 2018	Density < reference (slightly -1.7 SD); Richness > reference (slightly 1.4 SD) Density in 2022 = 2018 to 2021; Richness in 2022 > 2018, = 2019 to 2021	Dry biomass > reference (moderately 3.6 SD); Dry biomass in 2022 = 2019 to 2021, > 2018	Density = reference and pre-breach; Taxonomic richness = reference and pre-breach Density in 2022 = 2018 to 2021; Taxonomic richness in 2022 = 2019, 2020, > 2018, 2021	
Lower (HAC-D)	Analytes of Interest = Cu, Fe Cu > upper WSQG, and reference and pre-breach 95th; Fe > lower WSQG, and reference and pre-breach 95th Cu in 2022 = 2018, 2021, > 2019, 2020 relative to reference; Fe in 2022 < 2018, > 2019, = 2020, 2021 relative to reference; TOC in 2022 = 2018 to 2021 relative to reference Temporal changes in metal concentrations associated with variability in sediment texture and physical characteristics among years	-		-	-	

Notes: "-" = no data available, WSQG = British Columbia Working Sediment Quality Guidelines, Chl-a = Chlorophyll-a, AFDM = Ash Free Dry Mass, BCF = Bioconcentration Factor, TTF = Trophic Transfer Factor; Peri = Periphyton; Caddis = Caddisfly; BIC = Composite-taxa benthic invertebrate, GL = guideline. Temporal changes presented as "relative to reference" refer to changes in the exposed-reference difference over time as evaluated using a 2-way Analysis of Variance. Analytes presented for zooplankton and fish tissue quality endpoints are primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2022 or in all monitoring years.

[a] Findings in 2022 are included at minimum. Additional years are displayed (as available) to support temporal comparisons.

[b] WSQG Lower = Lower BC Working Sediment Guideline; WSQG Upper = Upper BC Working Sediment Quality Guideline (BCMOECCS 2021a,b).

[c] Magnitude of significant differences are classed as highly (>5x SD), moderately (5x to 2x SD), and slightly (<2x SD) different, where SD is the pooled standard deviation.

[d] BCWQG = British Columbia Water Quality Guideline for the protection of aquatic life - interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

- Copper and selenium in upper Hazeltine Creek and copper and iron in lower Hazeltine Creek were the analytes most elevated relative to sediment quality guidelines and reference. Copper concentrations in upper Hazeltine Creek sediments were temporally stable from 2019 to 2022, while selenium concentrations in 2022 were higher than in 2018 to 2020 but this increase was associated with higher TOC and lower sand content of sediments in 2022 (when evaluated independently of reference comparisons). Copper and iron concentrations in lower Hazeltine Creek sediments in 2022 were similar to or lower than in 2018 and TOC content of these sediments was temporally stable from 2018 to 2022, relative to reference.
- Periphyton productivity (measured as chlorophyll-a) in upper Hazeltine Creek areas was similar to or higher than reference and/or pre-breach from 2018 to 2022. Mean chlorophyll-a (mass per unit area) in upper Hazeltine Creek in 2022 was below the BCWQG and above the threshold for moderately enriched streams. Periphyton community condition was similar to reference and/or temporally stable for most endpoints. Community composition differences relative to reference were indicative of healthy periphyton communities in upper Hazeltine Creek.
- Benthic invertebrate community monitoring indicated that the community in upper Hazeltine Creek areas has recovered to reference and/or pre-breach conditions when primary metrics (density, richness, Simpson's Evenness and Diversity) are considered. Some remaining key differences in the benthic community structure at both areas of upper Hazeltine Creek, compared to pre-breach conditions, indicate the community composition has not fully recovered to pre-breach conditions, and differences between the two areas suggest greater recovery at HAC-U than HAC-R1.
- Concentrations of copper and selenium were higher than reference and increased over time and showed some evidence of moderately higher bioavailability and/or trophic transfer of selenium and copper in upper Hazeltine Creek, and selenium in lower Hazeltine Creek. Selenium concentrations in most tissues in Hazeltine Creek (upper and lower) have increased since 2018 compared to reference (except composite-taxa benthic invertebrate samples from lower Hazeltine Creek) but remained similar to or lower than pre-breach in upper Hazeltine Creek while those in lower Hazeltine Creek were higher than pre-breach in 2022. Mean selenium concentrations in benthic invertebrate tissue have exceeded the BC interim guideline since 2020 and 2022 in upper (HAC-R1 and HAC-U) and lower (HAC-D) Hazeltine Creek (1.23-, 1.67- and 1.14-times guideline, respectively). Copper was elevated relative to reference in 2022, and higher than pre-breach in most tissues and sampling years but the

difference relative to reference has been similar to reference over monitoring years except at HAC-U where concentrations in composite taxa-benthic invertebrate tissue samples were higher in 2022 than 2018 to 2021 (relative to reference). Copper TTFs were stable or decreasing over time and lower than pre-breach except for composite taxa-benthic invertebrate tissue samples from HAC-U which increased over time, and higher than pre-breach. This temporal increase in copper concentrations and TTFs in benthic invertebrates was limited to composite-taxa benthic invertebrate tissues from Reach 2 (HAC-U), indicating a potentially localized increase. The concentration and TTFs of most secondary analytes were similar to reference and pre-breach, and for analytes with increased concentrations, none showed bioaccumulation in tissues indicating equivocal mine-related effects over time.

7.4 Edney Creek

7.4.1 Aquatic Life

Periphyton and benthic invertebrate tissue quality monitoring in lower Edney Creek in 2022 indicated that tissue concentrations of several primary and secondary analytes were significantly higher at the exposed area (E1) than reference. However, for most metals, there was no consistent evidence of increasing metal concentrations in periphyton and/or benthic invertebrate tissues from the exposed area relative to the reference area over time. Copper was an exception, with concentrations in all exposed area tissues (i.e., periphyton, caddisfly, and composite-taxa benthic invertebrates) that were higher than reference. Most analytes demonstrated a lack of consistency among tissue types in concentrations and TTFs (except copper), BCFs that were only slightly above reference (except copper and cadmium), and TTFs that did not demonstrate increased bioavailability. These results collectively indicate that the potential mine-influence on analyte concentrations in lower Edney Creek appears limited to increased copper concentrations in benthic invertebrate tissues. Copper concentrations in exposed caddisfly and composite-taxa tissues were higher than reference in 2022, but copper TTFs were lower than reference in all years, indicating there is no evidence of increased copper bioavailability in aquatic biota in lower Edney Creek. However, the significant increase in copper concentrations in exposed caddisfly tissues in 2020, and again in 2022, relative to reference, is consistent with the recent completion of final remediation works in this area (in the summer of 2020 and 2021). Mean concentrations of selenium in caddisfly and composite benthic invertebrate tissue samples were well below the BC interim guideline for aquatic life, indicating that no selenium-associated effects to aquatic life would be expected.

7.4.2 Key Findings

Key findings of CEMP monitoring of Edney Creek in 2022 (Table 7.4) are:

- Periphyton and benthic invertebrate tissue from lower Edney Creek (E1) showed significantly elevated concentrations of several primary and secondary analytes relative to reference, including copper. For most analytes there was no evidence of increasing concentrations or bioavailability, and results were inconsistent among tissue types. Copper concentrations were higher in all tissue types in 2022 than 2019 to 2021, relative to reference, which was accompanied by higher BCFs than reference, but TTFs remained lower than reference. Mean selenium concentrations in benthic invertebrate tissue were below the BC interim guideline for aquatic life.

Table 7.4: Summary of Mount Polley CEMP Results for Lower Edney Creek, 2022 [a]

Periphyton and Benthic Invertebrate Tissue Quality [b]
Mean Se in caddisfly and BIC < BCWQG Protection of Aquatic Life Cu concentrations in 2022 (Peri, BIC, Caddis) > reference; Cu concentrations in 2022 = 2019 to 2021 (Peri and BIC), > 2019 to 2021 (Caddis), relative to reference Cu BCFs in 2022 = reference (BIC), slightly > reference (Caddis), moderately > reference (Peri) Cu TTFs in 2022 < reference, = 2019 to 2021 Secondary analytes showed some increases in concentration relative to reference but equivocal as to whether observed increases were mine-related and there was little or no evidence of increased metal bioavailability

Notes: TTFs = Trophic Transfer Factors; BCF = Bioconcentration Factor; Peri = Periphyton; Caddis = Caddisfly; BIC = Composite-taxa benthic invertebrate. Temporal changes presented as "relative to reference" refer to changes in the exposed-reference difference over time as evaluated using a 2-way Analysis of Variance. Analytes presented for zooplankton and fish tissue quality endpoints are primary and secondary analytes (Table 2.4) with a significant positive exposed - reference difference in 2022 or in all monitoring years.

[a] Findings in 2022 are included at minimum. Additional years are displayed (as available) to support temporal comparisons.

[b] BCWQG = British Columbia Water Quality Guideline for the protection of aquatic life - interim selenium guideline for benthic invertebrates (4 mg/kg dw; BCMOE 2014).

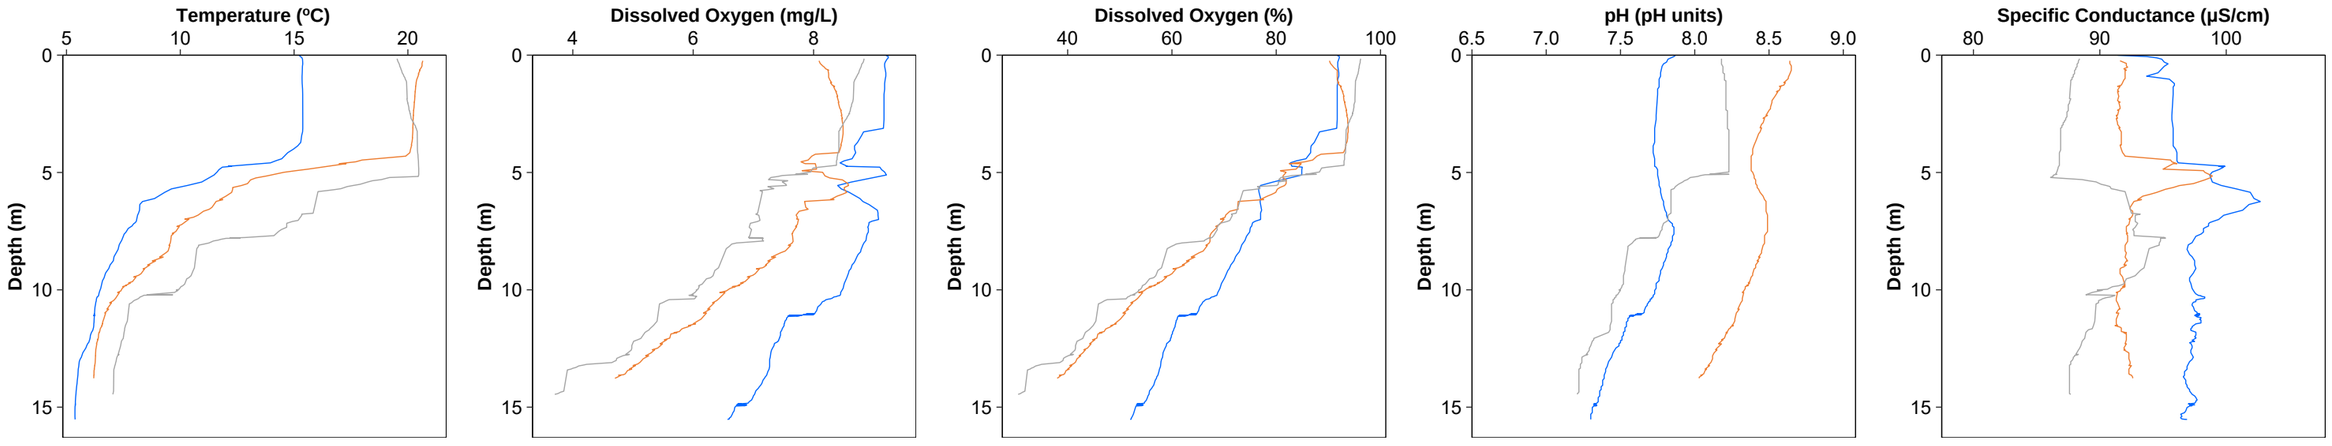
APPENDIX A
SAMPLING LOCATIONS AND SUPPORTING INFORMATION

APPENDIX A.1
LAKES

Bootjack Lake (BOL-B2; Reference)



Polley Lake (POL-P2; Exposed)

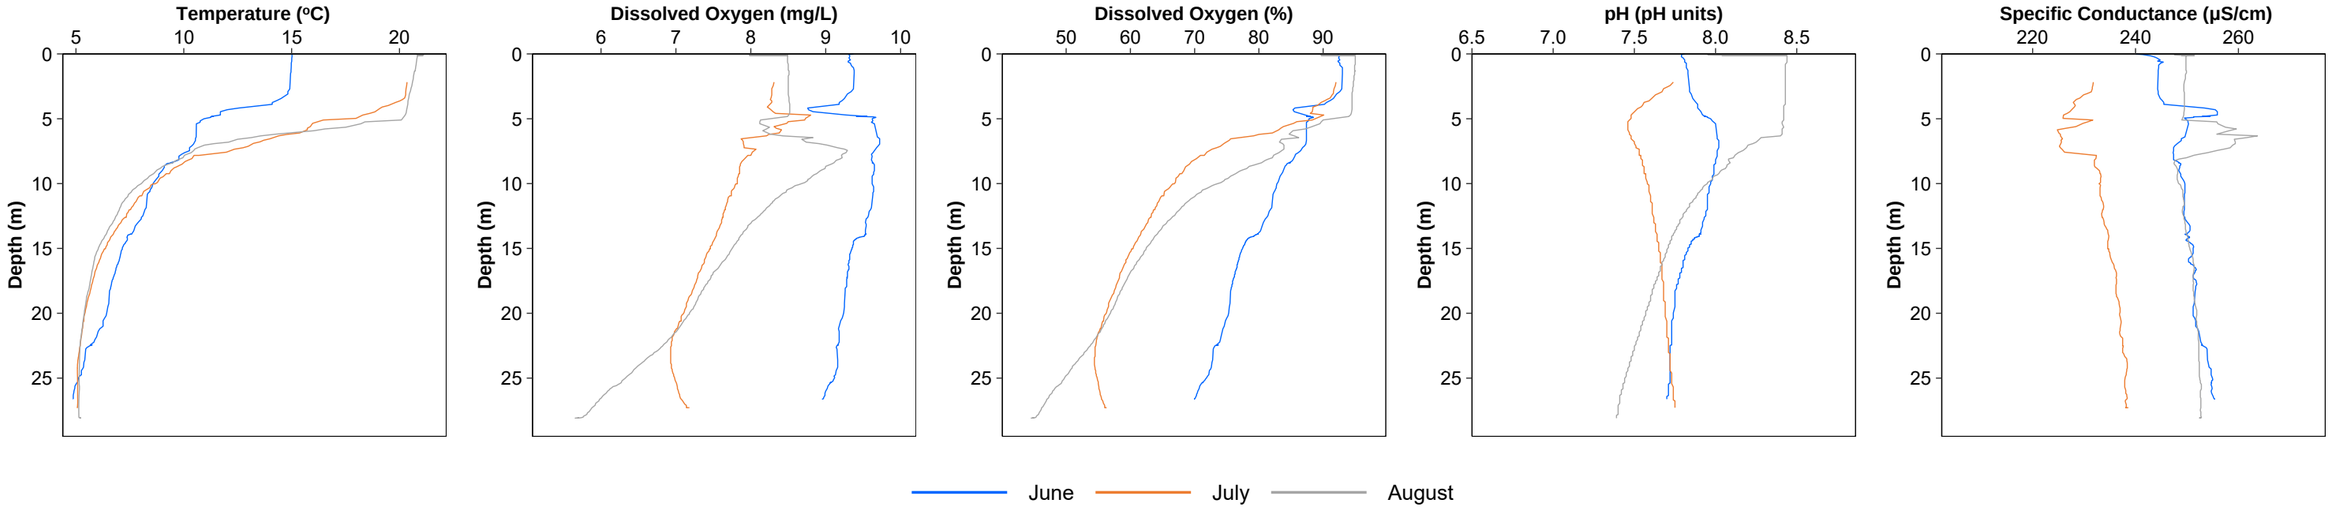


Figure A.1.1: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Plankton Sampling Events for Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Areas, June to August 2022

Notes: mg/L = milligrams per litre, µS/cm = microSiemens per centimeter, ºC = degrees Celsius, % = percent.

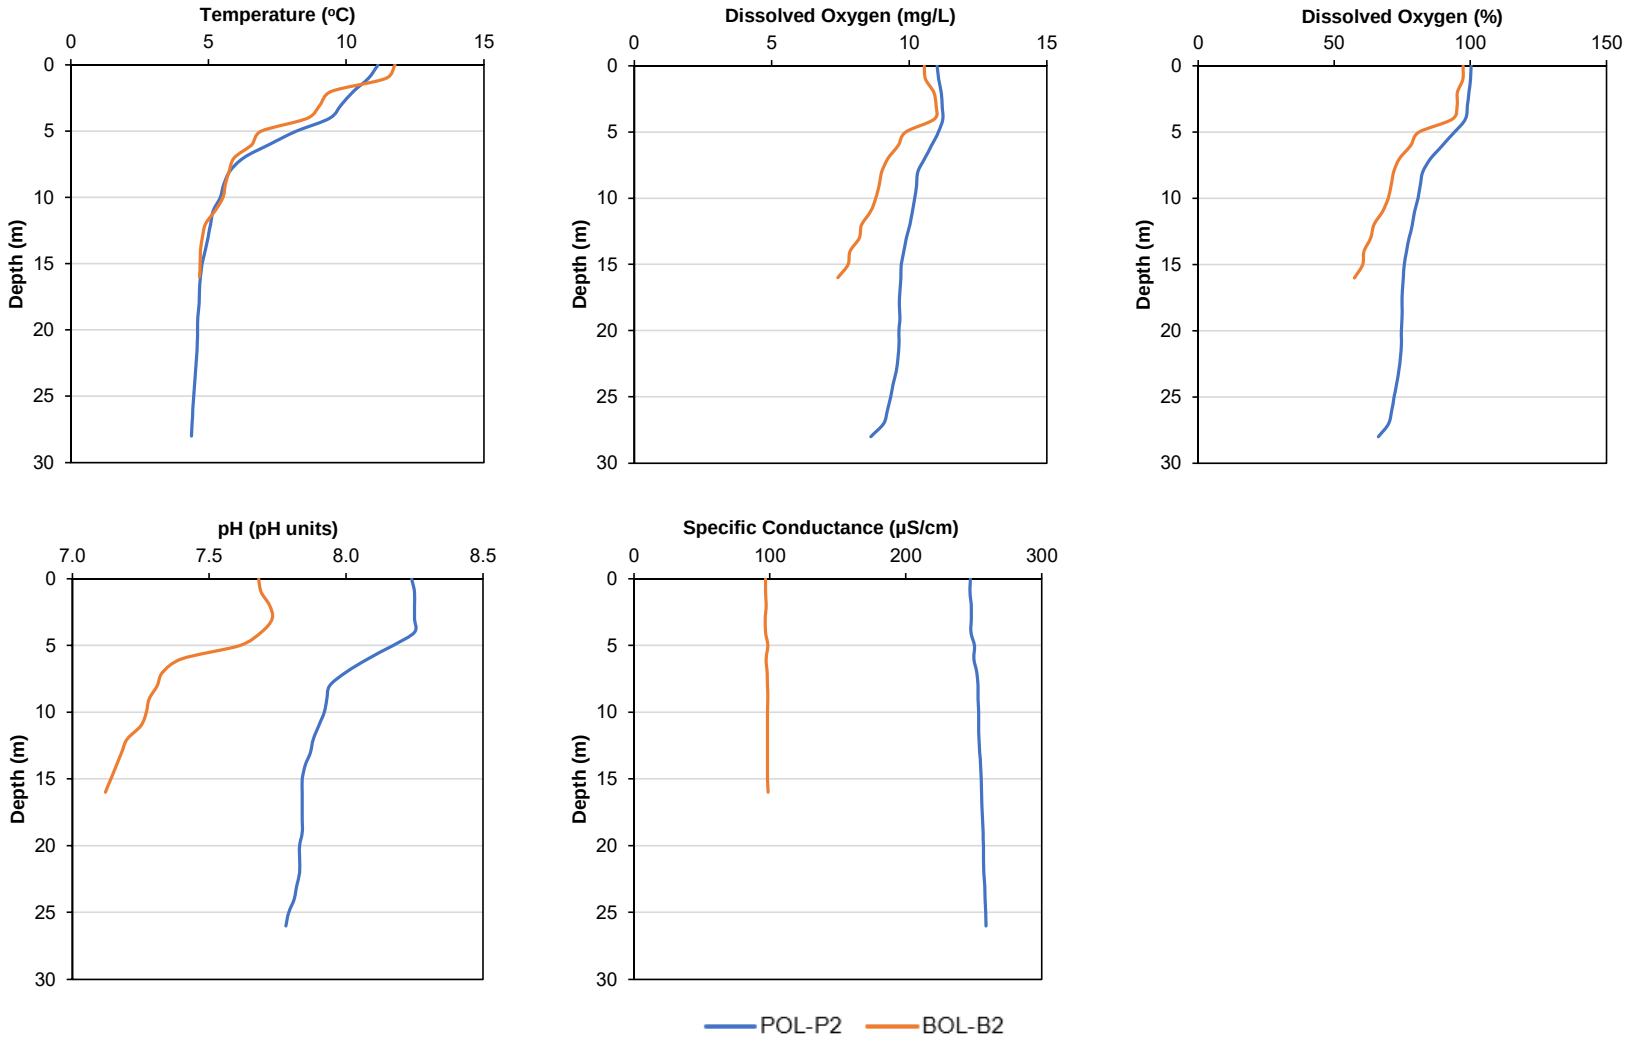

Figure A.1.2: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Fish Monitoring for Polley Lake (POL-P2; Exposed) and Bootjack Lake (BOL-B2; Reference) Areas, May 2022

Notes: mg/L = milligrams per litre, µS/cm = microSiemens per centimeter, °C = degrees Celsius, % = percent.

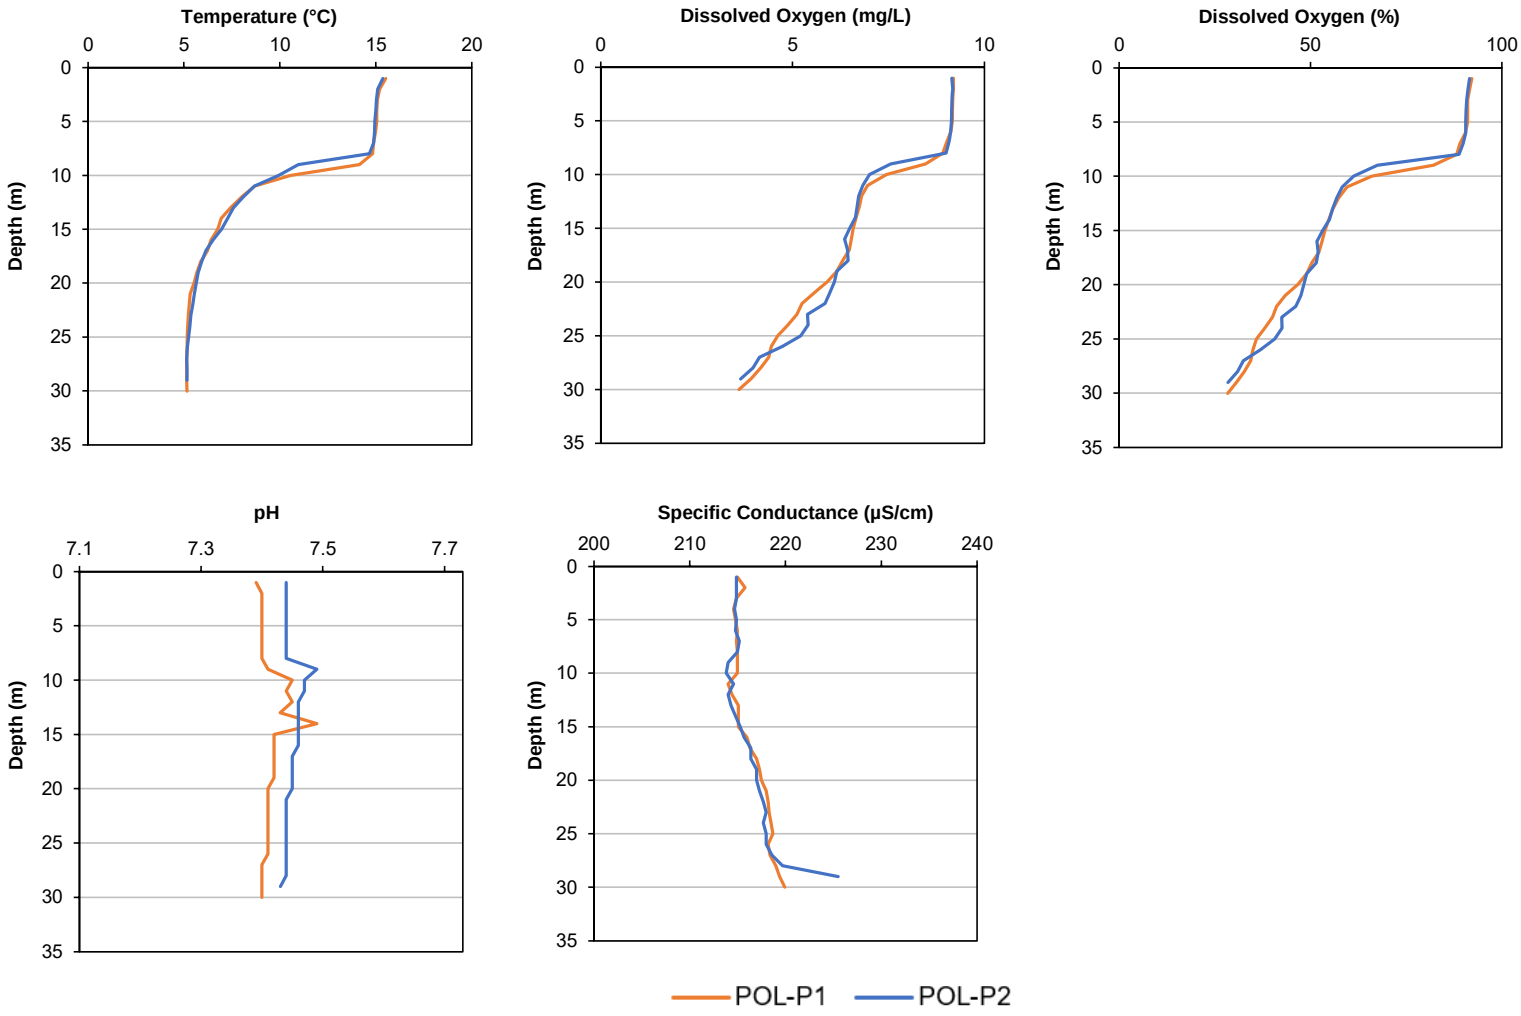

Figure A.1.3: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Fish Monitoring for Polley Lake (POL-P1, POL-P2; Exposed), September 2022

Notes: mg/L = milligrams per litre, µS/cm = microSiemens per centimeter, °C = degrees Celsius, % = percent.

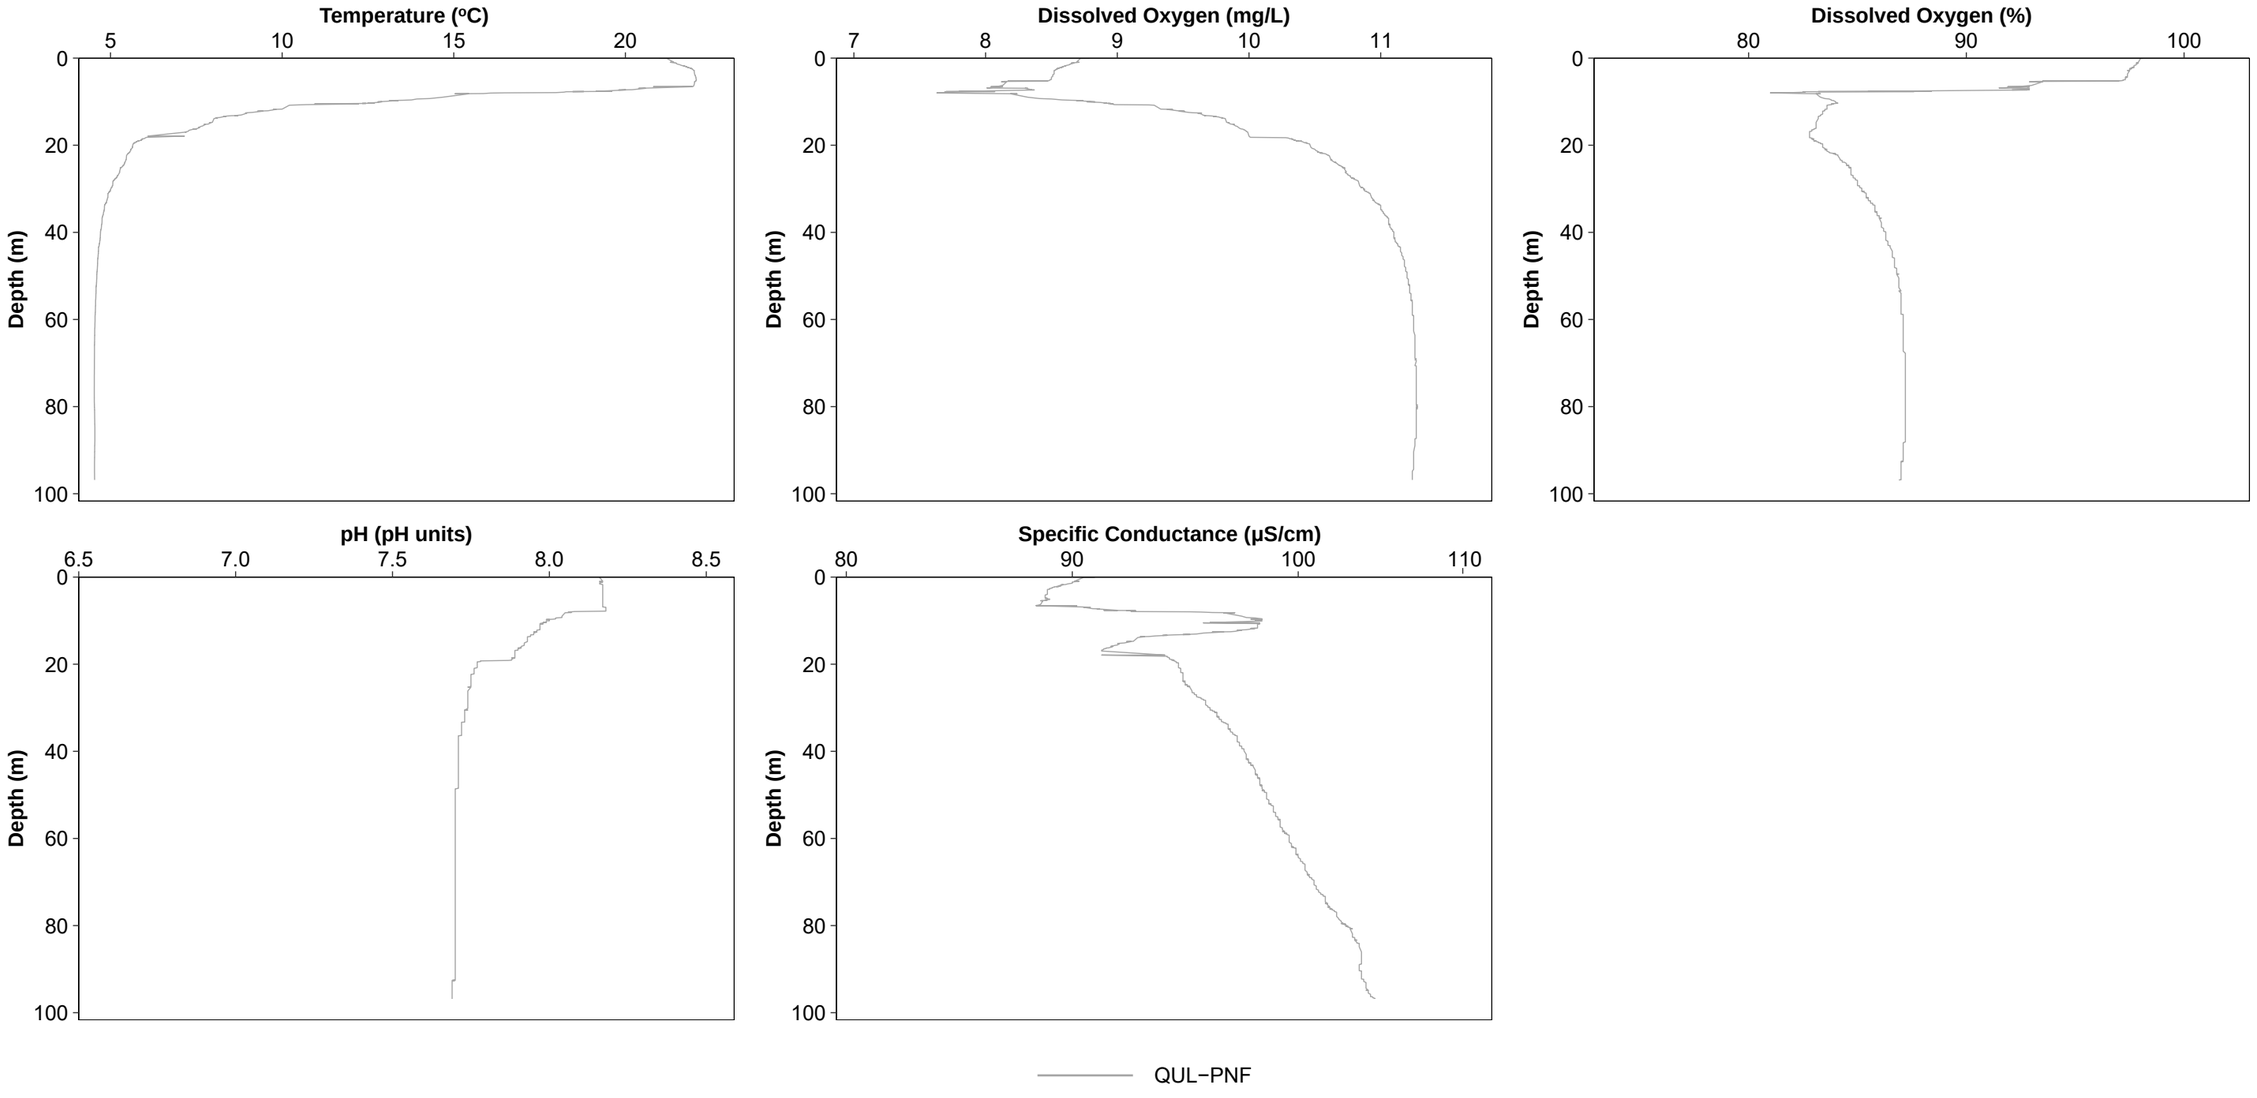

Figure A.1.4: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Sediment Quality and Benthic Invertebrate Monitoring for Quesnel Lake at QUL-PNF (Exposed) Deep Area, August 2022

Notes: mg/L = milligrams per litre, µS/cm = microSiemens per centimeter, °C = degrees Celsius, % = percent.

Quesnel Lake – QUL-ZOO-7 (Reference)

Quesnel Lake – QUL-ZOO-1 (Exposed)

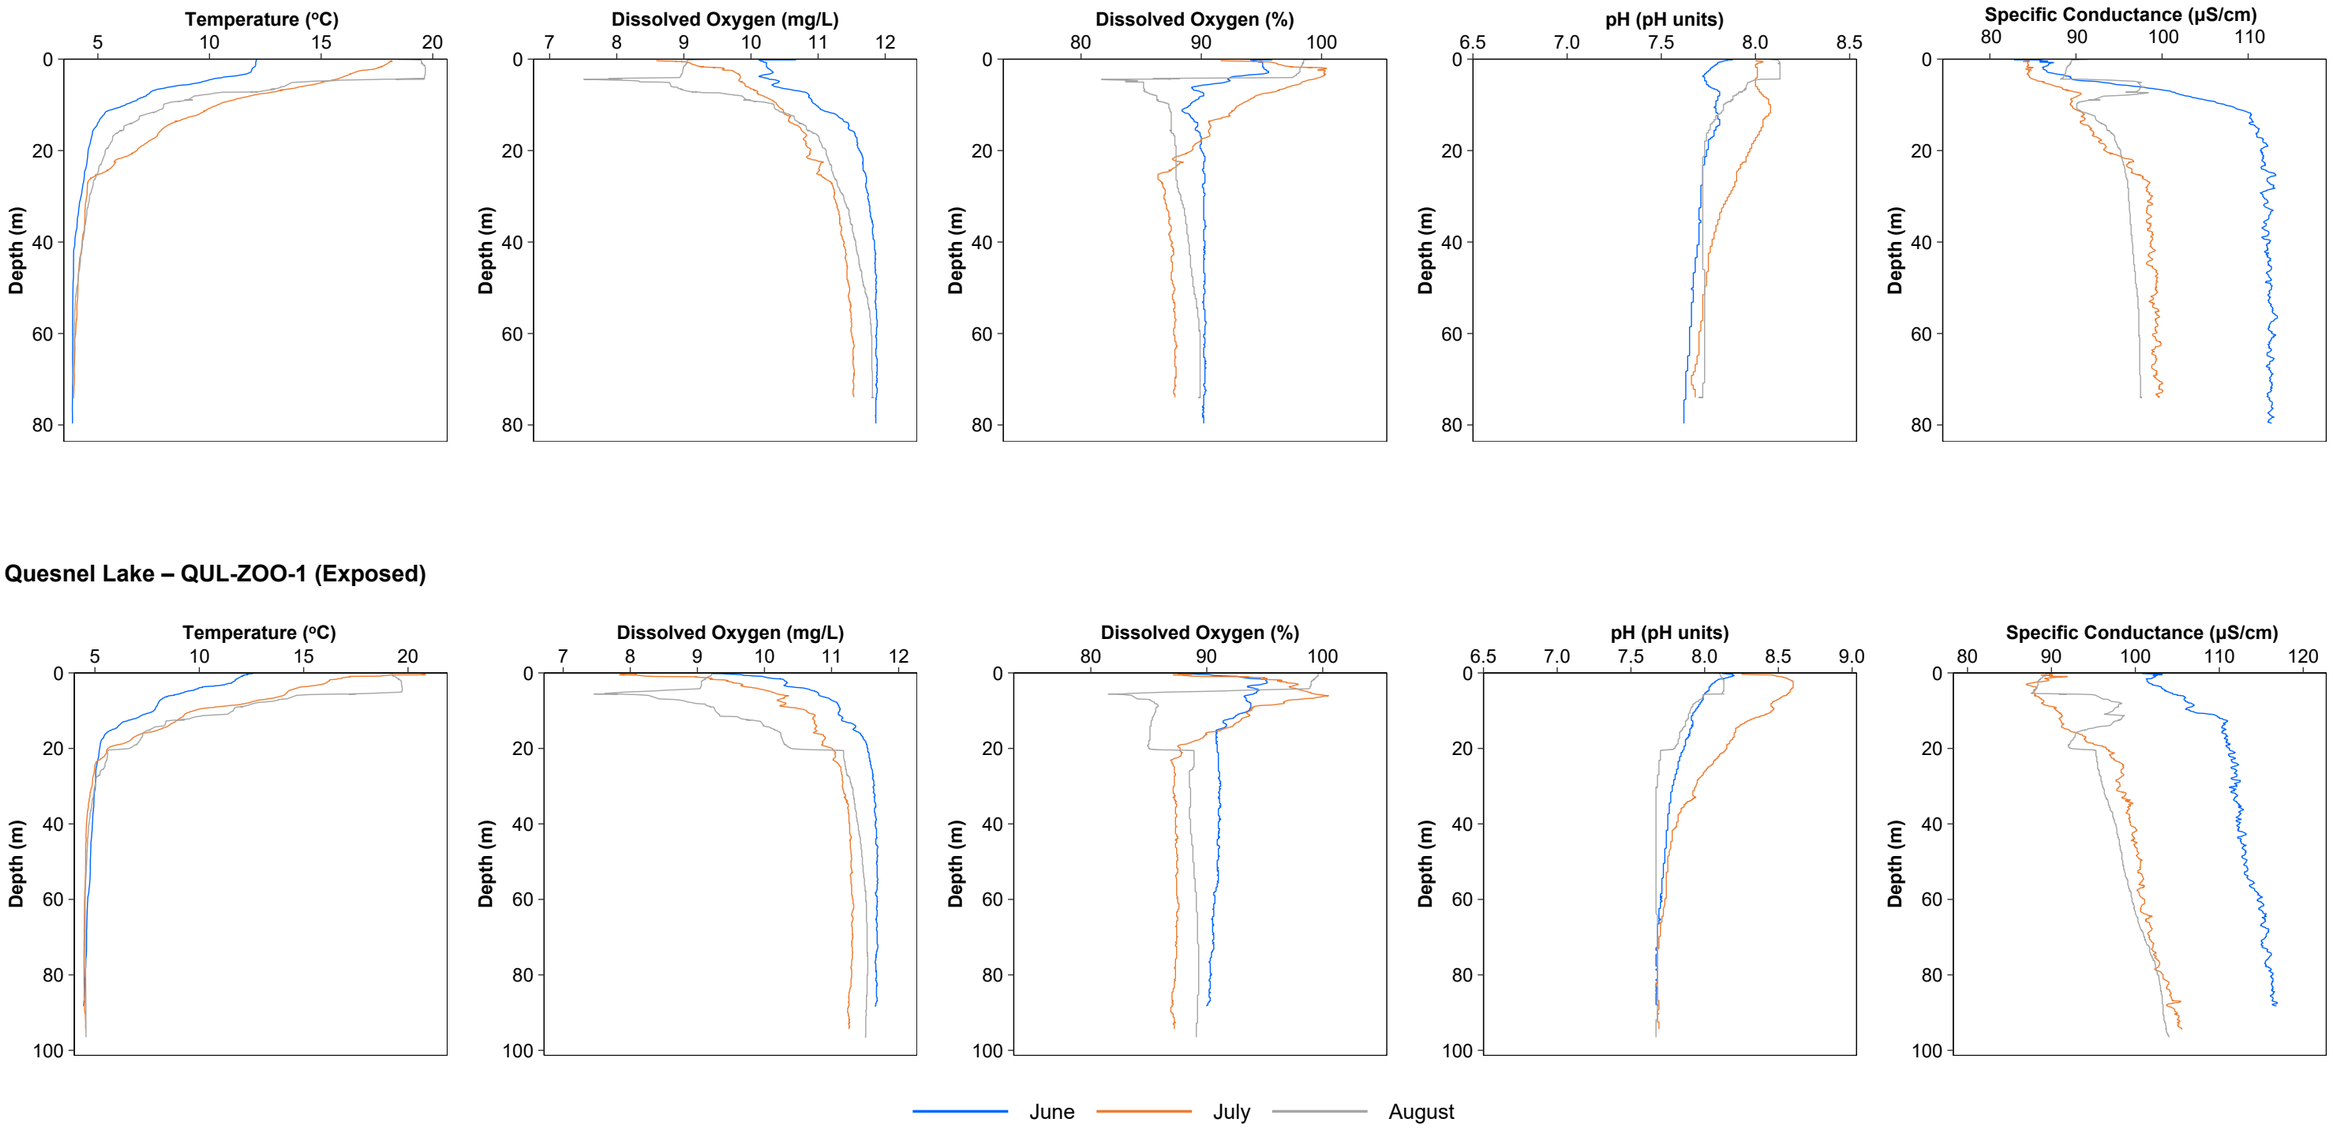

Figure A.1.5: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Plankton Sampling Events for Quesnel Lake at QUL-ZOO-1 (Exposed) and QUL-ZOO-7 (Reference) Areas, June to August, 2022

Notes: mg/L = milligrams per litre, µS/cm = microSiemens per centimeter, ºC = degrees Celsius, % = percent.

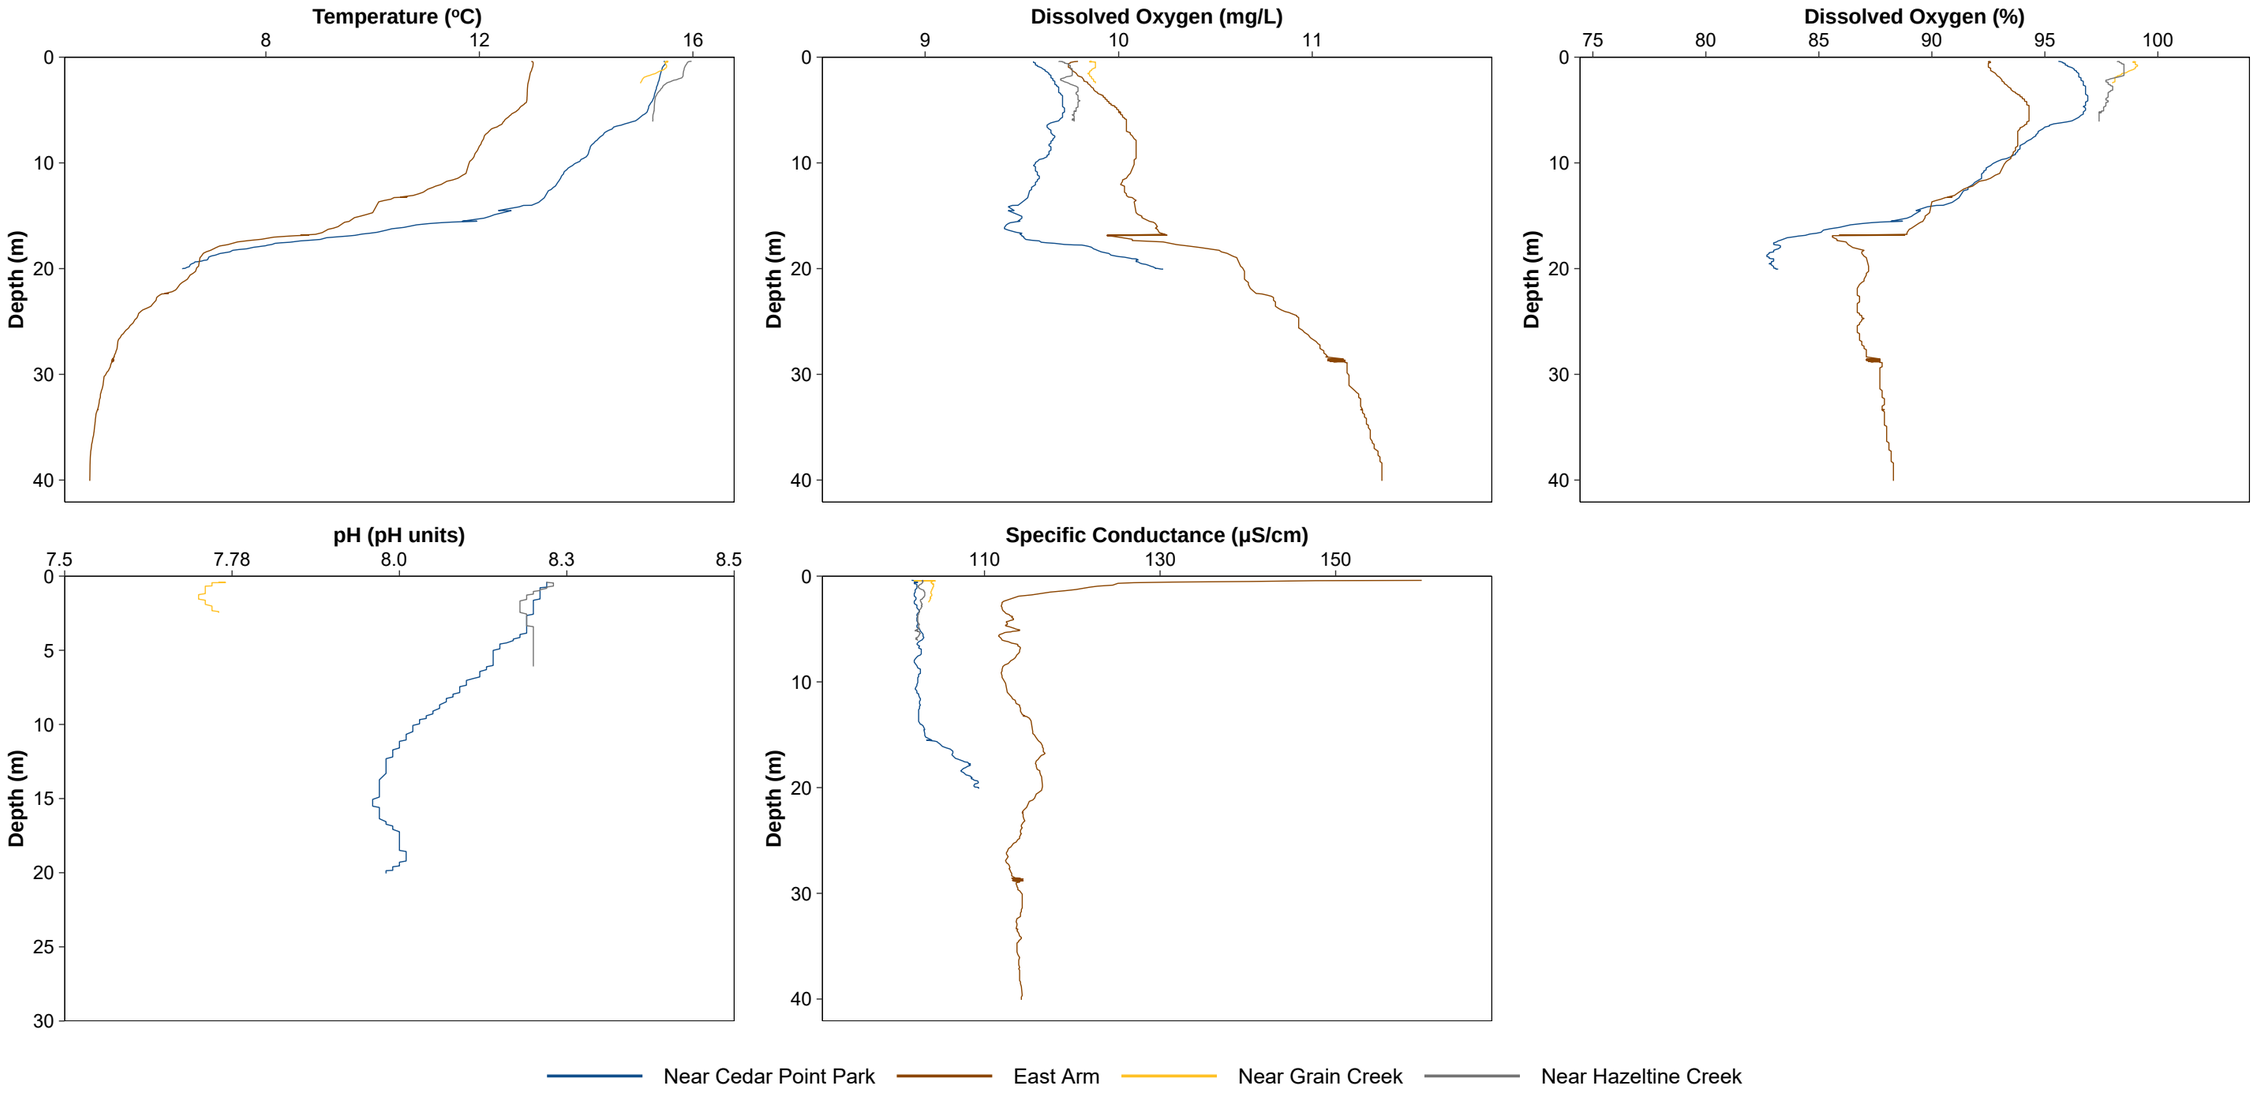

Figure A.1.6: Vertical Profiles of Temperature, Dissolved Oxygen, pH, and Specific Conductance during Fish Monitoring for Quesnel Lake (Exposed and Reference) Areas, October 2022

Notes: Accurate pH results for the East Arm (Reference) could not be recorded due to an equipment malfunction, therefore are not displayed. mg/L = milligrams per litre, µS/cm = microSiemens per centimeter, ºC = degrees Celsius, % = percent

Table A.1.1: Sediment and Benthic Invertebrate Community Monitoring Methods and Locations for Polley Lake (Exposed), Bootjack Lake (Reference), and Quesnel Lake (Exposed and Reference) Shallow and Deep Areas, August 2022

Note: "-" = no data available or not applicable.

[a] Benthic invertebrate community samples were collected using a Petite Ponar, with 5 grabs per sample, 250 µm sieve size. No macrophytes or algae were documented in the samples collected.

Notes: "-" = no data available, Y = Yes, N = No. DI = Depth-Integrated. Measurement increments on Secchi disk rope were more precise in July (to nearest 0.10 m) than in June and August (to nearest 0.5 m).

[a] Zooplankton tissue hauls for BOL-B2-1 in July were collected at a depth of 16 m (Haul #1) and 15 m (Haul #2), as the first haul potentially had some suspended sediment present. The presented depth is a mean of these two haul depths.

[b] pH not recorded due to probe malfunction.

[c] Field duplicate sample collected at this station. For phytoplankton sampling, the duplicate identified was a chlorophyll-a productivity sample, for zooplankton tissue it was a split duplicate zooplankton tissue sample, and for water quality sampling it was a split duplicate water quality sample.

Table A.1.4: Habitat Information Associated with Fish Population Monitoring in Polley Lake, September 2022

Station ID		Exposed
		Polley Lake
Date Sampled		26-Sep-22
UTM (NAD83, Zone 10U)	Easting	595166
	Northing	5822183
Habitat Characteristics		
Surrounding Land Use		Mining, recreational
Riparian Vegetation (decreasing dominance)		Alder, cedar, spruce, grasses, reeds
Evidence of Anthropogenic Disturbances		Mining, access road, water intake pipe, public boat launch
Aquatic Vegetation	% Emergent	5
	% Submergent	15
	% Floating	5
	% Attached Algae	10
Shoreline (% area coverage)	% Bedrock	0
	% Boulder	0
	% Cobble	5
	% Gravel	5
	% Sand / Finer	75
	% Organic Debris	15
Littoral Substrate (% area coverage)	% Bedrock	0
	% Boulder	0
	% Cobble	5
	% Gravel	5
	% Sand / Finer	75
	% Organic Debris	15

Note: Littoral assessment largely based on shoreline observations, as majority of lake could not be observed.

B1 INTRODUCTION

B1.1 Background

A variety of factors can influence the physical, chemical, and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Depending on the magnitude of inaccuracy or imprecision within the data, these sources of variation have the potential to affect interpretation and the reliability of conclusions made from the data. Therefore, it is important to ensure that programs incorporate appropriate steps to control the non-natural sources of data variability (i.e., minimize the variability that does not reflect natural spatial and temporal variability in the environment) and thus assure the quality of the data. Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. A data quality review (DQR) involves comparison of actual field and laboratory measurement performance to Data Quality Objectives (DQOs) established for a particular study, such as evaluation of Laboratory Reporting Limits (LRL), blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). Trusted analytical laboratories certified by Canadian Association for Laboratory Accreditation (CALA) with a rigorous internal quality assurance program were selected to ensure the highest possible data quality. DQOs were established *a priori* to reflect reasonable and achievable performance expectations. Programs involving a large number of samples and analytes usually yield some results that exceed DQOs. This is particularly so for multi-element scans since the analytical conditions are not necessarily optimal for every element included in the scan. Scan results may be considered acceptable if no more than 20% of the parameters fail to meet DQOs. Overall, the intent of DQR is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of the project.

B1.2 Quality Control Samples

A DQR was conducted on all laboratory data collected as part of the Mount Polley Mine Comprehensive Environmental Monitoring Program (CEMP) 2022. The objective of a DQR is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

A DQR involves the examination of analytical results associated with several types of Quality Control (QC) samples collected (or prepared) in the field and laboratory. General QC samples collected for this project, and a description of each, include the following:

- **Blanks** are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed in the same way as regular samples. These samples will reflect any contamination of samples occurring in the field (in the case of field or trip blanks) or in the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be non-detectable.
- **Laboratory Duplicates** are replicate sub-samples created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.
- **Field Duplicates** are samples collected from a randomly selected field station that are homogenized to the extent possible, split and analyzed separately in the laboratory. The duplicate samples are handled and analyzed in an identical manner in the laboratory.
- **Spike Recovery Samples** are created in the laboratory by adding a known amount/concentration of a given analyte (or mixture of analytes) to a randomly selected test sample previously divided to create two sub-samples. The spiked and regular sub-samples are then analyzed in an identical manner. The spike recovery represents the difference between the measured spike amount (total amount in the spiked sample minus the amount in the original sample) relative to the known spike amount (as a percentage). Two types of spike recovery samples are commonly analyzed. Spiked blanks (or blank spikes) are created by adding a known concentration of analytes to an uncontaminated blank (e.g. resin gel, distilled water) whereas matrix spikes (MS) are created using field-collected samples. The analysis of spiked samples provides an indication of the accuracy of analytical results.
- **Certified Reference Materials** are commercially prepared (or commercially homogenized) samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to target results to provide a measure of analytical accuracy. The results are reported as the percent of the known concentration that was recovered in the analysis.
- **Laboratory Control Samples** are created in the laboratory to have a known analyte concentration in a matrix free of interferences, such as deionized water or reference sand.

The sample results are compared to the target results to confirm that the analytical method is accurate in a purified reference sample. The results are reported as the percent of the known concentration that was recovered in the analysis.

- **Reference Toxicant Tests** are toxicity tests run concurrent to the sediment toxicity test where a reference toxicant with laboratory-developed limits are used. The results of the reference toxicant testing should fall within the developed limits. This testing ensures that internal test systems are in check and that the sensitivity of the test organisms are within an expected range.

- **Laboratory Sorting Duplicates** are randomly selected grabs of the initially sorted benthic invertebrate community material. These samples are recounted and the number of benthic invertebrates that were not recovered during the initial sort was determined. In order to reduce bias, the recounting was conducted by an analyst uninvolved in the initial sample processing. This check was performed on 10% of samples and determines the accuracy through assessment of recovery (sorting) efficiency and quantifies any under-estimation of organism enumeration.

- **Taxonomic Quality Control Samples** are a randomly selected portion of a benthic invertebrate community field sample to be assessed by the laboratory using an internal quality control audit. A blind re-enumeration and re-identification of random samples is performed by an analyst uninvolved in the original sample processing. This assessment quantifies taxonomic misidentification among laboratory analysts and ensures accurate organism identities are reported.

- **Laboratory Subsamples** are community samples prepared by the laboratory to ensure that the fraction of the total sample examined was an accurate representation of the total number of organisms. By comparing the amount recovered between at least two sub-samples, one can assess the analytical precision. In addition, comparisons of the sub-samples from the whole community sample allows for an evaluation of sub-sampling accuracy.

B2 WATER CHEMISTRY

B2.1 Laboratory Reporting Limits

The analytical ALS laboratory reports for water chemistry (VA222B4117, VA22B4435, KS2202711, VA22B7687, VA22B8478, VA22C0064, VA22C0091, and VA22C0362; Appendix G) were examined to provide an inventory of analytes for which one or more results were below the LRL. The range of reported LRLs for these analytes (were assessed relative to existing British Columbia water quality guidelines (BCMOECCS 2021a,b; Table B.1). For analytes with results <LRL, all reported LRLs were lower than applicable BCWQG guidelines. Overall, the achieved LRLs were appropriate for this study.

B2.2 Laboratory and Field Blanks

A total of 134 method blank (MB) samples were analyzed in the ALS Laboratory Reports (VA222B4117, VA22B4435, KS2202711, VA22B7687, VA22B8478, VA22C0064, VA22C0091, and VA22C0362; Appendix G). Of the 756 reported MB results, only two (total alkalinity in one sample and total manganese in one sample; see laboratory reports VA22B7687 and VA22C0091, respectively; Appendix G) exceeded the laboratory DQO and had detectable concentrations. However, results for these analytes were considered reliable by the laboratory, as they were greater than five-times the detected MB result. As the number of MBs that exceeded the laboratory DQO was low (0.294%), and the MB results were deemed as not having impact on the reliability of the results, these laboratory flags had a negligible impact on data reliability.

One field blank and one trip blank sample were submitted to ALS for water chemistry analyses to assess the potential for field sampling and shipping/transport contamination (KS2202711; Appendix G). Field and trip blanks were subject to the same laboratory DQOs as were used for MBs (i.e., concentrations should be <LRL). All analytes in the field blank and trip blank samples were below detection, indicating no appreciable field sampling or shipping/transportation contamination.

B2.3 Data Precision

A total of 22 laboratory duplicate samples were used to evaluate precision within the ALS Laboratory Reports (VA222B4117, VA22B4435, KS2202711, VA22B7687, VA22B8478, VA22C0064, VA22C0091, and VA22C0362; Appendix G), totaling 743 individual analyte results. All measurements were within the laboratory DQO, indicating that the laboratory analytical precision can be considered excellent.

Table B.1: Laboratory Reporting Limit (LRL) Evaluation for Water Chemistry Relative to BCWQG, Mount Polley Mine, 2022

Analyte	Units	British Columbia Water Quality Guidelines[a]		Range of LRLs	No. Sample Results < LRL

Notes: "-" = no applicable guideline. Only analytes one or more result <LRL or LRLs above applicable guidelines are displayed. are displayed. The total number of water chemistry samples collected in 2022 was 217, which included six field duplicate samples. <LRL counts include results for one trip and one field blank (n=2 samples).

[a] British Columbia Water Quality Guidelines (BCWQG; BCMOECCS 2021a,b).

Field sampling precision looks at relative percent difference (RPD), calculated as follows:

$$RPD = \frac{|R1 - R2|}{(|R1 + R2|/2)} * 100$$

Where R1 is the value of the original ("parent") sample and R2 is the value of the duplicate sample, with the absolute difference and sum of the two samples used. RPDs cannot be calculated if both values are below the LRL. If the original and duplicate sample have the same value, then the RPD is 0%.

There are two applicable DQOs for field duplicates:

1. Each RPD comparison between the original and duplicate result should be ≤ 30%; and,
2. Within each original and duplicate pairing (i.e., each duplicate pair), fewer than 20% of the total comparisons should be above the 30% DQO.

Six pairs of field duplicate samples were collected to assess water chemistry field sampling precision (Table B.2). Several RPDs could not be calculated as both analyte concentrations were below the LRL. Of the six field duplicate sets, five of six sets had <20% of analyte comparisons in exceedance of the RPD DQO (Table B.2), indicating excellent field precision. Several analytes of interest exceeded the RPD DQO. Though RPDs for these analytes were above the 30% DQO, they were not consistently above the DQO in all duplicate sets (i.e., were >30% RPD in only one or two duplicate sets; Table B.2). High RPDs could be a result of field sampling inconsistencies, contamination (field or laboratory), or variability associated with multi-element scans (see section B2.6). Overall, water chemistry samples can be considered to have excellent field precision and reproducibility.

B2.4 Data Accuracy

Data accuracy was evaluated based on results of 139 Laboratory Control Samples (LCS) and 19 Matrix Spike (MS) samples within the ALS Laboratory Reports (VA222B4117, VA22B4435, KS2202711, VA22B7687, VA22B8478, VA22C0064, VA22C0091, and VA22C0362; Appendix G). All of 688 LCS individual analyte results met the laboratory DQO. Out of 614 individual MS analyte results, 118 (19.2%) individual MS results could not be reliably calculated due to high background concentrations (Appendix G); however, the remainder of the MS results met the laboratory DQO. As all LCS and MS results that could be reliably calculated met the laboratory DQO, the accuracy achieved by the laboratory in this study can be considered acceptable.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: LRL = Laboratory Reporting Limit. If one result in a duplicate pair was below the LRL, RPD was calculated using the LRL in place of the value below detection results. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: LRL = Laboratory Reporting Limit. If one result in a duplicate pair was below the LRL, RPD was calculated using the LRL in place of the value below detection results. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated.

B2.5 Hold Times

The recommended hold times were exceeded for several physical tests, such as laboratory pH (hold time of 15 minutes; exceeded in all samples collected), turbidity, and conductivity (Appendix G)[1]. For these physical tests (pH, turbidity, conductivity), *in situ* measures were used for data interpretation and, as such, hold time exceedances for these laboratory results have no impact on data interpretability. The recommended hold time for total suspended solids (TSS), total dissolved solids (TDS), and dissolved orthophosphate were exceeded in two samples (TSS and orthophosphate) and four samples (TDS; VA22B4435, VA22B4117; Appendix G). Hold time for nitrite and nitrate were exceeded in two samples each (VA22B7687; Appendix G). Most of these hold time exceedances occurred after receipt of the samples by the laboratory (i.e., samples were received by the laboratory in sufficient time for analysis). For two samples, the hold times were exceeded prior to laboratory receipt due to a combination of challenges associated with the logistics of expedited sample shipments from a remote area and the short hold times. Analyte results with hold time exceedances were similar to those samples without hold time exceedances 2022 and were within the range of historic results, suggesting little if any impact of the hold time exceedances on analyte results

B2.6 Other Concerns

Results for several analytes showed dissolved concentrations that were greater than the corresponding total concentrations (VA220362, VA22B4435, VA22C0091; Appendix G). Differences were less than two-times the concentration of total analytes and these results were verified by repeat analysis. This unexpected result could be a result of contamination during field filtration, during the sample preparation at the laboratory, or could represent inevitable variability associated with multi-element scans.

B2.7 Data Quality Statement

Water chemistry data collected for the 2022 CEMP were of acceptable quality as characterized by good detectability, appropriate LRLs, negligible analyte concentrations in MBs, good laboratory precision and accuracy, and few hold time exceedances. Only three primary analytes (arsenic, and copper, and iron) and four secondary analytes (cadmium, manganese, total phosphorous, and dissolved tin) were identified as having failed a DQO (in field duplicate samples), and these analytes were not consistently elevated across sample pairs. Since all other quality control samples for these analytes were good, overall

[1] Laboratory-filtered chlorophyll-a results exceeded the recommended hold times as reported in laboratory reports VA22B4117 and VA22B4435. These results were excluded from the DQR section field-filtered chlorophyll-a results reported in VA22B4431 were used for data analysis.

quality of these analyte data would be good. Overall, the 2022 water quality data can be used with a good level of confidence for interpretation.

B3 SEDIMENT CHEMISTRY

B3.1 Laboratory Reporting Limits

The analytical ALS laboratory reports for sediment chemistry (VA22B8489 and VA22C0370; Appendix G) were examined to provide an inventory of analytes for which for which one or more results were below the LRL. The range of reported LRLs for these analytes were assessed relative to applicable British Columbia working sediment guidelines (BCMOECCS 2021a,b; Appendix Table B.3). Analytes that had LRLs that were frequently below detection did not have associated guidelines (i.e., all analytes that had associated guidelines were 100% detectable; Appendix Table B.3). Overall, the achieved LRLs were appropriate for this study.

B3.2 Laboratory Blanks

A total of 12 MB samples were analyzed in the ALS Laboratory Reports (VA22B8489 and VA22C0370; Appendix G). All 144 reported MB results met the laboratory DQO, indicating no inadvertent contamination within the laboratory.

B3.3 Data Precision

A total of 12 laboratory duplicate samples were used to evaluate precision in the ALS Laboratory Reports (VA22B8489 and VA22C0370; Appendix G). Of the 148 analyte results, only two results (antimony and lead; VA22B8489) did not meet the laboratory DQO due to sample heterogeneity. As these results only represents 1.35% of all laboratory duplicate analyte results, laboratory analytical precision was considered excellent.

A total of five sets of field duplicate samples were collected to assess sediment chemistry field sampling precision (Appendix Table B.4; see Section B.2.3 for explanation on RPD calculation and DQOs). Several RPDs could not be calculated as both analyte concentrations were below the LRL. Of the 202 comparisons that could be calculated, only seven RPDs exceeded the DQO of 30% (3.47% of all comparisons; Appendix Table B.4). These exceedances were isolated to two of the five sets of samples, and included one comparison for each total nitrogen, antimony, cadmium, lead, titanium, and zirconium. As such, it is expected that differences were related to sample heterogeneity and/or variability during the multi-element scan. Since the overall occurrence of field duplicate analyses DQO exceedances was low, samples were considered to have excellent field precision and reproducibility.

B3.4 Data Accuracy

Table B.3: Laboratory Reporting Limits (LRLs) for Sediment Chemistry Analyses, Mount Polley Mine, 2022

Analyte	Unit	BCWSG[a]		Range of LRLs	No. Sample Results < LRL
		Long-term	Short-term		
Anions and Nutrients					
Total Nitrogen	%	-	-	0.02	3 (6.0%)
Metals					
Bismuth	mg/kg	-	-	0.1	22 (44.0%)
Boron	mg/kg	-	-	5.0	14 (28.0%)
Thallium	mg/kg	-	-	0.05	14 (28.0%)
Tin	mg/kg	-	-	0.20	2 (4.00%)
Zirconium	mg/kg	-	-	1.0	3 (6.00%)

Notes: "-" = no applicable guideline. Only analytes with one or more results < LRL or LRLs above applicable guidelines are displayed. The total number of sediment samples collected in 2022 was 50, which includes six field duplicate samples.

[a] British Columbia Working Sediment Guidelines (BCWSG; BCMOECCS 2021a) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2021b).

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: Relative Percent Difference (RPD) was calculated using < Laboratory Reporting Limit (LRL) results at the LRL if one result in a duplicate pair was below the LRL. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated.

Data accuracy for sediment chemistry analyses completed by ALS was evaluated based on the analysis of 16 LCS samples and 10 reference material (RM) samples. Of the 148 individual LCS results, only one result for zirconium (0.676% of LCS samples) did not meet the laboratory DQO due to a greater recovery limit compared to the upper control limit (VA22B8489; Appendix G). However, this result exceeded the DQO by fewer than 10% of analytes in a multi-element scan, which is considered acceptable as per the OMOE and the CCME (VA22B8489; Appendix G). All 130 individual RM results met the laboratory DQO. Overall, accuracy achieved by the laboratory was considered excellent.

B3.5 Hold Times and General Laboratory Flags

There were no exceedances in hold times for any samples. All samples were delivered to the laboratory and were analyzed within the appropriate hold times.

B3.6 Other Concerns

The measurement uncertainty for particle size analysis in samples BOL-S_SE-3 and BOL-S_SE-4 from August 2022 were higher than usual due to limited sample availability (VA22C0370; Appendix G). The minimum standard sample size is 100g, but this may sometimes be hard to achieve at sites with fine substrate (as is found at Bootjack Lake) since decanting water may also lead to loss of important sample material. Results for calcium and iron were flagged in one sample each due to the result exceeding the maximum concentration inputted for the method used (VA22C0370; Appendix G)[2]. However, the results were correct and within the calibration range and are not expected to affect data interpretation.

B3.7 Data Quality Statement

Sediment chemistry data collected for the 2022 CEMP were of good quality as characterized by appropriate LRLs, appropriate detectability, negligible concentrations in MB samples, laboratory blanks, excellent laboratory precision and field sampling precision, and excellent laboratory accuracy. All quality control samples generally met the laboratory DQOs, and overall the associated data can be used with a high level of confidence in the derivation of conclusions.

[2] Samples were diluted for the analysis so that the results were within the laboratory's calibration range. When these results were back-calculated using the dilution factor, the final results were higher than the range input by laboratory staff for the analysis method. The qualifier/flag was automatically added to these results,

B4 SEDIMENT TOXICITY

B4.1 Laboratory Control

Sediment toxicity test laboratory controls met the acceptable criteria and water quality requirements of the Environment Canada protocols (Nautilus Environmental; Appendix G). Sediment toxicity data were considered of excellent quality for data interpretation.

B4.2 Reference Toxicants

The results of the reference toxicant (NaCl) on *Hyallela azteca* produced toxicity endpoints that met the passing control criterion of >80% survival. The results for the test were within the acceptable range of organism performance (mean LC_{50} within two standard deviations of historical laboratory values; Nautilus Environmental; Appendix G). The required one-day holding period before test initiation was not met due to the late arrival of *H. azteca* from the supplier. However, this delay did not appear to affect the test results as water quality was within the acceptable ranges and there were no mortalities upon arrival.

B4.3 Data Quality Statement

Based on acceptability criteria, water quality requirements of the Environment Canada protocols and reference toxicant test results, data from sediment toxicity tests can be used with a high degree of confidence in the 2022 CEMP.

B5 PHYTOPLANKTON COMMUNITY AND PRODUCTIVITY

B5.1 Laboratory Reporting Limits

The analytical ALS Laboratory Reports for phytoplankton productivity were examined to assess the LRLs for chlorophyll-a results (see laboratory reports VA22B4431, VA22B7705, VA22C0064, and VA22C0362; Appendix G)[3]. All individual measures of chlorophyll-a were above the LRL; therefore, the achieved LRLs were appropriate for the study.

B5.2 Laboratory Blanks

A total of three MB samples were analyzed in the ALS Laboratory Reports (VA22B4431, and VA22B7705; Appendix G). All chlorophyll-a results met the laboratory DQO, indicating that no inadvertent laboratory contamination occurred.

B5.3 Data Precision

Three sets of field duplicates were collected to assess the precision of field sampling for chlorophyll-a (Appendix Table B.5; see Section B.2.3 for explanation on RPD calculation and DQOs). All RPDs met the DQO of 30%, and therefore, chlorophyll-a samples can be considered to have excellent field precision and reproducibility. An analysis of laboratory analytical precision using laboratory duplicates was not conducted for chlorophyll-a as the entire sample must be consumed for analysis.

B5.4 Data Accuracy

Chlorophyll-a accuracy was evaluated based on results of three LCS samples which all met the laboratory DQO (within 20% of accepted value; VA22B4431, VA22B7705; Appendix G). The accuracy achieved by the laboratory in this study was therefore considered excellent.

B5.5 Hold Times

Recommended preparation hold times for chlorophyll-a were exceeded by one day in four samples from August (VA22C0362; Appendix G). Chlorophyll-a samples from August were not field filtered due to logistical issues, and as such, had shorter hold times (48 hours) than the field filtered chlorophyll-a samples collected in June and July. Overall, hold times for chlorophyll-a were exceeded in 21.1% of samples. Upon examination, chlorophyll-a concentrations in samples that exceeded hold times appear similar to those in similar samples

[3] Reports with field filtered chlorophyll-a from June and July (VA22B4431 and VA22B7705) were used for control/blank counts. Laboratory quality control/blank counts for unfiltered (aqueous) chlorophyll-a results from reports VA22C0064 and VA22C0062 were tabulated along with the water chemistry results in Section B2. LRL analysis was conducted with all four reports.

Table B.5: Field Duplicate Results for Aqueous Chlorophyll-a, Mount Polley Mine CEMP, 2022

Parameter	Units	QUL-ZOO-1_CHLA-1_2022-06	QUL-ZOO-1_CHLA-1X_2022-06	RPD (%)	POL-P2_CHLA-1_2022-07	POL-P2_CHLA-1X_2022-07	RPD (%)	QUL-ZOO-1_WS_DI-1_2022-08	QUL-ZOO-1_WS_DI-1X_2022-08	RPD (%)
Chlorophyll-a	µg/L	1.58	1.63	3.12	2.57	2.56	0.390	1.04	1.01	2.93

that did not exceed hold times, suggesting that these exceeded hold times did not impact chlorophyll-a results. However, these hold time exceedances will be taken into consideration during interpretation (mainly, comparison to historical data from prior years).

B5.6 Phytoplankton Density Accuracy

Phytoplankton density was re-measured in a total of three samples to evaluate sub-sampling accuracy within the phytoplankton enumeration and identification laboratory report (10% of all samples; fp22-078, Appendix G). Since there was a high percent of agreement between the duplicate pairs (mean = 89.0%), the samples can be considered to have good laboratory subsampling precision and reproducibility (Appendix Table B.6).

B5.7 Zooplankton Abundance Accuracy

Zooplankton density was re-measured in a total of three samples to evaluate sub-sampling accuracy and taxonomic consistency within the zooplankton enumeration and identification laboratory report (10% of all samples; fz22-078, Appendix G). Since there was a high percent of agreement between the duplicate pairs (mean = 95.6%) the samples are considered to have excellent laboratory subsampling precision and reproducibility (Appendix Table B.7).

B5.8 Data Quality Statement

Plankton community data collected for the 2022 CEMP were of good quality as characterized by good or excellent sub-sampling accuracy. Additionally, productivity measurements (chlorophyll-a) results were characterized by appropriate LRLs, excellent detectability, negligible analyte concentrations in MBs, good laboratory precision, and good laboratory accuracy. Therefore, the associated data can be used with a good level of confidence in the derivation of conclusions.

Table B.6: Duplicate Freshwater Phytoplankton Density Samples, Mount Polley Mine CEMP, 2022

Sample ID	Laboratory ID	Original Density	Quality Assurance Density	Percent Agreement[a] (%)
BOL-B2_PHYTO-1_2022-06	fp22-078-002	2,081,855	1,757,654	84.4

			Average	**95.6**

[a] Percent agreement calculated as: (100- [(difference in abundance between samples) / total abundance of original sample)] *100)%.

B6 ZOOPLANKTON TISSUE CHEMISTRY

B6.1 Laboratory Reporting Limits

The analytical ALS Laboratory Reports for zooplankton tissue chemistry (VA22B7702, VA22B4432, and VA22C0442; Appendix G) were examined to provide an inventory of analytes for which sample results were less than the LRL. LRLs for selenium were compared to the British Columbia benthic invertebrate dietary guidelines (BCMOE 2014). The LRL was adjusted for several analytes across samples due to sample dilution, high moisture content, insufficient sample, or amount of sample used by the laboratory. For sample POL-P2_ZOOT-1_2022-08, LRLs for 35 of 37 analytes were adjusted due to laboratory dilution of sample (VA22C0442; Appendix G). All resulting selenium LRLs were below the available guideline for selenium (Appendix Table B.8), indicating that the achieved LRLs were appropriate for the study.

B6.2 Laboratory Blanks

A total of 11 MB samples were analyzed in the ALS Laboratory Reports (VA22B7702, VA22B4432, and VA22C0442; Appendix G). All 190 individual analyte results met the laboratory DQO, indicating that laboratory analytical precision was excellent.

B6.3 Data Precision

One laboratory duplicate sample was analyzed to evaluate laboratory precision for moisture within the zooplankton tissue chemistry results (VA22B7702; Appendix G). The number of laboratory duplicates for zooplankton tissue chemistry was low as sample volumes were limited and needed to be conserved for metals analysis. Efforts will be made in future sampling (where possible) to collect more sample volume and/or drain off more water when submitting the sample. The resulting one analyte result met the laboratory DQO. Due to limited laboratory duplicate sample results (i.e., one comparison), laboratory precision and reproducibility could not be assessed.

A total of three sets of field duplicate zooplankton tissue samples were collected to assess field sampling and reproducibility (Appendix Table B.9; see Section B.2.3 for explanation on RPD calculation and DQOs). Several RPDs could not be calculated as both analyte concentrations were below the LRL. For all three sets of field duplicate samples, <20% of analyte comparisons exceeded the DQO of 30% (Appendix Table B.9); as such, field precision was considered good. RPDs for certain analytes of interest (arsenic, iron, lead, nickel, tin, titanium, and vanadium) exceeded the DQO in one or more duplicate sets, but not in all three

Table B.8: Evaluation of Laboratory Reporting Limits (LRL) in Zooplankton Tissue Chemistry Results, Mount Polley Mine CEMP, 2022

Parameter	Units	Range of LRLs	No. Sample Results <LRL
Metals			
Bismuth	mg/kg	0.01 to 0.016	13 (41.9%)
Boron	mg/kg	1 to 2.2	5 (16.1%)
Lithium	mg/kg	0.5 to 0.83	4 (12.9%)
Mercury	mg/kg	0.01 to 0.055	2 (6.45%)
Mercury	mg/kg wwt	0.001 to 0.002	25 (80.6%)
Tellurium	mg/kg	0.02 to 0.033	30 (96.8%)

Notes: Only analytes for which at least one sample was <LRL are displayed. mg/kg = milligrams per kilogram dry weight, wwt = wet weight. The total number of samples in 2022 was 31, which included three field duplicate samples.

Table B.9: Field Duplicate Results for Zooplankton Tissue Chemistry, Mount Polley Mine CEMP, 2022

Analyte	Units	BOL-B2_ZOOT-3_2022-07	BOL-B2_ZOOT-3X_2022-07	RPD (%)	QUL-ZOO-1_ZOOT-1_2022-06	QUL-ZOO-1_ZOOT-1X_2022-06	RPD (%)	QUL-ZOO-1_ZOOT-1_2022-08	QUL-ZOO-1_ZOOT-1X_2022-08	RPD (%)

Zirconium	mg/kg	4.98	5.43	8.65	0.610	0.570	6.78	1.50	1.13	28.1

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: Relative Percent Difference (RPD) was calculated using < Laboratory Reporting Limit (LRL) results at the LRL if one result in a duplicate pair was below the LRL. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated; "wwt" indicates wet weight.

duplicate pairs. Differences are believed to be a result of natural variability, and these variations will be taken into consideration when interpreting the findings.

B6.4 Data Accuracy

Data accuracy was evaluated based on the results of 11 LCS samples (VA22B7702, VA22B4432, and VA22C0442; Appendix G). Of the 190 individual LCS results, only three samples (for silver) did not meet the laboratory DQO (VA22B7702 and VA22C0442; Appendix G). For these three samples, the laboratory DQO was marginally exceeded but results were considered acceptable as per CCME standards. As these results only represent 1.58% of LCS analyte results, the accuracy achieved by the laboratory in this study was considered excellent.

B6.5 Hold Times

Recommended hold times for the zooplankton tissue chemistry samples were met for all parameters in all samples (Appendix G).

B6.6 Data Quality Statement

Zooplankton tissue chemistry collected as part of the 2022 CEMP was of good quality as characterized by appropriate detection limits, no detectable concentrations in MBs, and good field sampling precision. Laboratory accuracy and precision could not be assessed, as comparisons were limited to analysis of moisture in one sample. The number of laboratory duplicates was low due to limited sample volume, laboratory dilution, and/or high moisture content. Field sampling precision was considered good, as fewer than 20% of all analyte comparisons from each field duplicate set exceeded the 30% DQO for RPDs. Overall, zooplankton tissue chemistry collected as part of the 2022 CEMP can be used with a high level of confidence in the derivation of conclusions, provided that natural variability is considered.

B7 PERIPHYTON COMMUNITY AND PRODUCTIVITY

B7.1 Laboratory Reporting Limits

Periphyton dry weight, ash weight, ash free dry weight, and chlorophyll-a results (VA22B8786; Appendix G) were examined to provide an inventory of analytes that were less than the LRL. All individual measures were found to be above the LRL. Therefore, the achieved LRLs were appropriate for the study.

B7.2 Laboratory Blanks

Four MB samples were analyzed in the ALS Laboratory Report (VA22B8786; Appendix G). All eight results for dry weight, ash weight, ash free, dry weight, and chlorophyll-a met the laboratory DQO, meaning that laboratory contamination had no impact on the results.

B7.3 Data Accuracy

Accuracy of periphyton productivity analytes was evaluated based on results of four LCS. All eight results met the laboratory DQO (within 30% of accepted value; VA22B8786, Appendix G). Therefore, accuracy achieved by the laboratory in this study was considered excellent.

B7.4 Density Accuracy

Periphyton density was re-measured in a total of two samples to evaluate sub-sampling accuracy and taxonomic consistency within the periphyton enumeration and identification laboratory report (10% of all samples; pp22-078; Appendix G). Since there was a high percent of agreement between the duplicate pairs (mean = 85.0%) the samples were considered to have good laboratory subsampling precision and reproducibility (Appendix Table B.10).

B7.5 Data Quality Statement

Periphyton community data collected for the 2022 CEMP were of acceptable quality as characterized by good sub-sampling accuracy. Additionally, productivity measurements (ash free dry weight and chlorophyll-a) results had appropriate LRLs, were of acceptable detectability, and demonstrated good laboratory precision and laboratory accuracy. Therefore, the associated data can be used with a high level of confidence in the derivation of conclusions.

Table B.10: Duplicate Freshwater Periphyton Density Samples, Mount Polley Mine CEMP, 2022

Sample ID	Laboratory ID	Original Density	Quality Assurance Density	Percent Agreement[a] (%)
EDC-U_PERI-2_2022-08	pp22-078-050	3,685,304	3,174,032	86.1
HAC-R1_PERI-4_2022-08	pp22-078-057	2,239,208	1,876,189	83.8
			Average	**85.0**

[a] Percent agreement calculated as: (100- [(difference in abundance between samples) / total abundance of original sample)] *100)%.

B8 BENTHIC INVERTEBRATE COMMUNITY

B8.1 Sorting Efficiency

The analytical laboratory reports for benthic invertebrate community composition (Appendix H) assessed the organism sorting efficiency relative to the laboratory's DQO (≥ 90%) in four samples (Appendix Table B.11). The average recovery was 99.3% and so organism sorting efficiency was considered excellent.

B8.2 Subsampling Precision and Accuracy

Of the 30 benthic invertebrate community samples analyzed, 25 were subsampled. The proportion of sub-sampled material ranged from 5% to 20% of the total sample material (Appendix Table B.12). Of the samples that were sub-sampled, four (13% of all samples) were assessed for precision and accuracy. All assessed samples met the laboratory DQO (<20%) for both precision and accuracy (Appendix Table B.13). Thus, the precision and accuracy for sub-sampling of the benthic invertebrate community samples was considered excellent.

B8.3 Taxonomic Identification Accuracy

The laboratory performed an internal audit of taxonomic identification for 13% of all samples (n = 4; Appendix Table B.14). The analysts reported total identification error rate (TIR) of 0%, percent difference in enumeration (PDE) of 0 to 0.645%, percent taxonomic disagreement (PTD) of 0% to 1.603%, and Bray Curtis Dissimilarity Index (BCDI, a measure of the differences in identifications between different analysts) of 0 to 0.01 (Appendix Table B.14). All TIRs were below the laboratory DQO (<5% TIR), which is based on CABIN laboratory methods (Environment Canada 2014), so the taxonomic accuracy of analyses was considered excellent.

B8.4 Data Quality Statement

Benthic community data collected for the 2022 CEMP were of excellent quality as characterized by excellent sorting efficiency, subsampling precision and accuracy, and excellent taxonomic identification accuracy. Therefore, the associated data can be used with a high level of confidence in the derivation of conclusions.

Table B.11: Benthic Invertebrate Community Sorting Efficiency, Mount Polley Mine CEMP, 2022

Habitat	Sample ID	Laboratory ID	Number of Organisms Recovered (Initial Sort)	Number of Organisms in Re-sort	Sorting Efficiency (%)
Creek	HAC-R1_BIC-1_2022- 08	CC230214	781	5	99.0

Notes: TIR = Total Identification Error Rate, PDE = Percent Difference in Enumeration, PTD = Percent Taxonomic Disagreement, BCDI = Bray Curtis Dissimilarity Index to quantify differences in identifications.

[a] For error rationale and calculations, refer to Cordillera report (Appendix G).

B9 BENTHIC INVERTEBRATE AND PERIPHYTON TISSUE CHEMISTRY

B9.1 Laboratory Reporting Limits

One analytical ALS Laboratory Report for benthic invertebrate and periphyton tissue chemistry (VA22B8779; Appendix G) was examined to provide an inventory of analytes for which sample results were less than the LRL. The maximum LRLs for these analytes were assessed relative to existing British Columbia benthic invertebrate dietary guidelines (available only for selenium; BCMOE 2014). Achieved LRLs were below the available guideline for selenium (Appendix Table B.15), indicating the achieved LRLs were appropriate for the study.

B9.2 Laboratory Blanks

A total of 22 MB samples were analyzed in the ALS Laboratory Report (VA22B8779; Appendix G). All the 407 individual results met the laboratory DQO. Therefore, laboratory precision was considered excellent.

B9.3 Data Precision

A total of 17 laboratory duplicate samples were used to evaluate precision within the ALS Laboratory Report (VA22B8779; Appendix G). Out of the 259 laboratory duplicate results, 29 results in five samples did not pass the laboratory DQO (i.e., 11.2% of all pairs) due to sample heterogeneity. For primary analytes, this included one duplicate result each for arsenic and copper and two duplicate results for iron that did not pass the laboratory DQO. For secondary analytes, this included one duplicate result each for barium, cobalt and uranium, and two duplicate pairs each for silver, titanium, and vanadium that did not pass the laboratory DQO. Since these analytes have been identified as potentially indicative of mine influence, consideration will be given to other quality control samples and interpretation of data. Since the overall occurrence of lab duplicate DQO exceedances was low, samples can be considered to have overall good laboratory precision and reproducibility.

A total of 10 sets of field duplicate benthic invertebrate samples were collected (five of each composite-taxa and caddisfly samples) and five sets periphyton tissue samples were collected to assess the precision associated with field sampling (Appendix Table B.16; see Section B.2.3 for explanation on RPD calculation and DQOs). Of the 15 sets of duplicate samples, 11 sets had >20% of analytes with RPDs >30%: all five of the periphyton duplicate sets (100%), four of five composite-taxa duplicate sets (80%), and two of five caddisfly duplicate sets (40%) had >20% of analytes with RPDs >30%. All primary and secondary analytes had at least one

Table B.15: Evaluation of Laboratory Reporting Limits (LRLs) in Benthic Invertebrate and Periphyton Tissue Chemistry Results Relative to Guidelines, Mount Polley

Parameter	Units	Range of LRLs	No. Sample Results < LRL
Antimony	mg/kg	0.01 to 0.054	5 (3.14%)
Beryllium	mg/kg	0.01 to 0.035	38 (23.9%)
Bismuth	mg/kg	0.01 to 0.035	91 (57.2%)
Boron	mg/kg	1 to 3.6	54 (34.0%)
Cadmium	mg/kg	0.01 to 0.035	4 (2.52%)
Cesium	mg/kg	0.005 to 0.0174	6 (3.77%)
Chromium	mg/kg	0.2 to 0.7	6 (3.77%)
Lead	mg/kg	0.05 to 0.174	13 (8.18%)
Lithium	mg/kg	0.5 to 1.74	54 (34.0%)
Nickel	mg/kg	0.2 to 0.7	7 (4.40%)
Silver	mg/kg	0.005 to 0.0174	20 (12.6%)
Tellurium	mg/kg	0.02 to 0.07	133 (83.6%)
Thallium	mg/kg	0.002 to 0.0072	23 (14.5%)
Tin	mg/kg	0.1 to 0.35	133 (83.6%)
Uranium	mg/kg	0.002 to 0.007	2 (1.26%)
Zirconium	mg/kg	0.2 to 0.7	37 (23.3%)

Notes: All concentrations are in milligrams per kilogram dry weight (mg/kg dw). The total number of samples in 2022 was 159, which included 15 field duplicate samples.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: Relative Percent Difference (RPD) was calculated using < Laboratory Reporting Limit (LRL) results at the LRL if one result in a duplicate pair was below the LRL. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated.

Value did not meet the data quality objective of ≤ 30% Relative Percent Difference (RPD).

Notes: Relative Percent Difference (RPD) was calculated using < Laboratory Reporting Limit (LRL) results at the LRL if one result in a duplicate pair was below the LRL. RPD was not calculated if both results were < LRL. "-" indicates that the RPD was not calculated.

RPD that exceeded the 30% RPD DQO, with iron (primary), barium, cadmium, cobalt, titanium, uranium, and vanadium (all secondary) exceeding the DQO in over half of the duplicate sets (Appendix Table B.16). This variability is not a result of inconsistent field sampling, but as a result of sample heterogeneity (e.g., taxonomic variability in composite-taxa samples or natural variability within a single taxon). Field crews strived to collect and/or split sample between duplicate sample sets evenly, but a perfect split is not always feasible. It should be mentioned that tissue samples were collected in replicates of eight for each periphyton, composite-taxa, and caddisfly tissue to account for sampling heterogeneity (i.e., a total of 24 tissue samples per sampling area). As a high proportion of all field duplicate analyses exceeded the DQO, samples were considered to have poor field precision. These sources of variability will be considered during data interpretation.

B9.4 Data Accuracy

Data accuracy was evaluated based on results of 12 RM samples and 22 LCS samples, which yielded 291 RM results and 407 LCS results (VA22B8779; Appendix G). Of these, one RM result (titanium) exceeded the DQO. As the laboratory DQO was only exceeded in 0.344% of RM results and all LCS results met the laboratory DQO, accuracy achieved by the laboratory in this study is therefore considered excellent.

B9.5 Hold Times

Recommended hold times for the benthic and periphyton tissue chemistry samples were met for all parameters (VA22B8779; Appendix G).

B9.6 Data Quality Statement

Benthic and periphyton tissue chemistry data collected as part of the 2022 CEMP was of good quality as characterized by good detectability and appropriate LRLs (below the BCMOE guideline for selenium), no detectable analyte concentrations in MBs, and good laboratory accuracy and precision. Evaluation of field precision indicated high variability among parents and duplicate sample results (high relative percent differences) for composite-taxa, caddisfly, and periphyton tissue quality. Though field duplicates exceeded the DQO in a high percentage of comparisons, this does not reflect incorrect sampling methods, but rather natural variability due to sample heterogeneity. Collection of replicate samples should help to address the natural variability in biological tissue samples. Interpretation benthic invertebrate and periphyton chemistry tissue results from the 2022 CEMP should be approached carefully and compared relative to historic results before derivation of conclusions. Several primary and secondary analytes did not meet the DQO in laboratory and field duplicate samples, further

suggesting natural heterogeneity in samples. These sources of variability will be considered during data interpretation.

B10 FISH TISSUE CHEMISTRY

B10.1 Laboratory Reporting Limits

The analytical ALS Laboratory Reports for fish tissue chemistry (see laboratory reports VA22B2820, VA22B2821, VA22B4917, and VA22B5055; Appendix G) were examined to provide an inventory of analytes for which the sample results were less than the LRL. The LRL range for these analytes were also assessed relative to available guidelines, namely for mercury and selenium (BCMOE 2014, CFIA 2015; Appendix Table B.17). Results for several analytes were frequently below the LRL; however, fish tissue guidelines did not exist for those analytes (Appendix Table B.17). All achieved LRLs were below the available guidelines for mercury and selenium; therefore the achieved LRLs were appropriate for this study.

B10.2 Laboratory Blanks

A total of 60 MB samples were analyzed in the ALS Laboratory Reports (see laboratory reports VA22B2820, VA22B2821, VA22B4917, and VA22B5055; Appendix G). All reported MB results (1,029) met the laboratory DQO (VA22B2820, VA22B2821, VA22B4917, and VA22B5055; Appendix G), therefore, laboratory precision was considered excellent.

B10.3 Data Precision

A total of 32 laboratory duplicate samples were used to evaluate laboratory precision within the ALS Laboratory Reports (see laboratory reports VA22B2820, VA22B2821, and VA22B4917, and VA22B5055; Appendix G). Of the 930 duplicate pair results, 11 (1.18%) did not meet the laboratory DQO due to sample heterogeneity (VA22B2820, VA22B2821, and VA22B4917, and VA22B5055; Appendix G), including one result each for calcium, manganese, and phosphorous, two results each for barium and strontium, and four results for chromium. As a relatively low number of laboratory duplicate samples exceeded the laboratory DQO, laboratory precision and reproducibility were overall considered good.

A total of 32 sets of field duplicate samples were collected to assess field sampling precision (Appendix Table B.18), with 12 sets collected during spring fish tissue monitoring and 20 sets collected during fall fish tissue monitoring. These samples consisted of eight kidney, eight liver, eight muscle, and eight ovary duplicate samples from longnose sucker and rainbow trout (spring tissue monitoring at Polley and Bootjack Lakes), lake trout, peamouth chub (fall tissue monitoring at Quesnel Lake), and rainbow trout (fall tissue monitoring at Quesnel River). Several RPDs could not be calculated as both analyte concentrations were below the LRL (see Section B.2.3 for explanation on RPD calculation and DQOs). Of the 32 field duplicate sets, 14 sets (43.8 % of sets) had >20% of analytes that exceeded the DQO of 30%.

Table B.17: Evaluation of Laboratory Reporting Limits (LRL) in Fish Tissue Chemistry Results, Mount Polley Mine CEMP, 2022

Parameter	Units	Range of LRLs	No. Sample Results < LRL
Metals

Silver	mg/kg	0.005 to 0.0064	80 (57.1%)
Tellurium	mg/kg	0.02 to 0.026	159 (89.3%)
Thallium	mg/kg	0.002 to 0.0034	65 (36.5%)
Tin	mg/kg	0.1 to 0.13	61 (34.3%)
Titanium	mg/kg	0.25 to 0.85	113 (80.7%)
Uranium	mg/kg	0.002 to 0.0026	76 (42.7%)
Vanadium	mg/kg	0.1 to 0.13	72 (40.4%)
Zirconium	mg/kg	0.2 to 0.26	111 (62.4%)

Notes: Only analytes with at least one result below the LRL is displayed. Fish tissue guidelines only exist for mercury and selenium. The total number of samples in 2022 was 178, which included 32 field duplicate samples.

Table B.18: **Field Duplicate Results for Fish Tissue Chemistry, Mount Polley Mine CEMP, 2022**

Analyte	Unit	BOL_LSU-Ki-6_2022-05	BOL_LSU-Ki-6X_2022-05	RPD (%)	BOL_LSU-Li-2_2022-05	BOL_LSU-Li-2X_2022-05	RPD (%)	BOL_RB-M-7_2022-05	BOL_RB-M-7X_2022-05	RPD (%)	BOL_RB-O-8_2022-05	BOL_RB-O-8X_2022-05	RPD (%)
