BC Contaminated Sites Regulation (CSR), BC Reg 375/96, O.C. 1480/96, Deposited December 16, 1996; last amended July 7, 2021 by BC Reg. 179/2021.
BC Approved Water Quality Guidelines (WQG): Aquatic Life, Wildlife and Agriculture - Guideline Summary. Water Quality Guidelines Series, WQG-20.
[a] = guideline is a minimum value, unless the background concentration or value is lowe
[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (19 to 664 mg/L). The guideline is calculated based on the individual hardness value for each sam
[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purpos
[d] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.4 to 12.0). The guideline is calculated based on the individual pH for each sample with a pH less than
[e] = zinc standards are not available for groundwater with a hardness greater than 400 mg/L
[f] = copper water quality guidelines are calculated using the BC Biotic Ligand Model, which take into account temperature, hardness, pH and dissolved organic carbon (DOC). As DOC has not been analyzed a standard cannot be calculated at this tin
[g] = WQG is for total molybdenum.
[h] = guideline is chloride dependent. The guideline range shown is based on the chloride range observed in the dataset. The guideline is calculated based on the individual chloride value for each sample.
[i] = guideline is temperature dependent. The guideline range shown is based on the temperature range observed in the datase
[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity rang
[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity rang
Bolded concentrations are higher than water quality guidelines.
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precisi *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedan
- = no guideline or no data.
Data Source: Analytical data provided by Mount Polley Mining Corporation.

(Mn) concentration is higher than the 30-day mean (chronic) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx) concentration is higher than the maximum (Acute) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx, Mn) concentration is higher than both the acute and chronic BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(F) concentration is higher than the British Columbia Contaminated Site Regulation for Protection of Fresh Water Aquatic Life (BC CSR AW-F) guideline.

**Table 1: Water Quality Summary, 2022**

| Parameter | Unit | CSR AW-F | Water Quality Guideline - Aquatic Life | | GW16-6b | GW16-6a | GW16-6a | GW16-6a | GW16-6a | GW16-5b | GW16-5b | GW16-5a | GW16-5a | GW16-4b | GW16-4b | GW16-4a | GW16-4a | GW16-3b | GW16-3b | GW16-3a | GW16-3a | GW16-2b | GW16-2b | GW16-2a | GW16-2a | GW16-1b | GW16-1b |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Chronic (Mn) | Acute (Mx) | 15-Nov-22 | 9-Mar-22 | 31-May-22 | 10-Aug-22 | 15-Nov-22 | 31-May-22 | 20-Sep-22 | 2-Jun-22 | 20-Sep-22 | 6-Jun-22 | 20-Sep-22 | 6-Jun-22 | 20-Sep-22 | 30-May-22 | 25-Jul-22 | 30-May-22 | 25-Jul-22 | 1-Jun-22 | 10-Aug-22 | 1-Jun-22 | 10-Aug-22 | 7-Jun-22 | 21-Sep-22 |

BC Contaminated Sites Regulation (CSR), BC Reg 375/96, O.C. 1480/96, Deposited December 16, 1996; last amended ,
BC Approved Water Quality Guidelines (WQG): Aquatic Life, Wildlife and Agriculture - Guideline Summary. Water Quality
[a] = guideline is a minimum value, unless the background concentration or value is lowe
[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the datase
[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline
[d] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.4 to 12.0
[e] = zinc standards are not available for groundwater with a hardness greater than 400 mg/L
[f] = copper water quality guidelines are calculated using the BC Biotic Ligand Model, which take into account temperature
[g] = WQG is for total molybdenum.
[h] = guideline is chloride dependent. The guideline range shown is based on the chloride range observed in the dataset. The guideline is calculated based on the individual chloride v
[i] = guideline is temperature dependent. The guideline range shown is based on the temperature range observed in the d
[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalir
[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity
Bolded concentrations are higher than water quality guidelines.
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precisi *after* ca
- = no guideline or no data.
Data Source: Analytical data provided by Mount Polley Mining Corporation.

(Mn) concentration is higher than the 30-day mean (chronic) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx) concentration is higher than the maximum (Acute) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx, Mn) concentration is higher than both the acute and chronic BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(F) concentration is higher than the British Columbia Contaminated Site Regulation for Protection of Fresh Water Aquatic Life (BC CSR AW-F) guideline.

**Table 1: Water Quality Summary, 2022**

| Parameter | Unit | CSR AW-F | Water Quality Guideline - Aquatic Life | | GW16-1a | GW16-1a | GW15-2b | GW15-2b | GW15-2b | GW15-2a | GW15-2a | GW15-2a | GW15-2a | GW14-1 | GW14-1 | GW14-1 | GW14-1 | GW14-1 | GW12-5b | GW12-5b | GW12-5a | GW12-5a | GW12-4a | GW12-4a | GW12-4b | GW12-4b | GW12-3b |

BC Contaminated Sites Regulation (CSR), BC Reg 375/96, O.C. 1480/96, Deposited December 16, 1996; last amended ,
BC Approved Water Quality Guidelines (WQG): Aquatic Life, Wildlife and Agriculture - Guideline Summary. Water Quality
[a] = guideline is a minimum value, unless the background concentration or value is lowe
[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the datase
[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline
[d] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.4 to 12.0
[e] = zinc standards are not available for groundwater with a hardness greater than 400 mg/L
[f] = copper water quality guidelines are calculated using the BC Biotic Ligand Model, which take into account temperature
[g] = WQG is for total molybdenum.
[h] = guideline is chloride dependent. The guideline range shown is based on the chloride range observed in the dataset. The guideline is calculated based on the individual chloride v
[i] = guideline is temperature dependent. The guideline range shown is based on the temperature range observed in the d
[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalir
[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity
Bolded concentrations are higher than water quality guidelines.
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precisi *after* c
- = no guideline or no data.
Data Source: Analytical data provided by Mount Polley Mining Corporation.

(Mn) concentration is higher than the 30-day mean (chronic) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx) concentration is higher than the maximum (Acute) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx, Mn) concentration is higher than both the acute and chronic BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(F) concentration is higher than the British Columbia Contaminated Site Regulation for Protection of Fresh Water Aquatic Life (BC CSR AW-F) guideline.

**Table 1: Water Quality Summary, 2022**

BC Contaminated Sites Regulation (CSR), BC Reg 375/96, O.C. 1480/96, Deposited December 16, 1996; last amended ,
BC Approved Water Quality Guidelines (WQG): Aquatic Life, Wildlife and Agriculture - Guideline Summary. Water Quality
(a) = guideline is a minimum value, unless the background concentration or value is lowe
(b) = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the datase
(c) = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline
(d) = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.4 to 12.0
(e) = zinc standards are not available for groundwater with a hardness greater than 400 mg/L
(f) = copper water quality guidelines are calculated using the BC Biotic Ligand Model, which take into account temperature
(g) = WQG is for total molybdenum.
(h) = guideline is chloride dependent. The guideline range shown is based on the chloride range observed in the dataset. The guideline is calculated based on the individual chloride v
(i) = guideline is temperature dependent. The guideline range shown is based on the temperature range observed in the d
(Mn) = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalir
(Mx) = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity
Bolded concentrations are higher than water quality guidelines.
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precisi *after* ca
- = no guideline or no data.
Data Source: Analytical data provided by Mount Polley Mining Corporation.

(Mn) concentration is higher than the 30-day mean (chronic) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx) concentration is higher than the maximum (Acute) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx, Mn) concentration is higher than both the acute and chronic BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(F) concentration is higher than the British Columbia Contaminated Site Regulation for Protection of Fresh Water Aquatic Life (BC CSR AW-F) guideline.

**Table 1: Water Quality Summary, 2022**

| Parameter | Unit | CSR AW-F | Water Quality Guideline - Aquatic Life | | GW00-1b | GW00-3a | GW00-3b | GW00-3b | GW05-01 | GW05-01 | GW05-01 | GW05-01 | GW05-01 | GW05-01 | GW05-01 | GW11-1a | GW11-1a | GW11-1b | GW11-1b |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Chronic (Mn) | Acute (Mx) | 13-Sep-22 | 13-Sep-22 | 30-May-22 | 13-Sep-22 | 28-Feb-22 | 7-Jun-22 | 13-Oct-22 | 25-Oct-22 | 16-Nov-22 | 15-Dec-22 | 27-Dec-22 | 31-May-22 | 20-Sep-22 | 31-May-22 | 20-Sep-22 |

BC Contaminated Sites Regulation (CSR), BC Reg 375/96, O.C. 1480/96, Deposited December 16, 1996; last amended ,
BC Approved Water Quality Guidelines (WQG): Aquatic Life, Wildlife and Agriculture - Guideline Summary. Water Quality
(a) = guideline is a minimum value, unless the background concentration or value is lowe
(b) = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the datase
(c) = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline
(d) = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.4 to 12.0
(e) = zinc standards are not available for groundwater with a hardness greater than 400 mg/L
(f) = copper water quality guidelines are calculated using the BC Biotic Ligand Model, which take into account temperature
(g) = WQG is for total molybdenum.
(h) = guideline is chloride dependent. The guideline range shown is based on the chloride range observed in the dataset. The guideline is calculated based on the individual chloride v
(i) = guideline is temperature dependent. The guideline range shown is based on the temperature range observed in the d
(Mn) = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalir
(Mx) = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity
Bolded concentrations are higher than water quality guidelines.
Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precisi *after* c
- = no guideline or no data.
Data Source: Analytical data provided by Mount Polley Mining Corporation.

(Mn) concentration is higher than the 30-day mean (chronic) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx) concentration is higher than the maximum (Acute) BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(Mx, Mn) concentration is higher than both the acute and chronic BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

(F) concentration is higher than the British Columbia Contaminated Site Regulation for Protection of Fresh Water Aquatic Life (BC CSR AW-F) guideline.

**MPMC 2022 WIGHT PIT WATER LEVEL AND WATER CHEMISTRY REVIEW**

## 1.0 INTRODUCTION

At the request of Mount Polley Mining Corporation (MPMC), WSP Canada Inc. (WSP) has reviewed water level and water chemistry data for surface water and groundwater in the area of Wight Pit, located in the northeast corner of the Mount Polley Mine (the Site). It is understood that Wight Pit is currently being used as a water storage facility in support of other site dewatering activities, and that increases in groundwater levels at monitoring wells GW16-7 and GW16-8 were observed in the late summer to fall of 2022. The direction of groundwater flow from Wight Pit is towards the east, towards Polley Lake. Monitoring wells GW16-7 and GW16-8 are located approximately halfway between Wight Pit and Polley Lake.

The purpose of this technical memorandum is to summarize the reviewed data.

## 2.0 WIGHT PIT AREA DATA REVIEW

Water level and water chemistry data was provided to WSP by MPMC. The data was compiled into several graphs to compare water elevation data and chemistry data for selected locations around Wight Pit, including Wight Pit, Polley Lake, and the two monitoring wells GW16-7 and GW16-8.

Groundwater and surface water elevation data was provided for Polley Lake, Wight Pit, GW16-7 and GW16-8, and is shown in Attachment 1 *(Mount Polley Water Elevations)*. Although historical data is limited for Wight Pit, and recent data is limited for Polley Lake, Attachment 1 shows that groundwater elevations at MW16-7 and MW16-8 were less than the elevation of Wight Pit in August 2022, and also inferred to be less than the elevation of Polley Lake. The increase in water levels at the two monitoring wells in August 2022 is inferred to coincide with, and may be a result of, the filling of Wight Pit.

Water chemistry data was provided by MPMC, and the parameters of interest were identified by Aaron Zwiebel of MPMC. Parameters of interest include total copper, total selenium, total zinc, sulfate, and dissolved cadmium (all reported in mg/L).

WSP reviewed analytical data based on the sampling locations proximity to Wight Pit, Polley Lake, and GW16-7 and GW16-8. The sampling locations are shown in Attachment 2 (*MPMC CEMP Monitoring Locations – Surface Water Monitoring Map*) and are outlined below:

- Polley Lake North Station – surface (**P1-surface**)
- Polley Lake North Station – middle (**P1-MID**)
- Polley Lake North Station – bottom (**P1-bottom**)
- Polley Lake North Station – above thermocline (**P1-AT**)
- Polley Lake North Station – below thermocline (**P1-BT**)
- "Wight Pit Sump", functionally representing effluent surface water from White Pit Lake (**E10**)
- Wight Pit Surface (**WIP-S**)
- Wight Pit – 10 m depth (**WIP-10m**)
- Wight Pit – 20 m depth (**WIP-20m**)
- Wight Pit – 2 metres off the bottom – approximately 27 m (**WIP-B**)
- **GW16-7**
- **GW16-8**

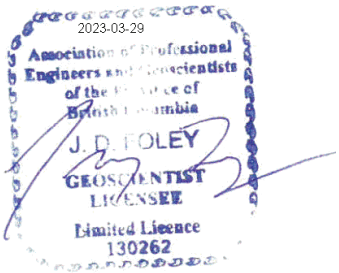
Analytical data has also been compared against the British Columbia (BC) Ministry of Environment and Climate Change Strategy Contaminated Site Regulation (CSR; BC Reg. 375/96, O.C. 1480/96, as updated [includes amendments up to BC Reg. 179/2021, updated to 7 July 2021]) for protection of freshwater aquatic life (BC CSR AW-F) standards (ENV 1996) and the BC Water Quality Guidelines for protection of aquatic life (ENV 2021). Note that there are limited chemistry results for the monitoring wells of interest (GW16-7 and GW16-8), with only one data sample from 24 November 2021, prior to the filling of Wight Pit. Therefore, we are unable to infer if the filling of Wight Pit is locally affecting the groundwater quality.

A brief summary of the chemistry plots in Attachment 3 (*Wight Pit-Polley Lake Chemistry*) identifies the following:

- **Total copper concentrations** are elevated in the Wight Pit sampling locations in comparison to the total copper concentrations in Polley Lake, and have decreased from the first sampling data point on 29 June 2022. Polley Lake total copper concentrations in 2022 are similar to those noted in 2021. The concentrations of total copper in the 24 November 2021 sample for GW16-7 and GW16-8 are approximately half an order of magnitude lower than the concentrations in Polley Lake. Comparison against BC WQGs for the protection of freshwater aquatic life requires additional parameter concentrations, including pH, hardness and dissolved organic carbon, the last of which is not available within the data set provided.
- **Total selenium concentrations** peaked in Wight Pit – S and Wight Pit - 10 m depth sampling locations in September 2022 before decreasing in the most recent samples collected in November 2022. In general, an increasing trend is noted in total selenium concentrations in the Wight Pit Sump since December 2021. Total selenium concentrations in the Polley Lake sample locations have remained stable since August 2021, with concentrations less than the BC WQGs for aquatic life. The concentrations of total selenium in the 24 November 2021 sample for GW16-7 and GW16-8 are similar to the concentrations in Polley Lake.

- **Total zinc concentrations** are stable in the Polley Lake sample locations, with concentrations inferred to be less than the BC WQGs for aquatic life (hardness dependant – calculations required). Total zinc concentrations have a general increasing trend in the Wight Pit - B and Wight Pit – 20 m sampling locations since data was available on 29 June 2022, and decreasing in the Wight Pit - S and Wight Pit – 10 m sampling locations. A peak concentration of total zinc was observed at the Wight Pit Sump location in June 2022, before decreasing in the fall samples collected in 2022. The concentration of total zinc in the 24 November 2021 sample for GW16-7 and GW16-8 is similar to the concentrations in Polley Lake.
- **Sulfate concentrations** are stable in the Polley Lake sample locations. Concentrations of sulfate in the Wight Pit Sump experienced a generally slight increasing trend from November 2021 to 16 November 2022. Concentrations have increased slightly in Wight Pit – B and Wight Pit – 20 m since 29 June 2022, and have generally decreased slightly in Wight Pit – S and Wight Pit – 10 m since 29 June 2022. The concentration of sulfate in the 11 November 2022 sample for GW16-8 (24.3 mg/L) is similar to the concentrations collected throughout the year. The sample for GW16-7 is slightly elevated compared to GW16-8, with a concentration of 183 mg/L during the 16 November 2022 sample, and has increased in concentration slightly over the last year compared to the 24 November 2021 sample (129 mg/L). Total sulphate concentrations in Polley Lake are inferred to be below the BC WQGs for aquatic life (hardness dependant – calculations required).
- **Dissolved cadmium concentrations** are stable in the Polley Lake sample locations and lower than those in Wight Pit. Dissolved cadmium concentrations in Polley Lake are inferred to be below the BC WQGs for aquatic life (hardness dependant – calculations required). Concentrations of dissolved cadmium in the Wight Pit locations is highest in Wight Pit – bottom, followed by Wight Pit – 20 m and Wight Pit – 10 m, with concentrations fluctuating since the first sample taken on 29 June 2022. Concentrations in the Wight Pit Sump appear to have an increasing trend from December 2021 to February 2022, before increasing during the fall 2022 sampling events. The concentration of dissolved cadmium from the 16 November 2022 sample for GW16-7 is the same as the sample collected on 24 November 2021 and is reported below the detection limit. GW16-8 is similar to the sample collected on 24 November 2021 (0.0000153 mg/L), but has increased slightly throughout the year as compared to the sampled collected on 16 November 2022 (0.0000254 mg/L).

Based on a review of the available information, the increased concentrations of the parameters of interest in the Wight Pit are not being observed in the Polley Lake sampling locations. Limited groundwater chemistry data is available for monitoring wells GW16-7 and GW16-8, and therefore short-term trends are not interpretable. However, in general, groundwater concentrations are less than concentrations in Wight Pit and similar to, or slightly greater than, concentrations in Polley Lake.



## 3.0 CLOSURE

The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

We hope this technical memo provides MPMC with the information you require at this time. Should you require additional information or have any questions, please feel free to contact the undersigned at your convenience. Should MPMC wish to update the provided water level and/or chemistry data graphs for any additional sampling at Wight Pit, Polley Lake, or the two monitoring wells, please provide WSP the data and we can update the plots accordingly.

| Uranium | mg/L | 0.0085 | - | 0.085 | 0.00010 | - | - | - | 0.00060 | - |
| Vanadium | mg/L | - | - | - | 0.0013 | - | - | - | 0.00098 | - |
| Zinc | mg/L | 0.0075 - 0.046 | 0.033 - 0.071 | 0.075 - 0.90 | <0.003 | - | - | - | <0.003 | - |

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (25 to 141 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (3.7500 to 8.6300 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg N/L) is based on field pH (9.0). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 9.0). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (25 to 141 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (3.7500 to 8.6300 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg N/L) is based on field pH (9.0). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 9.0). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (25 to 141 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (3.7500 to 8.6300 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg N/L) is based on field pH (9.0). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 9.0). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (25 to 141 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (3.7500 to 8.6300 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg N/L) is based on field pH (9.0). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 9.0). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (25 to 141 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (3.7500 to 8.6300 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg N/L) is based on field pH (9.0). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 9.0). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (25 to 141 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (3.7500 to 8.6300 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg N/L) is based on field pH (9.0). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 9.0). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (25 to 141 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (3.7500 to 8.6300 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (9.0) and water temperature (7.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg N/L) is based on field pH (9.0). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 9.0). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (205 to 447 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (11.0000 to 34.2000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.93 mg-N/L) is based on the combination of field pH (8.1) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (4.84 mg-N/L) is based on the combination of field pH (8.1) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (3.70 mg-N/L) is based on field pH (8.1). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.1). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (205 to 447 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (11.0000 to 34.2000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.93 mg-N/L) is based on the combination of field pH (8.1) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (4.84 mg-N/L) is based on the combination of field pH (8.1) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (3.70 mg-N/L) is based on field pH (8.1). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.1). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (205 to 447 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (11.0000 to 34.2000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.93 mg-N/L) is based on the combination of field pH (8.1) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (4.84 mg-N/L) is based on the combination of field pH (8.1) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (3.70 mg-N/L) is based on field pH (8.1). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.1). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (182 to 343 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (1.0100 to 4.5800 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (182 to 343 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[(d)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (1.0100 to 4.5800 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(g)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(h)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 7.9). The guideline is calculated based on the individual pH for each sample.

[(i)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (182 to 343 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[(d)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (1.0100 to 4.5800 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(g)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(h)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 7.9). The guideline is calculated based on the individual pH for each sample.

[(i)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (182 to 343 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (1.0100 to 4.5800 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (182 to 343 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (1.0100 to 4.5800 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (182 to 343 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (1.0100 to 4.5800 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (182 to 343 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (1.0100 to 4.5800 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (5.9°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C =

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (45 to 71 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5700 to 1.2600 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.16 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.84 mg-N/L) is based on the combination of field pH (8.9) and water temperature (5.8°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.9). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

| Titanium | mg/L | - | - | 1.0 | <0.01 | <0.01 |
| Uranium | mg/L | 0.0085 | - | 0.085 | 0.00018 | 0.00017 |
| Vanadium | mg/L | - | - | - | <0.0005 | <0.0005 |
| Zinc | mg/L | 0.0075 | 0.033 | 0.075 | <0.003 | **0.0099**[(Mn)] |

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (50 to 72 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 2.3200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(d)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.13 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.68 mg-N/L) is based on the combination of field pH (10.5) and water temperature (8.2°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(g)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 10.5). The guideline is calculated based on the individual pH for each sample.

[(h)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(Mx)] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**
mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[(a)] = guideline is a minimum value, unless the background concentration or value is lower.

[(b)] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (125 to 288 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[(c)] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes

[(d)] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (9.3200 to 12.5000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[(e)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (0.25 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(f)] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on the combination of field pH (8.7) and water temperature (3.3°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[(g)] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (1.31 mg-N/L) is based on field pH (8.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[(h)] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.1 to 8.7). The guideline is calculated based on the individual pH for each sample.

[(i)] = guideline is for chromium VI.

[(Mn)] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[(DL>Mn)] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (159 to 233 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 0.8000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (6.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (6.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.4 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter, °C = degrees celcius.

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (159 to 233 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 0.8000 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.39 mg-N/L) is based on the combination of field pH (7.9) and water temperature (6.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.25 mg-N/L) is based on the combination of field pH (7.9) and water temperature (6.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.7). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (7.4 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (135 to 177 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5300 to 2.0200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.53 mg-N/L) is based on the combination of field pH (7.2) and water temperature (16.7°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (10.10 mg-N/L) is based on the combination of field pH (7.7) and water temperature (5.1°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.9 to 7.7). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**
mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (135 to 177 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5300 to 2.0200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.53 mg-N/L) is based on the combination of field pH (7.2) and water temperature (16.7°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (10.10 mg-N/L) is based on the combination of field pH (7.7) and water temperature (5.1°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.9 to 7.7). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (135 to 177 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.5300 to 2.0200 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[d] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.53 mg-N/L) is based on the combination of field pH (7.2) and water temperature (16.7°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (10.10 mg-N/L) is based on the combination of field pH (7.7) and water temperature (5.1°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[g] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.9 to 7.7). The guideline is calculated based on the individual pH for each sample.

[h] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (220 to 280 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 1.0500 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.36 mg-N/L) is based on the combination of field pH (7.9) and water temperature (8.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.10 mg-N/L) is based on the combination of field pH (7.9) and water temperature (8.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.6 to 7.9). The guideline is calculated based on the individual pH for

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (220 to 280 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 1.0500 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.36 mg-N/L) is based on the combination of field pH (7.9) and water temperature (8.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (7.10 mg-N/L) is based on the combination of field pH (7.9) and water temperature (8.4°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.6). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.6 to 7.9). The guideline is calculated based on the individual pH for

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances.

Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (221 to 276 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 0.5100 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.22 mg-N/L) is based on the combination of field pH (6.6) and water temperature (24.7°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (6.79 mg-N/L) is based on the combination of field pH (7.9) and water temperature (14.0°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.6 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (221 to 276 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 0.5100 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.22 mg-N/L) is based on the combination of field pH (6.6) and water temperature (24.7°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (6.79 mg-N/L) is based on the combination of field pH (7.9) and water temperature (14.0°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.6 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

mg/L = milligrams per litre, mg-N/L = milligrams nitrogen per litre, mg-P/L = milligrams phosphorus per litre, BC CSR WQG = British Columbia Contaminated Sites Regulation Water Quality Guideline, NTU = nephelometric turbidity units, µS/cm = microseimens per centimeter,

[a] = guideline is a minimum value, unless the background concentration or value is lower.

[b] = guideline is hardness dependent. The guideline range shown is based on the hardness range observed in the dataset (221 to 276 mg/L). The guideline is calculated based on the individual hardness value for each sample.

[c] = for some samples, water hardness was greater than 250 mg/L. At this hardness, no BC ENV water quality guideline has been established for sulphate; however, the observed data were screened against the guideline for very hard water (i.e., 429 mg/L) for comparative purposes.

[d] = guideline is chloride dependent. The guideline range shown is based on the chloride concentration range observed in the dataset (0.2500 to 0.5100 mg/L). The guideline is calculated based on the individual chloride concentration in each sample.

[e] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (1.22 mg-N/L) is based on the combination of field pH (6.6) and water temperature (24.7°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[f] = the ammonia guideline is pH and temperature dependent. The guideline that results in the minimum ammonia guideline (6.79 mg-N/L) is based on the combination of field pH (7.9) and water temperature (14.0°C). Guidelines calculated with temperature and pH values falling outside the defined range (i.e., pH 6.0 to 10.0 and temperature 0°C to 30°C) should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH and temperature extremes. The guideline is calculated based on the individual field pH and temperature measurements for each sample.

[g] = the ammonia guideline is pH dependent. The guideline that results in the minimum ammonia guideline (11.30 mg-N/L) is based on field pH (7.5). Guidelines calculated with temperature and pH values falling outside the defined range should be used with caution, as the WQG does not necessarily accurately reflect toxic effects at the low and high pH extremes. The guideline is calculated based on the individual pH value.

[h] = guideline is pH dependent. The guideline range shown is based on the pH range observed in the dataset (6.6 to 7.9). The guideline is calculated based on the individual pH for each sample.

[i] = guideline is for chromium VI.

[Mn] = concentration is higher than the 30-day mean BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[Mx] = concentration is higher than the maximum BC ENV guideline or outside the recommended pH, DO or total alkalinity range.

[DL>Mn] = analytical detection limit is higher than the 30-day mean BC ENV guideline.

Bolded concentrations are higher than water quality guidelines.

Water quality data and guidelines shown in this table were rounded to reflect laboratory or field instrument precision *after* comparisons to guidelines. Therefore, values slightly above guidelines may be displayed as being equal to the guidelines and identified as exceedances. Concentrations equal to the guideline values were not identified as exceedances.

- = no guideline or no data.

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.

% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

**Notes:**

(a) = Concentrations equal to the guideline values were not identified as exceedances. Concentrations were screened against British Columbia Ministry of Environment and Climate Change Strategy (BC ENV) Working Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life.

**Value =** value is greater than the Lower SQG.

**Value** = value is greater than the Upper SQG.

BC SQG = British Columbia sediment quality guideline; CaCO3 = calcium carbonate; "-" = no guideline, no data available, or not applicable; < = less than; TOC = total organic carbon.
% = percent; µm = micrometre; m = metres; mm = millimetres; mg/kg = milligrams per kilogram

# Executive Summary

Mount Polley Mining Corporation (MPMC) operates a copper/gold open pit mining operation located 8 km southwest of the town of Likely and 56 km northeast of Williams Lake in central British Columbia. Mining is currently being carried out in the Springer Pit, and non-acid generating (NAG) and potentially acid generating (PAG) waste rock excavated from the pit will be consigned to the Northwest PAG Dump (NW PAG Dump).

MPMC retained WSP Canada Inc. (WSP) to carry out a geotechnical assessment of an updated proposed ultimate design of the NW PAG Dump. In September 2023, December 2023, and January 2024, WSP carried out a test pit and drilling program for foundation investigations within and around the proposed footprint of the ultimate NW PAG Dump. A summary of the 2023/2024 investigation and laboratory testing results is presented in a field data report (WSP 2024b).

This report provides:

- a description of the existing NW PAG Dump and previous slope stability performance
- a description of the proposed ultimate NW PAG Dump
- a summary of previous geotechnical field investigations
- a description of the site foundation conditions, and of engineering geology of the expected foundation materials and waste rock
- the factors that are expected to control the stability of the proposed ultimate NW PAG Dump
- discussion of the results of the slope stability analyses
- discussion of the results of the runout analyses
- discussion of the results of the rollout assessment
- a summary of recommendations regarding construction and operational procedures that are intended to enhance the short and long-term stability of the proposed ultimate NW PAG Dump

## *Current Performance*

The NW PAG Dump has been reviewed for slope stability performance annually since 2012 during the annual slope stability reviews completed by Golder/ WSP. In general, the NW PAG Dump has exhibited good slope stability performance over the years with minor areas of deformation that have been managed by MPMC.

## *Proposed Development*

The proposed NW PAG Dump development includes construction of three 40 to 50 m lifts above the current north lobe of the NW PAG Dump. The NW PAG Dump will be constructed from the bottom-up with angle of repose waste rock lift faces, 10 m wide catch-benches, and an overall slope angle of 28 degrees. The ultimate haul ramp will enter the NW PAG Dump from the southern portion of the dump and ascend across the slope face.

## Geotechnical Field Investigations

To date, five foundation investigation programs have been completed within and around the footprint of the NW PAG Dump. Test pits were excavated for geotechnical programs completed in 1999, 2010, and 2023, and boreholes drilled for geotechnical programs were completed in 2023 and 2024. Geotechnical laboratory testing was completed on samples from the 1999, 2023, and 2024 geotechnical field investigations.

## Site Characterization and Engineering Geology

The local surficial geology consists of Quaternary glacial deposits overlain by fill/anthropogenic deposits. Based on the foundation materials and cross-section review the following summarizes the surficial geology interpretation:

- Colluvium is interpreted to be a thin veneer underlying the eastern slope of the NW PAG Dump, with localized areas of thicker colluvium layers to the southwest of the dump footprint.
- Till is interpreted to cover the majority of the NW PAG Dump footprint, with variable thickness.
- Glaciofluvial deposits are located in isolated areas at the north end of the dump and near the center. Till typically overlies the glaciofluvial deposits.
- Fine-grained material is interpreted to be present in an isolated area on the west side of the NW PAG Dump at depth and is overlain by till. This material has been modeled as part of the till. It is possible that fine-grained material could be located in other parts of the foundation of the NW PAG Dump that were not investigated.
- Clay material is interpreted to be present in an isolated area on the northeast side of the NW PAG Dump about 0.9 m below original ground surface and is discontinuous (interbedded with silty clay). This material has been modeled as a separate unit as a sensitivity analysis.

## Summary and Recommendations

Based on the Hawley and Cunning (2017) waste rock dump slope stability rating and hazard classification system, the proposed ultimate NW PAG Dump is classified as presenting a moderate potential for instability and is therefore considered to be a moderate hazard waste rock dump (Class III).

The slope stability analyses results for the proposed ultimate NW PAG Dump design indicate that the dump will meet the design acceptance criteria for slope stability under static and pseudo-static conditions, with the exception of analyses completed with low clay material strength parameters (a phi less than about 27 degrees). The clay material was encountered in an isolated “pocket” north of the current toe of the dump in DH-NW-02 and was not found in the adjacent boreholes and test pits (DH-NW-03, DH-NW-03A, TP-NW-01, TP-NW-02, and TP-NW-03). No investigations have been completed immediately beneath the toe of the NW PAG Dump in this area as access is limited. The material was inferred to be discontinuous/interbedded with silty clay. The area of the current NW PAG Dump near where the clay material was encountered is stable, and has been since construction, indicating that at least a FOS of 1.0 is being achieved. Recommendations for construction near the clay material include:

- Remove the clay material prior to dumping in this area (even though the toe of the proposed ultimate NW PAG Dump does not cover the area where DH-NW-02 was drilled). The clay material was encountered in an old borrow area, therefore, more material could be removed from the borrow area to key into the till material below.

- Use low lift heights (about 5 m) when constructing the lower NAG lift in this area to limit development of potential excess pore pressures and not rapidly load the clay material if it does exist further south beneath the proposed ultimate NW PAG Dump design toe.
    - When constructing the low lifts, advancement could be such that the borrow area is encapsulated (where the potential clay material exists if it extends as far south as the proposed ultimate NW PAG Dump footprint). Once the area is encapsulated, waste rock can then be dumped into the encircled area. This method provides lateral support from the surrounding topography and the dump prior to dumping on top of the borrow area.

The runout analyses results indicate that under wet foundation conditions, it is likely that failure debris would impact the Bootjack Access Road and settling ponds. Based on the slope stability performance of the NW PAG Dump over the past 12 years, and on the slope stability analyses carried out for the proposed ultimate NW PAG Dump design, there is a low probability that a failure would occur in the NW PAG Dump due to the relatively high FOS indicated by the slope stability analyses.

Rock rollout could impact the Bootjack Access Road.

Settlement of the NW PAG Dump is expected to be limited and manageable.

Recommendations for the proposed ultimate NW PAG Dump construction include:

- Controlled loading rates
    - Prism and VWP data along with visual inspections and daily loading rates can all be used to understand if loading rates are having an adverse affect on dump construction.
- While constructing the NW PAG Dump, dumping operations should avoid concentrated dumping at a single location and should use as wide a strike length along the slope face as possible while advancing a lift.
- Construct berms at the edge of each catch-bench and free dump along the entire lift prior to constructing the next lift to limit rock rollout.
- Follow Standard Operating Procedures at Mount Polley Mine for:
    - Grading the dump and avoid ponding water on platforms.
    - Controlling the placement of waste rock being used for construction. The waste rock type should be discussed and planned in collaboration with geology and short-range engineering, as required.
      The material consigned to the NW PAG Dump should be good quality waste rock that is hard, coarse rock. Poor-quality material such as fault or overburden materials should be dumped in a central location of the dump such that it can be encapsulated and covered with good quality waste rock.

The stability of the NW PAG Dump slopes is being monitored by prisms (MPMC 2021). The prisms should be measured by the MPMC survey team on approximately a monthly basis for the active NW PAG Dump. Survey personnel should continue to ensure consistency in readings and use the same setup and monitoring procedures for each set of measurements. This will improve the ability to detect localized and short-term displacements as well as develop more accurate interpretations of long-term settlement trends. If any significant storm events occur that exceeds a five-year return period or daily maximum precipitation, the prisms should be read. Daily temperature and barometric pressure corrections should be applied to the monitoring data, as rapid changes in temperature or barometric pressure can have a significant impact on the day-to-day accuracy of the data.

A key component to the safe operation of the proposed ultimate NW PAG Dump to mitigate instability will be regular visual inspections. The following operational procedures are recommended for the proposed ultimate NW PAG Dump:

- The proposed ultimate NW PAG Dump should be visually inspected and photo-documented on a regular basis during construction, on approximately a weekly basis. The pit shifter or the geotechnical engineer should be completing the formal visual inspections. The following information should be investigated and recorded:
  - The crests of the NW PAG Dump lifts should be examined for signs of cracking and localized settlement and ponding water.
  - The faces of the NW PAG Dump lifts should be examined for signs of oversteepening, bulging in the middle, seepage, erosion, and the toe of the dump if it can be observed for signs of deformation.
  - The type of material being placed on the NW PAG Dump lifts and the loading rates should be documented.
- Dozer and haul truck operators should be continuously observing the construction of the NW PAG Dump lifts for signs of instability and reporting their observations to their pit shifter.

# Study Limitations

WSP Canada Inc. (WSP) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings, and other documents contained herein, has been prepared by WSP for the sole benefit of Mount Polley Mining Corporation (MPMC). # 1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) operates a copper/gold open pit mining operation located 8 km southwest of the town of Likely and 56 km northeast of Williams Lake in central British Columbia (BC). Mining is currently being carried out in the Springer Pit, and non-acid generating (NAG) and potentially acid generating (PAG) waste rock excavated from the pit will be consigned to the Northwest PAG Dump (NW PAG Dump).

A waste rock dump on the west side of the property was originally permitted in 1995 (Imperial 1995). In 2012, MPMC submitted a permit amendment for this waste rock dump (at the time called the temporary West Stockpile for PAG waste), requesting an increase in capacity from 15 Mt to 45 Mt (MPMC 2012). In 2013, Golder Associates Ltd. (Golder) conducted a geotechnical review of an updated design provided by MPMC for the Northwest Dump (Golder 2013a). After Golder submitted the geotechnical review of the Northwest Dump, MPMC modified the configuration of the dump. Golder provided an addendum technical memorandum summarizing updated slope stability analyses of the modified dump configuration (Golder 2013b).

MPMC retained WSP Canada Inc. (WSP) to carry out a geotechnical assessment of an updated proposed ultimate design of the NW PAG Dump. In September 2023, December 2023, and January 2024, WSP carried out a test pit and drilling program for foundation investigations within and around the proposed footprint of the ultimate NW PAG Dump. A summary of the 2023/2024 investigation and laboratory testing results is presented in a field data report (WSP 2024b).

This report provides:

- a description of the existing NW PAG Dump and previous slope stability performance
- a description of the proposed ultimate NW PAG Dump
- a summary of previous geotechnical field investigations
- a description of the site foundation conditions, and of engineering geology of the expected foundation materials and waste rock
- the factors that are expected to control the stability of the proposed ultimate NW PAG Dump
- discussion of the results of the slope stability analyses
- discussion of the results of the runout analyses
- discussion of the results of the rollout assessment
- a summary of recommendations regarding construction and operational procedures that are intended to enhance the short and long-term stability of the proposed ultimate NW PAG Dump

This report is to be read with the Study Limitations Section, which precedes the text and forms an integral part of this report.

# 2.0 EXISTING NORTHWEST POTENTIALLY ACID GENERATING DUMP AND PREVIOUS SLOPE STABILITY PERFORMANCE

The NW PAG Dump is located at the northwest end of the mine property to the west of the Springer Pit (Figure 1). Figure 2 shows the October 2023 configuration of the NW PAG Dump.

Golder/WSP has not provided construction quality assurance for the NW PAG Dump, rather Golder/WSP has provided geotechnical slope stability reviews of proposed ultimate designs provided by MPMC and slope stability reviews as construction has progressed during annual inspections.

The dump is separated into two areas, the south and north lobes. The south lobe was constructed between 2012 and 2013. MPMC indicated that trees were logged, and the topsoil was stripped from the foundation prior to construction of three lifts of NAG rock (each approximately 5 m high) which were advanced to the north (Golder 2013c). PAG rock was end-dumped on top of the NAG lifts in four 25 m high lifts from the bottom up to elev. 1,135 m. The south lobe is founded on gently to moderately sloping terrain that is inclined at approximately 20 to 30 degrees to the southwest and west. The north lobe began construction in 2013 and is ongoing. Again, MPMC indicated that trees were logged, and the topsoil was stripped from the foundation prior to construction of three lifts of NAG rock (each about 5 m high), which were advanced to the north (Golder 2015c). PAG rock has been end-dumped on top of the NAG lifts in four to five 25 m high lifts from the bottom up to elev. 1,138 m.

The NW PAG Dump has been reviewed for slope stability performance annually since 2012 during the annual slope stability reviews completed by Golder/WSP. Slope stability performance observations and previous recommendations are summarized in Table 1 and photographs are presented in Appendix A. In general, the NW PAG Dump has exhibited good slope stability performance over the years with minor areas of deformation that have been managed by MPMC.

**Table 1: Previous Slope Stability Performance of the NW PAG Dump**

| Year | Slope Stability Review Performance Observations | Recommendations Provided at Time of Observation | Recommendations Addressed by MPMC | Report | Appendix A, Figure No. |
|---|---|---|---|---|---|
| 2012 | ▪ NW PAG Dump was being advanced towards the north over natural topography and the lower NAG lift (south lobe).<br>▪ Settlement cracks observed on the southwest side of the first NAG lift. Bulging in the toe area was also evident. | ▪ Cracks should be filled with fine-grained material and continue visual inspections and monitoring, particularly during spring and fall when precipitation rates are higher. | Yes | Golder 2013c | A-1 |
| 2013 | ▪ North lobe of NW PAG Dump was being constructed to the north of the south lobe.<br>▪ No cracks along the crest or bulging in the toe area were observed. | ▪ Continue visual inspections and monitoring, particularly during spring and fall when precipitation rates are higher. | Ongoing | Golder 2015c | A-2 |
| 2014/2015 | ▪ A portion of a NAG lift was being placed adjacent to a soil stockpile at the base of the slope.<br>▪ Minor settlement cracks along some portions of the crest. | ▪ Avoid advancing portions of the toe of the dump over the soil stockpiles and if required, move/remove the soil stockpiles. | Yes | Golder 2016b | A-3 |
| 2016 | ▪ Cracks observed near the crest of the lower lift and some bulging in the waste dump face and toe was observed suggesting displacement in the foundation soils.<br>▪ Ponded water was observed at the toe of the lower lifts towards the north end of the dump. Was noted to be seeping from the toe of the dump. | ▪ The cracks should be filled with fine-grained material and continue visual inspection and monitoring.<br>▪ Ditches should be excavated to drain the ponded water away from the toe of the dump.<br>▪ Stability of the dump in the area of seepage to be visually monitored. | Yes | Golder 2017 | A-4 |
| 2017 | ▪ No cracks along the crest or bulging in the toe area were observed. | ▪ Continue visual inspections and monitoring, particularly during spring and fall when precipitation rates are higher. | Ongoing | Golder 2018 | A-5 |
| 2018 | ▪ No cracks along the crest or bulging in the toe area were observed. | ▪ Continue visual inspections and monitoring, particularly during spring and fall when precipitation rates are higher. | Ongoing | Golder 2019 | A-6 |
| 2019 | ▪ No cracks along the crest or bulging in the toe area were observed. | ▪ Continue visual inspections and monitoring, particularly during spring and fall when precipitation rates are higher. | Ongoing | Golder 2020 | A-7 |

**Table 1: Previous Slope Stability Performance of the NW PAG Dump**

| Year | Slope Stability Review Performance Observations | Recommendations Provided at Time of Observation | Recommendations Addressed by MPMC | Report | Appendix A, Figure No. |
|---|---|---|---|---|---|
| 2020 | ▪ Haul road along the north of the dump showing erosion channels.<br>▪ Evidence of water ponding along the lower lift haul road. | ▪ A ditch should be maintained on the sides of the haul ramp and water bars can be implemented along the edges of the road to promote water moving into the ditches.<br>▪ The lower lift haul road should be graded with fill material to divert water away from the crest of the road. | Yes | Golder 2021 | A-8 |
| 2021 | ▪ Evidence of water ponding along the lower lift haul road. | ▪ The lower lift haul road should be graded with fill material to divert water away from the crest of the road. | Yes | Golder 2022a | A-9 |
| 2022 | ▪ Minor settlement cracks developing in lower lifts.<br>▪ Evidence of water ponding along the lower lift haul road. | ▪ Monitor settlement cracks and doze to limit water infiltration into the dump crest.<br>▪ The lower lift haul road should be graded with fill material to divert water away from the crest of the road. | Yes | WSP 2023a | A-10 |
| 2023 | ▪ An area of the lower lift near the access road entrance was observed to be settling with about 30 to 40 cm of vertical displacement possibly due to foundation soil movement at the toe and ponding water at the crest. | ▪ Windrow material at the toe should be removed and a low lift buttress should be advanced to limit further movement. The lower lift should be dozed and brought to grade such that water cannot pond at the crest of the lift. | To be addressed in 2024 | WSP 2023c | A-11 |

# 3.0 PROPOSED ULTIMATE NORTHWEST POTENTIALLY ACID GENERATING DUMP DESIGN

MPMC have proposed a revised ultimate NW PAG Dump design shown in Figure 3. The development includes construction of three 40 to 50 m high lifts above the current north lobe of the NW PAG Dump. The dump will measure approximately 1,000 m in a north-south direction and will vary in width from 620 to 745 m. The top of the NW PAG Dump will be located at elev. 1,140 m. The elevation of the foundation topography (below the current north lobe of the NW PAG Dump) is approximately elev. 1,118 m along the east side to elev. 1,006 m along the west side. The maximum height of the NW PAG Dump will be approximately 140 m toe to crest. The NW PAG Dump will be constructed from the bottom-up with angle of repose waste rock lift faces, 10 m wide catch-benches, and an overall slope angle of 28 degrees. The ultimate haul ramp will enter the NW PAG Dump from the southern portion of the dump and ascend across the slope face.

The majority of the material to be placed on the NW PAG Dump will be on the north and west sides of the current NW PAG Dump north lobe. The footprint of the NW PAG Dump has already been stripped and the lower NAG lift has been constructed with approximately six PAG lifts at varying elevations above.

Cross-sections through the proposed ultimate NW PAG Dump design are shown in Appendix B and described in Section 5.8.

# 4.0 SUMMARY OF GEOTECHNICAL FIELD INVESTIGATIONS

To date, five foundation investigation programs have been completed within and around the footprint of the NW PAG Dump. Test pit locations for geotechnical programs completed in 1999, 2010, and 2023 as well as borehole locations for geotechnical programs completed in 2023 and 2024 are presented on Figure 4. The results of these geotechnical programs and their applicability to the proposed ultimate NW PAG Dump are discussed in the following sub-sections.

## 4.1 1999 Geotechnical Field Investigation

The 1999 field investigation program included nine test pit locations, four of which were within the proposed ultimate NW PAG Dump design footprint (Figure 4). The results of the field investigation indicate that the most consistent soil horizon encountered is a well-graded, silty sand till with some gravel and trace fines (Golder 2010b). A number of localized silt clay-rich deposits were encountered in TP14, TP15, and TP16. These deposits could correspond to localized wet to swampy areas (Golder 2010a).

Results of the 1999 test pit program are summarized in Table 2 and further detailed results are presented in Golder (2010a).

**Table 2: 1999 Field Investigation Summary (after Golder 2010a)**

| Test Pit ID | Northing (m)[(a)] | Easting (m)[(a)] | Ground Elevation (m) | Excavation Depth (m) | Bedrock Encountered | Within Footprint of Proposed Ultimate NW PAG Dump | Foundation Soil Description |
|---|---|---|---|---|---|---|---|
| TP10 | 3,178 | 1,344 | 1,053 | 2.5 | No | No | Clayey SILT with some sand and gravel (TILL) |
| TP11 | 3,368 | 1,205 | 1,042 | 2.4 | Yes | No | Silty GRAVEL with some sand and cobbles (TILL) |
| TP12 | 3,199 | 1,181 | 1,034 | 3.3 | No | No | Clayey-SILT with some sand, gravel, and cobbles (TILL) |
| TP13 (road cut) | 3,504 | 994 | 1,023 | 1.0 | No | No but near south lobe NW PAG Dump footprint | Silty GRAVEL with some sand and cobbles (TILL) |
| TP14 | 4,043 | 769 | 1,041 | 1.5 | No | Yes | CLAY with some silt, sand, and gravel Clayey SILT with some sand, gravel, and cobbles (TILL) |
| TP15 | 3,920 | 928 | 1,062 | 1.5 | No | Yes | CLAY with some silt, sand, and gravel Clayey SILT with some sand and gravel (TILL) |
| TP16 | 3,853 | 784 | 1,035 | 2.5 | No | Yes | CLAY with some silt, sand, and gravel |

**Table 2: 1999 Field Investigation Summary (after Golder 2010a)**

| Test Pit ID | Northing (m)[(a)] | Easting (m)[(a)] | Ground Elevation (m) | Excavation Depth (m) | Bedrock Encountered | Within Footprint of Proposed Ultimate NW PAG Dump | Foundation Soil Description |
|---|---|---|---|---|---|---|---|
| TP16A | 3,927 | 766 | 1,040 | N/A | No | Yes | Clayey SILT with some sand, gravel, and cobbles |
| TP17 | 4,279 | 871 | 1,048 | 1.6 | Yes | Yes | Clayey SILT with some sand and gravel<br>Silty SAND with some gravel and cobbles (TILL) |

(a) Test pit locations are presented in local mine grid.

## 4.2 2010 Geotechnical Field Investigation

The 2010 field investigation program included a total of two test pit locations that were both near the proposed ultimate NW PAG Dump footprint (Figure 4). Although these test pits are located outside the NW PAG Dump footprint they provide useful information regarding the interpretation of subsurface conditions for the general area of the NW PAG Dump. Both test pits encountered till overlying bedrock (Golder 2010b).

Results of the 2010 test pit program are presented in Table 3 and further detailed results are presented in Golder (2010b).

**Table 3: 2010 Field Investigation Summary (after Golder 2010b)**

| Test Pit ID | Northing (m)[(a)] | Easting (m)[(a)] | Ground Elevation (m) | Excavation Depth (m) | Bedrock Encountered | Within Footprint of Proposed Ultimate NW PAG Dump | Foundation Soil Description |
|---|---|---|---|---|---|---|---|
| TP1 | 3,742 | 940 | 1,062 | 1.2 | Yes | No but near south lobe NW PAG Dump footprint | TILL |
| TP2 | 3,304 | 1,158 | 992 | 2.0 | Yes | No | Sand SILT SAND and GRAVEL (TILL) |

(a) Test pit locations are presented in local mine grid.

## 4.3 2023 and 2024 Geotechnical Field Investigations

The 2023 and 2024 geotechnical field investigations for the NW PAG Dump included six test pits and 11 boreholes in and around the proposed ultimate NW PAG Dump design footprint (Figure 4). The following general stratigraphic units were encountered during the 2023 and 2024 investigations (WSP 2024b):

- Waste rock – 0.9 m to 33.4 m thick
- Colluvium – 0.8 m to 5.0 m thick

- Till – 3.2 m to 15.5 m thick
- Glaciofluvial deposits – 0.2 m to 3.5 m thick
- Fine-grained material – 1.4 m to 4.8 m thick
  - This material was initially interpreted as a Glaciolacustrine unit (GLU) during the 2023 geotechnical field investigation (WSP 2024b).
  - Clay material
    - 2.5 m thick interbedded material encountered during the 2023/2024 geotechnical field investigation.
- Bedrock – to depth

The results of the 2023 and 2024 geotechnical field investigations for the NW PAG Dump are summarized in Table 4 and further detailed results are presented in WSP (2024b).

**Table 4: Depth to Bedrock Logged During 2023 and 2024 Field Investigations (after WSP 2024b)**

| Test Pit or Borehole ID | Northing (m)[(a)] | Easting (m)[(a)] | Ground Elevation (m)[(a)] | Thickness of Waste Rock (m) | Thickness of Colluvium (m) | Maximum Thickness of Glaciofluvial Deposits (m)[(b)] | Maximum Thickness of Fine-grained Material (m)[(b)] | Maximum Thickness of Till (m)[(b)] | Overall Thickness of Overburden (m) | Elevation of Bedrock surface (masl) |

(a) Test pit and borehole locations are presented in local mine grid
(b) Maximum logged thickness recorded in logs; thinner layers not included.
(c) End of unit not reached.
(d) Seepage observed in these test pits.

## 4.4 Geotechnical Laboratory Testing of Foundation Soils

Geotechnical laboratory testing was completed on samples from the 1999, 2023, and 2024 geotechnical field investigations. The testing was carried out at the WSP Burnaby and Calgary Laboratories, and included the following geotechnical tests:

- Water content
- Particle size distribution (sieve and hydrometer)
- Atterberg Limits
- Specific gravity
- Modified Proctor
- Large direct shear

Laboratory testing was completed on one sample collected in the area of the NW PAG Dump in 1999 (Golder 2010a); no samples were tested from the area of the NW PAG Dump in 2010 (Golder 2010b), and 41 samples were tested from the area of the NW PAG Dump in 2023 and 2024 (WSP 2024b).

A review of the laboratory test results for each material type encountered in and around the NW PAG Dump is described in Section 5.4.

# 5.0 SITE CHARACTERIZATION AND ENGINEERING GEOLOGY

The following sections provide:

- A summary of a literature review of the glacial history and the surficial geology of the Mount Polley Mine and NW PAG Dump area, including the topography setting.
- Descriptions of the foundation soils and bedrock observed in the area of the proposed ultimate NW PAG Dump based on the field investigations and laboratory testing results.
- A description of the waste rock to be consigned to the NW PAG Dump.
- A summary of the groundwater conditions around the NW PAG Dump.
- A discussion of the site seismicity.
- A summary of the surficial geology interpretation for the area of the proposed ultimate NW PAG Dump design.

## 5.1 Regional Geomorphological Setting

The terrain and geomorphology of the area consists of low mountains and hummocky bedrock exposures dissected by a network of streams and lakes (Holland 1976; McAndless and Taylor 2006). Surface drainage patterns are influenced by bedrock topography; most of the stream valleys in the region have a northwest orientation and drain southward toward the lowland area north of the western arm of Quesnel Lake (Bichler and Bobrowsky 2003).

During the late Pleistocene, the area of Mount Polley Mine was covered by the Cordilleran Ice Sheet (Clague 1987 and 1988). The gently undulating topography and surface expression of the lowland area at the head of the west arm of Quesnel Lake is the result of glacial erosion and deposition of Quaternary sediments in an environment that evolved initially as a result of glacial advance followed by glacial retreat and inundation by meltwater, creating a glacial lake environment (Bichler and Bobrowsky 2003). The glacial landforms within the region indicate a predominantly northwesterly ice flow direction for the Cordilleran Ice Sheet in the Quesnel region (Clague 1988; Bichler and Bobrowsky 2003; Hashmi et al 2015).

## 5.2 Topography

The NW PAG Dump is located on the west flank of Mount Polley ridge between Polley Lake and Bootjack Lake. A foundation slope map is presented in Figure 5. At the north end of the NW PAG Dump the foundation is near elev. 1,004 m and slopes towards the south to approximately elev. 1,050 m. The eastern portion of the NW PAG Dump is founded on ground with slopes of 18 to 29 degrees. The western portion of the NW PAG Dump is founded on ground with slopes of 5 to 13 degrees.

Prior to construction in 2012, there were no identified major streams or drainage courses within the footprint of the NW PAG Dump. The footprint area was well drained by small, ephemeral streams that flowed in the spring and late fall. However, localized wet and swampy flat-lying areas occurred within localized depressions.

## 5.3 Regional Surface Geology

The regional surficial geology in the area of Mount Polley Mine is dominantly the result of erosion and deposition associated with the late Pleistocene (Wisconsinan) glacial episode referred to as the Fraser Glaciation (Clague 1987 and 1988).

The regional surficial geology is dominated by till, glaciofluvial, and glaciolacustrine sediments of the Fraser Glaciation (Bichler and Bobrowsky 2003; McAndless and Taylor 2006). The glacial stratigraphy locally contains colluvial deposits derived from landslides initiated on valley walls during the late Pleistocene and Holocene. Holocene fluvial deposits overlie the glacial deposits in areas local to watercourses and water bodies throughout the region (Bichler and Bobrowsky 2003). A generalized interpretation of the local Quaternary stratigraphy is presented in Figure 6.

Morainal till deposits more than 1 m thick are widespread and typically comprise poorly sorted, moderately to well-compacted silty clay diamicton.

Glaciofluvial deposits are common within the major valleys, deposited in a succession of well-defined terraces (Clague 1988; Bichler and Bobrowsky 2003). Glaciofluvial sediments typically comprise moderately sorted, weakly to moderately compacted cobbles or boulder gravel with a sand matrix. Gravel is also present locally in the form of hummocky blankets at higher elevations. Glaciofluvial fan deposits occur within valleys, with a similar composition to that of the glaciofluvial sediments, but typically with a greater sand content (Bichler and Bobrowsky 2003).

## 5.4 Local Surficial Geology

The local surficial geology consists of Quaternary glacial deposits overlain by fill/anthropogenic deposits. Based on the geotechnical field investigations completed to date in the area of the NW PAG Dump, a simplified stratigraphic sequence with estimated thicknesses based on site observations is summarized as follows:

- Topsoil
- Colluvium – 1 m to 5 m
- Glacial deposits
  - Till: 3 m to at least 16 m
  - Glaciofluvial deposits: up to 4 m
  - Fine-grained material
    - One unit 5 m thick encountered during the 2023/2024 geotechnical field investigation
    - This material was initially interpreted as a GLU during the 2023 geotechnical field investigation (WSP 2024b)
  - Clay material
    - One unit 2.5 m thick encountered during the 2023/2024 geotechnical field investigation
- Bedrock (Mount Polley Intrusive Complex) – to depth

Topsoil has not been considered in this assessment as WSP understands that topsoil materials have been stripped from the foundation and stockpiled for reclamation purposes.

The local surficial geology is based on information at test pit and borehole locations only. Conditions between test pits/boreholes and the extents of geologic units are unknown and are subject to uncertainty. The local surficial geology has been interpreted based on the field observations, and further interpreted based on the laboratory

testing completed on select samples. Some units may differ from what was presented in the factual report for the 2023/2024 geotechnical field investigations based on the laboratory testing (WSP 2024b).

Further details on each material type are described in the following sub-sections.

### 5.4.1 Colluvium

Colluvium in the area of the NW PAG Dump ranged in thickness from 0.8 m to 5 m, and locally exhibits greater thickness along the lower slopes of the west flank of Mount Polley ridge. The colluvium is expected to be the foundation soil directly underlying the east side of the proposed ultimate NW PAG Dump design.

The results of index tests completed on colluvium samples collected in the area of the NW PAG Dump are summarized in Table 5 and in Appendix C, Figures C-1 and C-2.

**Table 5: Summary of Index Test Results for Colluvium (after WSP 2024b)**

| Test | Average | Minimum | Maximum | Number of Tests |
|---|---|---|---|---|
| Water Content (%) | 11.8 | 9.0 | 16.9 | 4 |
| Liquid Limit | 32.0 | 26.0 | 42.0 | 4 |
| Plastic Limit | 17.5 | 12.0 | 28.0 | 4 |
| Plasticity Index | 14.5 | 14.0 | 16.0 | 4 |
| Specific Gravity | - | - | - | 0 |
| % Gravel | 43.8 | 33.0 | 56.0 | 4 |
| % Sand | 32.8 | 31.0 | 34.0 | 4 |
| % Fines | 23.5 | 13.0 | 33.0 | 4 |

The natural water content test results indicated an average of 12% and a range of 9% to 17%. It is noted that some samples were not tested immediately at the WSP Laboratory, therefore, the natural water contents may not reliably represent actual in-situ moisture conditions of the colluvium.

The particle size distribution test results indicated sand and gravel sized particles are present in all colluvium samples, with fines content raging from 13% to 33%. As indicated by the Atterberg Limit results, the fines component is generally intermediate plasticity, and range from silt to silty clay. The colluvium was typically described as very soft to stiff, and well-graded with trace organics.

Large direct shear testing was completed on a colluvium sample (WSP 2024b). The peak friction angle obtained was 35 degrees, with a cohesion of 30 kPa. The residual friction angle was 34.5 degrees, with a cohesion of 0 kPa.

### 5.4.2 Till

Till encountered in the area of the NW PAG Dump ranged in thickness from 3.2 m to 15.5 m. The till is expected to be the foundation soil underlying the majority of the west side of the proposed ultimate NW PAG Dump design.

The results of index tests completed on till samples collected in the area of the NW PAG Dump are summarized in Table 6 and in Appendix C, Figures C-3 and C-4.

**Table 6: Summary of Index Test Results for Till (after WSP 2024b)**

| Test | Average | Minimum | Maximum | Number of Tests |
|---|---|---|---|---|
| Water Content (%) | 12.3 | 6.8 | 23.0 | 2 |
| Liquid Limit[(a)] | 26.7 | 19.0 | 54.0 | 20 |
| Plastic Limit[(a)] | 14.1 | 12.0 | 17.0 | 20 |
| Plasticity Index[(a)] | 12.6 | 5.0 | 37.0 | 20 |
| Specific Gravity | 2.73 | 2.68 | 2.76 | 4 |
| % Gravel | 29.4 | 7.0 | 61.5 | 19 |
| % Sand | 33.5 | 10.0 | 57.4 | 19 |
| % Fines | 37.1 | 11.3 | 83.0 | 19 |

(a) One “non-plastic” test included in test count but not test results statistics.

The natural water content results indicated an average of 12% and a range of 7% to 23%. It is noted that some samples were not tested immediately at the WSP Laboratory, therefore, the natural water contents may not reliably represent actual in-situ moisture conditions of the till. The ranges and average moisture content are similar to values observed for till samples collected at the Southeast Rock Disposal Site (SERDS) and the Tailings Storage Facility (TSF) (WSP 2023 and 2024a).

The particle size distribution test results indicated sand and gravel sized particles are present in all till samples, the fines content ranging from 11% to 83%. As indicated by the Atterberg Limit results, the fines component is generally low to medium plasticity, and ranges from clays to silty clays. The ranges and averages for the particle size distribution and Atterberg Limit tests are similar to values observed for till samples collected from the SERDS and the TSF (WSP 2023 and 2024a). The till was typically described as loose to very stiff, and well-graded.

One sample from the 2023/2024 geotechnical field investigation, TP-NW-04-03, appears to be an outlier in regard to test results for water content, particle size distribution, and Atterberg Limits. The water content for the till sample was the highest at 23%; however, this value is considered unreliable due to the method of sampling and the extended period of time between when sampling and testing were carried out. The fines content was 83% and behaved like a high plasticity clay. This sample was a grab sample from a test pit at the northwest corner of the current NW PAG Dump (Figure 4) and there was no indication in the test pit log as to where this high fines material may have occurred. It is possible that within the till there was a depositional period where materials with more fines were deposited in this localized area; however, this was not observed during the test pit logging as the sample was a similar colour to the surrounding till and the depositional area may have been relatively small

Large direct shear testing was completed on a till sample (WSP 2024b). The peak friction angle is 32.5 degrees with a cohesion of 55 kPa. The residual friction angle is 32.5 degrees with a cohesion of 0 kPa. Direct shear testing of samples of till collected from near the SERDS and the TSF were also completed on remoulded grab samples, and those results were compared to the current test results for till in the area of the NW PAG Dump. Direct shear test results for samples of till collected near the SERDS indicated an average residual friction angle of 34 degrees with a cohesion of 0 kPa (WSP 2024a). Direct shear test results for samples of till collected near the TSF indicate an average peak friction angle of 34.6 degrees with a cohesion of 0 kPa (WSP 2023).

The results of index testing and direct shear testing of till samples collected near the NW PAG Dump are similar to the test results for till encountered near the SERDS and TSF, with the exception of the direct shear testing. This is likely due to the sample size used for the direct shear testing. For the purposes of this geotechnical assessment, the results of the large direct shear test completed for the till sample collected in the area of the NW PAG Dump in 2023 may be considered to represent a lower bound.

### 5.4.3 Glaciofluvial Deposits

Glaciofluvial deposits encountered in the area of the NW PAG Dump ranged in thickness from 0.2 m to 3.5 m. The glaciofluvial deposits were typically interbedded with the till on the north end of the dump and on the western portion near the centre of the NW PAG Dump footprint.

A summary of index testing completed on glaciofluvial material in the area of the NW PAG Dump is presented in Table 7 and in Appendix C, Figures C-5 and C-6.

**Table 7: Summary of Index Test Results for Glaciofluvial Deposits**

| Test | Average | Minimum | Maximum | Number of Tests |
|---|---|---|---|---|
| Water Content (%) | 7.1 | 5.2 | 9.7 | 5 |
| Liquid Limit[(a)] | 21.0 | 19.0 | 25.0 | 5 |
| Plastic Limit[(a)] | 13.8 | 12.0 | 17.0 | 5 |
| Plasticity Index[(a)] | 7.3 | 7.0 | 8.0 | 5 |
| Specific Gravity | 2.74 | 2.73 | 2.75 | 2 |
| % Gravel | 49.7 | 20.1 | 67.4 | 5 |
| % Sand | 38.2 | 21.0 | 65.4 | 5 |
| % Fines | 12.1 | 7.1 | 15.0 | 5 |

(a) One “non-plastic” test included in test count but not test results statistics.

The natural water content results indicated an average of 7% and a range of 5% to 10%. It is noted that some samples were not tested immediately at the WSP Laboratory, therefore, the natural water contents may not reliably represent actual in-situ moisture conditions of the glaciofluvial material. The ranges and average moisture contents were similar to values observed for glaciofluvial deposits encountered at the TSF (WSP 2023).

The particle size distribution testing indicated sand and gravel sized particles were present in all glaciofluvial samples and a fines content that ranged from 7% to 15%. The fines from these samples were generally identified as non-plastic to low plasticity. The glaciofluvial deposits were typically described as very loose to firm, low plasticity fines, and well-graded, which was generally supported by the laboratory test results. In general, the glaciofluvial deposits had a more granular nature and were less firm than the till. The ranges and averages for the particle size distribution tests and Atterberg Limits were similar to values obtained for samples of the glaciofluvial deposits collected at the TSF (WSP 2023).

No direct shear testing was completed on samples of glaciofluvial deposits collected near the NW PAG Dump. Shear strength testing was completed on samples of glaciofluvial deposits from the TSF and indicated a peak shear strength of 35 to 36 degrees with a cohesion of 0 kPa (WSP 2023).

### 5.4.4 Fine-Grained Material

Fine-grained material was encountered in what is inferred to be a localized “pocket” near DH-NW-07 in the central toe area on the west side of the NW PAG Dump footprint. The fine-grained material was encountered directly overlying bedrock at elev. 1,000 m. The vertical interval over which the fine-grained material was encountered was approximately 4.8 m.

A summary of index testing completed on the fine-grained material in the area of the NW PAG Dump is presented in Table 8 and in Appendix C, Figures C-7 and C-8.

**Table 8: Summary of Index Test Results for the Fine-Grained Material**

| Test | Average | Minimum | Maximum | Number of Tests |
|---|---|---|---|---|
| Water Content (%) | 18.2 | 14.7 | 23.0 | 8 |
| Liquid Limit | 27.5 | 22.0 | 30.0 | 8 |
| Plastic Limit | 18.3 | 17.0 | 20.0 | 8 |
| Plasticity Index | 9.3 | 4.0 | 11.0 | 8 |
| Specific Gravity | 2.8 | 2.8 | 2.8 | 3 |
| % Gravel | 8.8 | 1.0 | 28.2 | 8 |
| % Sand | 13.6 | 5.0 | 24.3 | 8 |
| % Fines | 77.7 | 58.2 | 94.0 | 8 |

The natural water content results indicated an average of 18% and a range of 15% to 23%. It is noted that samples were not tested immediately at the WSP Laboratory, therefore, the natural water contents may not reliably represent actual in-situ moisture conditions of the fine-grained material.

The particle size distribution test results indicated minimal gravel and sand sized particles and a fines content that ranged from 58% to 94%. Atterberg Limit results indicated the fines component was generally low plasticity, and silty clays. The fine-grained material was typically described as stiff to hard, and well-graded. This was supported by the laboratory testing results. The ranges and averages from the particle size distribution and Atterberg Limit results were similar to values observed for samples of the fine-grained material collected at the SERDS and from the south embankment of the TSF (WSP 2023 and 2024a). The low plasticity and relatively low water content of the silty clay layer (index testing) encountered at this location was not considered representative of the intermediate or high plasticity GLU encountered within the footprint of the TSF (WSP 2023).

One Cone Penetration Test (CPT) was advanced in the fine-grained material at DH-NW-07B, which was located in the vicinity of DH-NW-07 where the fine-grained material was first encountered. Pore pressure dissipation testing (PPDT) was completed at three elevations within the CPT column. A report was prepared by Gregg Drilling and Testing Canada Ltd. (Gregg), which included a summary of the CPT and PPDT results along with test details (WSP 2024b).

Results of the CPT analysis carried out for the fine-grained layer in DH-NW-07B are presented as a series of depth profiles in Appendix D, Figure D-1, including profiles of the following parameters:

- Total cone tip resistance, $q_t$.
- Sleeve friction, fs.
- Porewater pressure that includes the penetration porewater pressure $u_2$, hydrostatic porewater pressure, piezometer data of vwp-07 at dh-nw-07, and the end of two PPDTs performed at a depth of 31.0 m and 31.42 m.
- Undrained shear strength, $S_u$. $S_u$ was estimated from CPT data using Mayne (2001):

$$s_u = \frac{(q_t - \sigma_{v0})}{N_{KT}}$$

Where $N_{KT}$ = 15 is a constant, $\sigma_{v0}$ is the total stress acting on the soil layer.

- Preconsolidation stress, $\sigma'_p$, from the CPT data was estimated from Mayne (2001):

$$\sigma'_p = 0.33\ (q_t - \sigma_{v0})$$

- Over consolidation ratio, OCR, that is the ratio of $\sigma'_p$ to the effective stress, $\sigma'_V$.

The peak undrained shear strength ratio ($S_u$-peak ratio) was calculated based on $qc_{1Ncs}$ as recommended by Idriss and Boulanger (2008). Appendix D, Figure D-2 presents the $S_u$-peak ratio determined by the Idriss and Boulanger (2008) method. The 33rd percentile of the peak undrained shear strength ratio for the fine-grained layer is 0.83. The fine-grained layer is highly over consolidated with an average OCR equal to 17 as shown in Appendix D, Figure D-1. Robertson (2016) presents the CPT soil behaviour type (SBT) chart for liquefaction and cyclic softening potential. Appendix D, Figure D-3 presents the CPT SBT chart for the fine-grained layer. The material exhibits a sand-like dilative and transitional dilative behavior.

The proposed ultimate NW PAG Dump design will have approximately 5 to 10 m of additional material placed in the vertical column in the area of the fine-grained material. This is a minimal amount of vertical effective stress that will be applied to the fine-grained material.

Despite this material being interpreted as having deposited in a glaciolacustrine environment (WSP 2024b), the results of the laboratory testing and CPT indicate that it does not behave as the intermediate or high plasticity GLU encountered within the footprint of the TSF. The fine-grained material is interpreted to be a component of the till, generally lacking the clastic component of sand, gravel and cobbles that is present in other portions of the till unit. For the purposes of the slope stability analyses, this material will be assessed combined with the till material parameters.

### 5.4.5 Clay Material

Clay material was encountered in what was inferred to be a localized “pocket” near DH-NW-02 on the northeast side of the NW PAG Dump footprint. The clay material was encountered 0.9 m below original ground surface. The vertical interval over which the clay material was encountered was approximately 2.6 m.

A summary of index testing completed on clay material in the area of the NW PAG Dump is presented in Table 9 and in Appendix C, Figures C-9 and C-10.

**Table 9: Summary of Index Test Results for Clay Material**

| Test | Average | Minimum | Maximum | Number of Tests |
|---|---|---|---|---|
| Water Content (%) | 48.4 | 38.4 | 58.3 | 2 |
| Liquid Limit[(a)] | 44.5 | 38.0 | 51.0 | 2 |
| Plastic Limit[(a)] | 18.5 | 16.0 | 21.0 | 2 |
| Plasticity Index | 26.0 | 22.0 | 30.0 | 2 |
| Specific Gravity | 2.69 | 2.69 | 2.69 | 1 |
| % Gravel | 5.3 | 1.6 | 8.9 | 2 |
| % Sand | 13.7 | 13.1 | 14.2 | 2 |
| % Fines | 81.1 | 76.9 | 85.3 | 2 |

The natural water content results indicated an average of 48% and a range of 38% to 58%. It is noted that samples were not tested immediately at the WSP Laboratory, therefore, the natural water contents may not reliably represent actual in-situ moisture conditions of the clay material.

The particle size distribution test results indicated minimal gravel and sand sized particles and a fines content that ranged from 77% to 85%. Atterberg Limit results indicated the fines component was generally intermediate to high plastic, silty clay to clay. The clay material was typically described as very soft to firm. The higher fines content in samples collected from the northeast side of the NW PAG Dump (DH-NW-02) may be indicative of an interval of lower energy deposition within the overall glaciofluvial environment.

No direct shear or advanced geotechnical laboratory testing has been completed on the clay material. The material was inferred to be interbedded (not continuous) and isolated to one borehole (DH-NW-02). The clay material was not encountered in TP-NW-01, TP-NW-02, DH-NW-03 or DH-NW-03A which are nearby (Figure 4). No test pit excavations or borehole drilling has been completed below the toe (within the footprint) of the NW PAG Dump near where the clay material was encountered due to the dump having already been constructed to the footprint extents in this area.

### 5.4.6 Bedrock

Bedrock in the area of the NW PAG Dump footprint is part of the Mount Polley Intrusive Complex, which is composed of several intrusive units including diorite, monzodiorite-monzonite, K-feldspar monzonite, and late dykes (Rees 2013). All of these rock types are considered to be medium strong to strong, with estimated uniaxial compressive strengths ranging from 25 to 100 MPa.

Bedrock was encountered in two test pits in 1999, two test pits in 2010, two test pits in 2023, and eight boreholes in 2023/2024. The test pits completed did not describe the bedrock other than observations indicating that it was weathered. Bedrock encountered in the sonic boreholes was typically pulverised and difficult to determine its particular compositional characteristics. The rock pieces were typically grey with brown staining (WSP 2024b).

## 5.5 Waste Rock

Waste rock from the Mount Polley pits generally consists of blasted intrusive rock that are observed to be hard and competent. Gradations of waste rock from the Mount Polley pits have not been assessed, but have been generally observed over a period of several years. Waste rock particle sizes are generally expected to range from a few centimetres up to 1 m, and consist predominantly of boulders and cobbles, with some gravel and sand based on observations of waste rock in the current NW PAG Dump and experience at the Mount Polley Mine.

From previous experience, waste rock at Mount Polley Mine has been observed to be good quality (with the exception of material from faulted areas and the upper bench in overburden). Slope stability performance at the current NW PAG Dump and in other waste rock dumps on site has been favorable in part due to the material quality. The existing waste rock dump slopes are generally at angle of repose (37 degrees) with no apparent indication of slope face or overall instability.

Waste rock fills typically exhibit a non-linear shear strength behaviour that is largely dependent upon the gradation, angularity, and degree of compaction of the particles (Leps 1970; Barton and Kjaernsli 1981). Research results from testing of rockfill shows that the measured friction angles are a function of applied normal stress for various rockfill gradations and densities. Figure 7 presents the non-linear shear strength of rockfill from triaxial tests after Leps (1970), which includes an upper bound for the shear strength behaviour for high density, well-graded strong particles and a lower bound for low density, poorly graded weak particles.

Selection of the appropriate shear strength function for waste rock is related to the material type to be placed. Table 10 presents a summary of the non-linear shear strength functions after Leps (1970) and Hawley and Cunning (2017) and provides recommended shear strength functions.

**Table 10: Shear Strength Functions for Waste Rock (after Hawley and Cunning 2017)**

| Particle Strength – Based on Leps (1970) Curve (Graph 3) | Shear Strength Function |
|---|---|
| Lower bound – low density, poorly graded, weak particles. | $\tau = 1.446\sigma^{0.898}$ |
| Lower quartile – between low and average rockfill. | $\tau = 1.576\sigma^{0.899}$ |
| Average rockfill | $\tau = 1.726\sigma^{0.899}$ |
| Upper quartile – between average and high rockfill. | $\tau = 1.899\sigma^{0.898}$ |
| Upper bound – high density, well-graded, strong particles, generally not suitable for sedimentary rockfill. | $\tau = 2.067\sigma^{0.899}$ |

$\tau$=$shear\ strength$; $\sigma = normal\ stress$.

## 5.6 Groundwater

Groundwater levels around the NW PAG Dump are generally expected to be at or near the contact between the waste rock and the underlying foundation soil and can be expected to fluctuate seasonally due to variations in precipitation and runoff from Mount Polley ridge.

During the December 2023 geotechnical investigation, artesian conditions were encountered in DH-NW-03A at 14.25 m depth in a layer of glaciofluvial deposits. Flow from the borehole was measured at approximately 0.1 gallon per second (about 0.4 L/s), with approximately 3.5 m of hydraulic head above ground surface before the borehole was grouted. No seepage from the borehole has been observed since grouting and the cause of the artesian conditions has not been investigated further. There is an area to the northeast of the NW PAG Dump and DH-NW-03A along Bootjack Road where MPMC staff have noted water flows continuously throughout the year indicating a potential seep in the area (an exact location was not provided to WSP).

Seeps and ponding water have also been observed along the toe of the current NW PAG Dump (Appendix E, Figures E-1 to E-3). This is likely due to the fine-grained material that has been stripped from the footprint of the dump and piled near the toe of the dump. Seepage from the NW PAG Dump is collected in a sump near the south end of the dump via a seepage collection pipe (Appendix E, Figure E-4) and in seepage collection ponds on the west side of the NW PAG Dump (Appendix E, Figure E-5).

A total of four vibrating wire piezometers (VWP) were installed in four boreholes during the 2023 geotechnical investigation to monitor the hydraulic heads in the different subsurface units. Seven rounds of hydraulic head readings have been collected by MPMC since installation of the VWPs to monitor the groundwater table in the dump area. A summary of the VWP installation details and latest reading of the corresponding hydraulic heads are presented in Table 11. Due to the relatively shallow depths of the piezometers, it has been assumed that the hydraulic head readings represent water table elevations at those locations. Cross-sections and graphs of hydraulic head data over time are presented in Appendix E.

**Table 11: Summary of Vibrating Wire Piezometers and Approximate Groundwater Elevations for NW PAG Dump**

| Borehole ID | VWP Serial No. | Unit | Tip Elevation (m) | Original Ground Elevation (m) | Reading Date | Hydraulic Head (m) | Groundwater Elevation (m) |
|---|---|---|---|---|---|---|---|
| DH-NW-02 | VW165268 | Glaciofluvial | 1,048.6 | 1,051.7 | April 8, 2024 | 2.3 | 1,050.8 |
| DH-NW-06 | VW170541 | Till/bedrock contact | 994.0 | 1,002.6 | | 10.7 | 1,004.7* |
| DH-NW-07 | VW162321 | Fine-grained material | 998.5 | 1,014.8 | | 19.7 | 1,018.2* |
| DH-NW-09 | VW169440 | Bedrock | 1,025.9 | 1,041.5 | | 14.0 | 1,040.0 |

*Hydraulic head is reading above original ground elevation.

Observations from the VWPs installed in the NW PAG Dump area are as follows:

- DH-NW-02 (Appendix E, Figures E-7 and E-8)
  - The VWP is installed in glaciofluvial material at the northeast toe of the NW PAG Dump, and the hydraulic head data collected fluctuate from elev. 1,050 to 1,051 m below original ground elevation.
- DH-NW-06 (Appendix E, Figures E-9 and E-10)
  - The VWP is installed at the till/bedrock contact below the current northwest toe of the NW PAG Dump, and the hydraulic head has been steadily reading about 2 m above original ground elevation.
- DH-NW-07 (Appendix E, Figures E-11 and E-12)
  - The VWP is installed in fine-grained material below the current west toe of the NW PAG Dump, and the hydraulic head has been steadily reading about 3 m above original ground elevation.
- DH-NW-09 (Appendix E, Figures E-13 and E-14)
  - The VWP is installed in bedrock below the current toe of the NW PAG Dump on the south end, and the hydraulic head has remained below original ground elevation around elev. 1,040 m.

During the 2023 test pit investigation, seepage was observed in the following test pits and depths:

- TP-NW-02 at a depth of 1 m in glaciofluvial material
- TP-NW-03 at a depth of 1 m in colluvium
- TP-NW-04 at a depth of 1.4 m in till

All of these test pits are located at the north to northwest end of the current NW PAG Dump.

Groundwater information collected to date indicates the following conceptual flow regime:

- Groundwater in the area of the NW PAG Dump flows largely from east to west with recharge at the Mount Polley ridge and discharge to the Bootjack Lake.

- The data collected during the field investigation indicate the groundwater below the NW PAG Dump is relatively shallow varying from about 1 m below ground surface up to 3 m above ground surface.
- Water ponding has been observed near the toe of the NW PAG Dump in the area of fine-grained material piles that likely limit infiltration.

Artesian conditions have been encountered in the fine-grained materials in DH-NW-07 (hydraulic head is 3 m above original ground in the dump). The localized condition could be the result of an elevated water table within the dump and poor drainage of the underlying fine-grained materials. No seepage face on the lower lift of the dump in this area has been observed.

The artesian conditions encountered in borehole DH-NW-06 at the till - bedrock contact may be the result of a regional flow within the bedrock aquifer under confined conditions due to the overlying till “capping” and preventing the upward flow of groundwater across the till – bedrock contact.

Assumptions regarding groundwater for the slope stability assessment are described further in Section 6.5.

## 5.7 Site Seismicity

Mount Polley Mine is located in an area of relatively low seismicity in British Columbia. WSP developed a site-specific seismic hazard model for the Mount Polley Mine based on historical seismicity and a review of geological and paleo-seismological features (WSP USA 2023). Earthquake ground motion parameters calculated from the site-specific hazard model are presented in Table 12.

**Table 12: Mount Polley Mine Seismic Hazard Values (after WSP USA 2023)**

| Exceedance Probability | Return Period (years) | Peak Ground Acceleration (g) |
|---|---|---|
| 5% in 50 years | 1,000 | 0.026 |
| 2% in 50 years | 2,475 | 0.048 |
| 1% in 50 years | 5,000 | 0.076 |
| 0.5% in 50 years | 10,000 | 0.116 |

Return periods are not exact representations of annual exceedance probabilities.

These values were compared to the National Building Code (NBC) of Canada seismic hazard tool for the latitude and longitude location of the NW PAG Dump. The peak ground acceleration (PGA) values are similar, therefore, the assessment completed by WSP USA (2023) were used for the pseudo-static slope stability analyses.

## 5.8 Cross-Section Review

The original topography in the area of the NW PAG Dump (from 2006), a LiDAR drone scan of the dump completed in October 2023, and the proposed NW PAG Dump design provided by MPMC were reviewed using the Seequent 3D modelling software Leapfrog Works (© 2023 Seequent). Several cross-sections were cut through the surfaces of the 3D model to identify critical cross-sections for the slope stability and runout analyses.

A description of each of the cross-sections is provided below:

- Cross-section A (Appendix B, Figure B-2): This cross-section was cut to review topography below the southern portion of the NW PAG Dump and through DH-NW-09, TP-NW-09, and TP-NW-10. The topography slopes at about 20 degrees on the east side, to a shallow slope of about 8 degrees below the majority of the NW PAG Dump and steepens past the toe of the dump to Bootjack Lake. The cross-section indicates that the NW PAG Dump is near its ultimate configuration in this area with an overall height of 107 m (toe to crest). The field investigation information indicates colluvium in the area with till at depth over bedrock. The bedrock elevation at the south end of the dump is typically around elev. 1,026 m or higher towards the south.
- Cross-sections B and C (Appendix B, Figures B-3 and B-4): These cross-sections were cut to review topography below the southern portion of the NW PAG Dump and through DH-NW-08 and DH-NW-09. The topography is shallow to moderate in this area, sloping at approximately 8 degrees. The cross-sections indicate that the NW PAG Dump is at its ultimate height in this area with an overall height of 111 m (toe to crest) and available storage to the west. The field investigation information indicates colluvium overlying till with bedrock between elev. 1,017 m and elev. 1,026 m.
- Cross-sections D, E, and F (Appendix B, Figures B-5 to B-7): These cross-sections were cut to review topography below the central portion of the NW PAG Dump and through DH-NW-06, DH-NW-07, DH-NW-07B, DH-NW-07C, DH-NW-08, and DH-NW-11. The topography is moderately sloping at approximately 22 degrees on the east side, to a shallow slope of about 7 degrees below the majority of the NW PAG Dump. The cross-sections indicate that the NW PAG Dump is at its ultimate height in this area with an overall height of 133 m (toe to crest) and available storage to the west. The field investigation information indicates a thin veneer of colluvium over till interbedded with some glaciofluvial material, with a pocket of fine-grained material near the toe of the dump (interpreted to be a component of the till), overlying bedrock between elev. 993 m to elev. 1,002 m.
- Cross-sections G and H (Appendix B, Figures B-8 to B-9): These cross-sections were cut to review topography below the northwest portion of the NW PAG Dump and through DH-NW-05 and DH-NW-06. The topography is moderately sloping at approximately 25 degrees on the east side, to a shallow slope of about 9 degrees below the majority of the NW PAG Dump. The cross-sections indicate that the NW PAG Dump is at its ultimate height in this area with an overall height of 141 m (toe to crest) and available storage to the west. The field investigation information indicates till interbedded with some glaciofluvial material overlying bedrock around elev. 992 m.
- Cross-section I (Appendix B, Figure B-10): This cross-section was cut to review topography below the northern portion of the NW PAG Dump and through TP-NW-04. The cross-section is oblique to the slope of the topography and indicates a shallow slope of about 6 degrees on the north side, to a steep slope of about 17 degrees on the south end where the dump ties into original topography. The cross-section indicates that the NW PAG Dump is at its ultimate configuration in this area with an overall height of 128 m (toe to crest) with available storage to the north. The field investigation information indicates colluvium in the area with till at depth over bedrock.

- Cross-section J (Appendix B, Figure B-11): This cross-section is two separate sections with different orientations stitched together to review topography below the northeast portion of the NW PAG Dump and through DH-NW-03A and TP-NW-03. The topography is moderately sloping at approximately 16 degrees on the east side, to a shallow slope of about 5 degrees below the majority of the NW PAG Dump. The cross-section indicates that the NW PAG Dump is not at its ultimate configuration in this area with approximately 19 m of height for storage. The field investigation information indicates a thin veneer of colluvium in the area with till interbedded with glaciofluvial material overlying bedrock at about elev. 1,004 m.
  - This cross-section is near DH-NW-03 where artesian conditions were encountered when drilling intersected the glaciofluvial deposits at depth.
  - This cross-section is near DH-NW-02 where clay material was encountered near the toe of the dump, outside the footprint of the proposed ultimate NW PAG Dump design in what is interpreted to be an isolated area.

## 5.9 Surficial Geology Interpretation

Based on the foundation materials and cross-section review, a surficial geology interpretation is shown in Figure 8 for the area of the proposed ultimate NW PAG Dump design. The following summarizes the interpretation:

- Colluvium is interpreted to be a thin veneer underlying the eastern slope of the NW PAG Dump, with localized areas of thicker colluvium layers to the southwest of the dump footprint.
- Till is interpreted to cover the majority of the NW PAG Dump footprint, with variable thickness.
- Glaciofluvial deposits are located in isolated areas at the north end of the dump and near the center. Till typically overlies the glaciofluvial deposits.
- Fine-grained material is interpreted to be present in an isolated area on the west side of the NW PAG Dump at depth and is overlain by till. This material has been modeled as part of the till. It is possible that fine-grained material could be located in other parts of the foundation of the NW PAG Dump that were not investigated.
- Clay material is interpreted to be present in an isolated area on the northeast side of the NW PAG Dump about 0.9 m below original ground surface and is discontinuous (interbedded with silty clay). This material has been modeled as a separate unit as a sensitivity analysis.

# 6.0 SLOPE STABILITY ASSESSMENT

The following sections provide:

- A description of the slope stability rating and hazard classifications for the proposed ultimate NW PAG Dump using the Waste Dump Stockpile Stability Rating and Hazard Classification (WSRHC) system (Hawley and Cunning 2017).
- Rationale used to select the design acceptance criteria (BCMWRPRC 1991 and Hawley and Cunning 2017).
- Identification of the potential instability mechanisms for the proposed ultimate NW PAG Dump design.
- A discussion regarding the slope stability modeling methodology and assumptions.
- A description of the selected material strength parameters and assumptions.
- A discussion of the slope stability model scenarios and slope stability results.

## 6.1 Slope Stability Rating and Hazard Classification

The WSRHC system is based on Hawley and Cunning (2017) and incorporates many concepts that were used in the B.C. Mines Ministry 1991 dump slope stability classification guidelines (BCMWRPRC 1991). The WSRHC system requires evaluation of 22 key factors or attributes that affect slope stability of a waste rock dump. Numerical ratings are assigned to each factor, and the sum of these ratings defines the waste rock dump slope stability rating.

The WSRHC results for the proposed ultimate NW PAG Dump design are summarized in Table 13 and presented in Illustration 1.

**Table 13: NW PAG Stability Rating and Hazard Classification Results**

| WSRHC Factors | Rating |
|---|---|
| Engineering Geology Index | 26.5 |
| Design Performance Index | 30.5 |
| Waste Rock and Stockpile Stability Rating | 57 |
| Waste Rock and Stockpile Hazard Class | III |
| Instability Hazard | Moderate Hazard |

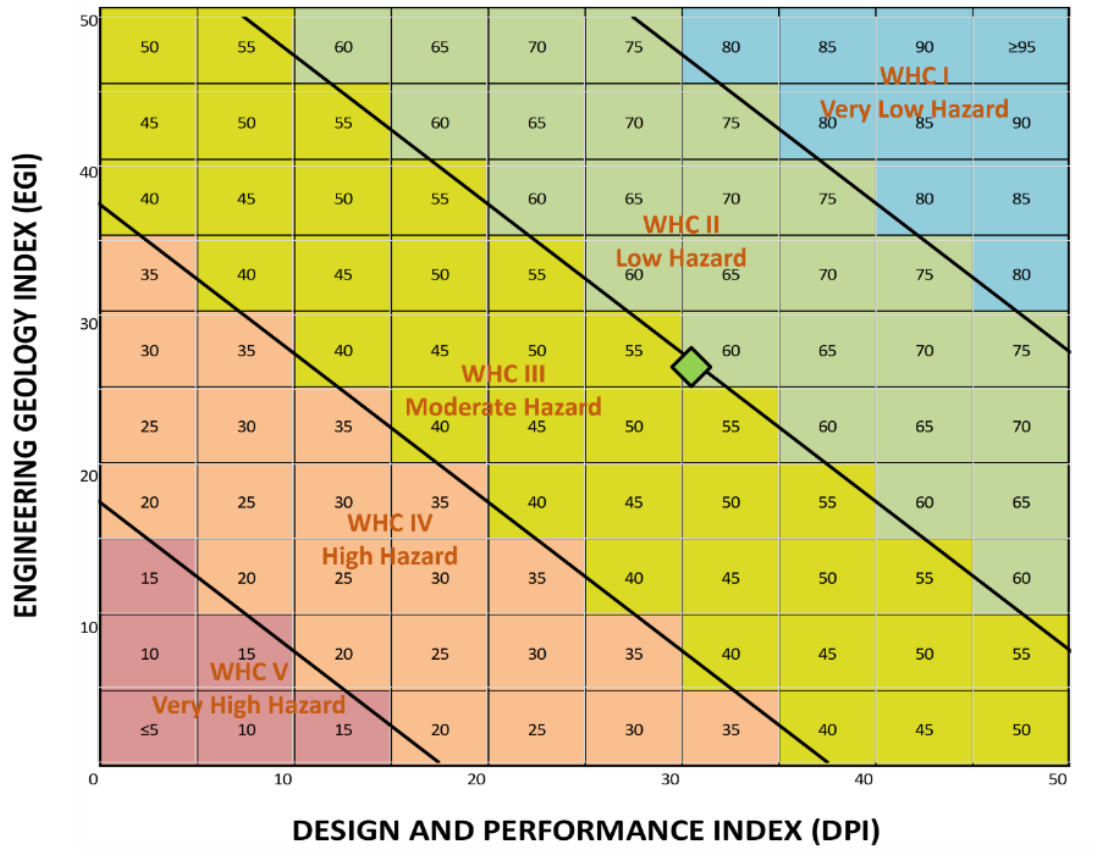

**Illustration 1: Proposed Ultimate NW PAG Dump Design Slope Stability Rating and Hazard Classification**

The proposed ultimate NW PAG Dump design is classified as presenting a moderate potential for instability and is therefore considered to be a moderate hazard waste rock dump (Class III). Further details of the WSRHC are presented in Appendix F.

## 6.2 Instability Mechanisms

The site topography was reviewed with respect to the proposed ultimate NW PAG Dump design to identify areas with adverse combinations of foundation slope angles, foundation soils, and overall waste rock dump height. The cross-section review presented in Section 5.8 and Appendix B supported the selection of cross-sections for slope stability analyses.

The following two potential slope failure mechanisms were assessed in the slope stability analyses:

- **Dump lift/face stability (shallow-seated):** Failure surfaces either pass through the NW PAG Dump face, or local failure occurs at the toe (no effect on overall slope stability of the dump).
- **Overall stability (deep-seated):** Deep failure surfaces pass through the NW PAG Dump body and/or the foundation contact and affect the overall slope stability of the dump.

## 6.3 Potential Liquefaction

Soils that are susceptible to static or dynamic liquefaction are generally loose, uniform to poorly graded clean sands that are susceptible to collapse of structure under rapid loading. The proposed ultimate NW PAG Dump design is underlain by colluvium, till, glaciofluvial, fine-grained material, and clay material deposits. The particle size distribution curves and Atterberg Limit results from laboratory testing for these materials are presented in Appendix C. A uniformity coefficient can be calculated from the particle size distribution curves to determine whether the soil is well-graded or uniform, as shown by Equation 1.0 (Budhu 2009).

$$C_u = \frac{D_{60}}{D_{10}} \quad (1.0)$$

A soil that has a uniformity coefficient less than 4 contains particles of uniform size and a uniformity coefficient greater than 4 indicates a wider assortment of particles sizes and is described as well-graded soil. This relationship has been used to support justification as to whether or not the materials are susceptible to liquefaction.

Colluvium in the area of the NW PAG Dump consists of well-graded gravels, sands, and fines in varying proportions with trace cobbles. The colluvium is typically very soft to stiff with trace organics. The particle size distribution curve (Appendix C, Figure C-11) indicates a high coefficient of uniformity (above 4) which aligns with descriptions of the material being well-graded. Due to voids being filled with fines, the well-graded colluvium is typically not susceptible to structure collapse and liquefaction upon loading.

Till in the area of the NW PAG Dump is typically a loose to stiff, well-graded material with abundant fines based on observations and laboratory testing completed. The particle size distribution curve (Appendix C, Figure C-12) indicates a high coefficient of uniformity (above 4) which aligns with descriptions of the material being well-graded. Due to the voids between the coarser fraction of the till being filled with fines, based on the descriptions of the till and the resulting particle size distribution curves, the till is not susceptible to liquefaction.

Glaciofluvial deposits in the area of the NW PAG Dump are typically a thin layer (interbedded with till) composed of gravels and sands, with lower percentages of fines. The glaciofluvial deposits were described as loose to stiff. The glaciofluvial deposits were observed and tested to be more granular and less firm than the till found in the area of the NW PAG Dump. There is one sample of glaciofluvial material from DH-NW-11 (GS-08) that has a particle size distribution curve that lies within a potential liquefiable soils envelope (Appendix C, Figure C-13). However, this sample has a high uniformity coefficient (above 4) and is considered to be a well-graded soil. Based on the descriptions of the glaciofluvial deposits, the majority of the resulting particle size distribution curves (Appendix C, Figure C-13), the uniformity coefficients, and the proposed construction methodology for the proposed ultimate NW PAG Dump (low lift heights over a large area), the glaciofluvial material is unlikely to be susceptible to liquefaction.

A pocket of fine-grained material was encountered near the toe of the current NW PAG Dump on the west side in DH-NW-07. The material was logged as clay with trace gravel and sand, and generally stiff to hard. The uniformity coefficients based on the particle size distribution curves (Appendix C, Figure C-14) of the fine-grained material are high (above 4). Due to the voids between the coarser fraction of the fine-grained materials being filled with fines, based on the descriptions of the material and the resulting particle size distribution curves, the fine-grained material is not susceptible to structure collapse and liquefaction.

Clay material was found interbedded with coarser glaciofluvial deposits in DH-NW-02 and was described as very soft to firm with a high fines content. Uniformity coefficients were not calculated for the clay material as a $D_{10}$ value is not achieved in the laboratory testing (the material has a very high fines content). However, based on the descriptions of the material and the particle size distribution curves (Appendix C, Figure C-15), the clay material is not susceptible to liquefaction.

The Mount Polley Mine area is in a low seismicity area. The likelihood of dynamic loading due to an earthquake is relatively low for the area.

Based on experience at Mount Polley Mine, the waste rock is typically coarse grained and free-draining. It will exist in a relatively loose state due to the construction methodology (bottom-up construction) and is unlikely to exhibit a significant loss of shear strength when subject to cyclical external forces. The waste rock will generally be unsaturated and would be expected to settle during earthquakes, but not be susceptible to liquefaction due to absence of water. Fine-grained material that could be mined (i.e. overburden, weathered, or altered rock, or fault gouge) should be placed within the center or east side of the NW PAG Dump such that it can be encapsulated with better quality material. This construction methodology will contain any potentially liquefiable material within the dump such that it is unlikely to cause slope stability issues near the face/edges of the dump.

## 6.4 Design Factors of Safety

In keeping with the current state of practice, WSP has used Hawley and Cunning (2017) in conjunction with the British Columbia Mine Rock and Overburden Piles Research Committee (BCMWRPRC) Investigation and Design Manual, Interim Guidelines (BCMWRPRC 1991) to determine the slope stability design acceptability criteria for the proposed ultimate NW PAG Dump design.

The BCMWRPRC (1991) recommended factors of safety (FOS) are presented in Table 14.

**Table 14: BCMWRPRC (1991) Recommended Factors of Safety for Waste Rock Dumps**

| Stability Condition | Factor of Safety | |
|---|---|---|
| **Stability of Dump Face** | **Case A** | **Case B** |
| Short-term | 1.0 | 1.0 |
| Long-term | 1.2 | 1.1 |
| **Overall Stability (Deep-seated Stability)** | | |
| Short-term (Static) | 1.3–1.5 | 1.1–1.3 |
| Long-term (Static) | 1.5 | 1.3 |
| Long-term (Pseudo-static) | 1.1–1.3 | 1.0 |
| **Case A**<br>▪ low level of confidence in critical analysis parameters<br>▪ possibly unconservative interpretation of conditions, assumptions<br>▪ severe consequences of failure<br>▪ simplified stability analyses method (chart, simplified method of slices)<br>▪ stability analyses method poorly simulates physical conditions<br>▪ poor understanding of potential failure mechanisms | | |
| **Case B**<br>▪ high level of confidence in critical analyses parameters<br>▪ conservative interpretation of conditions, assumptions<br>▪ minimal consequences of failure<br>▪ rigorous stability analysis method<br>▪ stability analysis method simulates physical conditions well<br>▪ high level of confidence in critical failure mechanism(s) | | |

The Hawley and Cunning (2017) suggested FOS based on the consequence of failure and the confidence in the factors that will control stability are shown in Table 15.

**Table 15: Suggested Stability Criteria Factors of Safety (Hawley and Cunning 2017)**

| Consequence | Confidence | Minimum Static FOS | Minimum Pseudo-static FOS |
|---|---|---|---|
| Low | Low | 1.3–1.4 | 1.05–1.1 |
| | Moderate | 1.2–1.3 | 1.0–1.05 |
| | High | 1.1–1.2 | 1.0 |
| Moderate | Low | 1.4–1.5 | 1.1–1.15 |
| | Moderate | 1.3–1.4 | 1.05–1.1 |
| | High | 1.2–1.3 | 1.0–1.05 |
| High | Low | ≥ 1.5 | 1.15 |
| | Moderate | 1.4–1.5 | 1.1–1.15 |
| | High | 1.3–1.4 | 1.05–1.1 |

FOS = factor of safety.

Notes (abridged; for the complete stability acceptance criteria, refer to Hawley and Cunning 2017).

Consequence:

**Low**—Waste rock dumps and stockpiles with overall fill slopes less than 25 degrees and less than 100 m high and repose angle slopes less than 50 m high. No critical infrastructure or unrestricted access within potential runout shadow. Limited potential for environmental impact. Long-term (more than 5 years) exposure for sites subject to very low to low (less than 250 mm) annual precipitation.

**Moderate**— Waste rock dumps with overall fill slopes less than 30 degrees and less than 250 m high or response angle slopes less than 100 m high. No critical infrastructure or unrestricted access, or robust containment/mitigative measures to protect critical infrastructure and access within potential runout shadow. Potential for moderate environmental impact, but manageable. Long-term (more than 5 years) exposure for sites subject to moderate (less than 250-1000 mm) annual precipitation.

**High**— Waste rock dumps with overall fill slopes more than 30 degrees and more than 250 m high, or with repose angle slopes more than 200 m high. Critical infrastructure or unrestricted access within potential runout shadow with limited runout mitigation/containment measures. Potential for high environmental impact that would be difficult to manage. Long-term (more than 5 years) exposure for sites subject to high (1000-2000 mm) annual precipitation or intensive rainy season(s).

Confidence:

**Low**—limited confidence in foundation conditions, waste rock properties, piezometric pressures, analyses technique or potential instability mechanism(s). Poorly defined or optimistic input parameters; high data variability.

**Moderate**—moderate confidence in foundation conditions, waste rock properties, piezometric pressures, analyses technique or potential instability mechanism(s). Input parameters adequately defined, moderate data variability.

**High**—high confidence in foundation conditions, waste rock properties, piezometric pressures, analyses technique or potential instability mechanism(s). Well-defined, conservative input parameters adequately defined, low data variability.

The choice of a design FOS involves consideration of the level of confidence in the understanding of the factors that will control slope stability, the input parameters, the analysis methods, and the consequences of failure. The guidelines summarized in Table 14 and Table 15 provide a range of suggested FOS to account for the consideration of these various factors. The following observations are provided regarding considerations and assumptions for consequence and confidence of the proposed ultimate NW PAG Dump design:

## *Consequence:*

- The proposed ultimate NW PAG Dump design height is moderate (140 m toe to crest at its highest point) with angle of repose waste rock lift faces about 40 m high, 10 m wide catch-benches, and an overall slope angle of 28 degrees. A low consequence (Hawley and Cunning 2017) criterion with respect to waste rock dump construction is considered appropriate.
- MPMC have a monitoring plan (MPMC 2021) and access requirements when entering the runout zone and active mining area of the NW PAG Dump. There is signage in place and gates such that public access is also

restricted. A low consequence (Hawley and Cunning 2017) criterion with respect to access in and around the NW PAG Dump is considered appropriate.

- The NW PAG Dump is located near the Bootjack Access Road to the north (public access road and access road to Mount Polley Mine), near Bootjack Lake to the west, and settling ponds to the west. If failure were to occur on the NW PAG Dump slopes, a runout could impact one of these areas and has a severe consequence of failure. This presents a high consequence (Hawley and Cunning 2017) and Case A (BCMWRPRC 1991) criterion.
- Long-term exposure (over five years) for the NW PAG Dump will be subject to moderate annual precipitation at 612 mm/year. This presents a moderate consequence (Hawley and Cunning 2017).

***Confidence:***

- Past experience with waste rock dump construction at the Mount Polley Mine has provided a good understanding of the geologic and hydrogeologic conditions at the mine site, and the probable range of foundation material strength parameters. Consequently, there is a reasonable degree of confidence in the design strength parameters used in the analyses. Several field investigations and laboratory testing programs have been carried out for the property which also increases the degree of confidence in the foundation conditions and the design strength parameters. A high confidence (Hawley and Cunning 2017) and Case B (BCMWRPRC 1991) criterion with respect to material properties is considered appropriate since laboratory testing has been completed on the foundation materials and field investigations have been completed in the NW PAG Dump footprint area.
- Good quality waste rock is expected to be prioritized in the NW PAG Dump, with poorer quality waste rock being contained within the center of the dump or close to the eastern edge. No laboratory testing has been completed on waste rock at Mount Polley Mine; however, the behaviour of waste rock on site is well understood due to the favorable slope stability performance of other waste rock dumps at Mount Polley Mine and the observed gradations of the material. It has been assumed that the material is similar to other good quality waste rock encountered on site. Based on the gradations observed on site of the waste rock, the average rockfill Leps shear strength function applied to the slope stability analyses is appropriate (Table 10). A high confidence (Hawley and Cunning 2017) and Case B (BCMWRPRC 1991) criterion with respect to material properties for the waste rock is considered appropriate.
- Groundwater conditions are currently being monitored by VWPs in four locations in different geologic units. Readings from the VWPs and an understanding of the conceptual groundwater model satisfies a moderate confidence criterion from Hawley and Cunning (2017) and Case B from BCMWRPRC (1991).
- Limit equilibrium analyses methods have been used for the slope stability assessment and are considered to be sufficiently rigorous. This satisfies a high confidence criterion from Hawley and Cunning (2017) and Case B from BCMWRPRC (1991).
- Past mining and construction experience at the Mount Polley Mine and other mines in British Columbia has provided many opportunities to observe and understand the types of failure mechanism that develop at the mines. Consequently, there is a reasonable to high level of confidence in the understanding of the potential failure mechanisms. This satisfies a high confidence criterion from Hawley and Cunning (2017) and Case B from BCMWRPRC (1991).

Following the suggested design criteria by BCMWRPRC (1991) and Hawley and Cunning (2017), the proposed ultimate NW PAG Dump design is considered to have a moderate to high consequence of failure and high confidence of understanding the factors that control slope stability. On this basis, Table 16 presents the design FOS selected for the slope stability assessment.

**Table 16: Recommended Design Acceptance Criteria Factors of Safety for Proposed Ultimate NW PAG Dump**

| Stability Condition | Static or Pseudo-static Condition | Minimum Design Factor of Safety | Source |
|---|---|---|---|
| Shallow-Seated Slope Stability of Dump Face | Static – short-term | 1.0 | BCMWRPRC (1991) Case A |
| | Static – long-term | 1.2 | BCMWRPRC (1991) Case A |
| | Pseudo-static – long-term | 1.0 | BCMWRPRC (1991) Case A |
| Overall Deep-Seated Stability | Static – short-term | 1.4 | Hawley and Cunning (2017) and BCMWRPRC (1991) Case A |
| | Static – long-term | 1.5 | BCMWRPRC (1991) Case A |
| | Pseudo-static – long-term | 1.3 | Hawley and Cunning (2017) |

## 6.5 Slope Stability Methodology and Assumptions

The 2D slope stability analyses were carried out using the Slope/W limit equilibrium analysis software (© 2023 Seequent). The Morgenstern-Price method of slices was employed to find potential failure surfaces and their corresponding FOS. The slope stability of the NW PAG Dump was assessed for both static and pseudo-static (seismic) loading conditions, with fully saturated foundation soils.

The following methodology and assumptions were considered for the slope stability analyses:

- Based on the cross-section review completed (Appendix B and Section 5.8) the following cross-sections were selected for the slope stability analyses:
  - Cross-section E
    - representing the isolated fine-grained material identified in DH-NW-07/DH-NW-07B/DH-NW-07C which has been interpreted to be a component of the till.
  - Cross-section G
    - representing the highest overall waste rock dump height from the cross-section review.
  - Cross-section J
    - representing artesian conditions encountered at the north end of the proposed ultimate NW PAG Dump design in the glaciofluvial unit. Based on field observations a +3.5 m hydraulic head above the foundation soils was modelled, only applying to the glaciofluvial material.
    - representing the isolated clay material identified in DH-NW-02. Based on field observations, the unit has been modeled as a 2.5 m thick layer.

- The existing and new waste rock at the NW PAG Dump are considered free-draining and likely will not have excess pore pressures build up within the blasted rock. This is based on observations of other waste rock dumps on site, the performance to date of the NW PAG Dump, the proposed construction methodology of 40 m lifts bottom-up, the relatively small increase in overall height of the proposed ultimate NW PAG Dump, and on the conditions of the waste rock consigned to the dump.
- Organics and topsoil were not considered in the slope stability models as this material has been stripped from the foundation footprint of the NW PAG Dump (WSP 2023b).
- The foundation materials generally consist of colluvium, till, and glaciofluvial deposits, in addition to the pocket of fine-grained material and clay material in the area of the proposed ultimate NW PAG Dump design. The laboratory testing indicates that the till and colluvium have similar geotechnical properties, and these materials comprise the majority of the foundation materials. As such, for the purposes of slope stability modeling, till/colluvium was assumed as the major foundation material. Based on the 2023 and 2024 field investigations, the following approximate till/colluvium thicknesses were assumed:
  - Cross-section E: approximately 12 m thick till/colluvium layer at the NW PAG Dump toe, transitioning to a 29 m thick layer below the second and third lifts of the dump.
  - Cross-section G: approximately 9 m thick till/colluvium layer below the NW PAG Dump.
  - Cross-section J
    - approximately 14 m thick till/colluvium layer with a 7 m thick glaciofluvial layer below.
    - approximately 2.5 m thick clay layer near the toe of the dump, into a 11.5 m thick layer of till/colluvium, then a 7 m thick glaciofluvial layer.
- Due to no advance testing having been completed on the clay material to be modeled along cross-section J, a sensitivity analysis was completed for the isolated pocket of material by varying the shear strength to understand its impact on slope stability.
- The foundation materials were assumed to be saturated to original ground surface for the slope stability analyses. To model saturated conditions, a water table was included at the top of the foundation soils. These groundwater conditions are considered to be representative of periods of heavy precipitation, as occurs in the spring and fall. The proposed model conditions are also consistent with the VWP readings which indicate that groundwater is likely near or above original ground surface (Section 5.6), and are based on observations of water seepage at the toe of the current NW PAG Dump (Appendix E, Figures E-4 and E-5).
  - A sensitivity analysis was completed for cross-section J with an elevated hydraulic head applied to the glaciofluvial deposit to assess artesian conditions.
- The bedrock below the foundation soils within the area of the proposed ultimate NW PAG Dump consists of hard and competent intrusive rock. The bedrock is expected to exhibit sufficient strength to prevent a foundation failure through the bedrock. As well, the bedrock has not been characterized for faults or weak layers at orientations that could result in instability. Therefore, the bedrock has been modeled as a hard, infinite strength layer in the slope stability analyses, which prevents the automated search routine from searching for potential failure surfaced below this hard layer.

- To model seismic conditions, the pseudo-static method of analysis was used. This method of analysis applies a horizontal force to the failure mass proportional to the design horizontal acceleration. To account for the non-rigid response of the foundation soils and waste rock, the horizontal seismic loading considered in the assessment was one-half the peak ground acceleration (Hynes-Griffin and Franklin 1984). A 2% in 50 years or a 1-in-2,475-year return period earthquake event was used to assess long-term stability of the NW PAG Dump, to satisfy guidelines provided in industry (Hawley and Cunning 2017, BCMWRPRC 1991). The design PGA is 0.048 for the 2,745-year return period.
- No reduction has been applied to the strength parameters for the foundation materials. The foundation materials are expected to generally be dense. Due to the relatively low lift heights proposed to be constructed, pore water pressure generation is not anticipated (Hynes-Griffin and Franklin 1984), and the waste rock is expected to be free-draining.
    - Due to the uncertainty regarding the strength of the clay material, the sensitivity analysis was deemed sufficient to review strength reduction for the material.

## 6.6 Material Strength Properties

The material strength properties used in the slope stability analyses of the proposed ultimate NW PAG Dump are based on the glacial deposit review, previous field investigations and laboratory testing, and previous experience at the Mount Polley Mine. The material strength properties for the slope stability assessment of the proposed ultimate NW PAG Dump design are summarized in Table 17.

**Table 17: Material Strength Properties Selected for Slope Stability Analyses**

| Material | Unit Weight (kN/m$^3$) | Strength Model Type | Strength Parameters | Reference |
|---|---|---|---|---|
| Waste Rock | 19.6 | Non-linear strength curve | $\tau = 1.726\sigma^{0.899}$ | Strength function of Leps (1970) for average quality rockfill which matches observations of waste rock placed in the NW PAG Dump to date. |
| Colluvium/Till | 22 | Mohr-Coulomb | Cohesion = 0 kPa<br>Friction angle = 34º | Average peak and residual shear strength parameters from laboratory testing on till and colluvium material at Mount Polley Mine (WSP 2023b and 2024a) |
| | | | Cohesion = 0 kPa<br>Friction angle = 32.5º | Lower bound of direct shear testing on till near the NW PAG Dump (WSP 2024b). |
| Glaciofluvial | 22 | Mohr-Coulomb | Cohesion = 0 kPa<br>Friction angle = 34º | Triaxial testing of undisturbed glaciofluvial samples (Golder 2015b) |
| Fine-grained Material | 20 | Mohr-Coulomb | Same parameters as colluvium/till | Discussed in Section 5.4.4 |
| Clay Material | 20 | Mohr-Coulomb | Cohesion = 0 kPa<br>Friction angle = varied from 20 to 35º | Discussed in Section 5.4.5 |
| Bedrock | 26 | Impenetrable | | Did not model failure surfaces through bedrock |

$\tau$=*shear strength*; $\sigma$ = *normal stress*.

## 6.7 Slope Stability Analyses Results

The following slope stability modelling scenarios were completed for the proposed ultimate NW PAG Dump cross-sections:

- Base Case – Lower lift configuration slope stability (static and pseudo-static)
- Base Case – Ultimate configuration slope stability (static and pseudo-static)
- Sensitivity analyses (static and pseudo-static)
  - Cross-section G – till lower bound strength
  - Cross-section J – artesian conditions
  - Cross-section J – clay material strength varied

The results of the slope stability analyses are presented in Appendix G and are summarized in Table 18.

**Table 18: Results of Slope Stability Analyses for the Proposed Ultimate NW PAG Dump Design**

| Cross-section | Slope Stability Condition | Target Static FOS (short- and long-term) | Indicated FOS | Target Pseudo-Static FOS (long-term) | Indicated FOS | Appendix G, Figure No. |
|---|---|---|---|---|---|---|
| Cross-section E | Overall | 1.4 - 1.5 | 1.6 | 1.3 | 1.5 | G-1 |
| | Lower Lift | 1.0 - 1.2 | 1.4 | 1.0 | 1.3 | G-2 |
| Cross-section G | Overall | 1.4 - 1.5 | 1.6 | 1.3 | 1.5 | G-3 |
| | Lower Lift | 1.0 - 1.2 | 1.5 | 1.0 | 1.4 | G-4 |
| Cross-section G (*till sensitivity*) | Overall | 1.4 - 1.5 | 1.6 | 1.3 | 1.5 | G-5 |
| | Lower Lift | 1.0 - 1.2 | 1.4 | 1.0 | 1.3 | G-6 |
| Cross-section J (*artesian conditions*) | Overall | 1.4 - 1.5 | 1.6 | 1.3 | 1.5 | G-7 |
| | Lower Lift | 1.0 - 1.2 | 1.5 | 1.0 | 1.5 | G-8 |
| Cross-section J *Clay material: phi = 35 degrees* | Overall | 1.4 - 1.5 | 1.7 | Did not complete pseudo-static analyses for sensitivity analysis | | G-9 and G-10 |
| | Lower Lift | 1.0 - 1.2 | 1.5 | | | |
| Cross-section J *Clay material: phi = 30 degrees* | Overall | 1.4 - 1.5 | 1.7 | | | |
| | Lower Lift | 1.0 - 1.2 | 1.3 | | | |
| Cross-section J *Clay material: phi = 25 degrees* | Overall | 1.4 - 1.5 | 1.5 | | | |
| | Lower Lift | 1.0 - 1.2 | 1.1 | | | |
| Cross-section J *Clay material: phi = 20 degrees* | Overall | 1.4 - 1.5 | 1.5 | | | |
| | Lower Lift | 1.0 - 1.2 | 1.0 | | | |

The results of the slope stability analyses indicate that the proposed ultimate NW PAG Dump design is expected to exhibit adequate stability with respect to shallow-seated rock lift face and overall deep-seated foundation instability for short and long-term, static and pseudo-static conditions. This is largely due to the good quality foundation soil material (well-graded, generally dense material), the angle of repose waste rock lift faces with wide catch-benches at each lift (giving an overall slope of 28 degrees), and the good quality waste rock that is expected to be placed in the NW PAG Dump.

Sensitivity analyses were completed for the following scenarios:

- **Lower bound till strength parameters:** the results for the slope stability analyses indicate that for a lower bound till strength, the NW PAG Dump is expected to exhibit adequate slope stability.
- **Artesian conditions:** the results for the slope stability analyses indicate that for artesian conditions in the glaciofluvial deposits, the NW PAG Dump is expected to exhibit adequate slope stability.
- **Clay material strength parameters:** the results for the slope stability analyses indicate that when varying the strength of the clay material, the NW PAG Dump is expected to exhibit adequate overall slope stability for a phi ranging from 20 to 35 degrees for the clay material. The results of the lower lift clay strength sensitivity analyses indicate that the design criteria is met for a phi of 35 and 30 degrees; however, for a phi of 25 and 20 degrees the design criteria is not met. Graphs of the results for the overall and lower lift slope stability comparing FOS and strength (phi) are presented in Illustrations 2 and 3.

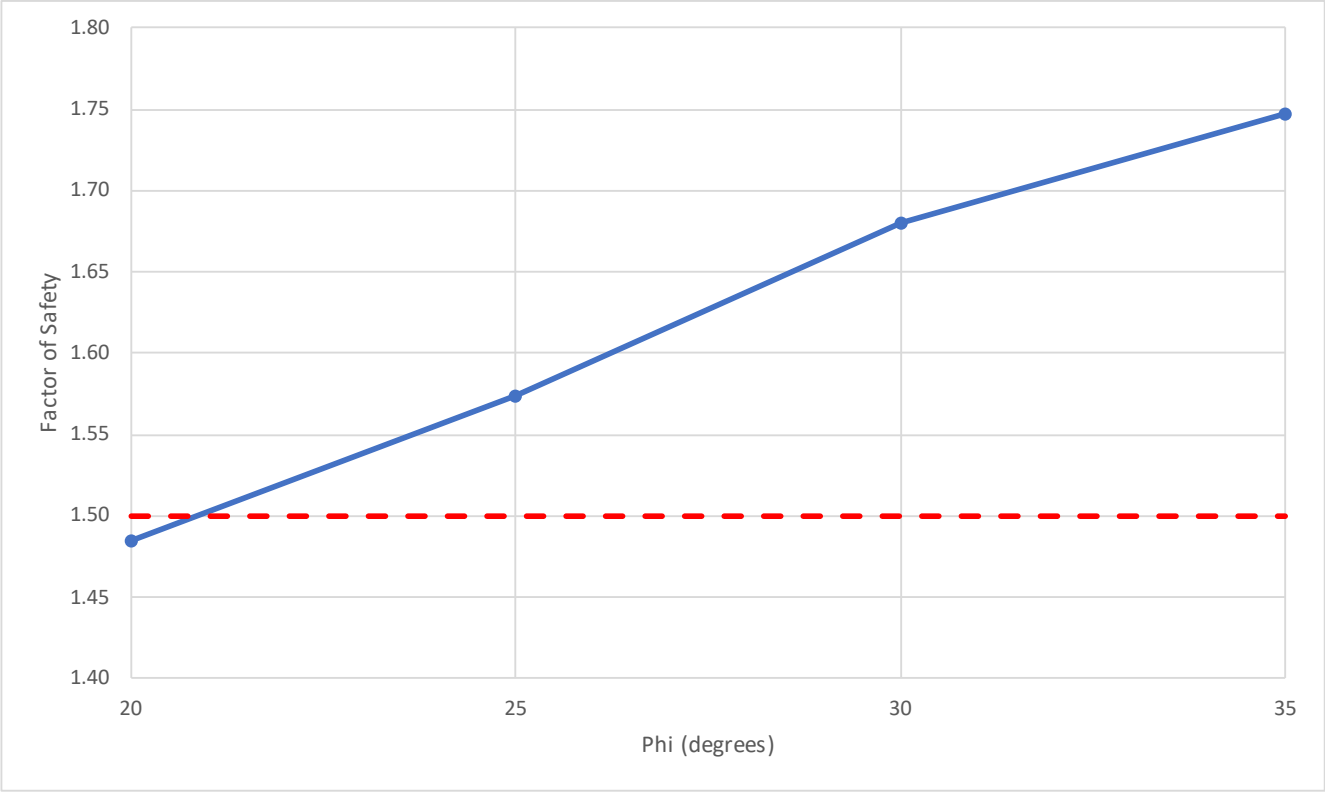

**Illustration 2: Factor of Safety vs. Phi (degrees) for Clay Material Strength Sensitivity Analysis - Overall**

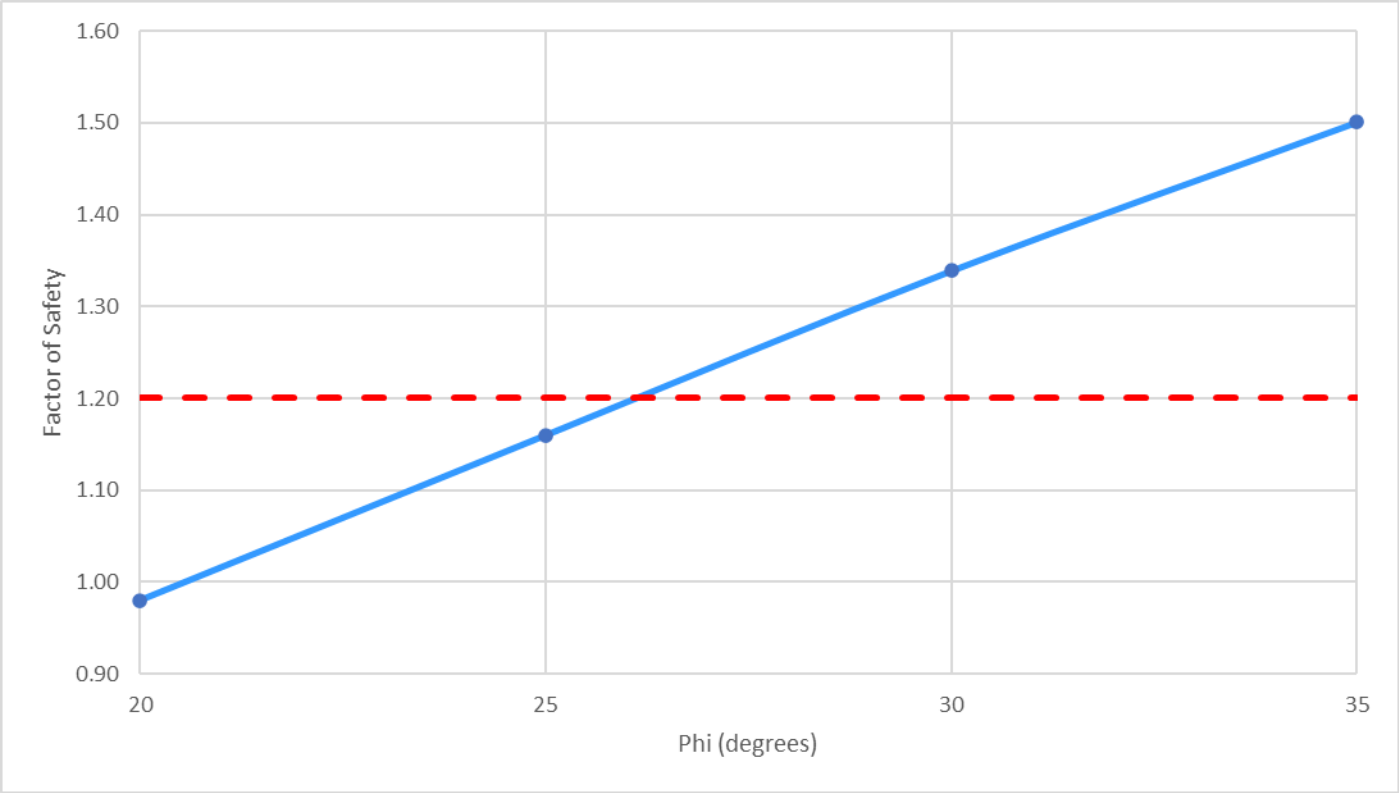

**Illustration 3: Factor of Safety vs. Phi (degrees) for Clay Material Strength Sensitivity Analysis - Lower Lift**

# 7.0 PREDICTIVE RUNOUT ASSESSMENT

Predictive runout analyses have been carried out for the proposed ultimate NW PAG Dump design to determine if potential failure debris may reach infrastructure around the dump. The following sections detail the methodology and results of the predictive runout analyses, including the rationale for the selected failure surfaces modelled based on hazards and consequences of failure identified.

## 7.1 Predictive Runout Assessment Methodology

The predictive runout assessments for the proposed waste rock dumps were completed using the 2D software DAN-W (Release 8) (Hungr Geotechnical Research Inc. 2008). This software is based on solving hydrodynamic equations which are applied to conservation of momentum for thin slices of a flowing mass.

The runout models considered a frictional rheology for the foundation soils beneath the proposed ultimate NW PAG Dump. With a frictional rheology, the analysis results are dictated primarily by the dynamic friction angle between the failed waste rock mass and the foundation material the failed mass is moving over. The dynamic friction angle comprises the basal friction angle that is modified by pore pressure, which can reach values much lower than the static friction angle of the material (as measured in direct shear or triaxial type tests). The dynamic friction angle is used in calculating the flow resistance term in the frictional model, in which the flow is controlled by the effective normal stress on the base of the sliding mass.

An internal friction angle is used in the models which defines the internal friction acting within the waste rock dump.

The waste rock within the proposed ultimate NW PAG Dump was modelled using a frictional rheology given that the waste rock is relatively well-drained and composed of generally good quality material.

The 2D DAN-W runout models are run with 50 elements (default), no energy loss in the failed material, and with vertical slices.

## 7.2 Predictive Runout Assessment Failure Surfaces

Predictive runout models have been constructed to represent critical failure surfaces for potential deep-seated (overall) and shallow-seated (toe) failures through the proposed ultimate NW PAG Dump. By analyzing both failure mechanisms, the predictive runout assessment will provide a hazard area for the NW PAG Dump and determine if potential failure debris could runout and reach infrastructure around the dump.

The predictive runout assessment failure surfaces are based on the slope stability assessment results. The failure surfaces have been chosen based on the slip surfaces generated in the Slope/W software for the slope stability models, and a best-fit failure surface was created in DAN-W to represent shallow and deep-seated failures for each scenario.

The predictive runout models and their corresponding slope stability models are presented in Table 19.

**Table 19: Summary of Predictive Runout Models and Corresponding Slope Stability Models**

| Cross-Section | Scenario | Slope Stability Model | Cross-Section Appendix B, Figure No. | Slope Stability Appendix G, Figure No. | Runout Analyses Appendix H, Figure No. |
|---|---|---|---|---|---|
| E | Overall | Overall failure through till/colluvium and fine-grained material, saturated | B-6 | G-1 | H-2 |
| | Lower Lift | Lower lift failure through till/colluvium and fine-grained material, saturated | | G-2 | H-3 |
| G | Overall | Overall failure through till/colluvium, saturated | B-8 | G-3 | H-4 |
| | Lower Lift | Lower lift failure through till/colluvium, saturated | | G-4 | H-5 |

Runout modelling was not completed on cross-section J since this cross-section does not represent a critical geometry for the dump. The stability modeling was completed on cross-section J to investigate the slope stability of the potential clay material at the toe. The results of the stability assessment indicated that a potential failure through the clay material would likely develop in the lower lift and, therefore, would not have a significant runout distance.

## 7.3 Predictive Runout Assessment Material Properties

Material properties for the predictive runout analyses were determined using typical values based on previous runout analyses on waste rock failures and typical values determined from case studies compiled by Golder & Hungr (1994).

An internal friction angle of 37 degrees for the waste rock is used in the analyses based on the results of a review of shear strength data of the material. The internal friction angle is only applied to the slide mass. A dynamic or basal friction angle of 33.5 degrees was assigned for the waste rock and is based on back analyses of waste rock dump failures (Golder & Hungr 1994, Hawley and Cunning 2017).

For the foundation materials, two conditions were considered in the runout analyses:

- Dry conditions – typical friction value of 19 degrees (Golder & Hungr 1994).
- Wet conditions – typical friction value of 14 degrees (Golder & Hungr 1994).

Frictional material properties considered for the NW PAG runout assessment are summarized in Table 20.

**Table 20: Material Properties for the Predictive Runout Analyses of the NW PAG Dump**

| Material | Rheology Type | Model Condition | Unit Weight (kN/m$^3$) | Dynamic Friction Angle (degrees) | Internal Friction Angle (degrees) |
|---|---|---|---|---|---|
| Waste Rock | Frictional | Dry (internal) | 19.6 | 33.5 | 37 |
| Foundation Soils | | Dry (basal) | 22 | 19 | N/A |
| | | Wet (basal) | | 14 | |

N/A = Internal friction angle is only applied to the failed mass.

## 7.4 Predictive Runout Assessment Results

The overall and lower lift failure models were run with a frictional rheology for the waste rock and foundation materials. The model was run under both dry and wet foundation conditions to determine a hazard zone for potential runout towards infrastructure. The results of the runout analyses are presented in Appendix H and summarized in Table 21.

**Table 21: Summary of Predictive Runout Analyses Results for the NW PAG Dump**

| Cross-section ID | Failure Mode | Runout Distance (m) | Appendix H, Figure No. |
|---|---|---|---|
| Cross-section E | Overall | Dry: 55 | H-2 |
| | | Wet: 115 (reaches settling ponds and Bootjack Access Road) | |
| | Lower Lift | Dry: 35 | H-3 |
| | | Wet: 55 | |
| Cross-section G | Overall | Dry: 50 | H-4 |
| | | Wet: 80 (reaches Bootjack Access Road) | |
| | Lower Lift | Dry: 15 | H-5 |
| | | Wet: 30 | |

The results of the runout analyses indicate that failure debris from an overall slope failure under wet foundation conditions is likely to reach the settling ponds and access road used by MPMC personnel on the west side of the NW PAG Dump.

Based on the slope stability performance of the waste rock dumps at the Mount Polley Mine over the past 25 years, and on the slope stability analyses carried out for the proposed ultimate NW PAG Dump design, there is a low probability that a failure would occur in the dump due to the relatively high FOS indicated by the slope stability analyses. The results of the runout analyses indicate that if a failure were to occur, there is a high likelihood that a runout would reach the settling ponds and access road under wet conditions. To help reduce the potential for failure debris to runout to infrastructure, it is recommended that only good quality rock be placed on the outside face of the dump, and that all poor-quality material be placed in the centre of the dump. While constructing the NW PAG Dump there should be two areas of operation at all times, the center of the dump for poor-quality material and the outside edge of the active dump lift faces for good quality material. Another way to help reduce the potential for failure to occur is to control loading rates such that excess pore pressure generation is minimized in the foundation materials.

# 8.0 ROCK ROLLOUT ASSESSMENT

The rock rollout assessment was completed for the proposed ultimate NW PAG Dump design along the west and north sides located above infrastructure such as the Bootjack Access Road, the settling ponds, and Bootjack Lake. The rock rollout assessment calculation considers rocks originating from the crest of the lower lift of the dump. It is expected that rock rollout will not be an issue for the subsequent lifts as free dump piles will be established along the top of each lift. Experience has shown that free dump piles are likely to contain rocks that roll down the face of subsequent lifts as they are constructed.

The predicted rollout distances are based on projecting a 23-degree shadow from the crest of the lowest lift to the topography below the lift (Golder & Hungr 1994). The rollout shadow for the proposed ultimate NW PAG Dump design is plotted over topography in Figure 9.

The rock rollout assessment for the proposed ultimate NW PAG Dump design indicates the Bootjack Access Road in the northwest corner of the dump is at risk of being struck by rock rollout during construction/advance of the first lower PAG lift over the smaller NAG lift. It is recommended that during the construction of the lowest PAG lift that access to the Bootjack Access Road in this area be restricted/closed.

Experience with the other waste rock dumps at the mine indicate that free dump piles on the top of each lift will retain rock rollout from the lift above, and that the infrastructure will not be at risk from the lifts located above the first lift.

The rock rollout potential of the proposed ultimate NW PAG Dump should be monitored as the dump is being constructed. If rocks reach the Bootjack Access Road or other infrastructure despite the efforts of constructing free dump piles and crest berms on the benches of the individual lifts, it may be necessary to consider additional rock rollout mitigation structures or to adjust the design of the dump.

# 9.0 SETTLEMENT

Potential settlement issues related to site conditions include:

- Settlement of the foundation materials resulting in potential slope failure.
  - Materials in the foundation may consolidate in response to loading by waste rock, resulting in settlement of the foundation.
    - The foundation materials below the existing waste rock in the NW PAG Dump have been loaded with 30 to 140 m of waste rock for several years, and by glaciers prior to that.
    - Loading by the proposed ultimate NW PAG Dump will induce further settlement, but settlements are anticipated to be small, because no soft or unconsolidated deposits were encountered in the footprint of the NW PAG Dump. Preconsolidation pressures in the isolated fine-grained material were estimated at over 5,000 kPa (Appendix D, Figure D-1).
    - Loading of the NW PAG Dump will induce settlement that will be taken up by successive placement of lifts of waste rock by the bottom-up method. The rate of loading is controlled by operational procedures.
  - Differential settlement may occur due to the presence of existing waste rock in the NW PAG Dump, due to differences in soil thickness and compressibility, and due to changes in loading across the dump.
    - The design does not include a liner or filter, or other elements that are sensitive to differential settlements.
  - Settlements of bedrock that would impact the performance of the NW PAG Dump are not considered credible. There are no known underground workings below the NW PAG Dump that could result in subsidence.

# 10.0 CONSTRUCTION AND OPERATIONAL CONSIDERATIONS

## 10.1 Construction Recommendations

The proposed ultimate NW PAG Dump is expected to exhibit adequate slope stability during construction. To help reduce the potential for failure material to runout as far as the Bootjack Access Road if failure of the proposed ultimate NW PAG Dump were to occur, it is recommended that only good quality rock be placed on the outside face of the waste dump, and that all poor-quality material be placed in the center or east side of the NW PAG Dump. While constructing the NW PAG Dump there should be two areas of operation at all times, the center or eastern side of the dump for poor-quality material and the outside edge of the active dump lift faces for good quality material.

The wide catch-benches around the proposed ultimate NW PAG Dump should be free-dumped on prior to constructing the next lift to help contain rock rollout as the dump is constructed higher. As well, berms should be constructed at the edge of each lift to help contain rock rollout.

## 10.2 Topsoil Management

WSP understands that all topsoil and reclamation suitable materials have been stripped from the footprint of the proposed ultimate NW PAG Dump. Windrow material that has been stockpiled at the toe of the current NW PAG Dump should be relocated such that it does not affect the overall slope stability of the dump or impede drainage from the dump.

## 10.3 Slope Stability Monitoring

The waste rock that will be consigned to the proposed ultimate NW PAG Dump will be an essentially cohesionless material. When a cohesionless material is at its angle of repose, the FOS of shallow potential failure surfaces in the face of a lift is close to 1.0. Under these conditions, shear strains occur within the zone located at shallow depths below the face of the dump, which results in down-slope displacement of the crest. Compaction settlement of material in the bottom of the dump also contributes to this downward displacement of the face of the dump. Displacement of the face and the crest of the dump can also occur when the dump face is advanced over weak foundation materials that can initiate somewhat deeper-seated instability along the waste rock/foundation interface.

If the down-slope movements occur rapidly, they can pose a hazard to people and equipment operating at the crest and near the toe of the dump. However, such shear failures at the crest of dumps do not occur without warning. Rather, they are preceded by the development of cracks, deformation and a period of accelerating displacement rates. Furthermore, larger failures that involve shear strains along or within the foundations are preceded by deep-seated displacements at the dump crest. These crest displacements can be monitored to provide advance warning of impending crest failures and deeper-seated overall failures.

The stability of the NW PAG Dump slopes is being monitored by prisms (MPMC 2021). The prisms should be measured by the MPMC survey team on approximately a monthly basis for the active NW PAG Dump. Survey personnel should continue to ensure consistency in readings and use the same setup and monitoring procedures for each set of measurements. This will improve the ability to detect localized and short-term displacements as well as develop more accurate interpretations of long-term settlement trends. If any significant storm events occur that exceeds a five-year return period or daily maximum precipitation, the prisms should be read. Daily temperature and barometric pressure corrections should be applied to the monitoring data, as rapid changes in temperature or barometric pressure can have a significant impact on the day-to-day accuracy of the data.

The following general guidelines should be used in collecting and interpreting the monitoring data (MPMC 2021):

- Slope distance should be recorded in the waste rock dump monitoring spreadsheets.
  - Slope distance data should be used with caution. It is possible for a portion of the slope to move a significant distance perpendicular to the line of sight with very little change in the slope distance measurement. Therefore, the 3D displacements must also be reviewed for signs of long-term displacement.
- Velocity threshold criteria have been established for the waste rock dumps based on previous experience. However, these data must also be reviewed for signs of acceleration. If a prism is showing acceleration—regardless of the measured velocity—access should be restricted to the area and the source of the displacement should be investigated (Figure 10).
- If prisms are moved or reset, the prism should be renamed, and a new data collection sheet should be completed. The old prism should become inactive in the data collection sheet.

A major part of the slope stability monitoring program will be the regular visual inspections of the waste rock dump crests, platforms, and slope faces for early evidence of slope instability. The waste rock dumps should be inspected once per quarter and during periods of high precipitation that may cause additional infiltration into the dump or additional erosion. These regular inspections should ideally be carried out by the same individual to maintain continuity of the observations. The observations should be recorded so that a record of the stability performance is available should it be required in the event of instability.

The visual reviews should include the following:

- inspecting the crests for signs of cracking and localized settlement and ponding water
- inspecting the faces of the waste rock dumps for signs of over-steepening, bulging in the middle or at the toe of the face, seepage, and erosion
- inspecting the foundation, or toe of the waste rock dump, for signs of deformation

Visual observations should be documented on inspection forms.

# 11.0 SUMMARY AND RECOMMENDATIONS

Based on the Hawley and Cunning (2017) WSRHC system, the proposed ultimate NW PAG Dump design is classified as presenting a moderate potential for instability and is therefore considered to be a moderate hazard waste rock dump (Class III).

The slope stability analyses results for the proposed ultimate NW PAG Dump design indicate that the dump will meet the design acceptance criteria for slope stability under static and pseudo-static conditions, with the exception of analyses completed with low clay material strength parameters (a phi less than about 27 degrees). The clay material was encountered in an isolated “pocket” north of the current toe of the dump in DH-NW-02 and was not found in the adjacent boreholes and test pits (DH-NW-03, DH-NW-03A, TP-NW-01, TP-NW-02, and TP-NW-03). No investigations have been completed immediately beneath the toe of the NW PAG Dump in this area as access is limited. The material was also interpreted to be discontinuous/interbedded with silty clay. The area of the current NW PAG Dump near where the clay material was encountered is stable, and has been since construction, indicating that at least a FOS of 1.0 is being achieved. Recommendations for construction near the clay material include:

- Remove the clay material prior to dumping in this area (even though the toe of the proposed ultimate NW PAG Dump does not cover the area where DH-NW-02 was drilled). The clay material was encountered in an old borrow area, therefore, more material could be removed from the borrow area to key into the till material below.
- Use low lift heights (about 5 m) when constructing the lower NAG lift in this area to limit development of potential excess pore pressures and not rapidly load the clay material if it does exist further south beneath the proposed ultimate NW PAG Dump design toe.
    - When constructing the low lifts, advancement could be such that the borrow area is encapsulated (where the potential clay material exists if it extends as far south as the proposed ultimate NW PAG Dump footprint). Once the area is encapsulated, waste rock can then be dumped into the encircled area. This method provides lateral support from the surrounding topography and the dump prior to dumping on top of the borrow area.

The runout analyses results indicate that under wet foundation conditions, it is likely that failure debris would impact the Bootjack Access Road and settling ponds. Based on the slope stability performance of the NW PAG Dump over the past 12 years, and on the slope stability analyses carried out for the proposed ultimate NW PAG Dump design, there is a low probability that a failure would occur in the NW PAG Dump due to the relatively high FOS indicated by the slope stability analyses.

Rock rollout could impact the Bootjack Access Road.

Settlement of the NW PAG Dump is expected to be limited and manageable.

Recommendations for the proposed ultimate NW PAG Dump construction include:

- Controlled loading rates
    - Prism and VWP data along with visual inspections and daily loading rates can all be used to understand if loading rates are having an adverse affect on dump construction.

- While constructing the NW PAG Dump, dumping operations should avoid concentrated dumping at a single location and should use as wide a strike length along the slope face as possible while advancing a lift.
- Construct berms at the edge of each catch-bench and free dump along the entire lift prior to constructing the next lift to limit rock rollout.
- Follow Standard Operating Procedures at Mount Polley Mine for:
  - Grading the dump and avoid ponding water on platforms.
  - Controlling the placement of waste rock being used for construction. The waste rock type should be discussed and planned in collaboration with geology and short-range engineering, as required. The material consigned to the NW PAG Dump should be good quality waste rock that is hard, coarse rock. Poor-quality material such as faults or overburden materials should be dumped in a central location of the dump such that it can be encapsulated and covered with good quality waste rock.

The stability of the NW PAG Dump slopes is being monitored by prisms (MPMC 2021). The prisms should be measured by the MPMC survey team on approximately a monthly basis for the active NW PAG Dump. Survey personnel should continue to ensure consistency in readings and use the same setup and monitoring procedures for each set of measurements. This will improve the ability to detect localized and short-term displacements as well as develop more accurate interpretations of long-term settlement trends. If any significant storm events occur that exceeds a five-year return period or daily maximum precipitation, the prisms should be read. Daily temperature and barometric pressure corrections should be applied to the monitoring data, as rapid changes in temperature or barometric pressure can have a significant impact on the day-to-day accuracy of the data.

A key component to the safe operation of the proposed ultimate NW PAG Dump to mitigate instability will be regular visual inspections. The following operational procedures are recommended for the proposed ultimate NW PAG Dump:

- The proposed ultimate NW PAG Dump should be visually inspected and photo-documented on a regular basis during construction, on approximately a weekly basis. The pit shifter or the geotechnical engineer should be completing the formal visual inspections. The following information should be investigated and recorded:
  - The crests of the NW PAG Dump lifts should be examined for signs of cracking and localized settlement and ponding water.
  - The faces of the NW PAG Dump lifts should be examined for signs of oversteepening, bulging in the middle, seepage, erosion, and the toe of the dump, if it can be observed, for signs of deformation.
  - The type of material being placed on the NW PAG Dump lifts and the loading rates should be documented.
- Dozer and haul truck operators should be continuously observing the construction of the NW PAG Dump lifts for signs of instability and reporting their observations to their pit shifter.

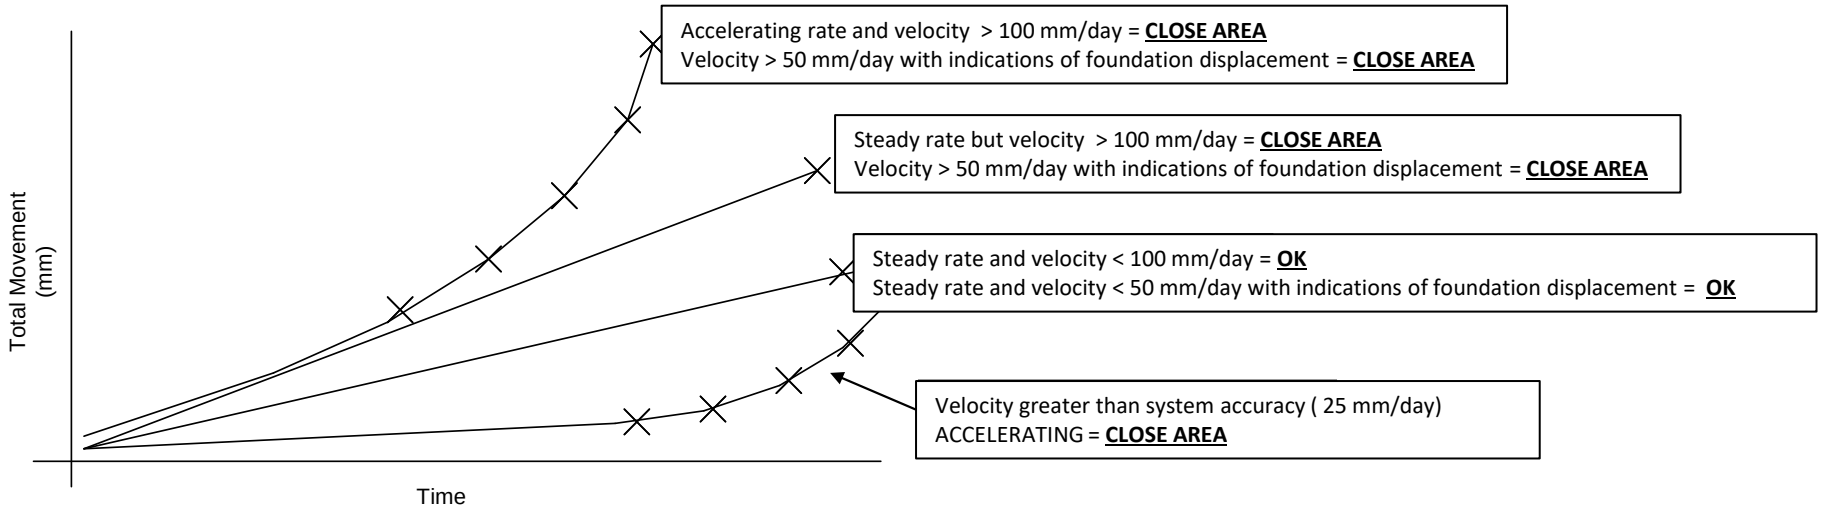
## Prism Data Interpretation Procedures



A) Daily displacement (mm)
(How many millimetres did it move? Was this less than or more than the monitoring system accuracy?)

B) Daily velocity (mm/day)
(How fast is it moving?)

C) Direction of movement (azimuth)
(Does the direction of movement make sense? Is it moving away from the dump face, parallel to the dump face, or into the dump?)

D) Direction of movement (vertical)
(Are all of the psirms moving upward? If so, is it possible that the base station or back-sight is settling?)

E) Total displacement graph
(Is it accelerating?)

**APPENDIX F**

# Hazard Classification

## Waste Rock Dump Stability Rating and Hazard Classification

A stability rating and hazard classification for the proposed ultimate NW PAG Dump was carried out using the Waste Dump and Stockpile Stability Rating and Hazard Classification (WSRHC) method (Hawley and Cunning 2017). This system evaluates 22 factors and attributes that are thought to affect waste dump and stockpile stability. The following general steps are carried out in a WSRHC assessment:

1) The regional setting, foundation conditions, and material quality of the stockpile are assessed and assigned values. The individual values are summed, and a numerical Engineering Geology Index (EGI) is determined.

2) The geometry and mass, stability analyses, construction, and performance attributes are assessed and assigned values. The values are summed, and a Design and Performance Index (DPI) is determined.

**Table F-1: Waste Dump and Stockpile Stability Rating Breakdown (Hawley and Cunning 2017)**

| Engineering Geology Index (EGI) | Design and Performance Index (DPI) |
|---|---|
| Regional setting (max 10 pts.)<br>▪ Seismicity (0-2)<br>▪ Precipitation (0-8) | Geometry and mass (max 10 pts.)<br>▪ Height (0-4)<br>▪ Slope (0-4)<br>▪ Volume and mass (0-2) |
| Foundation conditions (max 20 pts.)<br>▪ Foundation slope (0-5)<br>▪ Foundation shape (0-2)<br>▪ Overburden type (0-4)<br>▪ Overburden thickness (0-2)<br>▪ Undrained failure potential (-20-0)<br>▪ Foundation liquefaction potential (-20-0)<br>▪ Bedrock (0-4)<br>▪ Groundwater (0-3) | Stability Analysis (max 10 pts.)<br>▪ Static stability (0-7)<br>▪ Dynamic stability (0-3)<br><br>Construction (max. 15 pts.)<br>▪ Construction method (0-8)<br>▪ Loading rate (0-7) |
| Material quality (max 20 pts.)<br>▪ Gradation (0-7)<br>▪ Intact strength and durability (0-8)<br>▪ Material liquefaction potential (-20-0)<br>▪ Chemical stability (-5 to +5) | Performance (max 15pts.)<br>▪ Stability performance (-15 to +15) |

3) The EGI and DPI are summed to establish a Waste Rock and Stockpile Stability Rating (WSR). The WSR is then classified within one of five Waste Rock and Stockpile Hazard Classes (WHC). Higher values of WSR indicate relatively low instability hazards.

**Table F-2: Summary of Waste Dump and Stockpile Stability Rating and Hazard Classification System (Hawley and Cunning 2017)**

| Waste Rock and Stockpile Stability Rating (WSR) | Waste Rock and Stockpile Hazard Class (WHC) | Instability Hazard |
|---|---|---|
| 80 – 100 | I | Very Low Hazard |
| 60 – 80 | II | Low Hazard |
| 40 – 60 | III | Moderate Hazard |
| 20 – 40 | IV | High Hazard |
| 0 – 20 | V | Very High Hazard |

Additional details on the WSRHC methodology, including a detailed explanation of each of the indices and the sub-parameters can be found in Chapter 3 of Hawley and Cunning (2017).

The classification for the proposed ultimate NW PAG Dump is presented in Table F-3.

**Table F-3: Waste Dump and Stockpile Stability Rating and Hazard Classification Rating Summary for the Proposed Ultimate NW PAG Dump**

| Index | Group | Factor | Rating | Description | Notes | Source |
|---|---|---|---|---|---|---|
| Engineering Geology Index (EGI) | Regional Setting | Seismicity | 1.5 | Low | Maximum Credible Earthquake PGA=0.116g, based on 1 in 10,000 return period | WSP USA 2023 |
| | | Precipitation | 4 | 350-1000 mm | Average precipitation = 612 mm | Golder 2022b |
| | Foundation Conditions | Foundation Slope | 4 | 5 – 15 º (Gentle) | Based on topographic assessment | Original site topography |
| | | Foundation Shape | 1 | Gentle slope | Planar slope with no lateral confinement | Original site topography |
| | | Overburden Type | 3 | Type IV | Variable till | WSP 2024b |
| | | Overburden Thickness | 0 | >5 m | Overburden thicknesses measured up to approximately 24 m deep | WSP 2024b |
| | | Undrained Failure Potential | -2.5 | Low | Based on dense till foundation | WSP 2024b |
| | | Foundation Liquefaction Potential | 0 | Negligible | Dense till | Assessment in this geotechnical report for the foundation soils. |
| | | Bedrock | 2 | Type C | Moderately competent; GSI/RMR 40-60 | WSP 2024b |
| | | Groundwater | 0 | High | Groundwater table at surface; artesian conditions encountered | WSP 2024b |
| | Material Quantity | Gradation | 5 | Coarse | Based on SERDS and expectation of fines mixed in waste rock | WSP 2024a |
| | | Intact Strength and Durability | 6 | Type 4 | Strong to very strong rock | Golder 2016a |
| | | Material Liquefaction Potential | 0 | Negligible | Well graded materials | WSP 2024b |
| | | Chemical Stability | 2.5 | Mildly reactive | PAG rock | - |
| Design and Performance Index (DPI) | Geometry & Mass | Height | 2.5 | Low-Moderate | 25 to 50 m high lifts | Based on proposed ultimate NW PAG Dump design and October 2023 current topography |
| | | Slope Angle | 2 | Moderate | 27-degree slope | Based on proposed ultimate NW PAG Dump design |
| | | Volume and Mass | 1 | Medium | 2.07e7 | Based on proposed ultimate NW PAG Dump design |
| | Stability Analysis | Static Stability | 5 | 1.3 – 1.5 | Slope Stability Analyses Results | - |
| | | Dynamic Stability | 3 | >1.15 | Slope Stability Analyses Results | - |
| | Construction | Construction Method | 6 | Method IV | Lifts are at a maximum height of 40 m | Based on proposed ultimate NW PAG Dump design |
| | | Loading Rate | 3.5 | Moderate | Assumed | - |
| | Performance | Stability Performance | 7.5 | Good | Minor settlement has occurred along access haul ramp to lifts | Golder 2013c, Golder 2016a, Golder 2017, WSP 2023a, WSP 2023c |
| **Engineering Geology Index Subtotal** | | | **26.5** | | | |

Electronic Copy: WSP Canada Inc.

# Executive Summary

Mount Polley Mining Corporation (MPMC) retained WSP Canada Inc. (WSP) to support a Life of Mine (LOM) geotechnical assessment for the open pits at the Mount Polley Mine which is located approximately 56 km northeast of the town of Williams Lake, British Columbia. The proposed ultimate pit design was provided by MPMC in October 2023. MPMC are currently mining copper and gold ore from the Springer Pit at the Mount Polley Mine, and are planning to expand the Springer, Cariboo, C2, and WX Pits through 2032.

This report presents the following:

- A review of the mine layout and geology.
- A summary of the current status of the open pits and the pit wall slope stability performance.
- A description of the proposed pit wall pushbacks, the interim, and the ultimate open pit designs.
- A discussion of the engineering geology.
- A discussion of the factors that are expected to control the slope stability of the proposed ultimate pit design.
- A discussion of the kinematics analyses methodology and results. Slope design recommendations are provided based on the kinematic analyses results.
- A summary of overall slope stability analyses for the open pits.
- A review of the proximity of the proposed ultimate pit design crest to the Northwest Potentially Acid Generating (NW PAG) Dump.
- A discussion of operational considerations while mining the proposed ultimate pit design.
- A summary of conclusions and recommendations.

## *Current Performance*

The pit wall slope stability performance of the Springer, Cariboo, C2, and WX Pits has been documented by WSP during annual slope stability reviews of the open pits. The most recent slope stability review was completed in September 2023 (WSP 2023). In general, the Springer, Cariboo, C2, and WX Pits are exhibiting good slope stability performance with no signs of overall slope instability. Many benches have broken back to discontinuous moderately dipping structures; however, adequate catchment remains on the majority of the benches.

## *Proposed Open Pit Development*

MPMC are proposing five expansions to the open pits at Mount Polley Mine including Springer Phase 5 (Sp-5), Springer Phase 6 (Sp-6), Springer Phase 6 Ramp Retreat (Sp-6-RR), WX, C-2-B, and the Cariboo Ramp Retreat (Car-RR). These expansions create the proposed ultimate pit design (SP-6/WX).

## *Engineering Geology*

Based on the current geological interpretation, the proposed ultimate pit design will be excavated through similar rock types as have been observed in the current pit walls. The following rock types are expected to be exposed on the various ultimate open pit design walls:

- Springer Pit
  - The west and south walls will be excavated through monzonite.
  - The north nose and northeast walls of the ultimate pit will be excavated through diorite and hydrothermal breccias (mineralized zone).
  - The upper part of the south end of the northeast wall will be excavated through the Bell Pit rehandle waste rock slope.
- Cariboo Pit
  - The east wall of the pushback will be excavated through monzonite.
  - The pit bottom will be mined further into breccia (mineralized zone) and monzonite.
- C2 Pit will be mined through mineralized breccias.
- WX Pit will be mined through monzonite and hydrothermal breccias (mineralized zone).

Several major continuous faults are interpreted to exist in the area of the open pits and have been exposed along the current pit walls.

In addition to the major faults, the rocks in the open pits also contain other geologic structures in the form of faults, dykes, and joint sets. The orientations of these structures have been determined through the following campaigns:

- Geotechnical mapping programs that have been carried out on an annual basis between 2008 and 2016, as well as 2023.
- Televiewer surveys carried out in boreholes that were drilled in the C2 Pit area in 2006.
- Photogrammetry carried out in 2014 and 2024.

In general, the structural sets identified in the 2016 LOM assessment (Golder 2016) remain similar to the sets identified in this 2024 LOM assessment.

Data from select exploration boreholes drilled by MPMC between 2004 and 2012 in the areas of the Springer, Cariboo, C2, and WX Pits were reviewed. The field estimate rock strengths from the exploration borehole review are comparable to the field estimate rock strengths presented in the 2016 LOM assessment which were based on 1997, 2008, 2009, 2010, 2011, and 2014 geotechnical mapping programs (Golder 2016). Overall, the $RMR_{76}$ values calculated using the updated 2024 dataset are comparable to those calculated for the 2016 LOM assessment.

Based on the current understanding of the hydrogeology in the area of the open pits, some water pressures are expected to exist within the pit walls during excavation of the proposed ultimate pit design.

The geotechnical domains for the 2024 LOM assessment of the proposed ultimate pit design are presented in Figure 10 and have been determined based on pit area and geology.

## *Summary of Conclusions and Recommendations*

Kinematic stability analyses have been carried out to assess the potential for single bench, double bench, and inter-ramp scale planar, wedge, and toppling instability of the proposed ultimate pit design provided by MPMC. Bench design configurations are presented in Table E-1 and Table E-2, and Figure 14.

**Table E-1: Summary of Springer/WX Pits Recommended Bench Design Configurations**

| Lithology | Wall Dip Direction (°) | Bench Height (m) | BFA (°) | IRA (°) | Bench Width (m) | Rationale |
|---|---|---|---|---|---|---|
| Monzodiorite | 280 | 12 | 70 | 43 | 8.5 | Single bench in the monzodiorite in the south and southeast walls of Springer/WX Pits due to planar failure along Set 4/3 and proximity to Polley Fault. Current single bench wall exposures indicate the recommended design is performing adequately. |
| | 330 | 12 | 70 | 43 | 8.5 | Single bench in the monzodiorite in the south and southeast walls of Springer/WX Pits due to planar failure along Set 4/3 and proximity to Polley Fault. Current single bench wall exposures indicate the recommended design is performing adequately. |
| | 056 | 24 | 65 | 46.5 | 11.5 | Double benching in southwest wall acceptable with shallower BFA controlled by Set 5A. |
| Breccia | 035 | 24 | 70 | 50 | 11.5 | Double benching in breccia (particularly in the WX Pit) in the southwest and west walls. |
| | 085 | 24 | 70 | 50 | 11.5 | Set 5A will likely control BFA for double benches in the breccia. |
| | 097 | 24 | 70 | 50 | 11.5 | Set 5A will likely control BFA for double benches in the breccia. |
| | 220 | 12 | 70 | 43 | 8.5 | Single benches recommended due to confluence of several faults in the northeast wall in the breccia. Transition from double to single benches will be in the north corner of the Springer Pit. |
| Diorite | 220 | 12 | 70 | 43 | 8.5 | Single bench in the diorite to control raveling from Polley and Springer Faults. |

**Table E-2: Summary of Cariboo/C2 Pits Recommended Bench Design Configurations**

| Lithology | Wall Dip Direction (°) | Bench Height (m) | BFA (°) | IRA (°) | Bench Width (m) | Rationale |
|---|---|---|---|---|---|---|
| Monzodiorite | 195 | 12 | 70 | 43 | 8.5 | Single benches in Polley Fault. |
| | 238 | 12 | 70 | 43 | 8.5 | Single benches due to toppling along East Cariboo Fault. |
| | 317 | 12/24 | 70 | 43/49 | 8.5/12 | Single benches in proximity to Polley Fault. Otherwise double benches at 70 degree BFA. Double benches acceptable along southeast wall of Cariboo/C2 Pits. |
| Breccia | 188 | 24 | 70 | 49 | 12 | Double benches in C2 Pit. |
| | 195 | 12 | 70 | 43 | 8.5 | Single benches in Polley Fault. |
| | 317 | 12/24 | 70 | 43/49 | 8.5/12 | Single benches in proximity to Polley Fault. Otherwise double benches at 70 degree BFA. |

The following slope design considerations are based on the proposed ultimate pit bench design recommendations:

- The proposed SP-5 design will mine through the inactive Bell Dump along the northeast wall of the ultimate pit in two areas (Figure 17). Single benching with an overall slope angle of 37 degrees will be required through the waste rock rehandle slopes in these areas.
- The proposed Sp-5 design indicates double benches in the Cariboo Pit east wall where toppling failure is likely to occur in the weathered monzodiorite, east of the East Cariboo Fault, due to closely jointed/faulted rock (Figure 17). Previous toppling failure occurred in the area in 2017 and, as such, single benches have previously been recommended to the east of the East Cariboo Fault (the hangingwall). The Phase 5 pushback design is limited by the Bootjack mine access road which is located at the crest of the proposed double-benched east wall, increasing the consequence of a failure. Double benching in this area could impact the slope stability of the Bootjack mine access road and interfere will access to site due to the higher potential for toppling failure. Using a single bench configuration would require a reduction in the inter-ramp slope angle. Single benches are recommended in walls that are excavated in the East Cariboo Fault and to the east of the fault based on previous pit wall performance and proximity to the access road to Mount Polley Mine.
- The proposed Sp-6/WX design has at least two double benches at the bottom of the south/southeast wall, where single benches are recommended due to adverse structural conditions experienced in this wall previously (Figure 17).
- The proposed Sp-6/WX design contains a triple bench (36 m high bench) at the bottom of the southwest wall of the WX Pit below the ramp (Figure 17). A triple bench at the bottom of WX Pit would allow MPMC to access additional high-grade ore at the bottom of the pit. The achievability of the triple bench excavation should be evaluated once mining has progressed into the WX Pit to confirm rock type and structure in the area.
- When mining through the Polley Fault on any pit walls, single benching is recommended based on previous experience and performance (Figure 17).
- When mining through the C-2-B Pit, single benches may be required through the Polley Fault along the southeast wall (Figure 17). Previous slope performance in the area of the Polley Fault along this wall has included increased ravel due to the poor rock quality and catch-benches have become infilled over time. Since only two double benches are proposed in this area, it is possible that ravel from the fault can be contained on the wider catch-benches. As mining progresses through the area with double benches, regular inspections of the wall performance should be completed and if catchment becomes limited, a step out or rock rollout berm may be required.

Several major continuous faults are interpreted to exist in the area of the open pits and have been exposed along the current pit walls (described in Section 5.1). The influence that these faults are expected to have limited impact on the proposed ultimate pit walls due to the steep nature of the majority of the faults (Section 6.5.1), with the exception of the Polley and East Cariboo Faults which have slope design considerations described in the above bullets.

Upon review of previous slope stability analyses completed for Springer Pit (Golder 2015b and 2016), these analyses were determined to be adequate for the current proposed ultimate pit design based on the following:

- Similar overall wall heights (with the exception of the southwest wall).
- Similar overall slope angles.
- Similar groundwater conditions.
- Similar rock mass strengths expected.

Due to the proximity of the NW PAG Dump to the crest of the proposed ultimate pit design MPMC should consider specific monitoring equipment and plans, as well as single benches within the first one to two benches below the dump (Section 7.0)

Operational controls should be implemented during the excavation of the proposed ultimate pit design, and include blasting practices, bench cleaning, slope monitoring, and geologic mapping (Section 8.0).

# Study Limitations

WSP Canada Inc. (WSP) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

# 1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) retained WSP Canada Inc. (WSP) to support a Life of Mine (LOM) geotechnical assessment for the open pits at the Mount Polley Mine which is located approximately 56 km northeast of the town of Williams Lake, British Columbia. The proposed ultimate pit design was provided by MPMC in October 2023. MPMC are currently mining copper and gold ore from the Springer Pit at the Mount Polley Mine, and are planning to expand the Springer, Cariboo, C2, and WX Pits through 2032.

This report presents the following:

- A review of the mine layout and geology.
- A summary of the current status of the open pits and the pit wall slope stability performance.
- A description of the proposed pit wall pushbacks, the interim, and the ultimate open pit designs.
- A discussion of the engineering geology.
- A discussion of the factors that are expected to control the slope stability of the proposed ultimate pit design.
- A discussion of the kinematics analyses methodology and results. Slope design recommendations are provided based on the kinematic analyses results.
- A summary of overall slope stability analyses for the open pits.
- A review of the proximity of the proposed ultimate pit design crest to the Northwest Potentially Acid Generating (NW PAG) Dump.
- A discussion of operational considerations while mining the proposed ultimate pit design.
- A summary of conclusions and recommendations.

# 2.0 MOUNT POLLEY MINE LAYOUT AND GEOLOGY

## 2.1 Mine Layout

The Mount Polley Mine site is shown in Figure 1. The Springer Pit is located to the northwest of the Cariboo Pit and to the southwest of the mined out North Bell Pit (now backfilled). The Cariboo Pit is located to the southwest of the Springer Pit. The C2 Pit is located to the south of Cariboo Pit and the WX Pit is located south of Springer Pit and southwest of Cariboo Pit.

## 2.2 Geology of Open Pits

The Mount Polley deposits are located within an alkalic intrusive complex within the northwest–southeast trending Quesnel Trough, a 35 km wide, northwest trending volcanic sedimentary belt (Figure 2) (Rees 2013). The copper and gold mineralization are contained predominately within north–south trending, elongated intrusive breccia stocks that have intruded diorites and monzonite porphyries. Later-stage north–south trending dykes have been intruded along the regional structural trend.

The country rock are Nicola Group volcanic rocks, and intrusive rocks of Mount Polley that were emplaced into the Nicola Group in the very late Triassic. Mount Polley lies in the core of a broad regional, northwest-trending syncline at the western limit of the Middle Jurassic folding. The Mount Polley Intrusive Complex (MPIC) consists of silica-saturated and -undersaturated intermediate intrusions and related magmatic-hydrothermal breccias that host the mineralization. Country rocks of the Nicola Group flank the MPIC on most sides except to the north where the MPIC is unconformably overlapped by younger post-Nicola deposits. The Nicola Group is a diverse package of fine- to medium grained basaltic to andesitic volcanic and hypabyssal coherent rocks or breccias, breccia or conglomerate of undifferentiated igneous-hydrothermal or volcaniclastic origin, volcanogenic sandstone and siltstone, and rare massive limestone. The MPIC is made up of several intrusive units such as diorite, monzodiorite-monzonite, K-feldspar monzonite, and late dykes (Rees 2013).

The mineralized hydrothermal breccia in the Springer Pit occurs along a north-northwest–south-southeast trend. To the west, the mineralized breccia zone is bounded by a “mix” of breccia and intrusive rocks, which are then bounded by monzonite rocks. Intrusive diorite rocks bound the mineralized breccia to the north and northeast. Finally, a series of younger north–south trending augite porphyry dykes are observed to exist throughout the pit area. These dykes are often chlorite and calcite-altered, and commonly faulted. These younger dykes intersect the different rock types and the major faults.

In general, the rocks in the Cariboo Pit consist of monzonite intrusion breccias that have intruded the host monzonite rocks. Monzonite is exposed in the majority of the pit walls, while breccias are exposed in the centre of the pit. However, localized blocks of diorite are exposed in the northeast and east walls, while plagioclase porphyry is exposed along the southeast wall.

The rocks in the C2 Pit are hydrothermal breccias. The rocks in the WX Pit are hydrothermal breccias and monzonite.

Based on the current geological interpretation, the proposed ultimate pit design will be excavated through similar rock types as have been observed in the current pit walls. The following rock types are expected to be exposed on the various ultimate open pit design walls:

- Springer Pit
  - The west and south walls will be excavated through monzonite.

  - The north nose and northeast walls of the ultimate pit will be excavated through diorite and hydrothermal breccias (mineralized zone).
  - The upper part of the south end of the northeast wall will be excavated through the Bell Pit rehandle waste rock slope.
- Cariboo Pit
  - The east wall of the pushback will be excavated through monzonite.
  - The pit bottom will be mined further into the breccia (mineralized zone) and monzonite.
- C2 Pit will be mined through mineralized breccias.
- WX Pit will be mined through monzonite and hydrothermal breccias (mineralized zone).

# 3.0 MOUNT POLLEY MINE OPEN PIT CURRENT STATUS AND SLOPE STABILITY PERFORMANCE

The pit wall slope stability performance of the Springer, Cariboo, C2, and WX Pits has been documented by WSP during annual slope stability reviews of the open pits. The most recent slope stability review was completed in September 2023 (WSP 2023). In general, the Springer, Cariboo, C2, and WX Pits are exhibiting good slope stability performance with no signs of overall slope instability. Many benches have broken back to discontinuous moderately dipping structures; however, adequate catchment remains on the majority of the benches.

A summary of each pit's slope stability performance is presented in the sub-sections below. Select photographs from the 2023 slope stability review are presented in Appendix A.

## 3.1 Springer Pit

### 3.1.1 Current Status

The status of the Springer Pit as of October 2023 is shown in Figure 3. Springer Pit is approximately 1,000 m long and approximately 650 m wide. The pit floor at the south end of the pit had been excavated to elev. 950 m. Access to the Springer Pit is via the Cariboo Ramp from the southeast side of the pit where Springer and Cariboo Pits meet. The ramp runs along the northeast wall of Springer Pit and gains access to various benches within the pit where mining is occurring.

Table 1 summarizes the approximate geometry of the walls in the Springer Pit as of October 2023. Note that overall wall heights are approximate.

**Table 1: Springer Pit Wall Geometry**

| Wall | Approximate Wall Geometry | Approximate Crest Elevation (m) | Approximate Toe Elevation (m) | Approximate Overall Slope Height (m) |
|---|---|---|---|---|
| South | 16 single benches | 1,130 | 933 | 197 |
| West – South Portion | Three double benches and one single bench (half a double bench) | 1,061 | 975 | 86 |
| West – North Portion | Five double benches and one single bench (half a double bench) | 1,120 | 975 | 145 |
| North Nose | Seven double benches and one single bench (half a double bench) | 1,155 | 975 | 180 |
| Northeast – North Portion | 16 single benches | 1,170 | 975 | 195 |
| Northeast – Central Portion | 18 single benches | 1,168 | 950 | 218 |

### 3.1.2 Slope Stability Performance

The overall rock mass quality in the monzonite, diorite, and breccias in Springer Pit is good, and the slopes continue to exhibit favourable overall and bench-scale slope stability (Appendix A, Photograph A-1). Large-scale geological structures are favourably oriented with respect to the north and northeast walls. Along the west and south walls bench faces have broken back to moderately dipping joints in some of the benches. There are some steeply dipping north-south striking dykes in the south wall that are causing minor bench-scale raveling (Appendix A, Photograph A-2). A faulted dyke is exposed over three double benches in the south portion of the west wall. Raveling of clay, gouge, and broken rock has created small talus slopes at the base of the exposure (Appendix A,

Photograph A-3). The south wall catch-benches have some ravel infilling in localized areas, but there continues to be adequate catchment along the wall. The west wall catch-benches have some ravel infilling in localized areas, but there continues to be adequate catchment along the wall.

The catch-benches have limited catchment available in the following two areas within Springer Pit:

1) The nose area on the northeast wall where the saddle was mined down between 2021 and 2023. The benches have been filled with  from rock overspill while mining down the saddle between the Cariboo and Springer Pits. Catchment on the benches is limited in this localized area (Appendix A, Photograph A-4).

2) Where the Polley Fault intersects the northeast wall. The single benches are gradually being infilled with ravel material due to the poor quality rock within the fault zone (Appendix A, Photograph A-5). Catchment is still available on the single benches where the Polley Fault intersects the wall.

The north and northeast walls are otherwise exhibiting adequate bench-scale slope stability performance, and there is adequate catchment on the walls.

## 3.2 Cariboo Pit

### 3.2.1 Current Status

The status of the Cariboo Pit as of October 2023 is shown in Figure 3. Mining of the Cariboo and Springer Pits re-started in late 2022 after being in care and maintenance since 2019. There is water accumulated at the bottom of the Cariboo Pit to elev. 951 m.

The main open pit access haul ramp, called the Cariboo Ramp, enters the Cariboo Pit from the south, descends along the southeast wall, wraps around the east and northeast walls, and descends west into the Springer Pit.

Table 2 summarizes the approximate geometry of the walls in the Cariboo Pit as of October 2023. Note that overall wall heights are approximate.

**Table 2: Cariboo Pit Wall Geometry**

| Wall | Approximate Bench Geometry | Approximate Crest Elevation (m) | Approximate Toe Elevation (m) | Approximate Overall Slope Height (m) |
|---|---|---|---|---|
| Northeast | Rehandle waste rock slope – six to seven single benches | 1,165 | 1,060 | 105 |
| | Nine to ten single benches below rehandle slope | 1,060 | 955 | 105 |
| | Three single benches and six double benches | 1,170 | 963 | 207 |
| East | Four single benches above unload zone | 1,181 | 1,120 | 61 |
| | Seven double benches below unload zone and above Cariboo Ramp | 1,120 | 975 | 200 |
| | Three double benches below Cariboo Ramp (note benches are below the in-pit reservoir) | 975 | 920 | 55 |
| Southeast | One single bench and six double benches above Cariboo Ramp | 1,130 | 990 | 140 |
| | Three double benches below Cariboo Ramp | 990 | 920 | 70 |
| Cariboo Ramp | West side - three to seven single benches | 1,094 | 1,012 | 82 |
| | East side – six to three single benches | 1,082 | 1,006 | 76 |

### 3.2.2 Slope Stability Performance

Slope stability continues to be favourable in the Cariboo Pit, and the pit walls have not exhibited any signs of large, multi-bench instability (Appendix A, Photograph A-1). Bench-scale stability continues to be favourable and adequate catchment remains on the slopes. The overall rock mass quality in the monzonite and breccias in Cariboo Pit is generally good.

Most of the major geological structures are favourably oriented with respect to the northeast wall. North-south trending augite porphyry dykes are exposed in the wall and dip favourably to the east at steep angles. Localized back-break has occurred along moderately dipping structures; however, the overall catchment on the benches is still adequate.

The Bell Pit rehandle waste rock slope in the northeast wall is exhibiting good overall slope stability with no signs of bulging or instability in the face of the slope and no cracking behind the crest of the slope (Appendix A, Photograph A-6). South-southeasterly dipping structures strike sub-parallel to the northeast wall below the rehandle slope, and the bench faces are breaking back to these moderately dipping structures. Some of the benches mined below the rehandle slope are partially infilled with ravel material from the rehandled slope above. Overall, the benches currently have adequate catchment to contain the ongoing ravel material.

In April 2017, topping failure occurred at the crest of the east wall of the Cariboo Pit (Appendix A, Photograph A-7). The failure zone occurred due to toppling along closely spaced joints and faults that dip steeply to the east-northeast in the hangingwall of the East Cariboo Fault (Golder 2017). The toppling failure was contained in the weathered monzodiorite. The toppling failure zone was unloaded by excavating three to five single benches in 2017. The area has remained stable since it was unloaded with minor raveling continuing to occur in the weaker monzodiorite rock.

The Cariboo Pit southeast wall continues to exhibit adequate slope stability performance. There are bench-scale wedge failures that continue to ravel on the north side of the southeast wall. Adequate catchment remains along most of the wall, and the benches have not been significantly infilled by ravel debris.

## 3.3 C2 Pit

### 3.3.1 Current Status

The C2 Pit is a west-facing alcove that is located at the southwest end of the Cariboo Pit above the east side of the Cariboo Ramp (Figure 3). The crest of the wall is at elev. 1,159 m, and the pit floor is located at elev. 1,062 m. Three to four double benches have been excavated in the C2 Pit, to form a maximum wall height of approximately 90 m. Water has accumulated at the bottom of the C2 Pit to elev. 1,078 m.

### 3.3.2 Slope Stability Performance

The overall rock mass quality in the breccia mined in the C2 Pit is good, and the slopes continue to exhibit adequate overall and bench-scale slope stability (Appendix A, Photograph A-8). The walls have not exhibited signs of large, multi-bench instability. The major structures in the C2 Pit area appear to be north-south trending, moderate to steep easterly dipping joints and faults. Several steeply dipping north-south striking augite porphyry dykes are visible in the C2 Pit walls.

## 3.4 WX Pit

### 3.4.1 Current Status

The WX Pit is a small pit that was mined out immediately west of the C2 Pit, above the west side of the Cariboo Ramp (Figure 3). The crest of the ridge is at approximately elev. 1,156 m, and the floor of the WX Pit is at elev. 1,053 m. Three double benches were excavated to form a maximum wall height of approximately 80 m.

### 3.4.2 Slope Stability Performance

The overall rock mass quality in the monzonite in the WX Pit is fair, and the slopes are exhibiting adequate slope stability (Appendix A, Photograph A-9). Some of the double benches had wedge failures due to the intersection of northeast and north moderately dipping joints, that plunged out of the southwest wall. Since excavation, the walls have not exhibited any signs of large, multi-bench instability.

# 4.0 PROPOSED MOUNT POLLEY MINE OPEN PIT DEVELOPMENT

The pit configuration as of October 2023 is shown in Figure 3. MPMC are currently mining Springer Phase 4 (Sp-4) to a depth of elev. 848 m and access into the pit is via the Cariboo Ramp. The Cariboo Ramp runs from the south side of Cariboo Pit, then along the east and northeast walls to the current mining areas in Springer Pit. Single benches are 12 m high and double benches are 24 m high. MPMC are proposing five expansions to the open pits at Mount Polley Mine including Springer Phase 5 (Sp-5), Springer Phase 6 (Sp-6), Springer Phase 6 Ramp Retreat (Sp-6-RR), WX, C-2-B, and the Cariboo Ramp Retreat (Car-RR) (Appendix B, Figure B-1). These expansions create the proposed ultimate pit design (SP-6/WX) (Figure 4). The expansions are described in further detail below.

The surfaces provided by MPMC for each of the proposed year end designs are provided in Table 3.

**Table 3: Proposed Mining Phase Files**

| Mining Phase Name | MPMC Surface Name | Date Provided by MPMC |
|---|---|---|
| 2023 Year End Design | Period1 – 2023 ye | October 27, 2023 |
| 2024 Year End Design | Period2 – 2024 ye | |
| 2025 Year End Design | Period3 – 2025 ye | |
| 2026 Year End Design | Period4 – 2026 ye | |
| 2027 Year End Design | Period5 – 2027 ye | |
| 2028 Year End Design | Period6 – 2028 ye | |
| 2029 Year End Design | Period7 – 2029 ye | |
| 2030 Year End Design | Period8 – 2030 ye | |
| 2031 Year End Design | Period9 – 2031 ye | |
| 2032 Year End Design/ Ultimate Pit Design | Period10 – 2032 ye/ sp-6_rr_merged_srface | |

Sp-5 will expand the Springer Pit along the west, north, northeast, and east walls, as well as the northeast and east walls of Cariboo Pit (Appendix B, Figure B-2). The Springer Pit will be mined to elev. 808 m during this pushback, with wall heights ranging between 275 m on the west wall to about 400 m on the northeast wall. The upper northeast and east walls of the Cariboo Pit will be pushed back during Sp-5, but the pit bottom will not be excavated deeper (remains at elev. 920 m). Ten double benches are proposed along the west wall of Springer Pit. Twelve double benches are proposed along the north wall of Springer Pit. Twenty-six to thirty single benches are proposed along the northeast wall of Springer Pit. Four benches with bench face angles of 37 degrees and an overall slope of 30 degrees will be excavated in the Bell Pit rehandle waste rock slope in the middle of the northeast wall. Twelve single benches are proposed below the Bell Pit rehandle waste rock slope with a large alcove at elev. 1,012 m. Southeast of the Bell Pit rehandle waste rock slope, eight single benches will be excavated for a strike length of 150 m in the northeast wall of Cariboo Pit. Three double benches are proposed in the east wall of Cariboo Pit, in the previous east wall unload area of the Cariboo Pit. Initial access into the pit will be from the west wall of Springer Pit along the north and northeast walls until it meets the existing Cariboo Ramp approximately mid-way along the northeast wall of Springer Pit. The initial access ramp will be narrowed as the pit deepens to become light vehicle access and a geotechnical step-out. The current Cariboo Ramp into the pit will become the main access to the pit bottom.

Sp-6 and WX pushbacks will mine the west, south, and east walls of Springer Pit and expand the WX Pit (Appendix B, Figure B-3). The Springer Pit will be mined to elev. 760 m during Sp-6 with wall heights ranging from 200 m on the south wall to about 300 m on the west wall of Springer Pit. The Springer Pit wall height on the northeast wall will range between 390 to 410 m high (only the bottom five benches are being excavated in the northeast wall making the pit deeper). The west wall will mine about 14 double benches, the south wall will mine 11 single benches and two double benches. Five single benches will be excavated along the northeast wall to the pit bottom as part of the Sp-6 pushback. The WX Pit will be mined from elev. 1,053 m to elev. 856 m with wall heights ranging from 150 m on the east wall to 225 m on the west wall. Nine double benches are proposed in the west wall and 14 single benches are proposed in the southeast wall of the WX Pit. Access to the Sp-6 and WX pushback will be via the Cariboo Ramp which will travel along the east, south, then west walls of Springer Pit and deepen in WX Pit. The western portion of the ramp will narrow to become single access once the pushback wall reaches the same elevation as the North Springer Ramp from the previous Phase 5 pushback.

Sp-6-RR is proposed in the north wall of Springer Pit and will be a small retreat from elev. 890 to 820 m (Appendix B, Figure B-4). A ramp will be widened towards the south to connect to the pit bottom. Sp-6-RR will include three double benches in the north wall and seven single benches in the east wall. Wall heights for the SP-6-RR will be 72 m and 84 m. The area will be accessed via a backfilled ramp along the west wall of Springer Pit which will link to the main haul ramp which will run along the west and south walls of Springer Pit to the Cariboo Ramp.

C-2-B Pit is an expansion of the C2 Pit on the southeast side of the mining area (Appendix B, Figure B-5). The current C2 Pit will be mined from elev. 1,062 m to elev. 1,000 m. Three double benched are proposed for the expansion. Wall heights will vary from approximately 105 to 130 m. The benches will all be accessed from the existing Cariboo Ramp with the exception of the bottom two benches which will have a small ramp that is pushed from north to south.

The Car-RR will include mining of the Cariboo Pit bottom (Appendix B, Figure B-6). The retreat will include mining of four double benches in the southeast wall and nine single benches along the south wall and four single benches along the west wall. The pit bottom will be mined from elev. 921 m to elev. 904 m. Wall heights will range from 50 m in the west wall to about 290 m in the northeast wall. Upon completion, the Cariboo Ramp will be replaced with a waste rock backfill ramp from the south side of the pit to the north end.

Table 4 provides a summary of the proposed open pit development.

**Table 4: Summary of Proposed Open Pit Development**

| Expansion Phase | Description | Pit Floor Elevation |
|---|---|---|
| Sp-5 | Springer Pit will be expanded along the west, north, northeast, and east walls, as well as the upper northeast and east walls of Cariboo Pit. Wall heights will range from 275 m on the Springer Pit west wall to about 400 m on the Springer Pit northeast wall. | Springer Pit – elev. 808 m<br><br>Cariboo Pit – unchanged |
| Sp-6 & WX | Sp-6 and WX pushbacks will mine the west, south, and east walls of Springer Pit and expand the WX Pit. Wall heights ranging from 200 m on the south wall to about 300 m on the west wall of Springer Pit. The Springer Pit wall height on the northeast wall will range between 390 to 410 m high (only the bottom five benches are being excavated in the northeast wall making the pit deeper).<br><br>Wall heights in the WX Pit will range from 150 m on the east wall to 225 m on the west wall. | Springer Pit – elev. 760 m<br><br>WX Pit – elev. 856 m |

**Table 4: Summary of Proposed Open Pit Development**

| Expansion Phase | Description | Pit Floor Elevation |
|---|---|---|
| Sp-6-RR | Proposed in the north wall of Springer Pit and will be a small retreat from elev. 890 to 820 m. Wall heights for the SP-6-RR will be 72 m and 84 m. | Unchanged |
| C-B-2 | C-B-2 is an expansion of the C2 Pit on the southeast side of the mining area. Three double benched are proposed for the expansion. Wall heights will vary from approximately 105 to 130 m. | C2 Pit – elev. 1,000 m |
| Car-RR | The Car-RR will include mining of the Cariboo Pit bottom. Wall heights will range from 50 m in the west wall to about 290 m in the northeast wall. Upon completion, the Cariboo Ramp will be replaced with a waste rock backfill ramp from the south side of the pit to the north end. | Cariboo Pit – elev. 904 m |

MPMC propose the following mining sequence by year from end of 2023 to 2032:

- End of 2023 (Appendix B, Figures B-7 to B-8): mining will continue in the Springer Pit bottom in Sp-4 and mining of the upper benches of the northeast wall of Springer and Cariboo Pits will begin (Sp-5).
- End of 2024 (Appendix B, Figures B-9 to B-10): mining will continue at the Springer Pit bottom in Sp-4 and mining of the upper benches of the north, northeast, walls of Springer Pit, and northeast and east walls of Cariboo will be mined (Sp-5).
- End of 2025 (Appendix B, Figures B-11 to B-12): Sp-4 will continue at the Springer Pit bottom, Sp-5 will continue in the upper benches and the C-2-B pushback will begin.
- End of 2026 (Appendix B, Figures B-13 to B-14): By 2026 Sp-4 will be complete to the Springer Pit bottom (elev. 845 m) and mining will continue in Sp-5 along the west, north, and northeast walls of Springer Pit.
- End of 2027 (Appendix B, Figures B-15 to B-16): mining will continue in Sp-5 and mining will begin in WX.
- End of 2028 (Appendix B, Figures B-17 to B-18): mining will continue in Sp-5 and WX, and Springer Phase 6 will begin in the south wall of Springer Pit.
- End of 2029 (Appendix B, Figures B-19 to B-20): mining will continue in WX and Sp-6, and the Car-RR will also begin. The Car-RR material will be removed from the area via the north Springer Pit ramp which will be widened using the width of the ramp below. A waste rock backfill ramp will be constructed after the retreat to re-establish access to the Springer and WX Pit bottoms.
- End of 2030 (Appendix B, Figures B-21 to B-22): mining will continue in WX and Sp-6.
- End of 2031 (Appendix B, Figures B-23 to B-24): mining will continue in WX and Sp-6, and the Sp-6 retreat will be mined in the north wall of Springer Pit.
- End of 2032 (Appendix B, Figures B-25 to B-26): mining will continue in WX.

# 5.0 MOUNT POLLEY MINE ENGINEERING GEOLOGY

The engineering geology model is supported by a literature review, the current structural geology model provided by MPMC, structural mapping data that have been collected from various mapping campaigns by WSP and MPMC, exploration drilling data collected by MPMC, and WSP's experience at the Mount Polley Mine.

Geotechnical domains have been developed on the basis of the data review. The development of the engineering geology model is described in the following sub-sections.

## 5.1 Major Faults in Open Pits

Several major continuous faults are interpreted to exist in the area of the open pits and have been exposed along the current pit walls. The major structures projected on the current pit are shown in Figure 5.

A brief description of the major fault structures in the area of the pits are as follows:

- The South Wishbone Fault is a vertical, northeast/southwest trending fault that truncates the mineralized breccia zone to the northwest (Figure 5). The Springer Pit wall has performed adequately in the area of the South Wishbone Fault previously with minor raveling along the fault (Figure 6).
- The Springer Fault is a steep, north-south trending, easterly-dipping fault with a dip of approximately 77 degrees. The fault zone has been intruded by a number of late-stage dykes. This fault is shown to terminate at the South Wishbone Fault and the Southwest Boundary Fault, to the northwest and southeast, respectively. The fault intersects the northeast wall of the Springer Pit at an oblique angle (Figure 5). The Springer Pit wall has performed adequately in the area of the Springer Fault previously with limited impact on the overall wall slope stability (Figure 6).
- The Springer South Boundary Fault is a steep, northeast-southwest trending, northwesterly-dipping fault with a dip of approximately 73 degrees. This fault is interpreted to terminate on the Springer Fault to the north and the Southwest Boundary Fault to the southwest. The fault intersects the northeast wall of the Springer Pit at a near perpendicular angle and intersects the west wall at an oblique angle (Figure 5). It is difficult to determine an exact fault trace in the current pit walls, however, the walls have performed adequately in the interpreted area of the fault (Figure 6).
- The Cariboo South Boundary Fault is a northeast-southwest trending fault that dips to the southwest at approximately 73 degrees. The fault is pervasive throughout the entire Springer Pit and does not truncate on any other faults (Figure 5). It is difficult to determine an exact fault trace in the current northeast and west walls of Springer Pit (Figures 6 and 7).
- The Polley Fault is a wide, steep, north/south trending, easterly-dipping zone of poor quality rock that dips at approximately 73 degrees (Figure 5). The Polley Fault is a broad zone that raveling has occurred in as mining has progressed (Figure 8).
- The Polley South Boundary Fault is a northeast-southwest trending fault. This fault offsets the mineralized breccia zone and is shown to terminate at the Southwest Boundary Fault to the south (Figure 5). It is difficult to determine an exact fault trace in the current pit walls, however, the walls have performed adequately in the interpreted area of the fault (Figure 8).

- The Polley Secondary Fault is a steep northeast/southwest trending fault that is dipping at approximately 66 degrees to the northwest (Figure 5). It is difficult to determine an exact fault trace in the current pit wall, however, the walls have performed adequately in the interpreted area of the fault (Figure 8).
- The Southwest Boundary Fault is a steep northwest/southeast trending fault that is dipping at approximately 62 degrees to the northeast (Figure 5). The fault truncates the mineralized breccia zone to the south. It terminates on the South Wishbone fault to the northwest and on the Polley Fault to the southeast. It is difficult to determine an exact fault trace in the current pit walls, however, the walls have performed adequately in the interpreted area of the fault.
- The East Cariboo Fault is a northwest-southeast striking fault that dips steeply to the northeast at approximately 86 degrees. The East Cariboo Fault is anticipated to intersect the ultimate pit in the east corner (Figure 5). Toppling instability has been observed to occur along the easterly dipping faults and joints in the upper weathered monzonite which is in the hangingwall of the East Cariboo Fault (Figure 9).
- A number of very continuous, north-south trending augite porphyry dykes have also been identified the Springer and Cariboo Pits (Figure 5). In general, these structures define a pervasive, penetrative fabric that dips to the east at steep inclinations (Figure 7).

## 5.2 Rock Fabric

In addition to the major faults, the rocks in the open pits also contain other geologic structures in the form of faults, dykes, and joint sets. The orientations of these structures have been determined through the following campaigns:

- Geotechnical mapping programs that have been carried out on an annual basis between 2008 and 2016, as well as 2023.
- Televiewer surveys were carried out in boreholes that were drilled in the C2 Pit area in 2006.
- Photogrammetry carried out in 2014 and 2024.

The structural data collection and compilation is described in the following sub-sections.

### 5.2.1 Structural Data Collection and Compilation

Structural data collected by various geotechnical campaigns between 2006 and 2024 were reviewed and compiled. Historical data had previously been reviewed based on feature type and pit only. For the purposes of this design review, approximate coordinates were assigned to the structural measurements using the 3D geological modeling software Leapfrog Works 2023.2.3 (Sequent 2023). For many of the traverses, specific locations and mapping directions were not provided. It was assumed that the location for the traverse was the centre of the traverse. Orientations of traverses were approximated using a topography surface from a similar timeframe to the mapping program. The current geologic interpretation map (Figure 2, Rees 2013) was then used in plan view to apply lithology to each measurement. The structural data by year is described in further detail in the following sub-sections and in Appendix C.

#### *5.2.1.1 2006 Televiewer Structural Data*

Televiewer data was collected from three boreholes in the east wall of the Cariboo Pit and the north wall of the C2 Pit (Appendix C, Figure C-2). A total of 118 structure orientation data points were collected including joints and faults. Table 5 summarizes the borehole information.

**Table 5: Summary of 2006 Borehole ATV Information**

| Borehole ID | Location | Number of Structural Data Points | Assigned Lithology |
|---|---|---|---|
| C2-06-47 | Cariboo Pit, East Wall | 22 | Breccia (Rees, 2013), BX1) |
| C2-06-51 | C2 Pit, North Wall | 46 | |
| C2-06-57 | C2 Pit, North Wall | 50 | |

Lithology was assigned to the borehole ATV data based on the plan view collar location on the geology map (Rees, 2013).

#### *5.2.1.2 2008 Structural Mapping Data*

Mapping data collected by Golder Associates Ltd. (Golder) in 2008 were digitized by overlaying the traverse locations map on a February 2008 open pit plan polyline file (Appendix C, Figure C-3). Excel mapping sheets from 2008 were used to assign structural features to each of the mapped locations. A total of 125 structural data points were included from the 2008 mapping dataset.

#### *5.2.1.3 2009 Structural Mapping Data*

Mapping data collected by Golder in 2009 were digitized by importing an open pit plan mapping stations figure from 2009 (Appendix C, Figure C-4). Field mapping sheets were used to obtain traverse lengths and distances along traverses for each measurement. The orientation of the traverses was estimated from the orientation of the bench at that location using a topography surface from August 2012. A total of 635 structure data points were included from the 2009 mapping dataset.

#### *5.2.1.4 2010 & 2011 Structural Mapping Data*

Mapping data collected by Golder in 2010 and 2011 were digitized using a 2010 topography surface. The data was mapped in the west, northwest, and north walls of Springer Pit in 2010 and the south wall of Springer Pit in 2011 (Appendix C, Figure C-5). No station or elevations were not provided for the structural mapping data. Elevations were assigned based on the lowest operating bench at the time of mapping. A total of 77 structural data points were included from the 2010/2011 mapping dataset.

#### *5.2.1.5 2014 Structural Mapping and Photogrammetry Mapping Data*

Mapping data collected by Golder in 2014 were digitized using station coordinates obtained from a 2014 stations location drawing (Appendix C, Figure C-6). Field mapping sheets contained traverse lengths and distances along the traverses which were used to estimate coordinates for each structural measurement. Where traverse locations were not provided, coordinates were estimated. It was assumed that the location for the station was the middle of the traverse. The orientation of the traverse was estimated from the orientation of the bench at that location using a December 2015 topography surface. A total of 349 structural data points were included from the 2014 mapping dataset.

Photogrammetry completed in the Springer Pit in 2014 by Golder was reviewed and compiled (Appendix C, Figure C-7). The dataset included structural measurements for the south and northeast walls of the Springer Pit. Structural data collected for the northeast wall were reviewed during completion of the 2016 LOM design review (Golder 2016). The south wall structural data was reviewed in Point Studio (Maptek 2023). A total of 620 structural data points were included from the 2014 photogrammetry dataset.

#### 5.2.1.6 2015 Structural Mapping Data

Mapping data was collected by Golder in 2015 along the north, northeast, and east walls of the C2 Pit (Appendix C, Figure C-8). The locations of the structural measurements were assigned to the bottom bench (lowest operating elevation) of the C2 Pit using a December 2015 topography surface. A total of 56 structural data points were included from this the 2015 mapping dataset.

#### 5.2.1.7 2016 Structural Mapping Data

Mapping data was collected by Golder in 2016 along the south wall of the WX Pit (Appendix C, Figure C-9). The locations of the structural measurements were assigned to the bottom bench (lowest accessible elevation) of the WX Pit using an October 2016 topography surface. The structural mapping was noted as being within the monzonite. A total of 12 structural data points were included from the 2016 mapping dataset.

#### 5.2.1.8 2023 Structural Mapping Data

Mapping data was collected from four areas of the Springer Pit during the 2023 slope stability review in September 2023 by WSP (WSP 2023) and an additional area in October 2023 by MPMC staff (Appendix C, Figure C-10). Coordinates were assigned to features based on locations in field notes and the use of an October 2023 topography surface. Traverses completed in September 2023 were along the south wall ramp (elev. 987 m bench), west wall south portion (elev. 988 m bench), west wall north portion (elev. 988 m bench), northeast wall (elev. 976 m bench), and northeast wall ramp (elev. 950 m). The traverse completed in November 2023 by MPMC was along the crest of the northeast wall of Springer Pit along the elev. 1,169 m bench. A total of 77 structural mapping points were included from the 2023 dataset.

#### 5.2.1.9 2024 Photogrammetry Mapping Data

Structural mapping was completed on a photogrammetry scan of WX Pit, along Cariboo Ramp, and along the south wall of Springer Pit (Appendix C, Figure C-11). The photogrammetry scan was provided by MPMC on November 28, 2023, and the structural mapping of the surface was completed by WSP in January 2024.

The following limitations were noted during the mapping data collection from the photogrammetry scan:

- In some instances, it was difficult to differentiate between joints and talus slopes. The WX Pit and Cariboo Ramp in particular have been exposed for over five years and ravel has made the bench faces difficult to see limiting the amount of mapping data collected.
- Very few structures were observed to be longer than a single bench (12 m).

A total of 94 structural mapping points were collected from the 2024 photogrammetry mapping.

### 5.2.2 Structural Data Review

The structural data from the various collection campaigns were combined, the locations were overlaid on the geologic map (Rees 2013) to be flagged for lithology and assigned to a pit. Magnetic declination was applied to the mapping data (not the televiewer and photogrammetry data as it is automatically applied while collecting this data) by year (Appendix C, Figure C-12).

The structural data was first filtered by rock type by overlaying the geologic map (Rees 2013) with the mapping data. The following rock types were assigned to structural data within the mine area:

- Breccia and mineralized breccia (BX1, BX2, and BX1m)

- Diorite
- K-feldspar Monzonite
- Monzodiorite

A stereographic projection of the structural data by rock type is presented in Appendix C, Figure C-13.

Next the data was filtered by pit area. The following pit areas were separated:

- Springer Pit
- Cariboo Pit
- WX Pit
- C2 Pit

Stereographic projects by pit and rock type are presented in in Appendix C, Figure C-14.

Next the data was separated on the basis of continuity by feature type as presented in Table 6 and Appendix C, Figure C-15.

**Table 6: Geologic Strcuture Continuity on the Basis of Structure Type**

| Discontinuous Structures | Continuous Structures |
|---|---|
| Joints | Fault |
| Veins | Dyke |
| Photogrammetry features (minimal features mapped were greater than a single bench (12 m)) | Major structures |

The mapping and photogrammetry data was further reviewed for continuity. Histograms of continuity for mapped structures are presented in Appendix C, Figures C-16 to C-18. The data show that most structures exhibit a continuity less than a single bench height (12 m). These data have been considered for the discontinuous structures (as presented in Table 6). The data also indicate that continuous structures have a range of continuity which is typically greater than a single bench height (12 m). The continuity information supports the separation of discontinuous and continuous data for further assessment in the kinematics (Section 6.4).

Structure set nomenclature from the 2016 LOM structural feature sets has been applied to the 2024 structural dataset. A summary of the structural sets observed in the 2016 data set are presented in Table 7.

**Table 7: Structural Sets for 2016 LOM Pit Slope Design Review (after Golder 2016)**

| Set | Description |
|---|---|
| Sets 1A and 1B | Include structures that strike parallel to the major northwest-southeast striking structural trend on site, and that dip to the northeast and southwest, respectively. These include structures that are related to and oriented sub-parallel to the Polley and the East Cariboo Faults. |
| Set 2 | Includes east-northeast--west-southwest striking structures that dip steeply toward the southeast. These structures are likely related to recent strike-slip faulting (Wafforn 2013), and to the Wishbone, Springer South Boundary, and similarly oriented faults. |
| Set 3 | Includes northeast-southwest to east-west striking structures that dip steeply toward the northwest. These structures may also be related to recent strike-slip faulting, and to the Wishbone, Springer South Boundary, and similarly oriented faults. |

**Table 7: Structural Sets for 2016 LOM Pit Slope Design Review (after Golder 2016)**

| Set | Description |
|---|---|
| Set 4 | Includes northeast-southwest striking structures that dip at a moderate inclination toward the northwest. These structures are likely related to the recent strike-slip faulting. These structure are well defined along the south side of the Cariboo Pit, and in the C2 and WX Pits. |
| Sets 5A and 5B | Include north-south striking structures that exhibit steep dips, and that dip toward the east and west, respectively. |
| Sets 6A and 6B | Includes structures that strike northeast-southwest and that dip toward the southwest and the northwest, respectively. |

A summary of the structural data review is presented in Table 8.

**Table 8: Structural Data Review Summary of Proposed Sets**

| Pit | Lithology | Scale | Set | Dip (degrees) | Dip Direction (degrees) | Set Description | Appendix C, Figure No. |
|---|---|---|---|---|---|---|---|
| Springer and WX | Monzodiorite | Discontinuous | Set 5A | 68 | 88 | Steep easterly dipping joint set | C-19 |
| | | | Set 5B | 80 | 275 | Steep west dipping joint set | |
| | | | Set 4 | 34 | 304 | Moderate northwesterly dipping set | |
| | | | Set 4/3 | 51 | 352 | Moderate to steep north to northwesterly dipping joint set | |
| | | Continuous | Set 5A/6A | 74 | 100 | Moderate to steep east to southeasterly dipping set | C-20 |
| | | | Set 3 | 71 | 345 | Steep west dipping set | |
| | | | Set 5B | 87 | 272 | Steep northwest dipping set | |
| Springer | Diorite | Discontinuous | Set 5A | 70 | 92 | Steep easterly dipping joint set | C-21 |
| | | | Set 4 | 34 | 309 | Shallow to moderate northwesterly dipping joint set | |
| | | | Set 1B | 78 | 201 | Steep southwesterly dipping joint set | |
| | | Continuous | Set 6A | 67 | 117 | Steep southeasterly dipping | C-22 |
| | | | Set 5A | 77 | 74 | Steep northeasterly dipping | |
| | | | Set 6B | 73 | 302 | Steep northwesterly dipping | |
| | | | Set 3 | 69 | 341 | Moderate northwesterly dipping | |
| | Breccia | Discontinuous | Set 5A | 69 | 86 | Steep easterly dipping joint set | C-23 |
| | | | Set 4 | 39 | 286 | Moderate northwesterly dipping joint set | |
| | | | Set 2/1B | 77 | 180 | Steep south dipping joint set | |
| | | | Set 3 | 83 | 354 | Steep north dipping joint set | |
| | | Continuous | Set 5A | 68 | 91 | Steep east dipping set | C-24 |
| | | | Set 1B | 63 | 215 | Moderate southwesterly dipping set | |
| | | | Set 4 | 43 | 295 | Moderate northwesterly dipping set | |
| | | | Set 3 | 85 | 331 | Steep northwesterly dipping set | |

**Table 8: Structural Data Review Summary of Proposed Sets**

| Pit | Lithology | Scale | Set | Dip (degrees) | Dip Direction (degrees) | Set Description | Appendix C, Figure No. |
|---|---|---|---|---|---|---|---|
| Cariboo | Monzodiorite | Discontinuous | Set 5A | 67 | 86 | Steep east dipping joint set | C-25 |
| | | | Set 4 | 62 | 22 | Moderate northeast dipping joint set | |
| | | | Set 1A | 38 | 350 | Moderate north dipping joint set | |
| | | Continuous | Set 5A/6A | 69 | 97 | Moderate to steep east to southeast dipping set | C-26 |
| | | | Set 3 | 61 | 349 | Moderate north dipping set | |
| Cariboo & C2 | Breccia | Discontinuous | Set 5A | 70 | 85 | Moderate east dipping set | C-27 |
| | | | Set 5B | 87 | 268 | Steep west dipping set | |
| | | | Set 6A | 69 | 145 | Moderate southeast dipping set | |
| | | | Set 2 | 72 | 178 | Steep south dipping set | |
| | | | Set 3 | 69 | 357 | Moderate north dipping set | |
| | | | Set 4 | 27 | 268 | Shallow west dipping set | |
| | | Continuous | Set 5A | 64 | 93 | Moderate east dipping set | C-28 |
| | | | Set 3 | 80 | 13 | Steep north dipping set | |
| | | | Set 3 | 82 | 334 | Steep northwest dipping set | |
| | | | Set 6A | 80 | 140 | Steep southeast dipping set | |
| | | | Set 1B | 86 | 206 | Steep southwest dipping set | |

In general, the structural sets identified in the 2016 LOM assessment remain similar to the sets identified in the 2024 LOM assessment.

### 5.2.3 Discontinuity Strength

In the absence of laboratory testing, discontinuity strength can be estimated using field recorded discontinuity parameters. The Barton-Bandis relationship between joint roughness coefficient (JRC), intact rock strength or joint contact strength (JCS), and slope height was used (Barton1976) to estimate discontinuity shear strengths. Details of the relationship are documented in Appendix C, Figures C-29 to C-32.

Field estimates of feature shape and roughness recorded during geotechnical mapping programs in 2008, 2009, 2010, 2011, 2014, 2015, and 2023 were compiled and statistically reviewed for both shape and roughness, separated into discontinuous and continuous feature scales. The dominant feature shape and roughness are undulating and rough, respectively. This combination makes up the majority of features in both discontinuous and continuous features.

From the feature combinations, JRC values can be estimated, and a weighted average is calculated for both the discontinuous and continuous structures (Appendix C, Figure C-30).

In the absence of laboratory unconfined compressive strength (UCS) testing, ISRM values logged for intervals in the exploration boreholes were compiled and averaged for each of the major lithologies. Table 9 presents the average minimum UCS used for the major lithologies (Appendix C, Figure C-31).

**Table 9: Summary of Average Minimum UCS Corresponding to Interval ISRM Value from Exploration Boreholes**

| Lithology | Average Minimum ISRM Strength | Corresponding Strength Range to Minimum (MPa) | Average Minimum Unconfined Compressive Strength, $\sigma_c$ (MPa) |
|---|---|---|---|
| Monzodiorite | R3 | 25-50 | **50** |
| Diorite | R4 | 50-100 | **60** |
| Breccia | R3 | 25-50 | **50** |

These values were used to calculate JCS. To account for minimal weathering on the features surfaces, the JCS was calculated as 75% of the average UCS estimation.

The Barton-Bandis relationship was assessed using RSData (RocScience 2022) and details are presented in Appendix C, Figure C-32. Strength parameters are extrapolated from RSData for varying slope heights and friction angles.

The following strength parameters were selected for the discontinuity data:

- Discontinuous structure surface strength parameters:
  - Cohesion: 0 kPa
  - Friction angle: 42 degrees
- Continuous structure surface strength parameters:
  - Cohesion: 40 kPa
  - Friction angle: 28 degrees

## 5.3 Exploration Borehole Review

Data from exploration boreholes drilled by MPMC between 2004 and 2012 in the areas of the Springer, Cariboo, C2, and WX Pits were reviewed. A database of 65 boreholes provided by MPMC was used in the review of rock mass ratings ($RMR_{76}$) for the 2016 LOM assessment (Golder 2016). Seventeen additional holes were provided by MPMC in late 2023 and early 2024 and were added to the database. Note that two of the boreholes, SD-07-22 and SD-04-16, had previously been reviewed during the 2016 LOM assessment (Golder 2016). The additional boreholes were selected to fill data gaps in the area of the WX Pit due to the large pushback in the pit, as well as capture additional geologic information through the proposed ultimate pit walls.

A summary of the boreholes reviewed is presented in Table 10 and Appendix D, Figures D-1 to D-3.

**Table 10: Summary of Additional Exploration Boreholes Reviewed for 2024 LOM Assessment (Data Provided by MPMC in 2023 and 2024)**

| Borehole ID | Easting (m)(1) | Northing (m)(1) | Elevation (masl) | Total Depth Along Hole (m) | Year |
|---|---|---|---|---|---|
| C2-11-86 | 1,997.0 | 2,719.5 | 1,102.9 | 409.3 | 2011 |
| CB-11-05 | 2,540.8 | 3,286.4 | 1,162.7 | 1,083.9 | 2011 |
| SD-04-16(2) | 1,959.4 | 3,151.9 | 1,135.6 | 730.61 | 2004 |
| SD-07-22(2) | 1,408.0 | 3,278.5 | 1,072.9 | 459.3 | 2007 |
| SD-11-107 | 1,490.5 | 4,054.1 | 1,164.7 | 1,233.0 | 2011 |
| SD-12-142 | 1,225.4 | 3,658.9 | 1,090.0 | 492.25 | 2012 |
| SD-12-133 | 1,801.6 | 3,377.2 | 1,035.9 | 599.24 | 2012 |
| WX-09-02 | 2,010.8 | 2,727.5 | 1,104.8 | 242.9 | 2009 |
| WX-10-07 | 1,823.2 | 2,771.6 | 1,141.0 | 418.4 | 2010 |
| WX-10-14 | 1,999.6 | 2,679.5 | 1,097.7 | 601.1 | 2010 |
| WX-10-16 | 1,746.6 | 2,630.6 | 1,074.2 | 532.5 | 2010 |
| WX-10-35 | 1,901.9 | 2,724.5 | 1,113.1 | 819.0 | 2010 |
| WX-10-37 | 1,600.0 | 2,725.0 | 1,064.0 | 730.6 | 2010 |
| WX-11-49 | 1,957.4 | 2,674.5 | 1,094.5 | 510.2 | 2011 |
| WX-11-50 | 1,554.8 | 3,078.2 | 1,093.0 | 630.0 | 2011 |
| WX-11-53 | 1,703.7 | 2,630.4 | 1,064.7 | 721.5 | 2011 |
| WX-11-55 | 1,998.7 | 2,578.4 | 1,084.5 | 663.5 | 2011 |

1) Coordinates are referenced to Mount Polley Mine Grid.

2) Boreholes were previously reviewed during the 2016 LOM assessment (Golder 2016).

Core photos, logged lithologies, total core recovery (TCR), rock quality designation (RQD), fracture count, rock strength data, and in four cases fracture condition were provided for the 17 exploration boreholes provided in 2023 and 2024. Downhole plots of the digital information provided are presented in Appendix E.

Only four of the 17 boreholes provided in 2023/2024 included sufficient information to calculate $RMR_{76}$, therefore, only four boreholes were added to the lithology statistics and $RMR_{76}$ database. The logged lithologies of 69 exploration boreholes were grouped according to Appendix D, Figure D-4. Lithological statistics are summarized in Table 11 and presented in Appendix D, Figure D-5.

**Table 11: Summary of Lithologic Units Intersected by Exploration Boreholes**

| Grouped Lithology | Total Meters Logged | % of Total Meterage |
|---|---|---|
| Breccia | 14,240.75 | 48.00% |
| Diorite | 1,489.58 | 5.02% |
| Monzodiorite | 8,831.77 | 29.77% |
| Dyke | 743.716 | 2.51% |
| Fault | 142.46 | 0.48% |
| Unknown | 4,126.54 | 13.91% |
| Other | 79.24 | 0.27% |
| Ignore | 15.38 | 0.05% |
| **TOTAL** | **29,669.43** | **100.00%** |

Most of the lithology intervals logged were within the monzodiorite and breccia. Core photos of typical lithologies are presented in Appendix D, Figures D-6 to D-10.

## 5.4 Rock Strength

### 5.4.1 Intact Rock Strength

Intact rock strength is generally expressed as the uniaxial compressive strength (UCS) of the rock, which is a laboratory compression test carried out on intact rock core cylinders. The intact strength of the rocks can also be estimated qualitatively using the International Society of Rock Mechanics (ISRM) (ISRM 2015) rock strength measurement system.

Previous estimates for breccia and monzonite rock exposed in the walls of the Springer Pit have been consistently Medium Strong to Strong (R3 to R4). Historical rock hardnesses from mapping programs indicate that rocks in the Springer Pit area are expected to be predominantly Strong (50 -100 MPa) in terms of intact rock strength (Golder 2016).

For the 2024 LOM assessment, rock strengths and corresponding UCS for each lithology was reviewed as part of the exploration borehole review (Section 5.3). The qualitative estimates of rock strength carried out during logging of the exploration boreholes indicate that the rocks in the open pit areas are Medium Strong to Strong (R3 to R4). The exception to this is the faults which are weak having an ISRM field intact rock strength average of R1. Table 12 summarizes the rock strength statistics based on the exploration borehole review of 69 boreholes.

**Table 12: Intact Rock Strength Estimates from Exploration Borehole Review**

| Lithology | Average Field Estimated Rock Strength (ISRM) | Description | Corresponding UCS Range (MPa) |
|---|---|---|---|
| Monzodiorite | R3 | Medium Strong Rock | 25 – 50 |
| Diorite | R4 | Strong Rock | 50 – 100 |
| Breccia | R3 | Medium Strong Rock | 25 – 50 |
| Dyke | R4 | Strong Rock | 50 – 100 |
| Fault | R1 | Weak Rock | 1.0 – 5.0 |

The field estimate rock strengths from the exploration borehole review are comparable to the field estimate rock strengths presented in the 2016 LOM assessment which were based on 1997, 2008, 2009, 2010, 2011, and 2014 geotechnical mapping programs (Golder 2016).

### 5.4.2 Rock Mass Strength

Rock mass classification systems are used to assess the various factors that influence the overall strength of a rock mass, including the influence of the intact rock strength and the fractures, to essentially grade the quality of the rock mass to determine its overall strength and deformation characteristics. For the purpose of this assessment, the $RMR_{76}$ system (Bieniawski 1976) has been used to assess the rock mass quality in the open pits.

A summary of the Rock Mass Rating ($RMR_{76}$) method is presented in Table 13.

**Table 13: $RMR_{76}$ Classification Parameters and Ratings (Bieniawski 1976)**

| Parameter | | | Ranges of Values | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| 1 | Strength of intact rock material | Point load strength index | >8 MPa | 4 – 8 MPa | 2 – 4 MPa | 1 – 2 MPa | For this low range – uniaxial compressive test is preferred | | |
| | | Uniaxial compressive strength | >200 MPa | 100 – 200 MPa | 50 – 100 MPa | 25 – 50 MPa | 10 – 25 MPa | 3 – 10 MPa | 1 – 3 MPa |
| | Rating | | 15 | 12 | 7 | 4 | 2 | 1 | 0 |
| 2 | Drill Core Quality RQD | | 90%–100% | 75%–90% | 50%–75% | 25%–50% | <25% | | |
| | Rating | | 20 | 17 | 13 | 8 | 3 | | |
| 3 | Spacing of Joints | | >3 m | 1 – 3 m | 0.3 – 1 m | 50 – 300 mm | <50 mm | | |
| | Rating | | 30 | 25 | 20 | 10 | 5 | | |
| 4 | Condition of Joint | | Very rough surfaces Not continuous No separation Hard joint wall rock | Slightly rough surfaces Separation <1 mm Hard joint wall rock | Slightly rough surfaces Separation <1 mm Soft joint wall rock | Slickensided surfaces OR gouge <5 mm thick OR joints open 1 -5 mm Continuous joints | Soft gouge >5 mm thick OR joints open >5 mm Continuous joints | | |
| | Rating | | 25 | 20 | 12 | 6 | 0 | | |

**Table 13: $RMR_{76}$ Classification Parameters and Ratings (Bieniawski 1976)**

| Parameter | | | Ranges of Values | | | |
|---|---|---|---|---|---|---|
| 5 | Groundwater | Inflow per 10 m per tunnel length | None | <25 litres/min | 25-125 litres/min | >125 litres/min |
| | | Ratio joint waste pressure / major principal stress | 0 | 0.0 – 0.2 | 0.2 – 0.5 | >0.5 |
| | | General Conditions | Completely dry | Moist only (interstitial water) | Water under moderate pressure | Severe water problems |
| | Rating | | 10 | 7 | 4 | 0 |

In order to obtain $RMR_{76}$ estimates, the rating for each parameter is assessed and the individual rating values are summed. $RMR_{76}$ varies from 0 to 100, i.e., from very poor to very good rock; the rock mass classes, and corresponding rating ranges are summarized in Table 14.

**Table 14: Rock Mass Rating System**

| $RMR_{76}$ Rating | Rock Mass Class |
|---|---|
| 81 to 100 | Very Good Rock |
| 61 to 80 | Good Rock |
| 41 to 60 | Fair Rock |
| 21 to 40 | Poor Rock |
| 20 or less | Very Poor Rock |

A summary of the data review is presented in Appendix F. MPMC previously provided 65 exploration boreholes to WSP that were used to calculate $RMR_{76}$ (Golder 2016). MPMC then provided the additional 17 boreholes, four of which were included in the $RMR_{76}$ database. The locations of the new exploration boreholes is presented in Appendix F, Figure F-2.

The $RMR_{76}$ for the major lithologies was calculated using the following assumptions:

- Intervals for geotechnical and geological data provided by MPMC do not always match. Geological logging was completed at a higher level of detail, including smaller dykes and geological intervals less than 25 cm thick. Contacts were also more accurate than those recorded in the geotechnical logging. Intervals less than 25 cm thick are not considered in the $RMR_{76}$ calculations as there are no unique geotechnical parameters logged for them.
- There are some differences in the depths of some lithologies. In these instances, the geotechnical intervals were assigned based on the major lithology logged in the geological data.

- **Parameter 1 – Strength of intact rock material**
  - For some intervals in the geotechnical data, multiple values were recorded for ISRM intact rock strength. The average of the *minimum* value recorded and the corresponding UCS range estimates for each lithology were used to assign a strength rating.
- **Parameter 2 – Drill core quality RQD**
  - The logged RQD was used to assign this rating for each interval.
- **Parameter 3 – Spacing of joints**
  - Average fracture count per meter for each lithology was used to determine a rating for approximate joint spacing.
- **Parameter 4 – Condition of joint**
  - The joint condition rating logged for each interval was used as recorded by MPMC for each interval.
- **Parameter 5 – Groundwater**
  - The slope was assumed to be dry.

Histograms of the $RMR_{76}$ by total length logged of each lithology type are presented in Appendix F, Figure F-6. A summary of the $RMR_{76}$ assessment for 2016 compared to 2024 is presented in Table 15.

**Table 15: Summary of $RMR_{76}$ Assessment of Exploration Borehole Geotechnical Data Comparing 2016 Results and 2024 Results**

| Lithology Group | Average RMR from Exploration Boreholes 2016 LOM Assessment | Average Minimum RMR 2024 LOM Assessment |
|---|---|---|
| Monzodiorite | 53 (Fair Rock) | 49 (Fair Rock) |
| Diorite | 57 (Fair Rock) | 53 (Fair Rock) |
| Breccia | 55 (Fair Rock) | 49 (Fair Rock) |
| Dykes | Not Reviewed | 53 (Fair Rock) |
| Faults | Not Reviewed | 24 (Poor Rock) |

Overall, the $RMR_{76}$ values calculated using the updated 2024 dataset are comparable to those calculated for the 2016 LOM assessment.

Interpretation of the $RMR_{76}$ assessment indicates the following:

- The monzodiorite rocks exhibit poor to good rock mass quality (Appendix F, Figure F-6). Although the average $RMR_{76}$ value calculated for the monzodiorite rocks is lower in the 2024 LOM assessment as compared to the 2016 LOM assessment, the lithology group is still within the Fair Rock quality range.

- The diorite rocks exhibit poor to good rock mass quality (Appendix F, Figure F-6). Although the average $RMR_{76}$ value calculated for the diorite rocks was lower in the 2024 LOM assessment as compared to the 2016 LOM assessment, the lithology group is still within the Fair Rock quality range.
- The breccia rocks exhibit poor to good rock mass quality (Appendix F, Figure F-6). Although the average $RMR_{76}$ value calculated for the breccia rocks was lower in the 2024 LOM assessment as compared to the 2016 LOM assessment, the lithology group is still within the Fair Rock quality range.
- The dyke rocks exhibit poor to good rock mass quality (Appendix F, Figure F-6). The average $RMR_{76}$ value calculated for the dyke rocks is within the Fair Rock quality range.
- The faults rocks exhibit very poor to poor rock mass quality (Appendix F, Figure F-6). The average $RMR_{76}$ value calculated for the fault rocks is within the Poor Rock quality range.

Geotechnical logging of exploration boreholes can often not include an evaluation of natural versus drill induced fractures. Hence, all fractures are logged, even if they are drill induced. This tends to overestimate fracture count and underestimate RQD, which in turn underestimates overall rock mass quality. Therefore, the rock mass quality estimates for the rock types in the area of the pits are likely slightly conservative.

## 5.5 Hydrogeology

The Springer, Cariboo, C2, and WX Pits are located on a ridge between the Bootjack and Polley Lakes (Figure 1). Groundwater flow direction is assumed from the topographic high in the area of the ridge towards low-lying areas and major natural drainage features such as the Bootjack and Polley Lakes to the west and east, respectively. The Bootjack Lake is at approximately elev. 992 m and the Polley Lake is at approximately elev. 929 m. In the area of the open pits, it is assumed that groundwater flows approximately from north to south and east to west based on the original topography in the area.

There are no piezometers or other hydrogeological instrumentation that have been installed in the vicinity of the open pits to monitor hydraulic heads. A hydrogeological investigation was conducted by Golder Associates Ltd. (Golder) in June 2015 near the Springer Pit for short-term water management. Collections of data between Springer Pit and Bootjack Lake was the objective of the investigation to understand seepage conditions. Overall, the data collected indicated that it is unlikely that seepage from the Springer Pit towards Bootjack Lake has occurred (Golder 2015a).

Water accumulation has been present in the Springer and Cariboo Pits dependent on where mining activities were occurring prior to 2019 when mining operations paused for care and maintenance. Since operations resumed in 2021, water accumulation to elev. 951 m has remained in Cariboo Pit as mining activities have focused on Springer Pit. Water accumulation to elev. 1,078 m has been present in the C2 Pit since mining was completed in 2016. No seepage has been visible in the walls below the C2 Pit along the Cariboo Ramp. The pit walls in the Springer and Cariboo Pits have exhibited limited, localized seepage in the following areas:

- Cariboo Pit
  - East wall near the East Cariboo Fault (elev. 1,123 m). Seepage was noted between 2019 and 2021, and again in 2023 in the upper benches of the unload area.
  - Lower east wall below the unload area on the southeast side (elev. 1,084 m to 976 m). Seepage has been noted since 2019. The amount of seepage has been variable.

- Springer Pit
  - Northeast wall along the Polley Fault. Minor seepage has been noted along the major fault for several years.
  - South wall near current mining activities at elev. 931 m. Minor seepage was noted during the 2023 slope stability review in September 2023. It is possible the seepage is due to tailings excavation in the area (water from the tailings seeping to the low point in the pit) or infiltration from the ridge along the top of the south wall.

Based on the current understanding of the hydrogeology in the area of the open pits, some water pressures are expected to exist within the pit walls during excavation of the proposed ultimate pit.

## 5.6 Geotechnical Domains

Geotechnical domains are generally defined as having four components: the geological, structural, rock mass, and hydrological models. Based on the current pit wall performance and engineering geology information compiled for the open pits at Mount Polley Mine, the following can be determined:

- **Geological:** The geology or lithologic units varies throughout the open pits. For the purposes of the 2024 LOM assessment, geology is considered the main divide for the geotechnical domains.
- **Structural:** The structural geology is controlled largely by the lithologic units encountered in the open pits and the Polley Fault (pervasive northwest-southeast striking structural trend that dips to the northeast and southwest). For the purposes of the 2024 LOM assessment, the structural trends are considered within each lithological unit, however, the geotechnical domains have not been subdivided further for structure.
- **Rock mass:** The rock strengths and rock mass characteristics are generally similar for the various rock types proposed to be exposed in the ultimate pits.
- **Hydrogeological:** There is limited hydrogeology information for the open pits and does not implicate the geotechnical domains.

The geotechnical domains for the 2024 LOM assessment of the proposed ultimate pit design are presented in Figure 10 and have been determined based on pit area and geology.

# 6.0 OPEN PIT SLOPE STABILITY ASSESSMENT

## 6.1 Rock Slope Design Terminology

A pit slope has four major components: the catch-bench, the bench face, the inter-ramp slope, and the overall slope (Figure 11). Bench configuration is defined by the vertical bench separation (bench height), catch-bench width (bench width), and bench face angle (BFA). The inter-ramp slope is formed by a series of uninterrupted benches, and the overall slope is formed by a series of inter-ramp slopes separated by haul roads or wide geotechnical benches.

The bench height is a function of the type of excavation equipment used, while BFA is normally a function of geotechnical factors such as material strength or structural discontinuities in the rock mass. However, where no such geological controls exist, it may be a function of the blasting damage, or the type of excavation equipment used.

It is common practice to establish catch-benches on a pit slope to retain loose material that may fall from either the immediate bench face above or from the upper part of the slope. Where conditions are suitable, it is also common practice to place benches at vertical intervals of two (or occasionally more) bench heights, creating a multi-bench slope configuration.

The inter-ramp angle (IRA) corresponds to the angle subtended by a line joining the toes of the benches on the wall and the horizontal. The overall slope angle corresponds to the angle formed by the line joining the toe of the lowest bench with the pit crest and the horizontal. The incorporation of ramps onto a wall will result in a slope that has a shallower overall slope angle than the IRA.

## 6.2 Rock Slope Failure Mechanisms

Rock slope design procedures are intended to establish pit wall design criteria based on the expected failure mechanisms, as determined by analyzing the engineering geology model. In this context, instability in rock slopes can generally be classified according to the following principal failure mechanisms:

- failures due to rock mass fabric and structural discontinuities (kinematic failures)
- failures due to rock mass strength
- failures due to a combination of kinematic failures and rock mass strength failures

The stability of slopes excavated in competent rock is normally a function of structurally controlled failure mechanisms. In high rock slopes or slopes excavated in incompetent rock, overall slope failure mechanisms that involve the development of failure surfaces through intact rock and along pre-existing geologic surfaces are also a concern. These two principal failure mechanisms are discussed in further detail in the following sections.

### 6.2.1 Structurally Controlled Failure Mechanisms

The three basic mechanisms of structurally controlled failure in rock slopes are plane failures, wedge failures, and toppling failures, as described below. These mechanisms are shown schematically in Figure 12.

**Planar failure** may occur when a geological discontinuity dips out of a rock slope at an angle that is shallower than the inclination of the slope but steeper than the effective angle of friction along the discontinuities. Planar failures will only develop to a significant extent if the strike of the geological discontinuity is within ±20 to 30 degrees of the strike of the rock slope.

**Wedge failure** may occur when two or more geological discontinuities intersect to form an unstable block. For wedge failure to occur, the line of intersection of the wedge must dip out of the slope at an inclination that is shallower than the inclination of the slope but steeper than the effective angle of friction along the discontinuities. Wedge failures will only develop to a significant extent if the azimuth of the line of intersection of the wedge is within ±45 degrees of the azimuth of the slope face.

**Toppling failure** may develop when a rock mass contains multiple, parallel, steeply in-dipping, continuous geologic structures, such as bedding or continuous joints or foliation planes, that strike nearly parallel to the strike of the face of the rock slope. Toppling failures will generally only develop when the strike of the structures is within ± 20 degrees of the strike of the slope face. Kinematically, the potential for toppling failure is determined by the slope angle, and by the spacing, inclination, and continuity of the toppling blocks. Widely spaced and/or discontinuous structures mitigate the potential for toppling, while closely spaced, continuous structures have the potential to develop into multi-bench, shallow-seated failures, which could result in overall wall failure.

All structurally controlled failure modes are influenced by groundwater pressure within the slope, and toppling failures are particularly sensitive to groundwater pressure. The magnitude and frequency of structurally controlled failures are directly related to the continuity of the structures along which sliding can occur. Rock mass structures that exhibit limited continuity, such as joints, may result in small bench-scale failures that are rarely of consequence to overall slope stability, but may adversely affect access ramps or equipment installations. Conversely, larger-scale failures can occur along continuous, through-going structures, such as regional faults and dykes. Therefore, it is these more continuous structures that are of primary concern for pit slope design.

### 6.2.2 Overall Rock Mass Strength Failure Mechanisms

Slopes excavated in weak or heavily fractured rock masses, or extremely high slopes, can be susceptible to overall rock mass failure, which involves the development of pseudo-circular type failure zones through intact rock (Figure 13). Where major structures are present with an appropriate orientation, these structures may be partially involved in a more complex failure mechanism by creating release planes for the rock mass failure.

## 6.3 Rock Slope Design Acceptance Criteria

Typical design acceptance criteria (DAC) (i.e., factor of safety and probability of failure acceptance criteria) for large open pit slopes are summarized in Table 16.

**Table 16: Typical Factor of Safety and Probability of Failure for Consequence of Failure Acceptance Criteria Values (after Read and Stacey 2009)**

| Slope Scale | Consequence of Failure[(a)] | Acceptance Criteria | |
|---|---|---|---|
| | | Minimum FOS | Maximum POF, P[FOS ≤ 1] (%) |
| Bench | Low to High | 1.1 | 25 to 50 |
| Inter-ramp | Low | 1.15–1.2 | 25 |
| | Medium | 1.2 | 20 |
| | High | 1.2–1.3 | 10 |
| Overall | Low | 1.2–1.3 | 15–20 |
| | Medium | 1.3 | 5–10 |
| | High | 1.3–1.5 | ≤5 |

(a) Consequence of failure semi-quantitatively evaluated.

FOS = factor of safety; POF = probability of failure.

No critical infrastructure is located near the proposed ultimate pit walls. Failure of a significant portion of one of the pit walls could impact mining production by limiting access to the pit floor and temporarily limit production from mining operations. The (NW PAG Dump is near the crest of the west wall of Springer Pit and if failure of this wall were to occur could impact the dump. Taking these factors into considerations, the open pits have a medium consequence of failure. The proposed design acceptance criteria for the proposed ultimate pit design are presented in Table 17.

**Table 17: Proposed Design Acceptance Criteria for the Proposed Ultimate Pit Design**

| Slope Scale | Minimum FOS | Maximum POF (%) |
|---|---|---|
| Bench | N/A | 50 |
| Double Bench | | 50 |
| Inter-ramp | | 20 |
| Overall | 1.3 | N/A |

## 6.4 Kinematic Stability Assessment

A kinematic stability assessment has been carried out to determine optimum bench and inter-ramp configurations for the various pit wall sectors in the proposed ultimate pit design. The following sub-sections describe the methodology for the kinematic assessment and the kinematic stability assessment results.

### 6.4.1 Methodology

Kinematic stability analyses have been carried out to assess the potential for bench-scale (single and double bench) and inter-ramp scale planar, wedge, and toppling instability of the proposed ultimate pit design.

In porphyry deposits, discontinuous structures are typically closely spaced and pervasive. These structures typically impact the slope stability of the individual benches. However, due to their limited continuity they typically do not impact the slope stability at the inter-ramp scale. The majority of the mapped structures in the open pits exhibit a continuity of less than a single bench height (12 m). In contrast, continuous faults and dykes are usually widely spaced and typically do not affect bench-scale stability, except locally where the structure is exposed in the bench face. However, due to their greater continuity, continuous structures can affect the performance at the inter-ramp scale due to the ability of these structures to form potential large-scale planar or wedge structures. It would be conservative to apply the discontinuous structures to the assessment of the double benches or the inter-ramp scale slopes since the kinematic analyses assume that the structures extend the full height of the slope. Therefore, the single benches were assessed for discontinuous structures, and double bench and inter-ramp slopes were assessed for continuous structures. The discontinuous and continuous structural sets are presented in Table 8 by pit area and lithology, and the continuity of the structures was presented in Section 5.2.2.

Since the major structures in the open pits are generally steeply dipping and at favourable orientations with respect to the pit walls, slope-scale kinematic analyses were not completed for these structures, and a discussion of how the major structures will interact with the pit walls is provided in Section 6.5.1.

The kinematic analyses were performed for specific wall orientations based on the proposed ultimate pit design provided by MPMC (Section 4.0) and for each lithologic unit that is encountered in each wall orientation based on the geologic interpretation (Rees 2013). The stability of the pit walls and the optimum design bench configurations will depend on the orientations of the walls with respect to the structural sets that are expected to be exposed in the pit walls for each lithologic unit. Therefore, recommendations regarding optimum design bench configurations are provided in terms of pit area, wall orientations, and lithology. The wall orientations are expressed in terms of the wall "dip-direction", *i.e.,* the direction the wall faces.

The kinematic slope stability analyses have been carried out in two stages:

1) Screening level assessment using the Dips software (RocScience 2023c).

2) Deterministic analyses using RocPlane and SWedge analyses software (RocScience 2023a and 2023b) based on the screening level assessment.

### 6.4.2 Kinematic Screening Level Assessment

The screening level assessment was carried out to identify which structural sets or combination of sets, if any, could result in planar, wedge, or toppling instability. Specific design sets or combination of sets were highlighted by the screening level assessment if the results indicated the percentage of sliding exceed the probability of failure (PoF) design acceptance criteria (Table 17).

The following criteria were used for the screening level kinematic stability assessment (Appendix F, Figures F-2 to F-37):

- A lateral limit of 90°, ±20° from the dip direction of the slope, was used for planar and toppling analyses.
- A kinematic window of 90˚, ±45° from the dip direction of the slope, was used for wedge analyses.
- Wedges will not be formed by two structures within the same structural set.
- Structures that are not interpreted to be part of a defined structural set (i.e., random structures) have not been included in the analyses.
- Strength parameters presented in Section 5.2.2 for discontinuous and continuous structures were used for the screening level assessment.

Deterministic analyses using RocPlane and SWedge were subsequently carried out on sets or combination of sets which were identified to exceed the design acceptance criteria during the screening level assessment. These analyses produce a series of statistics which are plotted as cumulative frequency (CF) curves.

The following considerations have been made for the deterministic analyses:

- Planar, wedge, and toppling failure analyses were carried out with respect to closely spaced and relatively discontinuous features.
- Slope heights:
  - Single benches: a slope height of 12 m was used. Discontinuous structures were considered.
  - Double benches: a slope height of 24 m was used. Continuous structures were considered.
  - Inter-ramp: a slope height of 72 m was used. Continuous structures were considered.

- Recent observations from the 2023 slope stability review indicate minimal wall seepage in all of the current open pits. Groundwater pressures are expected to dissipate at the bench-scale. Therefore, all bench-scale kinematic models (single and double bench) were completed under dry conditions. Groundwater pressures were assumed at 33% of the slope height for the inter-ramp kinematic models due to the larger and deeper failure mechanisms that could intersect the water table behind the slope. 33% was selected based on the Bootjack Lake elevation in relation to the proposed pit bottom and observations of seepage over the years of excavating the pits.

### 6.4.3 Kinematic Deterministic Analyses

#### *6.4.3.1 Single Bench*

Single bench kinematic deterministic assessments were carried out for the proposed ultimate pit design using the discontinuous structural sets presented in Table 8. A summary of all reviewed set combinations by structural domain are presented in Appendix G.

The deterministic review presented in Appendix G indicates there are three single bench planar failure mechanisms and three single bench wedge failure mechanisms that are expected to exceed the design acceptance criteria for the proposed ultimate pit design. These failure mechanisms have been further investigated with probabilistic analyses using cumulative frequency plots (Appendix G, Figures C-39 to G-40).

One single bench potential toppling failure mechanism was identified in the breccia rock in the east wall of the Cariboo Pit during the screening process. The wall orientation and rock type are near the East Cariboo Fault. The potential toppling mechanism is likely to be contained/mitigated by the current design in this area (i.e., single benches). Toppling is known to have occurred near the East Cariboo Fault and single benches have been used to mitigate this failure mechanism in this area. Therefore, the toppling potential in this area has not been investigated further since the design proposed for the east wall direction (i.e. single benches) is expected to be adequate.

#### *6.4.3.2 Double Bench*

Double bench kinematic deterministic assessments were carried out for the proposed ultimate pit design using the continuous structural sets presented in Table 8. A summary of all reviewed set combinations by structural domain are presented in Appendix G.

The deterministic review presented in Appendix G indicates there are six double bench planar failure mechanisms and six double bench wedge failure mechanisms that are expected to exceed the design acceptance criteria for the proposed ultimate pit design. These failure mechanisms have been further investigated with probabilistic analyses using cumulative frequency plots (Appendix G, Figures C-41 to G-42).

#### *6.4.3.3 Inter-ramp Slope*

Inter-ramp slope kinematic deterministic assessments were carried out for the proposed ultimate pit design using critical wall directions from the double bench deterministic assessment. There are two inter-ramp planar failure mechanisms and one inter-ramp wedge failure mechanism that are expected to exceed the design acceptance criteria for the proposed ultimate pit design. These failure mechanisms have been further investigated with probabilistic analyses using cumulative frequency plots (Appendix G, Figures C-43 to G-44).

### 6.4.4 Kinematic Slope Stability Analyses Results

#### *6.4.4.1 Single Bench*

Single bench kinematic stability assessments were carried out for the proposed ultimate pit design using the structural sets identified in the screening level assessment. A summary of the modelled, kinematically admissible planes and wedges (FOS less than 1.0) for the proposed ultimate pit design by wall direction for single benches are presented in Table 18.

**Table 18: Summary of Kinematic Results for Single Bench Analyses**

| Pit | Lithology | Wall Direction (Degrees) | Bench Height (m) | Structure Scale | Critical Mechanism | Set(s) | BFA @ P[FOS<1]=50% |
|---|---|---|---|---|---|---|---|
| Springer / WX | Monzodiorite | 330 | 12 | Discontinuous | Planar | Set 4/3 | **61** |
| | | | | | Wedge | Set 4/3 & Set 5B | 62 |
| | Diorite | 220 | 12 | Discontinuous | Planar | Set 1B | **80** |
| Cariboo / C2 | Breccia | 195 | 12 | Discontinuous | Planar | Set 2 | **74** |
| | | | | | Wedge | Set 5B & Set 6A | 90 |
| | | | | | Wedge | Set 5B & Set 2 | 75 |

**Bold** BFAs indicate critical BFAs for the wall direction.

Some of the results of the planar analyses indicate low BFAs in comparison to the wedge analyses for the same slope angles. These results are not consistent with observed performance to date in the open pit areas. This typically occurs where structures exhibit a continuity that is significantly less than the bench heights. Set 4/3 exposed on the southeast wall of the Springer Pit is an example of this. Consequently, the recommended BFAs used to develop the pit slope design recommendations are in part based on WSP's previous experience in the open pits.

#### *6.4.4.2 Double Bench Probability of Failure Assessment*

Double bench kinematic stability assessments were carried out for the proposed ultimate pit design using the structural sets identified in the screening level assessment. A summary of the modelled, kinematically admissible planes and wedges (FOS less than 1.0) for the proposed ultimate pit design by wall direction for double benches are presented in Table 19.

**Table 19: Summary of Kinematic Results for Double Bench Analyses**

| Pit | Lithology | Wall Direction (Degrees) | Bench Height (m) | Structural Scale | Critical Mechanism | Set(s) | BFA @ P[FOS<1]=50% |
|---|---|---|---|---|---|---|---|
| Springer/WX | Monzodiorite | 56 | 24 | Continuous | Wedge | Set 5A/6A & Set 3 | 90 |
| | | 97 | 24 | Continuous | Planar | Set 5A/6A | **82** |
| | | 330 | 24 | Continuous | Planar | Set 3C | **80** |
| | | | | Continuous | Wedge | Set 5B & Set 3C | 90 |
| | Breccia | 35 | 24 | Continuous | Planar | Set 5A | 90 |
| | | | | Continuous | Wedge | Set 5A & Set 3 | 90 |
| | | 85 | 24 | Continuous | Planar | Set 5A | **77** |
| | | | | Continuous | Wedge | Set 5A & Set 3 | 90 |
| Cariboo/C2 | Breccia | 195 | 24 | Continuous | Planar | Set 1B | 90 |
| | | 317 | 24 | Continuous | Planar | Set 3 | 90 |
| | | | | Continuous | Wedge | Set 3 & Set 3 | 90 |
| | | | | Continuous | Wedge | Set 3 & Set 1B | 90 |

**Bold** BFAs indicate critical BFAs for the wall direction.

#### *6.4.4.3 Inter-ramp Probability of Failure Assessment*

Inter-ramp kinematic stability assessments were carried out for the proposed ultimate pit design using the continuous structural sets identified in the screening level assessment. Inter-ramp models were created for the structural sets with the lowest results for continuous features for the double bench assessment. The results for inter-ramp slopes are presented in Table 20.

**Table 20: Summary of Kinematic Results for Inter-ramp Analyses**

| Pit | Lithology | Wall Direction (Degrees) | Bench Height (m) | Structural Scale | Critical Mechanism | Set(s) | Dry IRA @ P[FOS<1]=20% | 33% Saturation IRA @ P[FOS<1]=20% |
|---|---|---|---|---|---|---|---|---|
| Springer/WX | Monzodiorite | 56 | 72 | Continuous | Wedge | Set 5A/6A & Set 3 | 74 | 73 |
| | | 97 | 72 | Continuous | Planar | Set 5A/6A | **68** | **65** |
| | Breccia | 85 | 72 | Continuous | Planar | Set 5A | **63** | **60** |

### 6.4.5 Springer/WX Pit Recommended Bench Design Configurations

Bench design recommendations for walls to be excavated in the Springer/WX Pits are presented in Table 21 and Figure 14. The resulting BFAs were reviewed based on the critical case (i.e., the shallower indicated BFA) between the planar and wedge analyses and were selected based on the analyses, engineering judgement, and past performance of the pit area.

**Table 21: Summary of Springer/WX Pits Recommended Bench Design Configurations**

| Lithology | Wall Dip Direction (°) | Bench Height (m) | BFA (°) | IRA (°) | Catch-Bench Width (m) | Rationale |
|---|---|---|---|---|---|---|
| Monzodiorite | 280 | 12 | 70 | 43 | 8.5 | Single bench in the monzodiorite in the south and southeast walls of Springer/WX Pits due to planar failure along Set 4/3 and proximity to Polley Fault. Current single bench wall exposures indicate the recommended design is performing adequately. |
| | 330 | 12 | 70 | 43 | 8.5 | Single bench in the monzodiorite in the south and southeast walls of Springer/WX Pits due to planar failure along Set 4/3 and proximity to Polley Fault. Current single bench wall exposures indicate the recommended design is performing adequately. |
| | 056 | 24 | 65 | 46.5 | 11.5 | Double benching in southwest wall acceptable with shallower BFA controlled by Set 5A. |
| Breccia | 035 | 24 | 70 | 50 | 11.5 | Double benching in breccia (particularly in the WX Pit) in the southwest and west walls. |
| | 085 | 24 | 70 | 50 | 11.5 | Set 5A will likely control BFA for double benches in the breccia. |
| | 097 | 24 | 70 | 50 | 11.5 | Set 5A will likely control BFA for double benches in the breccia. |
| | 220 | 12 | 70 | 43 | 8.5 | Single benches recommended due to confluence of several faults in the northeast wall in the breccia. Transition from double to single benches will be in the north corner of the Springer Pit. |
| Diorite | 220 | 12 | 70 | 43 | 8.5 | Single bench in the diorite to control raveling from Polley and Springer Faults. |

The recommended bench design configuration for the Springer/WX Pits is similar to what has previously been proposed (Golder 2016) and to the proposed ultimate pit design that MPMC provided.

### 6.4.6 Cariboo/C2 Pit Recommended Bench Design Configurations

Bench design recommendations for walls to be excavated in the Cariboo/C2 Pits are presented in Table 22 and Figure 14. The resulting BFAs were reviewed based on the critical case (i.e., the shallower indicated BFA) between the planar and wedge analyses and were selected based on the analyses, engineering judgement, and past performance of the pit area.

**Table 22: Summary of Cariboo/C2 Pits Recommended Bench Design Configurations**

| Lithology | Wall Dip Direction (°) | Bench Height (m) | BFA (°) | IRA (°) | Catch-Bench Width (m) | Rationale |
|---|---|---|---|---|---|---|
| Monzodiorite | 195 | 12 | 70 | 43 | 8.5 | Single benches in Polley Fault. |
| | 238 | 12 | 70 | 43 | 8.5 | Single benches due to toppling along East Cariboo Fault. |
| | 317 | 12/24 | 70 | 43/49 | 8.5/12 | Single benches in proximity to Polley Fault. Otherwise double benches at 70 degree BFA. Double benches acceptable along southeast wall of Cariboo/C2 Pits. |
| Breccia | 188 | 24 | 70 | 49 | 12 | Double benches in C2 Pit. |
| | 195 | 12 | 70 | 43 | 8.5 | Single benches in Polley Fault. |
| | 317 | 12/24 | 70 | 43/49 | 8.5/12 | Single benches in proximity to Polley Fault. Otherwise double benches at 70 degree BFA. |

The recommended bench design configuration for the Cariboo/C2 Pits is similar to what has previously been proposed (Golder 2016) and to the proposed ultimate pit design that MPMC provided.

## 6.5 Overall Slope Stability Assessment

This section outlines the results of previous slope stability assessments that have been completed for ultimate pit walls, and the overall slope stability assessment for the 2024 LOM assessment.

### 6.5.1 Overall Slope Stability – Major Faults Assessment

Figures 5 and 15 show the projected location of the major faults with respect to the existing and the proposed ultimate pit walls, respectively.

Several major continuous faults are interpreted to exist in the area of the open pits and have been exposed along the current pit walls (described in Section 5.1). The influence that these faults are expected to have on the proposed ultimate pit walls are discussed below and the major structures projected on the proposed ultimate pit design are shown in Figure 15:

- The South Wishbone Fault is interpreted to intersect the ultimate pit through the north nose of the Springer Pit with about six double benches on the northwest side. The South Wishbone Fault does not create any adverse, large-scale wedges that could plunge out of the slope. Because the South Wishbone Fault is a vertical fault, is favorably oriented in the proposed ultimate pit wall, and has performed adequately in the previous pit wall (Figure 6), the fault is not expected to be a slope stability issue in the proposed ultimate pit design.
- The Springer Fault is interpreted to intersect the ultimate pit through the north end of the northeast wall through the entire pit wall at an oblique angle. The Springer Fault creates wedge intersections with the Springer South Boundary Fault and the Cariboo South Boundary Faults, however, both wedges are either into the pit wall or do not daylight on the overall slope. Due to the favorable orientation of the Springer Fault and the adequate performance of the pit wall in the area of the fault (Figure 6), the Springer Fault is not expected to be a slope stability concern in the ultimate pit design.

- The Springer South Boundary Fault is interpreted to intersect the northeast and west ultimate pit walls at similar angles as currently exposed in the Springer Pit. The Springer South Boundary Fault intersects the Springer Fault and they create an undaylighted wedge in the northeast wall. As a result, the Southwest Boundary Fault is not expected to be a slope stability issue in the ultimate pit due to the favorable orientation and adequate slope stability performance in the current pit walls (Figure 6).
- The Cariboo South Boundary Fault is interpreted to intersect the ultimate pit northeast wall near the Polley and Polley South Boundary Faults. Based on current performance in the northeast wall at the confluence of these faults, ongoing raveling is occurring (Figure 8). This is being managed by single benching and bench cleaning. The confluence of these faults may cause an area of raveling in the northeast wall of the ultimate pit but are unlikely to affect the overall slope stability due to the oblique angles at which the faults intersect the wall. The Cariboo South Boundary Fault will also intersect the ultimate pit west wall of the Springer Pit at an oblique angle. It is difficult to determine where the intersection of the Cariboo South Boundary Fault is in the current pit, however, the west wall has been performing adequately (Figure 7). Based on the fault model review there are no adverse wedges that intersect the ultimate pit wall with the Cariboo South Boundary Fault.
- The Polley South Boundary Fault is interpreted to intersect the ultimate pit near the Polley and Cariboo South Boundary Faults in the northeast wall of the Springer Pit. Based on current performance in the northeast wall at the confluence of these faults, ongoing raveling is occurring (Figure 8). This is being managed by single benching and bench cleaning. The confluence of these faults may cause an area of raveling in the northeast wall of the ultimate pit but are unlikely to affect the overall slope stability due to the oblique angles at which the faults intersect the wall. Based on the fault model review there are no adverse wedges that intersect the ultimate pit wall with the Polley South Boundary Fault.
- The Polley Fault is interpreted to intersect the proposed ultimate pit design along the central portion of the northeast wall towards the lower northeast corner of the wall, then along the northeast corner of the WX Pit, and along the southeast corner of the C2 Pit. The current northeast wall is experiencing ongoing ravel in the area of the fault which is being managed by the single benches in the fault zone (Figure 8). It is anticipated that similar behaviour will occur in the ultimate pit northeast wall. As benches are excavated in the Polley Fault zone, each bench will need to be cleaned prior to excavating the following bench to maintain adequate catchment for the ravel material. The southern end of the Polley Fault intersects the southeast corner near the C2 Pit and raveling is occurring along the intersection (Figure 7). It is anticipated that similar behaviour will occur in the ultimate pit southeast wall and single benching will be required.
- The Polley Secondary Fault is interpreted to intersect the lower portion of the northeast wall of the ultimate pit below the Polley Fault, the lower east wall of Springer Pit, and the west wall of the WX Pit. It is difficult to determine intersections on the current pit walls (Figures 7 and 8). It is anticipated that due to the oblique orientation the Polley Secondary Fault intersects the until pit wall, it should not affect the overall slope stability.
- The Southwest Boundary Fault is interpreted to intersect the ultimate pit west and east walls of Springer Pit. The Southwest Boundary Fault and Cariboo South Boundary Fault create a wedge in the west wall that plunges into the slope, therefore, this is unlikely to be a slope stability concern. There may be increased ravel between the two faults on the west wall of Springer Pit during excavation. Due to the orientation the Southwest Boundary Fault is interpreted to intersect the ultimate pit walls and based on previous performance of the pit walls in the area of the fault, it is not expected to be a slope stability concern in the ultimate pit.

- The East Cariboo Fault is anticipated to intersect the ultimate pit in the east corner. Toppling instability has been observed to occur along the easterly dipping faults and joints in the upper weathered monzonite which is in the hangingwall of the East Cariboo Fault (Figure 9). Similar rock mass behavior is anticipated in the area of the ultimate pit as new benches are excavated and single benching is recommended on the east side of the East Cariboo Fault.

### 6.5.2 Summary of Previous Slope Stability Assessments

#### *6.5.2.1 2015 Overall Slope Stability Assessment – Springer Pit Southwest Wall*

In 2015 a slope stability assessment was completed for the southwest wall of the Springer Pit. Circular type failure through overall rock mass was assessed (Golder 2015b). The 2015 assessment was carried out to demonstrate the long-term slope stability of the pit wall located between the Springer Pit and Bootjack Lake. Long-term slope stability conditions were assessed for the ultimate southwest wall pit design at the time, which at the time was proposed to be approximately 180 m high.

The walls in the October 2015 Springer Pit have exhibited adequate overall stability to date. The monzonite rocks excavated along the southwest wall are considered to exhibit competent rock mass quality. Structural mapping carried out in 2009, 2010, and 2014 were reviewed to determine their impact on slope stability. The joint surfaces were typically mapped as discontinuous and restricted to the bench faces. The intersections of these joints had formed wedges resulting in rockfall and raveling of the exposed bench faces in the southwest wall at the time. The mapped faults were determined to be continuous and observed over several of the exposed bench faces. However, the majority of the faults in the southwest wall are steeply dipping and are not expected to affect the overall slope stability conditions.

Slope stability analyses were carried out for dry and saturated pit walls, and for flooded pit conditions (Golder 2015b). The overall slope stability of the southwest wall was assessed using two-dimensional limit equilibrium methods for the ultimate pit through the most critical cross-section in the wall (Golder 2015b). The results of the slope stability analyses indicated that the proposed slope would exhibit FOS of between 2.8 and 1.3 with respect to potential circular failure through the near surface blast damaged rock mass for dry and saturated conditions, respectively.

#### *6.5.2.2 2016 Overall Slope Stability Assessment – Springer Pit Northeast Wall*

In 2016, Golder performed a slope stability assessment of the northeast wall in Springer Pit based on an updated proposed ultimate pit design at the time. The stability of the northeast wall in the Springer Pit was assessed with respect to potential circular type failure through the rock mass. The northeast wall was selected for analyses as it exhibited the most adverse combination of slope height and overall slope angle with an overall wall height of about 400 m. Field observations found localized seepage occurring into the pit through the northeast wall. Consequently, some water pressures were expected to exist within the wall (Golder 2016).

The overall slope stability of the northeast wall was assessed using two-dimensional limit equilibrium methods. To account for uncertainty in the groundwater conditions, a sensitivity analysis was carried out. The $r_u$ method was used to model groundwater pressures within the pit slopes. The $r_u$ method evaluates groundwater pressure as the ratio of the weight of the water pressure to the weight of the corresponding overburden pressure above a given point in the rock slope.

The following three groundwater scenarios were modeled:

- dry slope conditions
- some natural drainage of groundwater pressures within the rock slope, with $r_u$ values of 0.1 and 0.2

The results of the slope stability analyses indicated that the proposed slope would exhibit FOS of between 3.4 and 2.6 with respect to potential circular failure through the near surface blast damaged rock mass for dry conditions and for a $r_u$ of 0.2, respectively. Consequently, the slope is expected to exhibit adequate stability with respect to these two mechanisms. In summary, the results of the slope stability analyses indicated that the northeast wall of the Springer Pit was expected to exhibit adequate stability performance for the proposed mining scenario. Given that the other pit walls are expected to exhibit either lower wall heights or lower overall slope angles, and similar overall rock mass strengths are expected, the remaining pit walls are also expected to exhibit adequate overall slope stability (Golder 2016).

### 6.5.3 Overall Slope Stability Methodology and Assumptions for the 2024 LOM Assessment

Overall slope stability analyses were considered for the 2024 LOM assessment. After reviewing the previous slope stability analyses completed in 2015 and 2016 the following summary table was compiled to compare wall heights and overall slope angles between proposed pit designs for the given year (Table 23).
