**Table 23: Summary of Previous Slope Stability Analyses Designs for Springer Pit Compared to 2024 Design**

| Year | Pit | Wall | Wall Height (m) | Overall Slope Angle (degrees) | Elevation of Pit Bottom (m) |
|---|---|---|---|---|---|
| 2015 Assessment | Springer | Southwest | 180 | 40 | 932 |
| 2016 Assessment | | Northeast | 400 | 40 | 778 |
| 2024 Assessment | | Southwest | 300 | 40 | 760 |
| | | Northeast | 408 | 40 | |

The northeast wall height, overall slope angle, and pit bottom elevation presented for the proposed ultimate pit design for the 2024 LOM assessment are similar to the 2016 design (Golder 2016). As well, rock mass strengths are expected to be similar between both the 2016 and 2024 LOM assessments. The 2016 assessment considered dry and partially saturated conditions for the overall slope stability analyses which, based on a review of the Bootjack and Polley Lake elevations (elev. 992 m and elev. 929 m, respectively) in relation to the proposed ultimate pit bottom (elev. 760 m), and past experience with groundwater seepage into the pit, are considered appropriate for the overall slope stability of the proposed ultimate pit design. The FOS also range between 2.6 and 3.4 which is above the design acceptance criteria. Therefore, the analyses completed on the northeast wall of Springer Pit in 2016 are considered adequate for the current proposed ultimate pit design of the Springer northeast wall.

The southwest wall height for the proposed ultimate pit design for the 2024 LOM assessment is higher than the 2015 assessment (Golder 2015b). The overall slope angle is the same. Given that the rock mass strengths used in the 2015 assessment are similar to what has been presented in the 2024 LOM assessment (Section 5.4) and the FOS meet design criteria for dry and saturated conditions, it is expected that for a higher wall height and partially saturated conditions (approximately 1/3 to 2/3 the wall height), the southwest wall would continue to exhibit adequate slope stability and meet the design acceptance criteria.

The northeast wall is the highest wall in the proposed ultimate pit design; the remainder of the pit walls are lower with similar overall slope angles. Given that the other pit walls are expected to exhibit similar overall rock mass strengths in conjunction with lower wall heights and similar overall slope angles, the remaining pit walls are also expected to exhibit adequate overall slope stability

Pseudo-static seismic analyses for open pit slopes are typically considered overly conservative, and therefore, analyses are not common to be completed on large rock slopes. Read and Stacey (2009) state that there are no recorded case histories of large-scale earthquake-induced mine slope failures having disrupted mining operations. Due to the large size of open pit slopes, topographical amplification effects and scale related averaging effects results in quite different dynamic characteristics to soil slopes. A key limitation of earthquake stability of large open pit rock slopes is that accelerations in a high slope within a slip surface extending from the crest to ¼ of the slope depth are relatively constant, but average accelerations within a slip surface over the entire slope height is much lower than the maximum acceleration (at the crest) (Toh et al. 2013). Based on findings from Read and Stacey (2009) and Toh et al. (2013) no seismic analyses have been completed for the proposed ultimate pit design.

# 7.0 PROXIMITY TO NORTHWEST POTENTIALLY ACID GENERATING DUMP

The crest of northwest wall of the proposed ultimate pit design will be located approximately 8 m to 100 m away from the toe of the south lobe of the NW PAG Dump (Figure 16).

The south lobe of the NW PAG Dump was constructed between 2012 and 2013, MPMC indicated that trees were logged and the topsoil was stripped from the foundation of the dump prior to construction (Golder 2013). The NW PAG Dump is interpreted to be founded on a thin veneer of colluvium underlain by till in this area (WSP 2024). The south lobe is founded on gently to moderately sloping terrain that is inclined at approximately 20 to 30 degrees to the southwest and west. The south lobe has been inactive for approximately 10 years and has exhibited adequate slope stability performance during this time.

The northwest wall in Springer Pit below the NW PAG Dump is expected to exhibit similar overall rock mass strengths to other walls in the Springer Pit and expose monzodiorite and breccia rock types (Section 5.4). Double benching is proposed in this area of the ultimate pit design (Figure 16).

The following considerations should be made regarding the proximity of the NW PAG Dump to the crest of the proposed ultimate pit design:

- Blasting induced vibrations
  - Blasting induced vibrations due to mining near surface in the proposed ultimate pit near the NW PAG Dump could lead to localized slope instability or rockfall and rock rollout. To mitigate this risk the following should be considered:
    - A geophone could be installed in the area to monitor blast vibrations and how they impact the NW PAG Dump.
    - Smaller blast patterns for the first few benches could be considered to control wall blasting and limit vibrations that could impact the NW PAG Dump.
    - Visual inspections should be completed after a blast. Inspections should include review of the crest and toe of the NW PAG Dump to identify any cracking, raveling, or loose material that could pose a risk to workers and equipment below.
- Construction of a rock rollout catchment berm could be considered along the toe of the NW PAG Dump (if access is manageable prior to excavation of the upper benches in this area). As well, an additional catchment berm could be constructed along the inside edge of the haul road that will enter the proposed ultimate pit from the west side of the pit to provide additional catchment.
- Removal of unconsolidated materials
  - The Health, Safety and Reclamation Code (HSRC) for mines in BC indicates that all unconsolidated material within 2 m of the rim of a working face or wall in a surface mine shall be removed, and beyond this distance all unconsolidated material shall be sloped to an angle less than the natural angle of repose (EMLI 2024, Section 6.23.1). It is recommended that the first one to two benches (depending on the overburden depth) be single benched before double benching in bedrock. The single benches should be sloped to an overall slope of angle of repose (37 degrees) to satisfy the HSRC requirements.

- Development of a safe access plan below an inactive dump
  - As required by HSRC (EMLI 2024, Section 6.10.1) a procedure for controlling access to areas within the potential runout zone of all dumps should be prepared. This includes a monitoring program to allow work below inactive and dormant dumps. As well the procedure should include provisions for signage, working under adverse conditions, and should be reviewed annually.
- Potential for foundation soils to be susceptible to liquefaction under dynamic loading (i.e., earthquake loading) causing a potential failure and runout of the NW PAG Dump into the pit.
  - Based on laboratory testing of the colluvium and till in the footprint of the NW PAG Dump and several other areas on site, these materials are not susceptible to liquefaction. The particle grain size distribution curves indicate a high coefficient of uniformity which aligns with descriptions of the materials being well-graded. As well, due to the voids between the coarser fraction of the colluvium and till being filled with fines, the material are typically not susceptible to structure collapse and liquefaction upon loading.

# 8.0 OPERATIONAL CONSIDERATIONS

The following operational controls should be implemented during the excavation of the proposed ultimate pit design:

- Blasting practices:
  - Mining is going to occur concurrently during several phases of mining (for example on the northeast wall, at the Springer Pit bottom in Phase 4 and at the Springer Pit crest in the Phase 5 pushback). To limit overspill onto existing pit walls and to mitigate risk to personnel who may be working below, consider blasting the upper pushback design starting with a drop shot into the bench and work to the outer limits of the bench using the inner free face rather than the outer free face for energy release. This will help move material towards the pit wall rather than over the pit crest and onto benches below where personnel are mining below.
  - MPMC have been having good success with pre-shear blasting and limiting damage to the bench faces, as observed during the 2023 slope stability review (WSP 2023). Discussions with the mine planning team indicate that they have been successfully achieving design toes by completing a vertical pre-shear row, a trim row about 2.5 m offset from the pre-shear row (with about 0.5 m sub-drill), a buffer row about 6.5 m offset from the trim row (with about -0.5 m sub-drill), into production blasting with an 8 m by 7 m spacing. Continue to use the observational approach to decide if varying spacings for blasting need to be used based on rock type/rock quality to minimize damage to the bench faces.
- Bench cleaning:
  - When cleaning a bench, make sure equipment is pulling material inwards and not pushing debris over the pit wall, as this will decrease catchment and create hazardous work conditions at the pit bottom. Controlled blasting practices and cleaning material away from the crest of the pit will help maintain catchment on the benches below.
- Springer Pit nose area:
  - The nose area on the Springer Pit northeast wall is of particular concern while concurrently mining above and below (Figure 18). The area does not have any wider catch benches along the wall for additional catchment, and the benches are already limited in available catchment due to overspill from previous mining activities. A 3 to 4 m high rock berm should be constructed with a 15 m offset from the toe of the Phase 4 highwall while mining of the Phase 5 pushback is occurring at the crest to mitigate any rock rollout that may occur during mining operations (Figure 17). When mining operations need to access the area within the 15 m offset (i.e., blasting and mucking an ultimate Phase 4 bench), mining in the Phase 5 pushback should be stopped or diverted away from the nose. Once operations are finished in the 15 m offset area, the rock berm should be re-established and mining in the Phase 5 pushback may resume near the crest.
  - If catchment along the wall in the nose area becomes a slope stability concern, a step out may be required.
- Slope stability monitoring (i.e., prisms, LiDAR surveys, radar, etc.)
  - Complete slope stability monitoring of the excavated benches with slope stability monitoring equipment.
  - Follow the MO26 Pit Wall Stability Monitoring SOP (MPMC 2021b)

- Regular visual inspection (MPMC 2021a and 2021b)
  - Visual inspections of the bench faces and crest areas for early evidence of slope instability should be completed. The crest and benches should be examined for signs of cracking or instability at least once every two weeks, and more frequently during the spring runoff and heavy rainfall events. These regular inspections should ideally be carried out by the same individual to maintain continuity of the observations. The observations should be recorded digitally so that a record of the slope stability performance is available should it be required in the event of instability.
- Geologic mapping
  - Mapping should be carried out the pit is excavated, in order to confirm the design assumptions, and if required, to modify the pit wall designs in a timely manner. The orientation and character of the rock fabric and continuous structures should be collected. The mapping data collected should be reviewed in comparison to previous mapping data and the existing slope design recommendations. Major faults and geologic structures are best identified through routine manual geologic wall mapping. Geotechnical mapping techniques or photogrammetry techniques can be used to carry out the mapping of the fault and joint sets.
- Piezometer installation
  - Currently there are no piezometers installed around the proposed ultimate pit design. Various assumptions regarding pore water pressures for slope stability analyses have been used. To confirm pore water pressure assumptions, a vibrating wire piezometer could be installed in an exploration borehole that intersects the proposed ultimate pit design through the highest wall, i.e. the northeast wall of Springer Pit.

# 9.0 SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

The pit wall performance of the Springer, Cariboo, C2, and WX Pits has been documented by WSP during annual slope stability reviews of the open pits. The most recent slope stability review was completed in September 2023 (WSP 2023). In general, the Springer, Cariboo, C2, and WX Pits are exhibiting good slope stability performance with no signs of overall slope instability. Many benches have broken back to discontinuous moderately dipping structures; however, adequate catchment remains on the majority of the benches.

MPMC are proposing five expansions to the open pits at Mount Polley Mine including Springer Phase 5 (Sp-5), Springer Phase 6 (Sp-6), Springer Phase 6 Ramp Retreat (Sp-6-RR), WX, C-2-B, and the Cariboo Ramp Retreat (Car-RR) (Appendix B, Figure B-1). These expansions create the proposed ultimate pit design (SP-6/WX) (Figure 4).

The geotechnical domains for the 2024 LOM assessment of the proposed ultimate pit design are presented in Figure 10 and have been determined based on pit area and geology.

Kinematic stability analyses have been carried out to assess the potential for single bench, double bench, and inter-ramp scale planar, wedge, and toppling instability of the proposed ultimate pit design. Bench design configurations are presented in Table 24 and Table 25, and Figure 14.

**Table 24: Summary of Springer/WX Pits Recommended Bench Design Configurations**

| Lithology | Wall Dip Direction (°) | Bench Height (m) | BFA (°) | IRA (°) | Bench Width (m) | Rationale |
|---|---|---|---|---|---|---|
| Monzodiorite | 280 | 12 | 70 | 43 | 8.5 | Single bench in the monzodiorite in the south and southeast walls of Springer/WX Pits due to planar failure along Set 4/3 and proximity to Polley Fault. Current single bench wall exposures indicate the recommended design is performing adequately. |
| | 330 | 12 | 70 | 43 | 8.5 | Single bench in the monzodiorite in the south and southeast walls of Springer/WX Pits due to planar failure along Set 4/3 and proximity to Polley Fault. Current single bench wall exposures indicate the recommended design is performing adequately. |
| | 056 | 24 | 65 | 46.5 | 11.5 | Double benching in southwest wall acceptable with shallower BFA controlled by Set 5A. |
| Breccia | 035 | 24 | 70 | 50 | 11.5 | Double benching in breccia (particularly in the WX Pit) in the southwest and west walls. |
| | 085 | 24 | 70 | 50 | 11.5 | Set 5A will likely control BFA for double benches in the breccia. |
| | 097 | 24 | 70 | 50 | 11.5 | Set 5A will likely control BFA for double benches in the breccia. |
| | 220 | 12 | 70 | 43 | 8.5 | Single benches recommended due to confluence of several faults in the northeast wall in the breccia. Transition from double to single benches will be in the north corner of the Springer Pit. |
| Diorite | 220 | 12 | 70 | 43 | 8.5 | Single bench in the diorite to control raveling from Polley and Springer Faults. |

**Table 25: Summary of Cariboo/C2 Pits Recommended Bench Design Configurations**

| Lithology | Wall Dip Direction (°) | Bench Height (m) | BFA (°) | IRA (°) | Bench Width (m) | Rationale |
|---|---|---|---|---|---|---|
| Monzodiorite | 195 | 12 | 70 | 43 | 8.5 | Single benches in Polley Fault. |
| | 238 | 12 | 70 | 43 | 8.5 | Single benches due to toppling along East Cariboo Fault. |
| | 317 | 12/24 | 70 | 43/49 | 8.5/12 | Single benches in proximity to Polley Fault. Otherwise double benches at 70 degree BFA. Double benches acceptable along southeast wall of Cariboo/C2 Pits. |
| Breccia | 188 | 24 | 70 | 49 | 12 | Double benches in C2 Pit. |
| | 195 | 12 | 70 | 43 | 8.5 | Single benches in Polley Fault. |
| | 317 | 12/24 | 70 | 43/49 | 8.5/12 | Single benches in proximity to Polley Fault. Otherwise double benches at 70 degree BFA. |

The following slope design considerations are based on the proposed ultimate pit bench design recommendations:

- The proposed SP-5 design will mine through the inactive Bell Dump along the northeast wall of the ultimate pit in two areas (Figure 17). Single benching with an overall slope of 37 degrees will be required through the waste rock rehandle slopes in these areas.
- The proposed Sp-5 design indicates double benches in the Cariboo Pit east wall where toppling failure is likely to occur in the weathered monzodiorite, east of the East Cariboo Fault, due to closely jointed/faulted rock (Figure 17). Previous toppling failure occurred in the area in 2017 and, as such, single benches have previously been recommended to the east of the East Cariboo Fault (the hangingwall). The Phase 5 pushback design is limited by the Bootjack mine access road which is located at the crest of the proposed double-benched east wall, increasing the consequence of a failure. Double benching in this area could impact the slope stability of the Bootjack mine access road and interfere will access to site due to the higher potential for toppling failure. Using a single bench configuration would require a reduction in the inter-ramp slope angle. Single benches are recommended in walls that are excavated in the East Cariboo Fault and to the east of the fault. based on previous pit wall performance and proximity to the access road to Mount Polley Mine.
- The proposed Sp-6/WX design has at least two double benches at the bottom of the south/southeast wall, where single benches are recommended due to adverse structural conditions experienced in this wall previously (Figure 17).
- The proposed Sp-6/WX design contains a triple bench (36 m high bench) at the bottom of the southwest wall of the WX Pit below the ramp (Figure 17). A triple bench at the bottom of WX Pit would allow MPMC to access additional high-grade ore at the bottom of the pit. The achievability of the triple bench excavation should be evaluated once mining has progressed into the WX Pit to confirm rock type and structure in the area.
- When mining through the Polley Fault on any pit walls, single benching is recommended based on previous experience and performance (Figure 17).

- When mining through the C-2-B Pit, single benches may be required through the Polley Fault along the southeast wall (Figure 17). Previous slope performance in the area of the Polley Fault along this wall has included increased ravel due to the poor rock quality and catch-benches have become infilled over time. Since only two double benches are proposed in this area, it is possible that ravel from the fault can be contained on the wider catch-benches. As mining progresses through the area with double benches, regular inspections of the wall performance should be completed and if catchment becomes limited, a step out or rock rollout berm may be required.

Several major continuous faults are interpreted to exist in the area of the open pits and have been exposed along the current pit walls (described in Section 5.1). These faults are expected to have limited impact on the proposed ultimate pit walls due to the steep nature of the majority of the faults (Section 6.5.1), with the exception of the Polley and East Cariboo Faults which have slope design considerations described in the above bullets.

Upon review of previous slope stability analyses completed for Springer Pit (Golder 2015b and 2016), these analyses were determined to be adequate for the current proposed ultimate pit design based on the following:

- Similar overall wall heights (with the exception of the southwest wall).
- Similar overall slope angles.
- Similar groundwater conditions.
- Similar rock mass strengths expected.

Due to the proximity of the NW PAG Dump to the crest of the proposed ultimate pit design MPMC should consider specific monitoring equipment and plans, as well as single benches within the first one to two benches below the dump (Section 7.0)

Operational controls should be implemented during the excavation of the proposed ultimate pit design, and include blasting practices, bench cleaning, slope monitoring, and geologic mapping (Section 8.0).

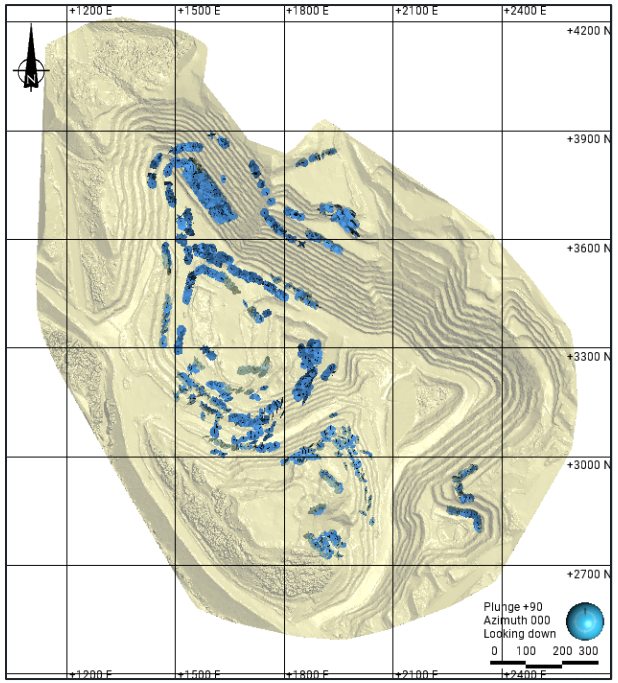
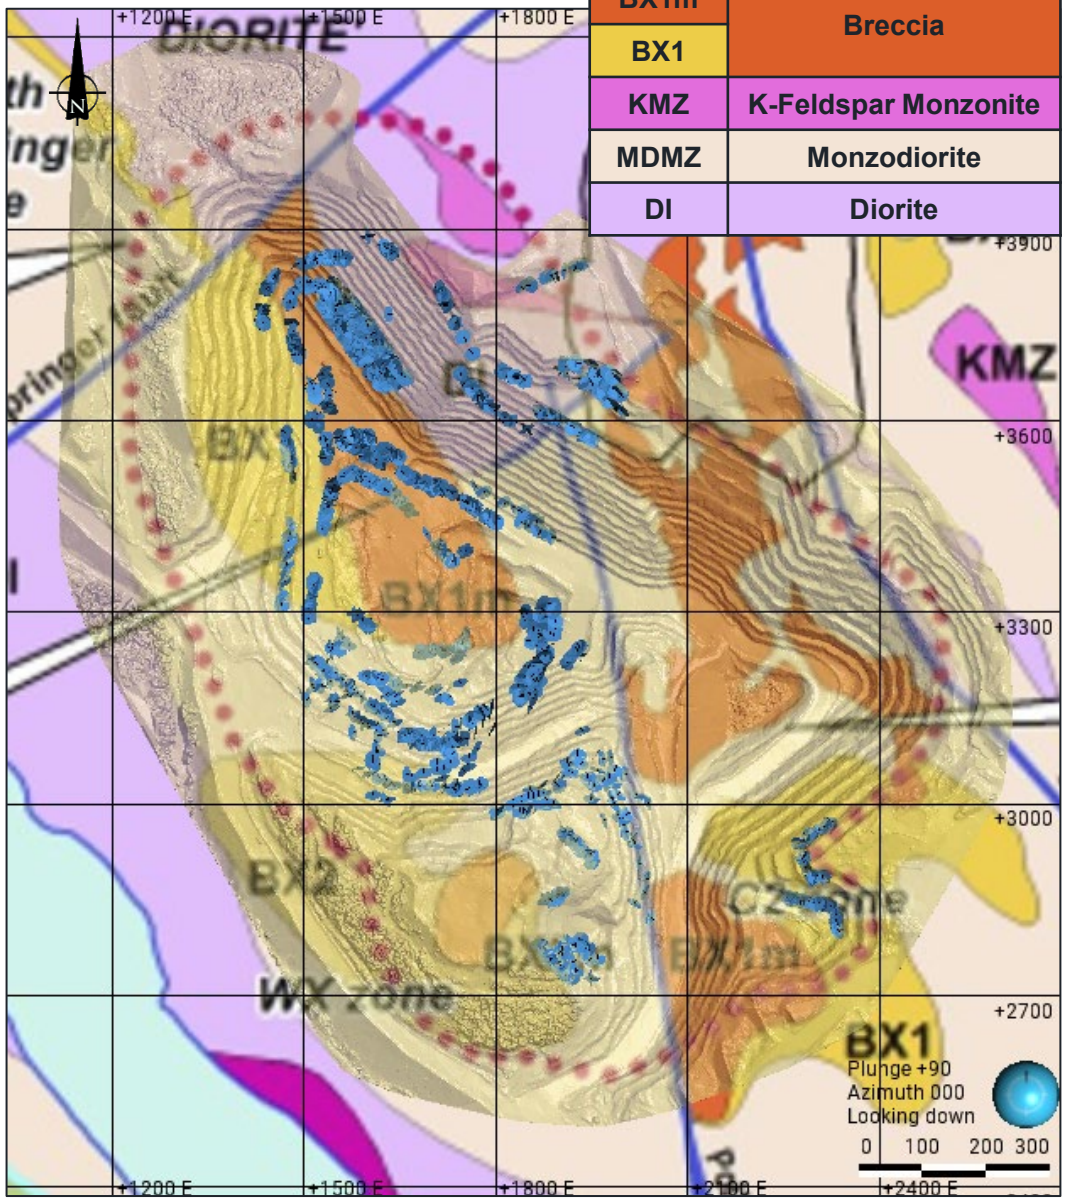
# Structural Data Review



# All Structural Data Included in the 2024 LOM Review



*2006 ATV and 2008 to 2024 Mapping & Photogrammetry Data*

The 2013 Rees Geology Map is shown overlain on the October 2023 topography to the right.

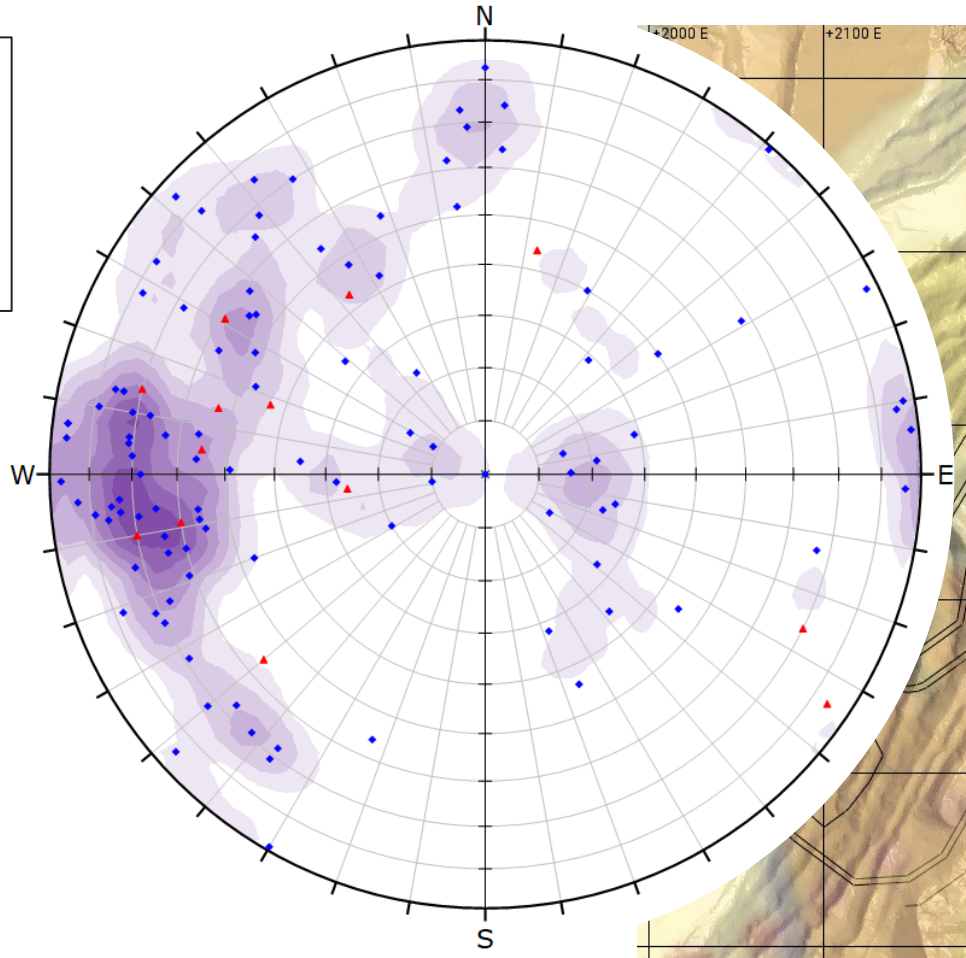
A total of 2,163 structure orientation datapoints were digitized and compiled for this structural review. The datapoints are represented by the blue discs.

| Year | Data Type | Number of Data Points |
|---|---|---|
| 2006 | ATV | 118 |
| 2008 | Mapping | 125 |
| 2009 | Mapping | 635 |
| 2010 | Mapping | 66 |
| 2011 | Mapping | 11 |
| 2014 | Mapping & Photogrammetry | 349 & 620 |
| 2015 | Mapping | 56 |
| 2016 | Mapping | 12 |
| 2023 | Mapping | 77 |
| 2024 | Photogrammetry | 94 |

# 2006 Televiewer Data

Three boreholes were drilled in 2006 around the planned C2 Pit extents.

Televiewer data was collected from all three holes.



All hole collars are within breccia (BX1) and the length of the boreholes are assumed to be in breccia as well.

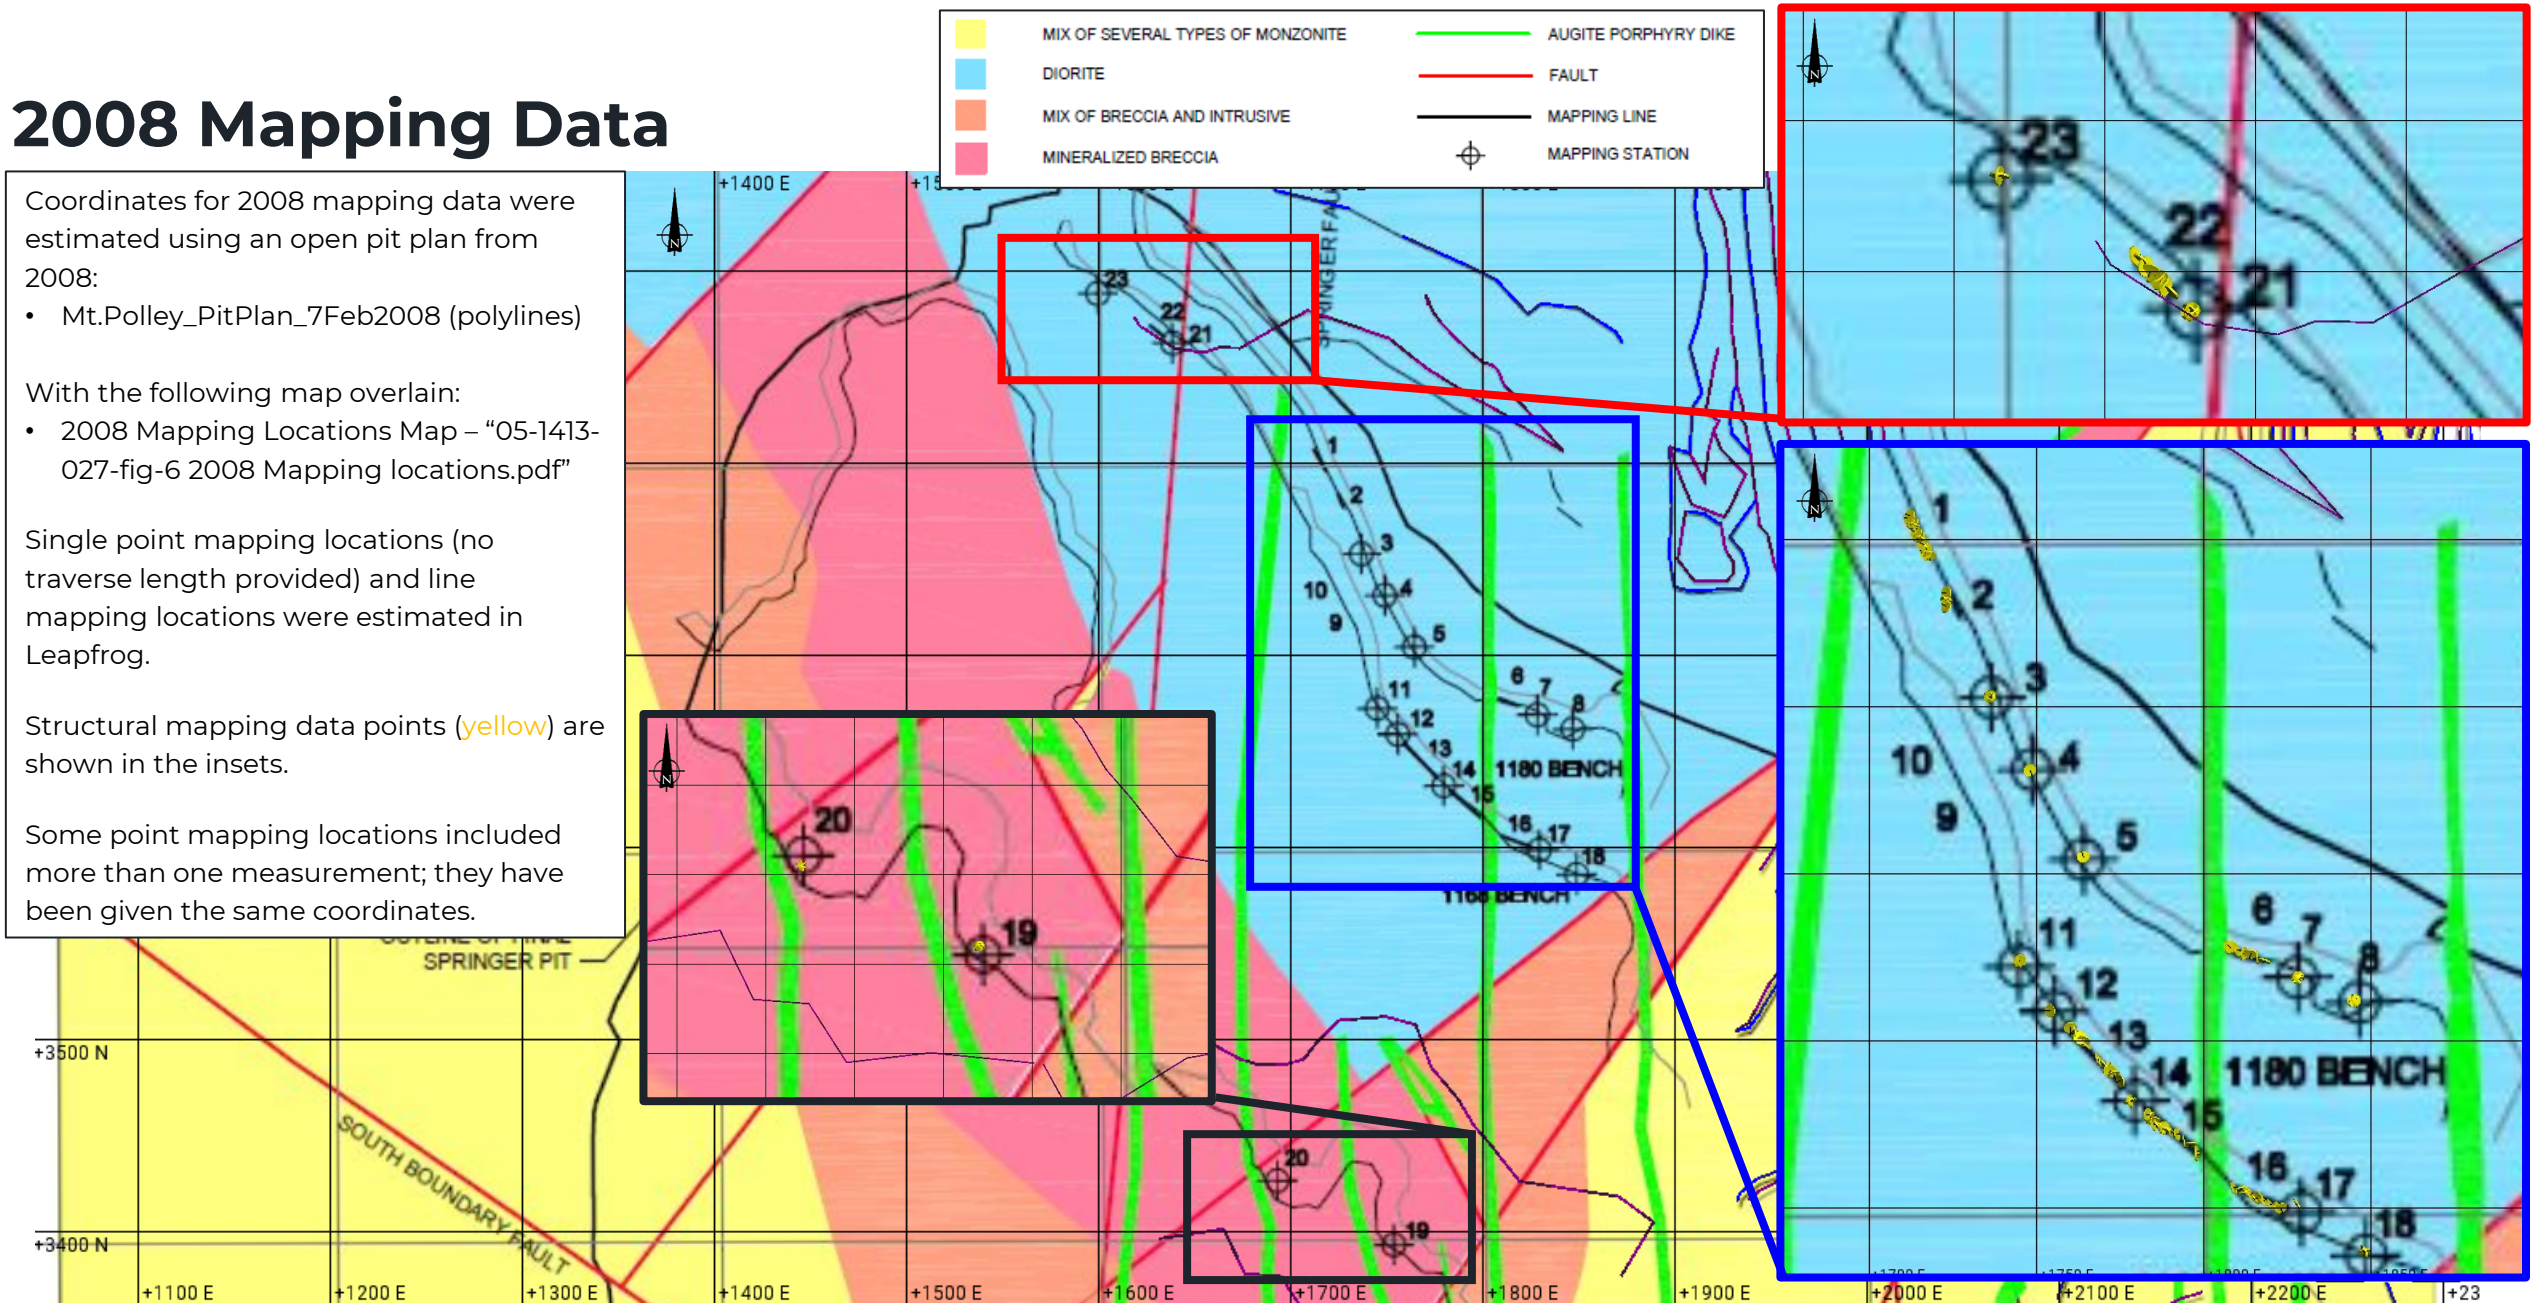
# 2008 Mapping Data

Coordinates for 2008 mapping data were estimated using an open pit plan from 2008:

- Mt.Polley_PitPlan_7Feb2008 (polylines)



With the following map overlain:

- 2008 Mapping Locations Map – "05-1413-027-fig-6 2008 Mapping locations.pdf"

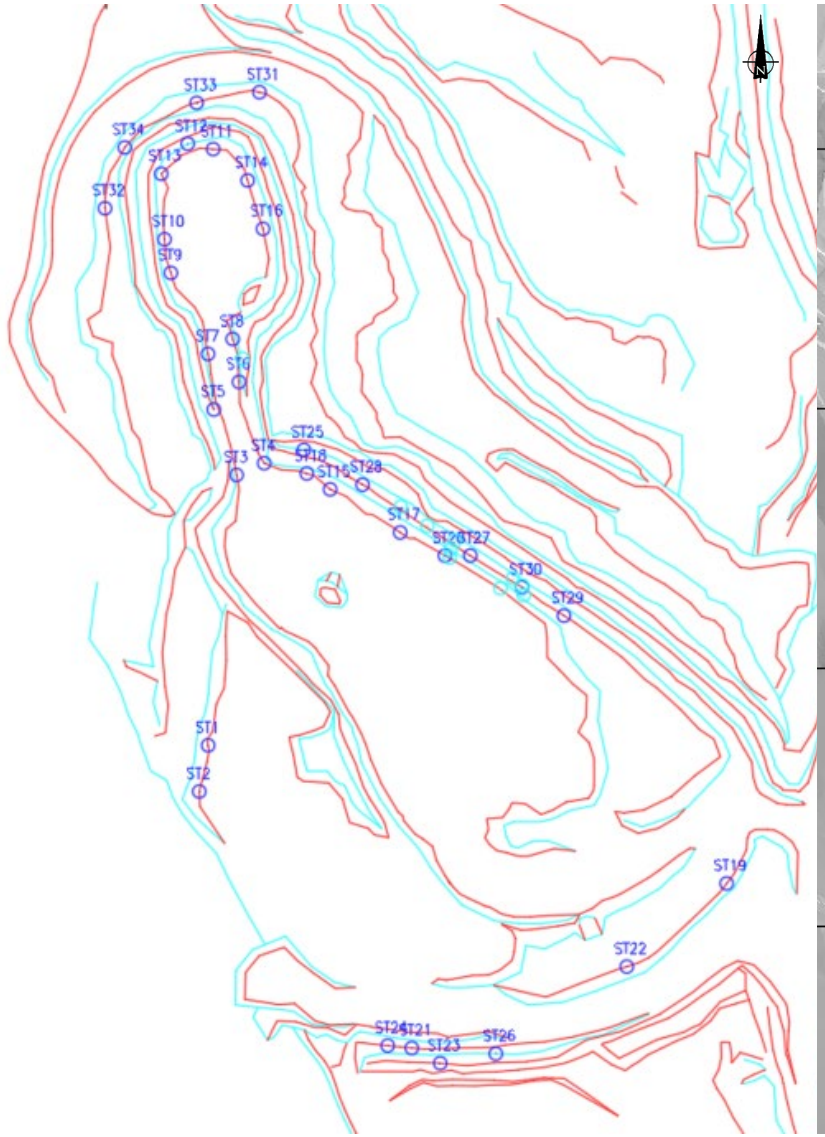
Single point mapping locations (no traverse length provided) and line mapping locations were estimated in Leapfrog.

Structural mapping data points (yellow) are shown in the insets.

Some point mapping locations included more than one measurement; they have been given the same coordinates.

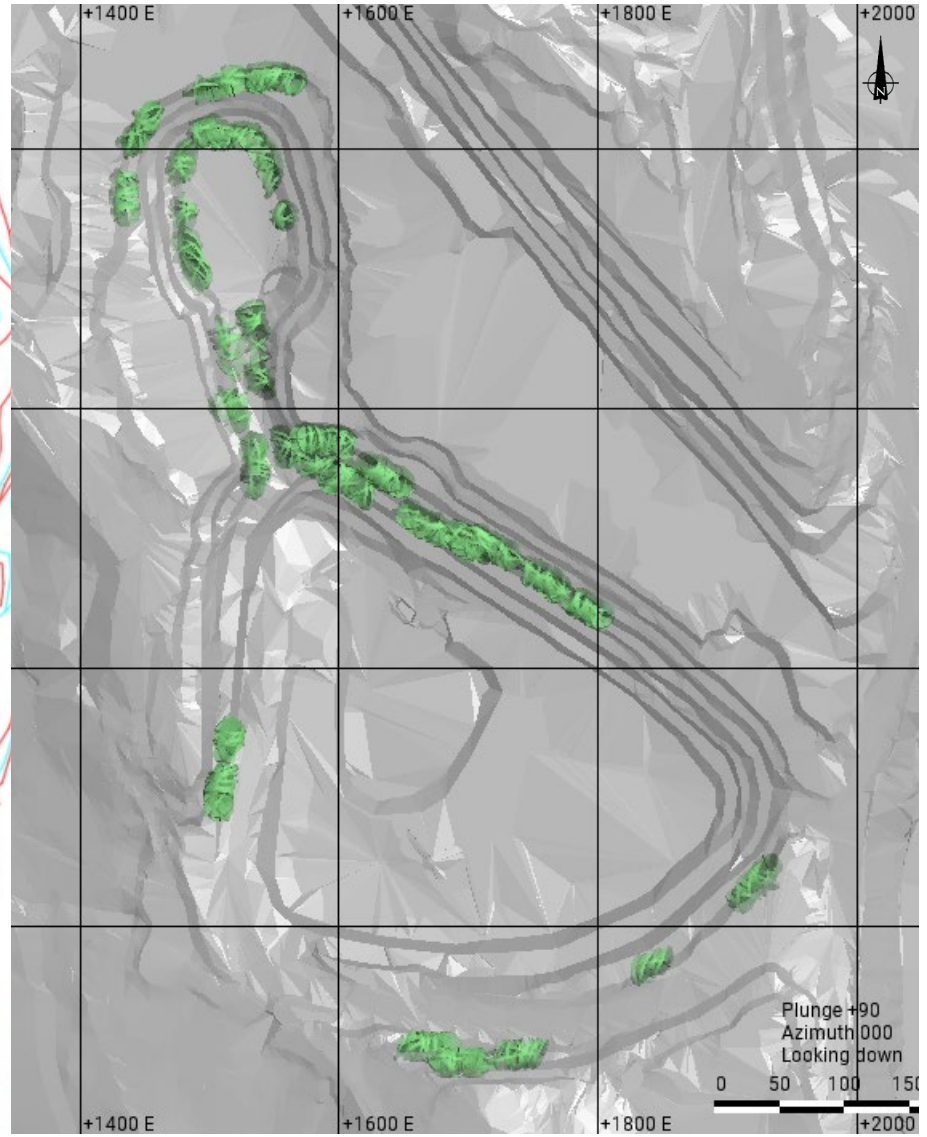
# 2009 Mapping Data

Coordinates for 2009 mapping data were estimated using the station locations on the following drawings:



- Figure 2 - 2009 Springer Pit and Mapping Stations.dwg

Field mapping sheets were used to obtain traverse lengths and distances along traverses for each measurement. The following assumptions were required to estimate these locations:

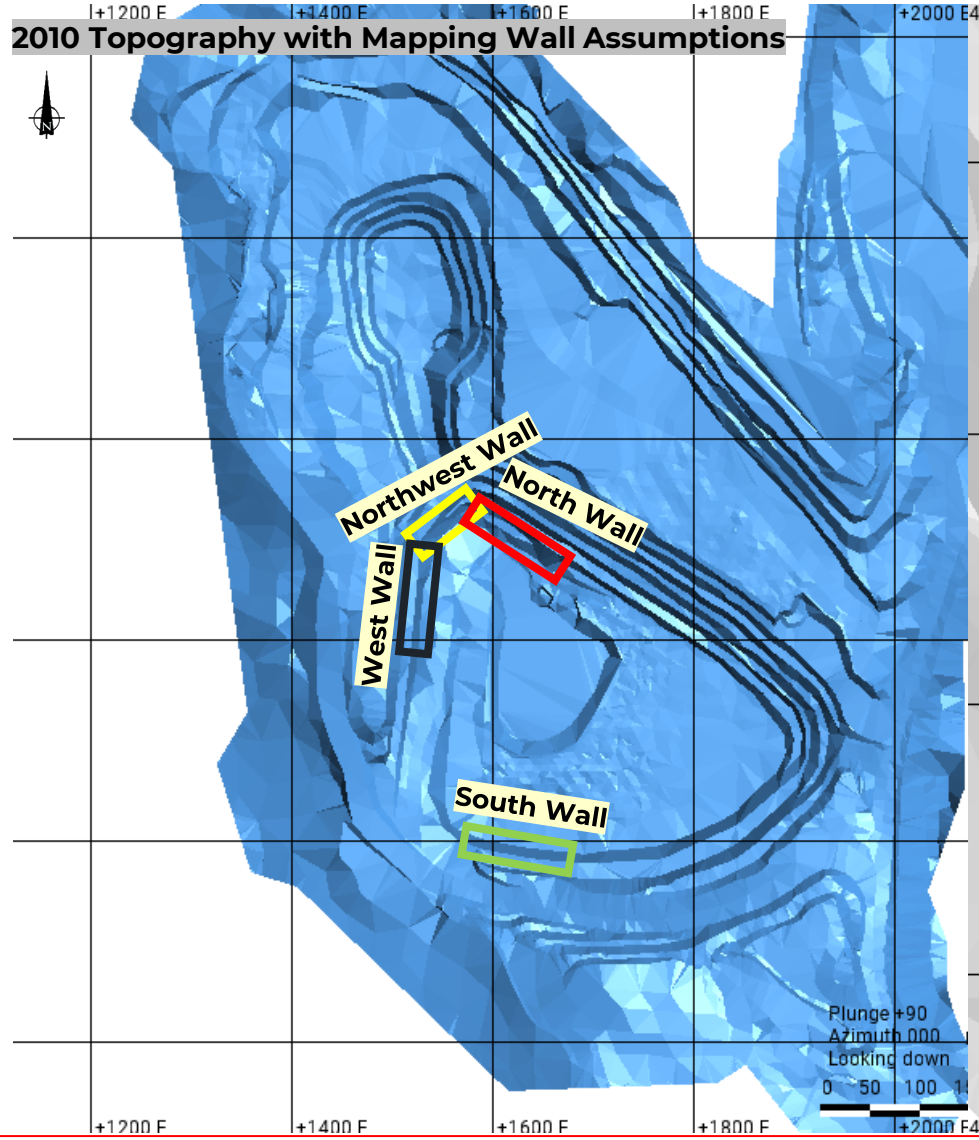


- The coordinate for the station was assumed to be the middle of the traverse
- The orientation of the traverse was estimated from the orientation of the bench at that location using the following open pit design:
    - topo_surface_clean.dxf from Aug 2012

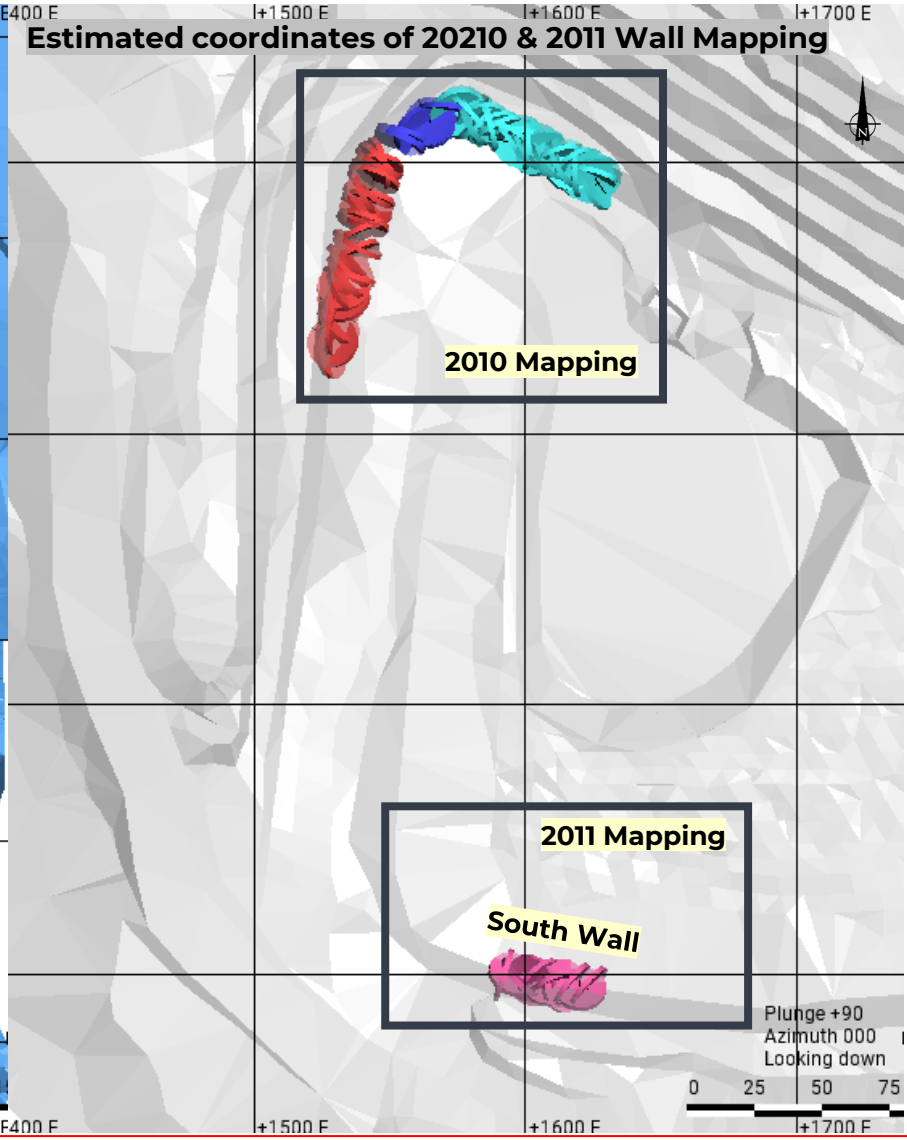
2009 structural mapping data is shown over the August 2012 topography at right.

**Figure 2 - 2009 Springer Pit and Mapping Stations**

**2009 Mapping on Aug 2012 topography**



# 2010 & 2011 Mapping Data



Coordinates for 2010 and 2011 mapping data were estimated using a topography surface from 2010:

- Surface Springer Bell Apr 2010.dxf

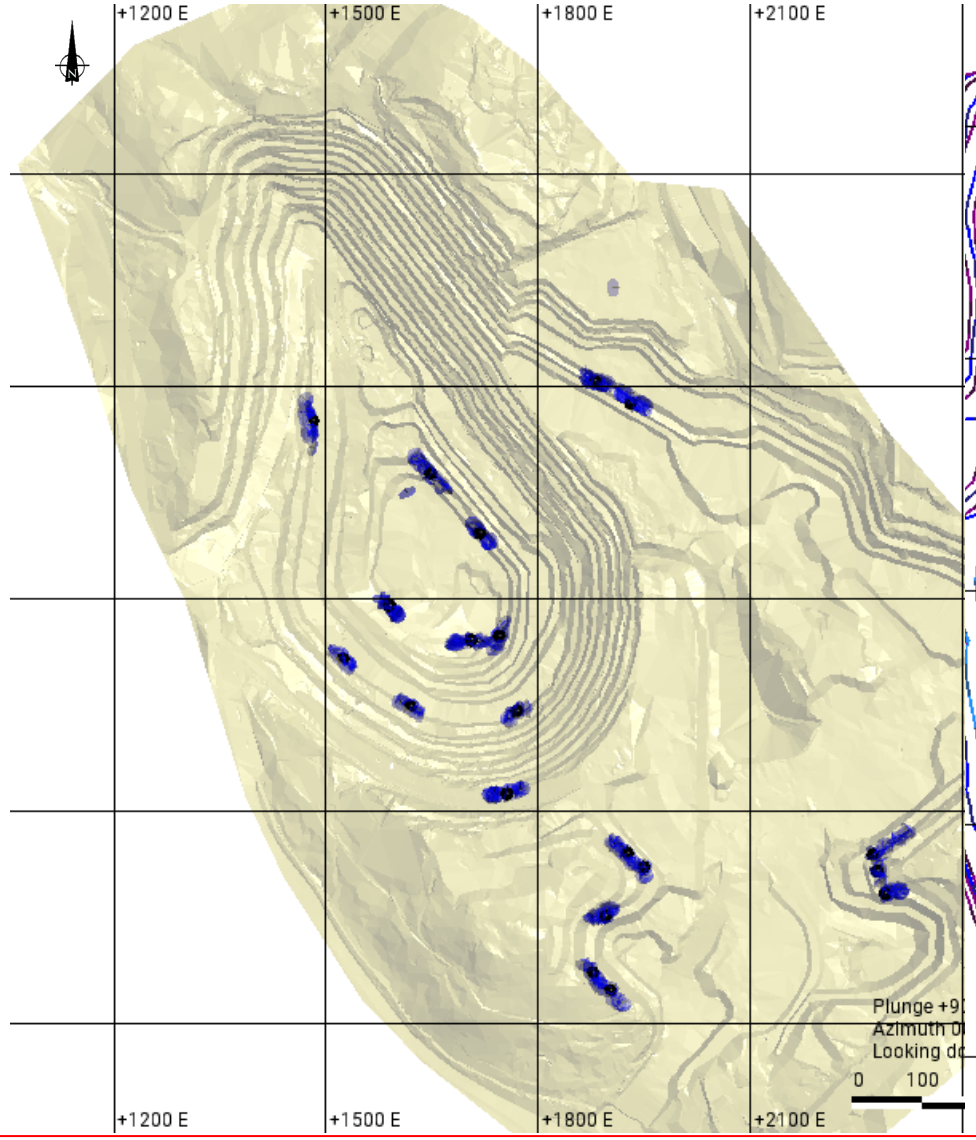
Wall locations were assigned to structures in the dataset, but no coordinates were provided for the traverses. Elevations were assigned based on the lowest operating bench at the time of mapping.

A total of 77 structural data points are included from the 2010 & 2011 mapping dataset.

# 2014 Mapping Data

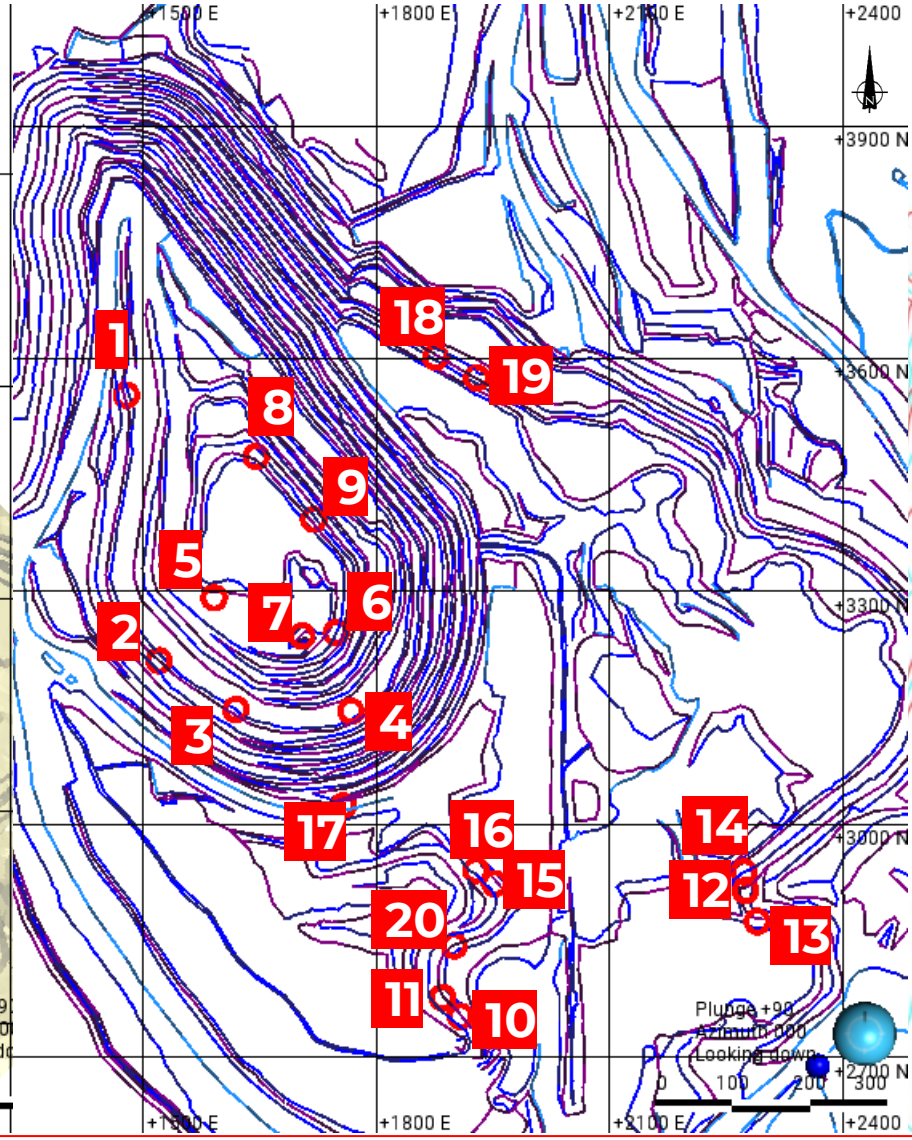
Coordinates for 2014 mapping data were estimated using station coordinates obtained from:

- Location of 2014 Mapping stations.dwg



Field mapping sheets contained traverse lengths and distances along traverses for each measurement. Traverse locations were not provided for every structure; coordinates for these structures were estimated.

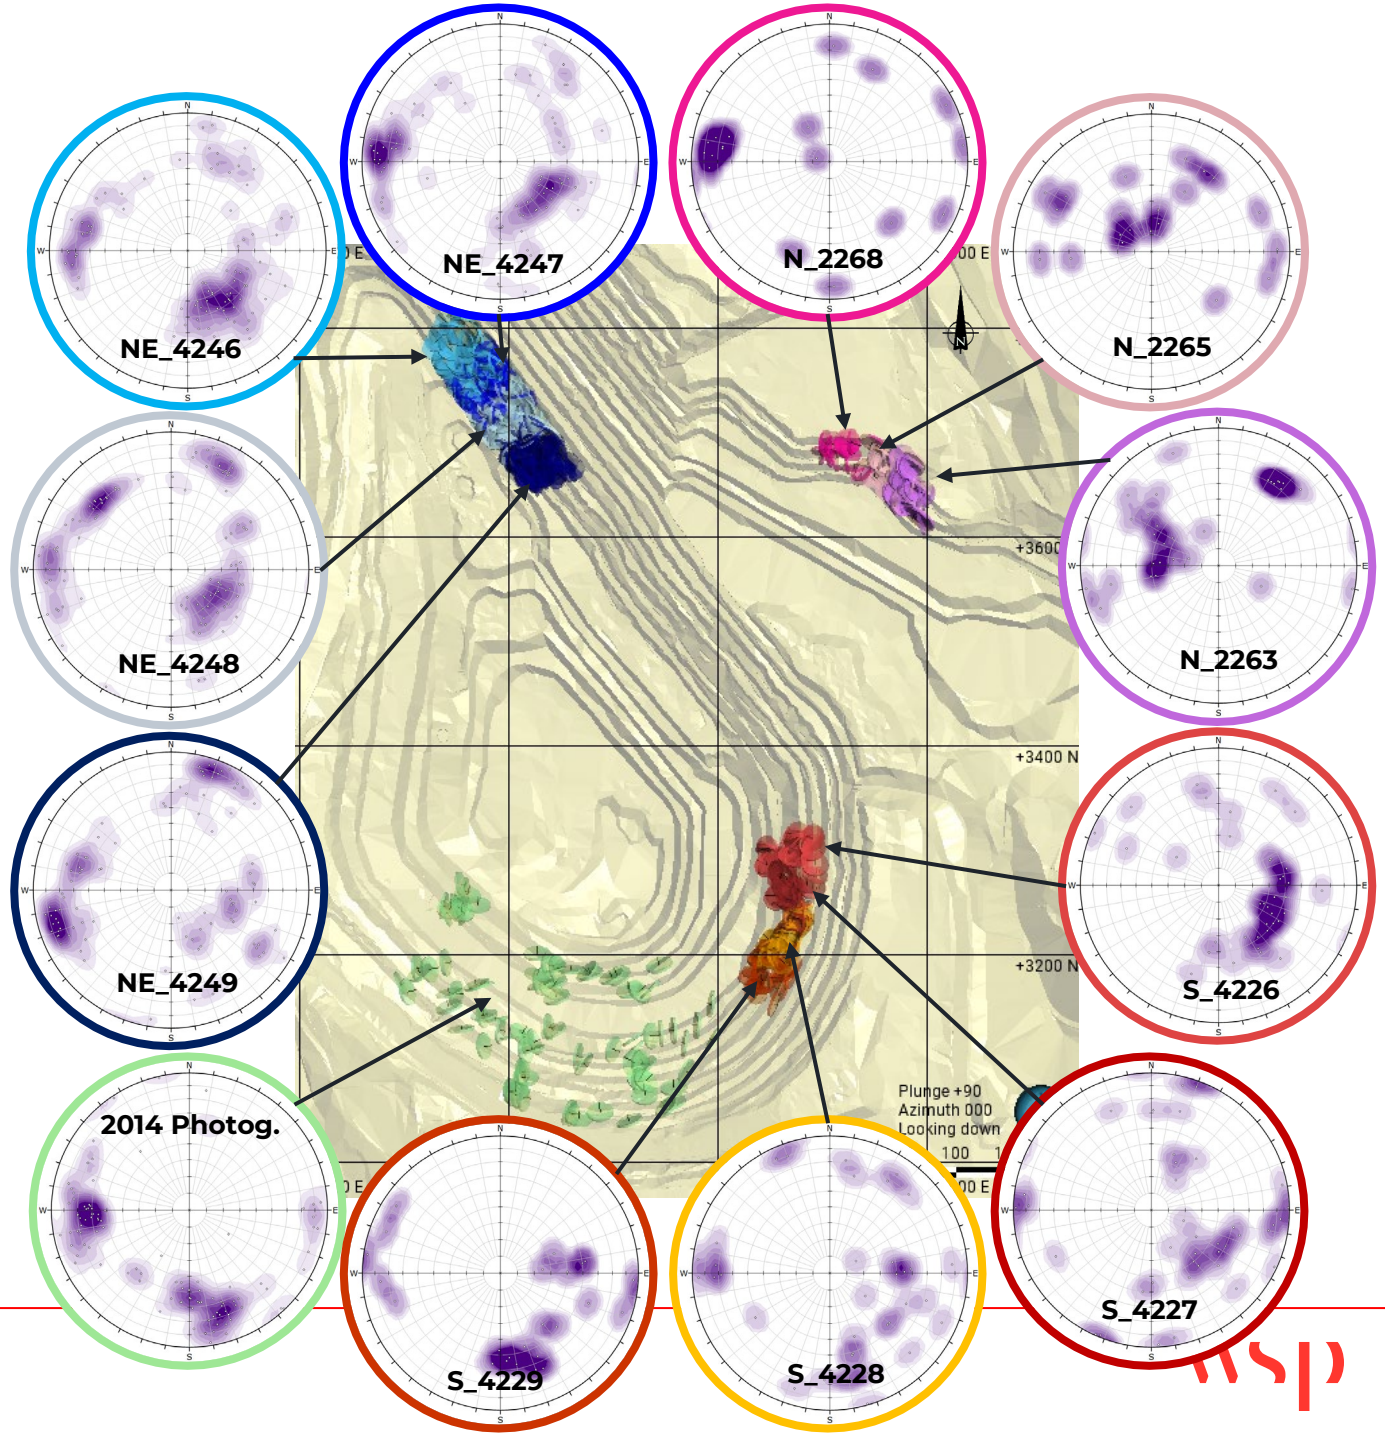
Assumptions were required to estimate locations as follows:



- The coordinate for the station was assumed to be the middle of the traverse
- The orientation of the traverse was estimated from the orientation of the bench at that location using the following pit design:
    - Fig 1 - Dec 31, 2015 Topo

The 2014 structural mapping data is shown over the December 2015 topography.

**2014 Mapping on Dec 2015 Topography Surface**

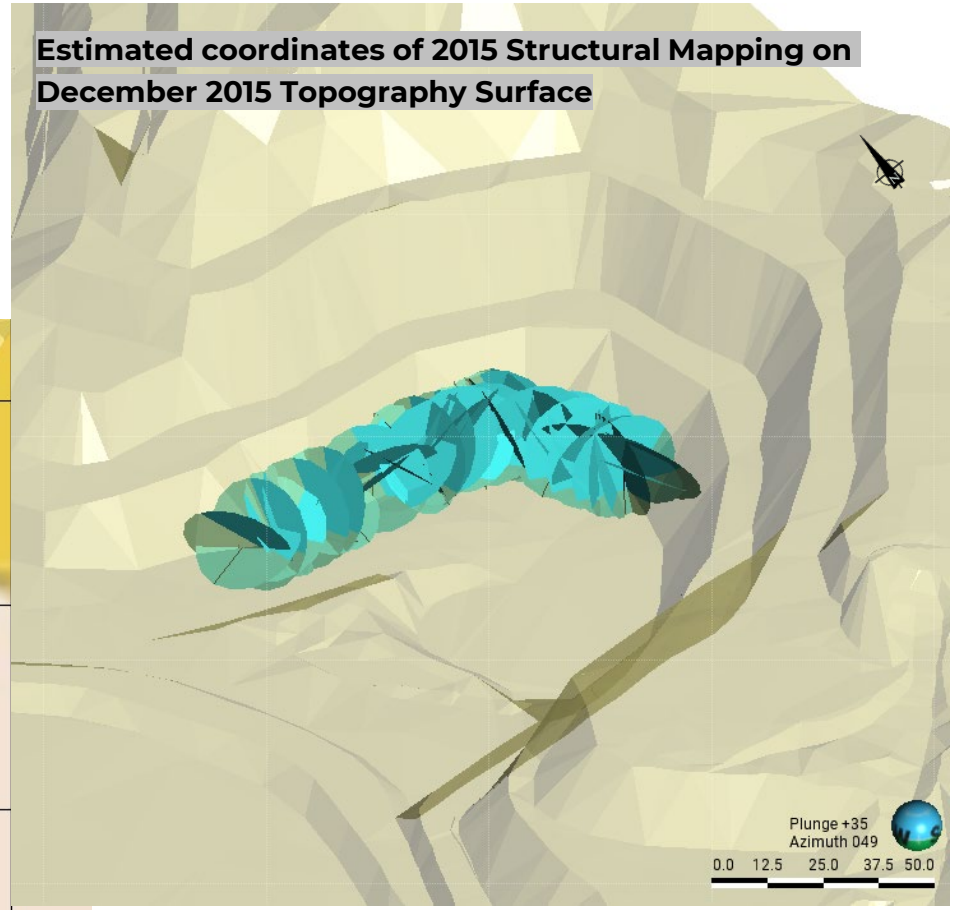


**Location of 2014 Mapping stations.dwg**

# 2014 Photogrammetry Data

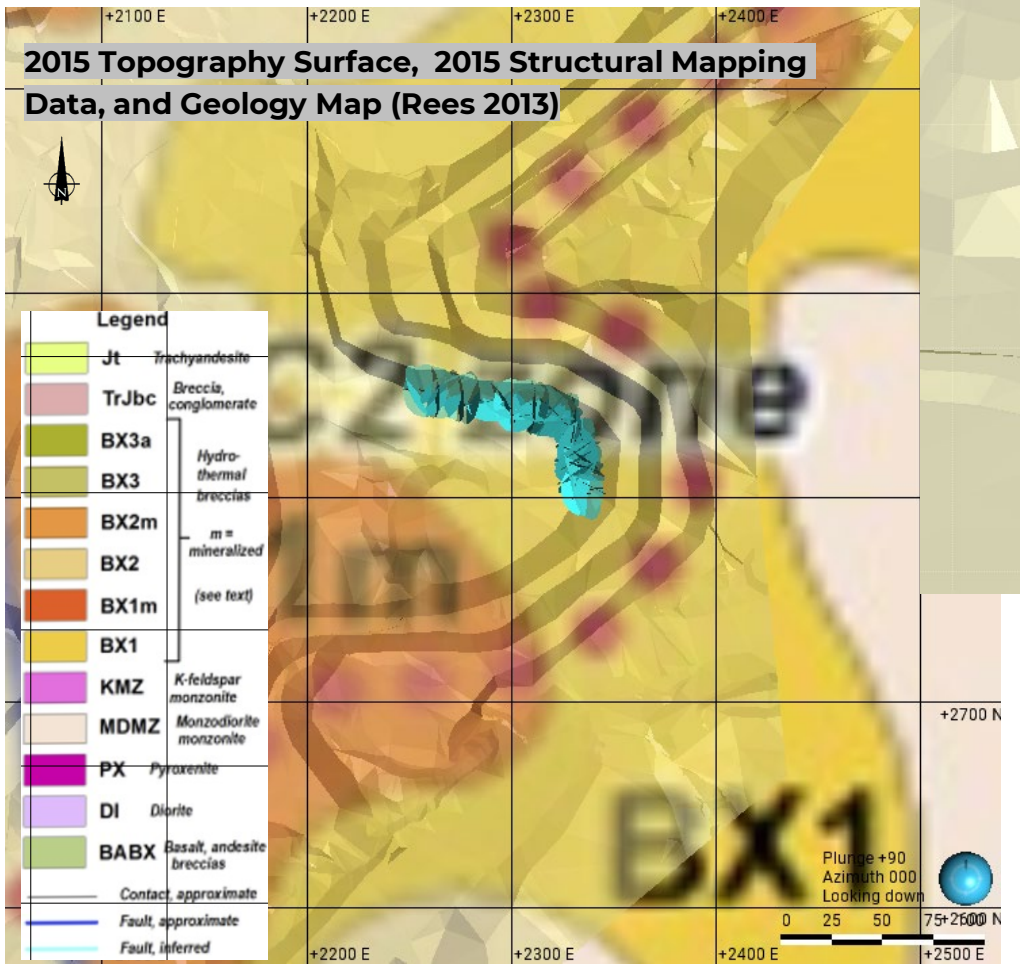
Photogrammetry was completed in 2014 by Golder for 12 locations around Springer Pit (shown with different colours on the figure). The south and northeast walls of the Springer Pit were mapped. The 2014 photogrammetry features are shown on the December 2015 topography surface.

**NOTE**: The data (522 points) labeled N_####, S_####, and NE_#### were assigned as 2012 data in the 2016 LOM review (Golder 2016). They have been corrected to 2014 data for the 2024 LOM review.



# 2015 C2 Mapping Data

Mapping data was collected by Golder in 2015 along the north, northeast, and east walls of C2 Pit.

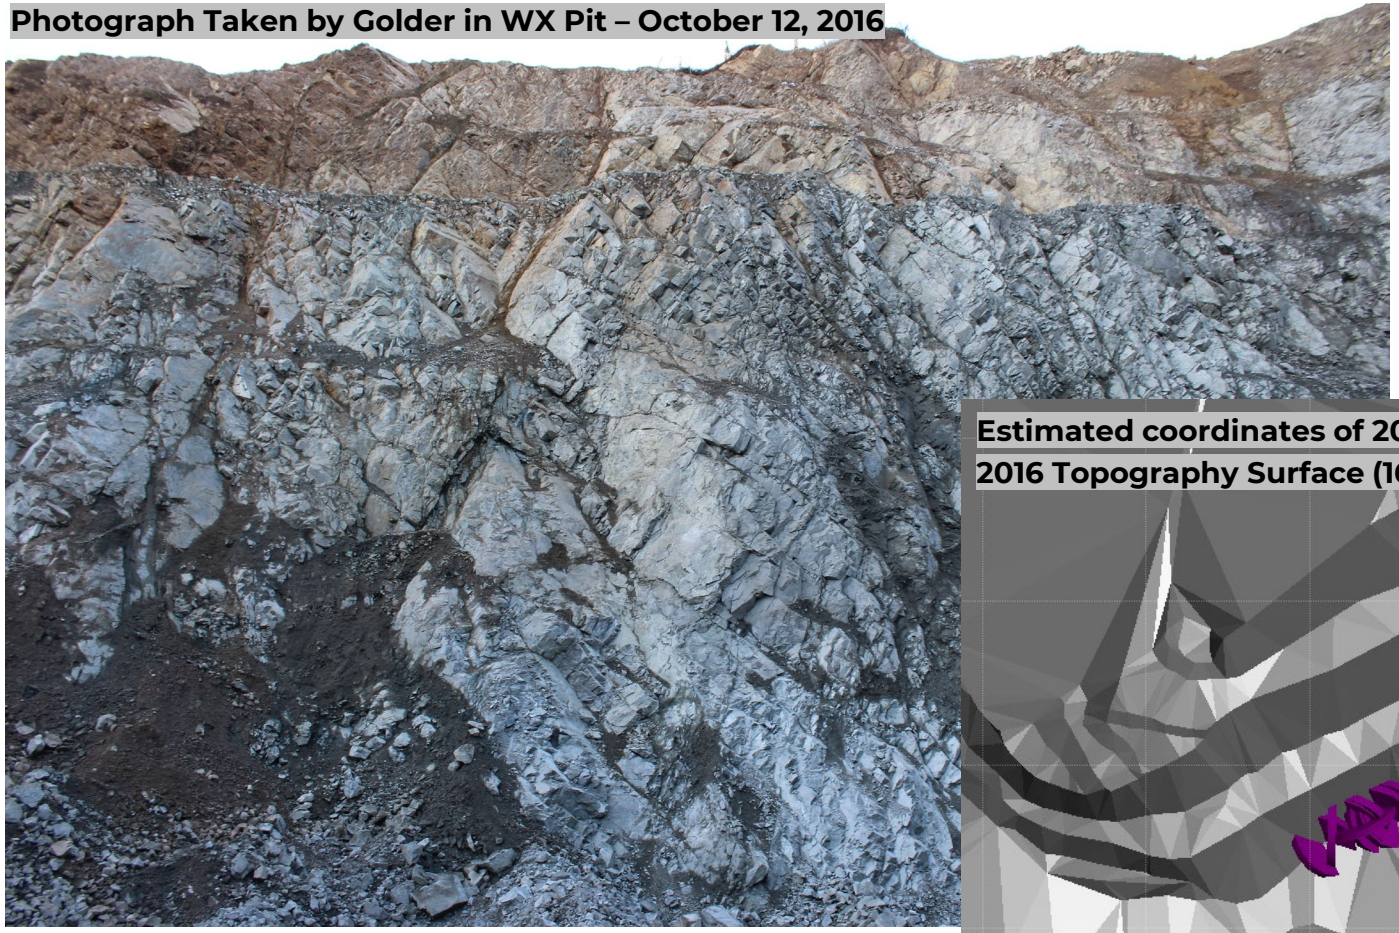


The location of mapping data was assigned to the bottom bench of the C2 Pit using the topography surface available for 2015.

Approximate locations of the 2015 structural mapping data is presented on the December 2015 topography surface and with geology map (Rees 2013).

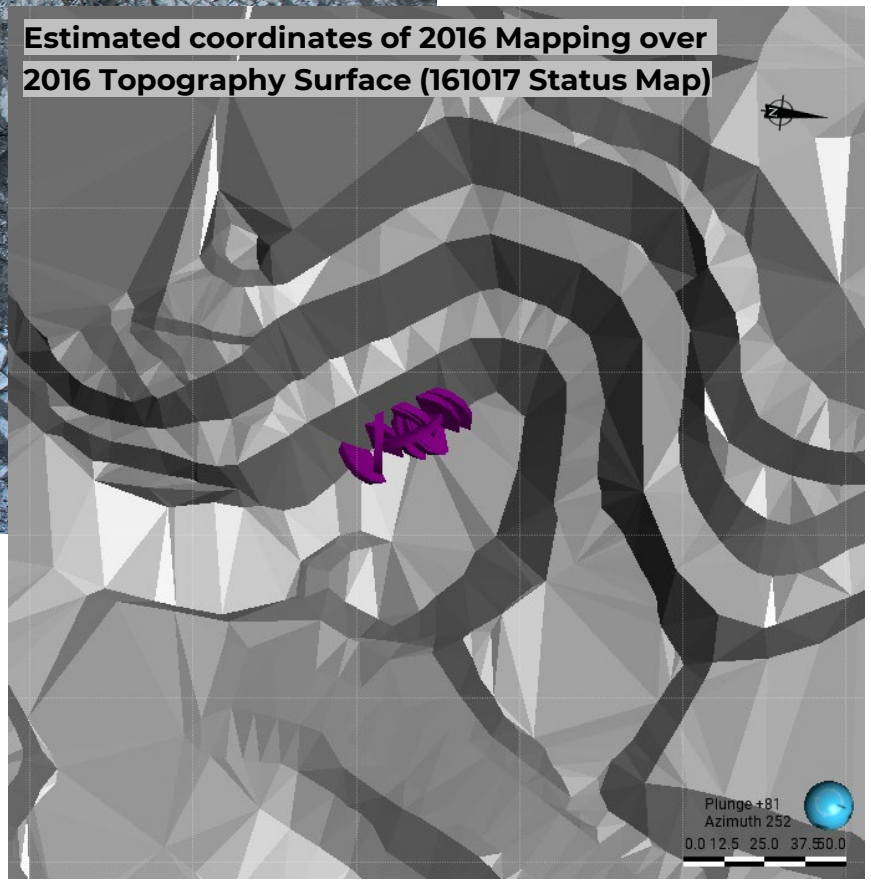
**Estimated coordinates of 2015 Structural Mapping on December 2015 Topography Surface**

**2015 Topography Surface, 2015 Structural Mapping Data, and Geology Map (Rees 2013)**



# 2016 Mapping Data

The 2016 mapping was conducted on October 12, 2016 by Golder. The measurements were taken on the south wall. The rock type was noted as monzonite with a field estimated intact rock strength of R3 to R4 (ISRM strength). The rock mass was also noted as fresh and dry.

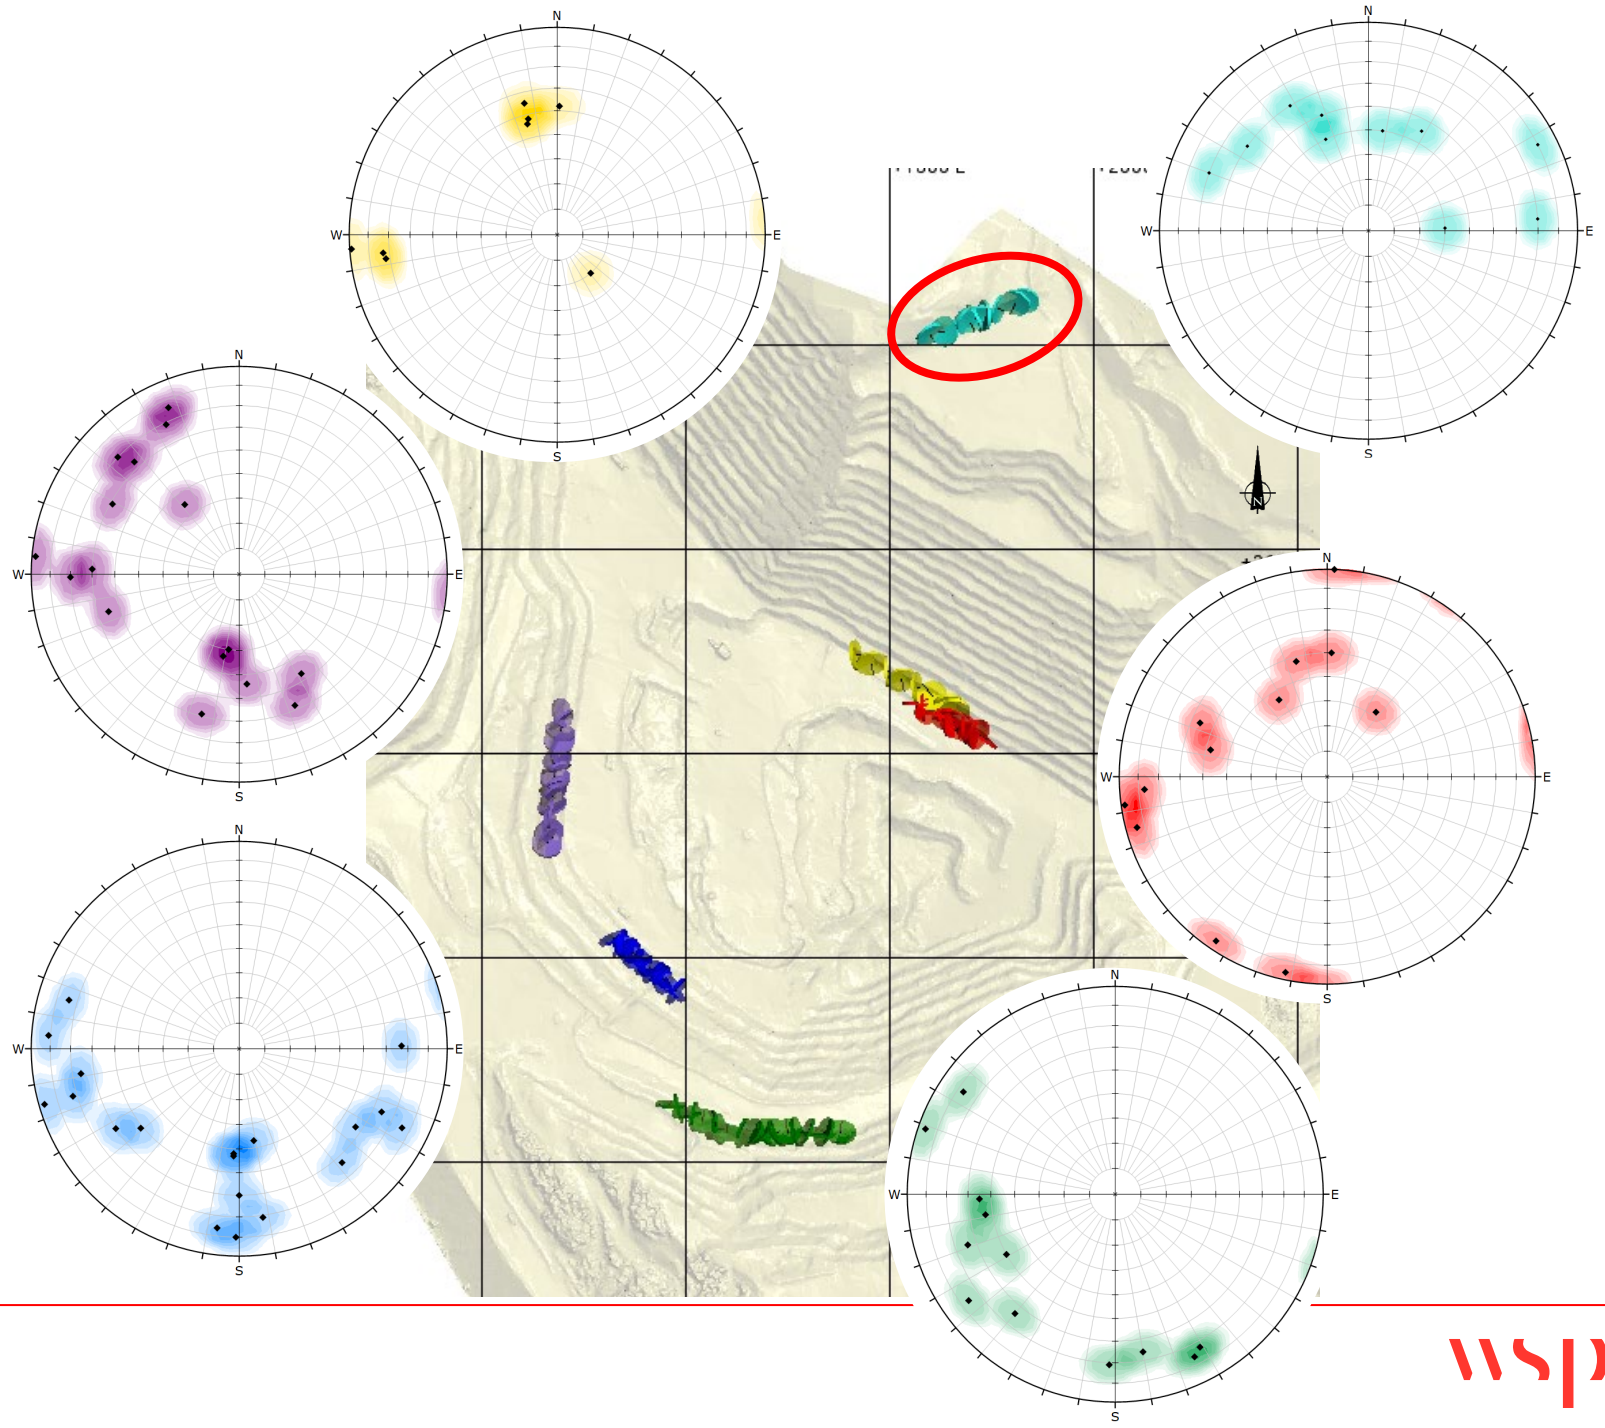


The coordinates of the mapping data were assigned to the bottom bench of the south wall in the WX Pit based on topography surface:

- 161017_mp_current_status_map.dxf

**Photograph Taken by Golder in WX Pit – October 12, 2016**

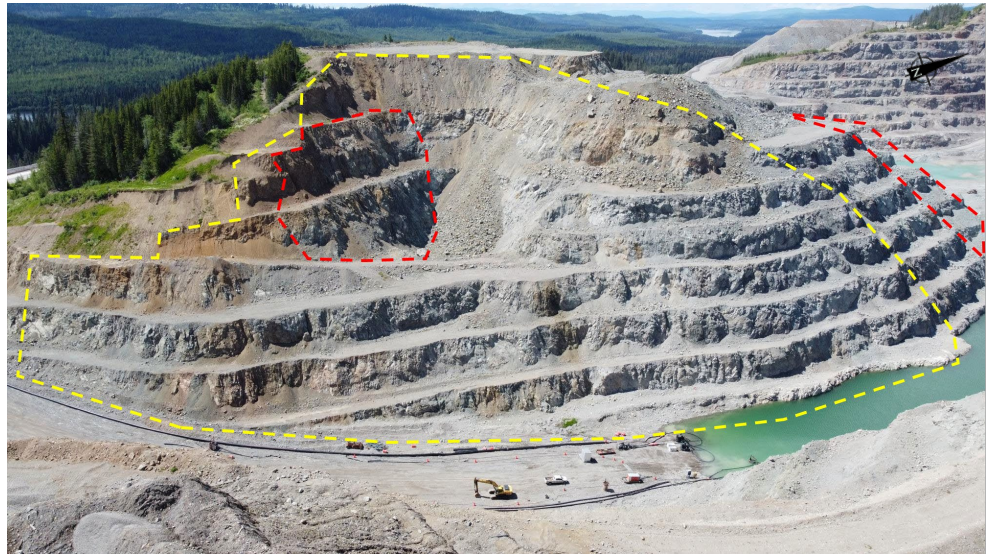
**Estimated coordinates of 2016 Mapping over 2016 Topography Surface (161017 Status Map)**



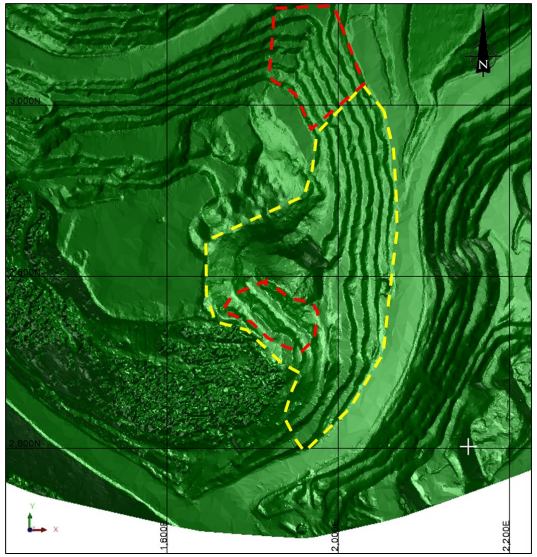
# 2023 Mapping Data

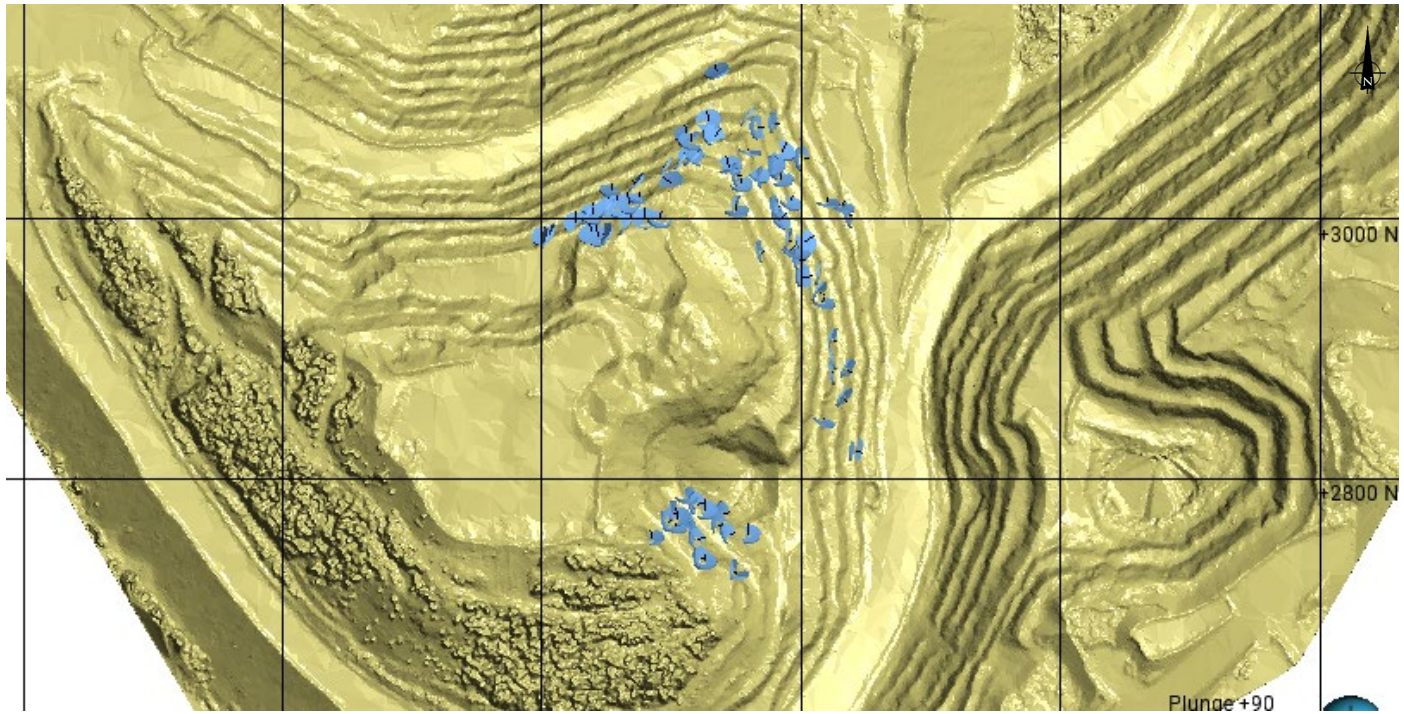
Mapping data collected by WSP during the September 2023 slope stability review. Approximate coordinates of structures estimated based on wall orientations and position along the traverse.

Approximate locations of the 2023 structural mapping data is presented on the October 2023 topography surface.



MPMC data collected in November 2023 is presented in **teal** in the red circle.

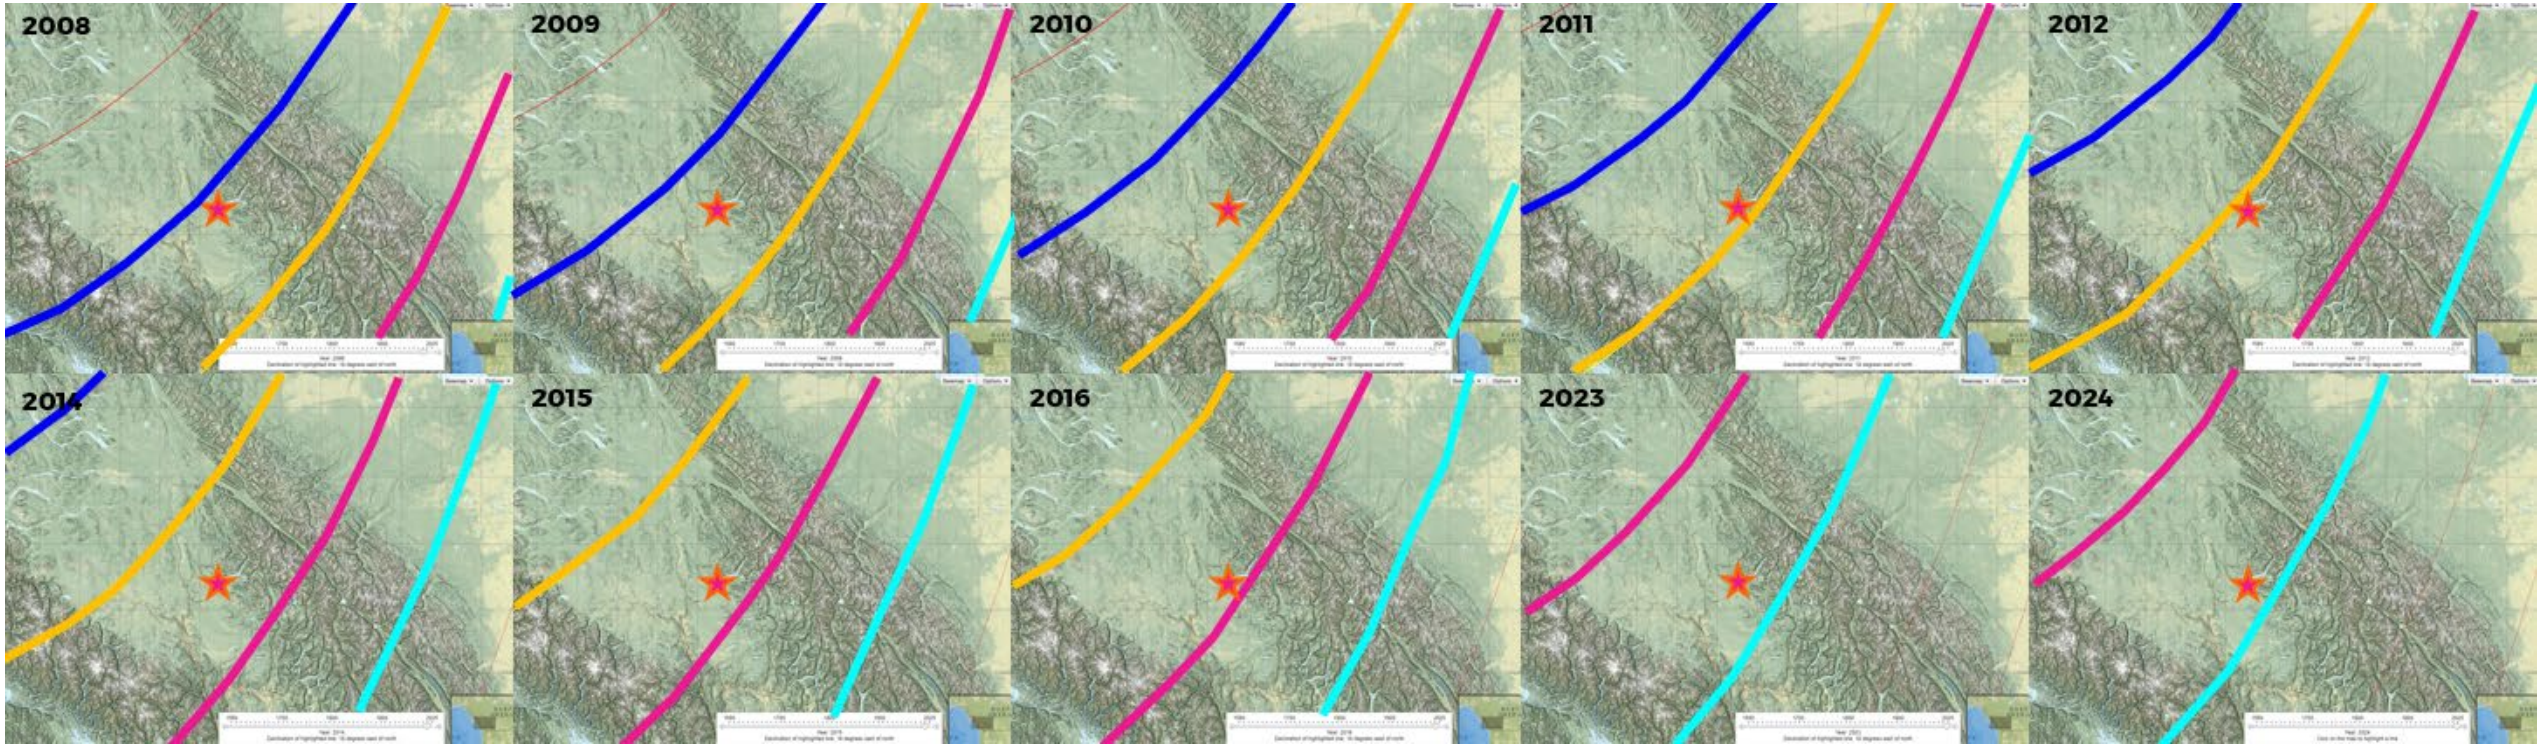




# 2024 Photogrammetry Data

Photogrammetry mapping completed within WX Pit, along Cariboo Ramp, and along the south wall of Springer Pit completed in January 2024. Structural orientations were picked using “230801-Full Pit_group1_densified_point_cloud” topographical surface scan provided by MPMC November 28, 2023.

A total of 94 structural mapping points were collected. Features picked are shown on the October 2023 topography in **blue**.



# Application of Magnetic Declination to Mapping Data

Magnetic declination was applied to the dip direction of mapped data based on the date they were collected. Magnetic declination was only applied to structural mapping data, not the televiewer or photogrammetry data.

The website Historical Declination Viewer (noaa.gov) was used to review the changes in declination with time.

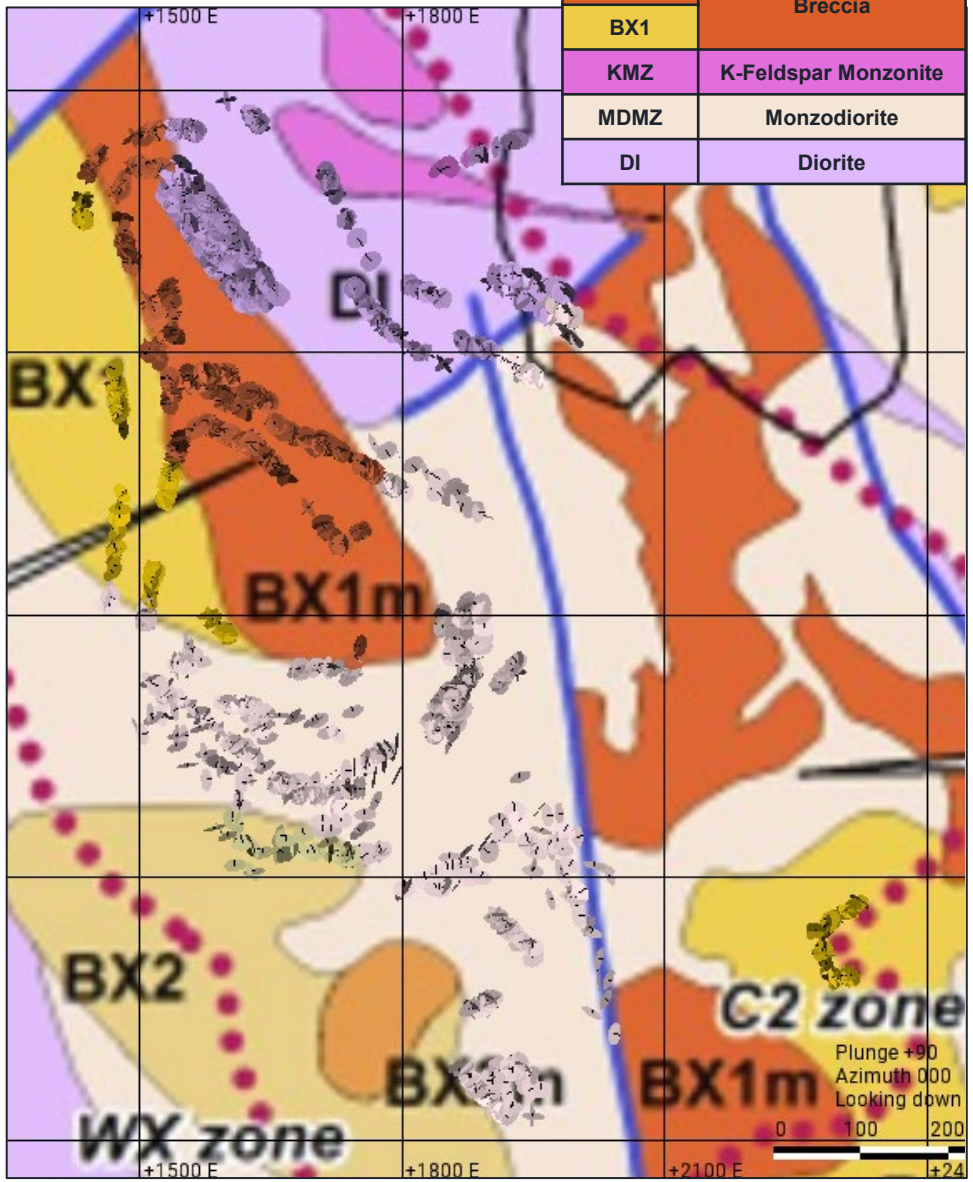
# All Structural Data Included in the 2024 LOM Review



*2006 ATV and 2008 to 2024 Mapping & Photogrammetry Data*

The geologic map (Rees 2013) was used to assign rock type to the mapping and photogrammetry data.

Note that rock type was assigned in plan view without taking changes in topography throughout the years into account. Consequently, these assigned rock types are approximate.

# Barton-Bandis

*Relationship for Strength Parameters*

Linear models of peak friction angle vs peak dilation angle indicate the following:

$$\tau = \sigma_n \tan(20 \log(\frac{\sigma_c}{\sigma_n}) + 30°)$$

$\sigma_c$ = unconfined compressive strength

$\sigma_n$ = effective normal strength

$\tau$ = peak shear strength

The generalized form of the equation above is shown below:

$$\tau = \sigma_n \tan(JRC \log(\frac{JCS}{\sigma_n}) + \varphi_b°)$$

$\varphi_b$ = residual shear strength

The *joint roughness coefficient* (JRC) represents a sliding scale of roughness which varies from approximately 20 to 0, from roughest to the smoothest end of the spectrum.

The *joint contact strength* (JCS) can replace $\sigma_c$ of the rock if the joint is unweathered but may reduce to approximately ¼ $\sigma_c$ if the joint walls are weathered.

*Rock Mass Classification: A Practical Approach in Civil Engineering*

| Relation Between Jr and JRCn Subscripts Refer to Block Size (cm) | | Jr | $JRC_{20}$ | $JRC_{100}$ |
|---|---|---|---|---|
| I | Rough | 4 | 20 | 11 |
| II | Smooth | 3 | 14 | 9 |
| III | Slickensided | 2 | 11 | 8 |
| | Stepped | | | |
| IV | Rough | 3 | 14 | 9 |
| V | Smooth | 2 | 11 | 8 |
| VI | Slickensided | 1.5 | 7 | 6 |
| | Undulating | | | |
| VII | Rough | 1.5 | 2.5 | 2.3 |
| VIII | Smooth | 1.0 | 1.5 | 0.9 |
| IX | Slickensided | 0.5 | 0.5 | 0.6 |
| | Planar | | | |

Figure 14.3: Suggested methods for the quantitative description of different classes of joints using $J_r$ and JRC. Subscript refer to block size in cms.

# Barton-Bandis

*JRC Workflow*

All completed mapping data collected from Mount Polley Mine were compiled and statistically reviewed for both shape and roughness, separated by continuity.

The tables below present a statistical summary of the discontinuous feature surfaces.

| Feature Shape | Count | Shape % of Total |
|---|---|---|
| Undulating | 532 | 59.0% |
| Curved | 58 | 6.5% |
| Planar | 270 | 29.9% |
| Stepped & Irregular | 41 | 4.5% |
| **Total Count** | **902** | **100.0%** |

| Feature Roughness | Count | Roughness % of Total |
|---|---|---|
| Smooth | 237 | 26.3% |
| Polished | 6 | 0.7% |
| Slickensided | 27 | 3.0% |
| Rough | 473 | 52.4% |
| Very Rough | 159 | 17.6% |
| **Total Count** | **902** | **100.0%** |

Combinations for feature roughness and shape were then reviewed together based on the quantitative description presented in the table on Figure C-29. JRC for 100 cm blocks were reviewed for both continuous and discontinuous feature surfaces. The table below presents a summary of the process for discontinuous and continuous features.

| Feature Combination | Discontinuous | | | Continuous | | |
|---|---|---|---|---|---|---|
| | Count | % of Total | Est. JRC 100cm block (Singh) | Count | % of Total | Est. JRC 100cm block (Singh) |
| Stepped & Irregular AND Rough or Very Rough | 35 | 4% | 11 | 2 | 1% | 11 |
| Undulating or Curved AND Rough or Very Rough, Smooth and Stepped | 474 | 53% | 9 | 128 | 36% | 9 |
| Undulating or Curved AND Smooth, or Stepped and Slickensided | 91 | 10% | 8 | 63 | 18% | 8 |
| Undulating or Curved AND Polished or Slickensided | 32 | 4% | 6 | 65 | 18% | 6 |
| Planar AND Rough or Very Rough | 129 | 14% | 2.3 | 45 | 13% | 2.3 |
| Planar AND Smooth | 140 | 16% | 0.9 | 43 | 12% | 0.9 |
| Planar AND Polished or Slickensided | 1 | 0% | 0.6 | 13 | 4% | *0.6* |
| **Count** | | | ***902*** | **Count** | | ***359*** |
| **Weighted Average JRC Values** | | | **6.65** | **Weighted Average** | | ***6.18*** |

# Barton-Bandis

*JCS Workflow*

Interval ISRM values logged for intervals in the exploration boreholes were compiled and averaged for each of the major lithologies. Where multiple ISRM values were recorded for one interval, the *minimum* value was selected.

| Lithology | Average ISRM Strength | Corresponding Strength Range (MPa) | Estimation of Unconfined Compressive Strength, $\sigma_c$ (MPa) |
|---|---|---|---|
| Monzodiorite | R3 | 25-50 | **50** |
| Diorite | R4 | 50-100 | **60** |
| Breccia | R3 | 25-50 | **50** |

Minimum UCS values from the corresponding interval ISRM range were averaged, providing an estimation of compressive strength for each of the major lithologies.

As features were not separated by lithology, an average compressive strength estimation for all lithologies was used for JCS calculations.

To account for minimal weathering on the features surfaces, the JCS was calculated as 75% of the average compressive strength estimation.

| Barton-Bandis Inputs into RSData | | Units |
|---|---|---|
| **Material Type** | Plastic | |
| **Assumed JRC Values (Continuous and Discontinuous)** | *6.18 and 6.65* | unitless |
| **Assume JCS to be 75% of intact rock strength** | 41.7 | MPa |
| **Slope Heights** | 48, 18, 12 | m |
| **Assumed Residual Friction Angle** | 20, 30 | degrees |
| **Unit Weight** | 26 | kN/m3 |

Discontinuous features typically affect bench-scale slopes, while continuous features extend over greater heights. For calculation of JRC values, 12 and 18 m high benches (one bench height and 1 ½ bench heights, respectively) were chosen for discontinuous features, and 48 m was chosen for continuous features.

As bench-scale features are typically opened by blasting and have less alteration, rough surfaces are assumed, and a 30-degree residual friction angle was used in calculations.

Continuous feature surfaces typically have more alteration or smoothing from movement, a residual friction angle of 20 degrees was used in calculations.

# Summary of Results

Results of the Barton-Bandis analysis using RSData are presented below.

| JCS 100cm | Assumed JCS @ 75% of UCS (MPa) | 41.7 |
|---|---|---|
| **DISCONTINUOUS FEATURES** | | |
| Discontinuous Fractures | Assumed JRC Value: | 6.65 |
| Assumed Residual Friction Angle (degrees) | Slope Height (m) | 12 | 18 |
| 30 | Cohesion (kPa) | 19 | 26 |
| | Friction Angle (degrees) | 42 | 41 |
| **CONTINUOUS FEATURES** | | |
| Continuous Fractures | Assumed JRC Value: | 6.18 |
| Assumed Residual Friction Angle (degrees) | Slope Height (m) | 48 |
| 20 | Cohesion (kPa) | 40 |
| | Friction Angle (degrees) | 28 |

For continuous features, 40 kPa cohesion and a friction angle of 28 degrees were selected for modeling.

A friction angle of 42 degrees was selected for discontinuous features. Due to the open nature of these features, a cohesion of 0 kPa was applied for modeling.

**APPENDIX D**

# Exploration Borehole Review

# Historical Exploration Boreholes

MPMC provided WSP with borehole logs from historical exploration campaigns in the mine area.

The data provided was used as provided. Minimal QAQC, such as removing duplicates and blanks, was completed.

The table below summarizes the data provided by MPMC for the 17 boreholes. Note that two boreholes, SD-07-22 and SD-04-16, had previously been provided for the 2016 Life of Mine assessment (Golder 2016).

| Borehole ID | Year | Geology Data Included? | Geotechnical* Data Included? | JCon Included? |

# Summary Table of Drilled Lithologic Units

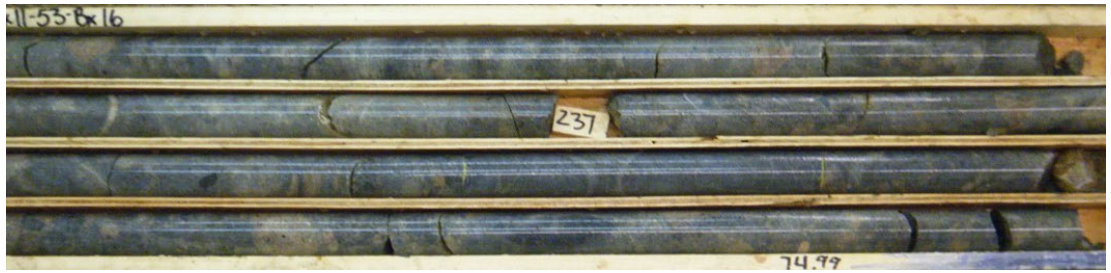
A database of 65 boreholes provided by MPMC was used in the review of rock mass ratings (RMR) for the 2016 LOM assessment (Golder 2016) (blue collars in image to the right). Seventeen additional holes were provided by MPMC in late 2023 and early 2024, and added to the database (red collars in image to the right). Note that two of the boreholes, SD-07-22 and SD-04-16, had previously been reviewed during the 2016 LOM assessment.

Lithological intersections and statistics are summarized below. Most of the lithology intervals logged were within the Breccia group (mineralization).

| Grouped Lithology | Total Meters Logged | % of Total Meterage |
|---|---|---|
| Breccia | 14,240.75 | 48.00% |
| Diorite | 1,489.58 | 5.02% |
| Monzodiorite | 8,831.77 | 29.77% |
| Dyke | 743.716 | 2.51% |
| Fault | 142.46 | 0.48% |
| Unknown | 4,126.54 | 13.91% |
| Other | 79.24 | 0.27% |
| Ignore | 15.38 | 0.05% |
| TOTAL | 29,669.43 | 100.00% |

# Lithology Examples

*Fragment Breccia, Polymictic Breccia, Intrusive Breccia*



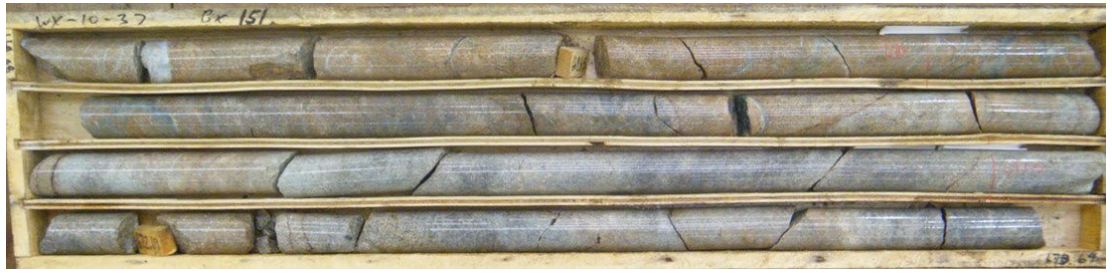
**Fragment Breccia, WX-10-37:** 319.71 m to 324.24 m

**Fragment Breccia, WX-10-14:** 64 m to 68.03 m

**Polymictic Breccia, WX-11-50:** 144.25 m to 148.62 m

**Polymictic Breccia, WX-11-53:** 70.57 m to 74.99 m

**Intrusive Breccia, WX-10-35:** 91.85m to 95.81 m



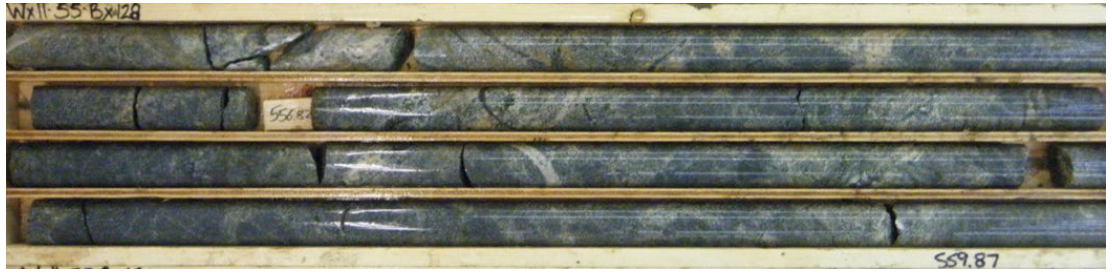
**Intrusive Breccia, WX-11-55:** 225.85m to 230.30 m

# Lithology Examples

*Monzonite, Brecciated Monzonite, Brecciated Monzodiorite*

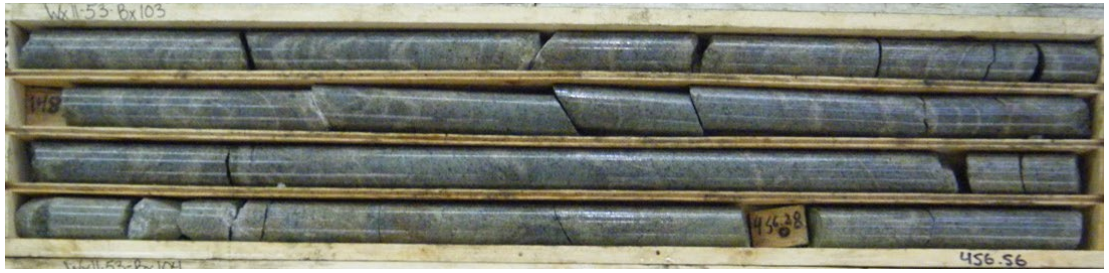
**Monzonite, WX-11-53:** 202.15 m to 206.67 m

**Monzonite, WX-10-37:** 669.08 m to 678.69 m



**Brecciated Monzonite, WX-10-16:** 419.23 m to 423.56 m

**Brecciated Monzonite, WX-10-14:** 79.95 m to 84.32 m

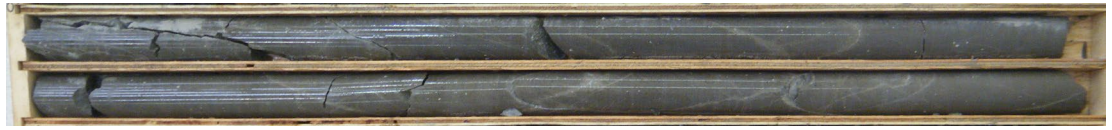


**Brecciated Monzodiorite, WX-11-49:** 79.22 m to 83.52 m

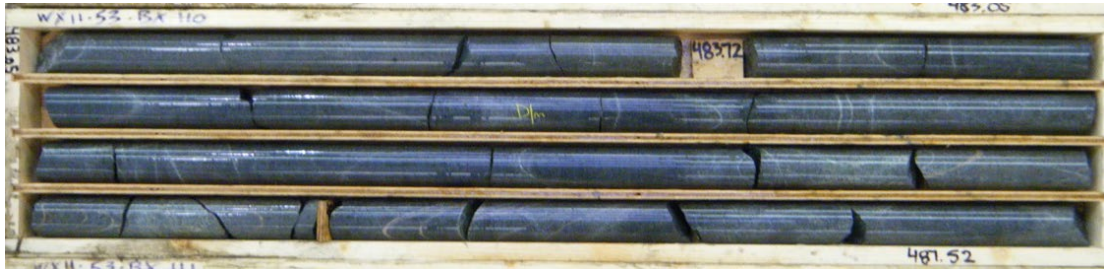
**Brecciated Monzodiorite, WX-11-55:** 555.53 m to 559.87 m

# Lithology Examples

*Monzodiorite, Monzonite Dyke, Diorite*



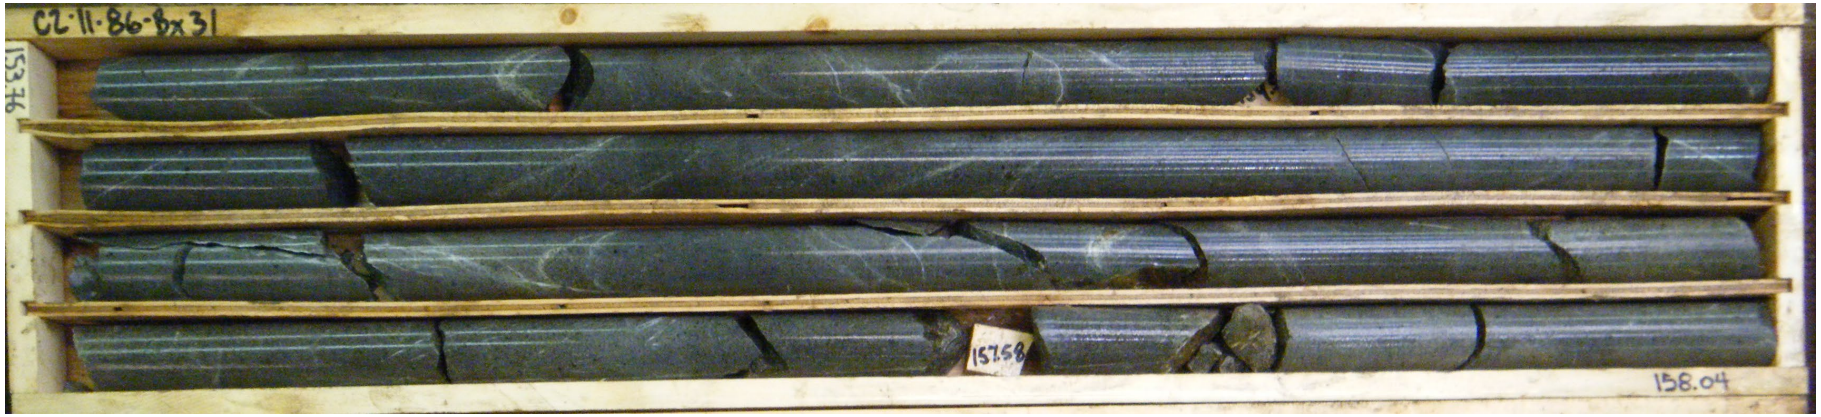
**Monzodiorite, WX-11-53:** 452.09 m to 456.56 m



**Monzodiorite, WX-11-53:** 452.09 m to 456.56 m

**Monzonite Dyke, WX-11-50:** 279.88 m to 282.90 m

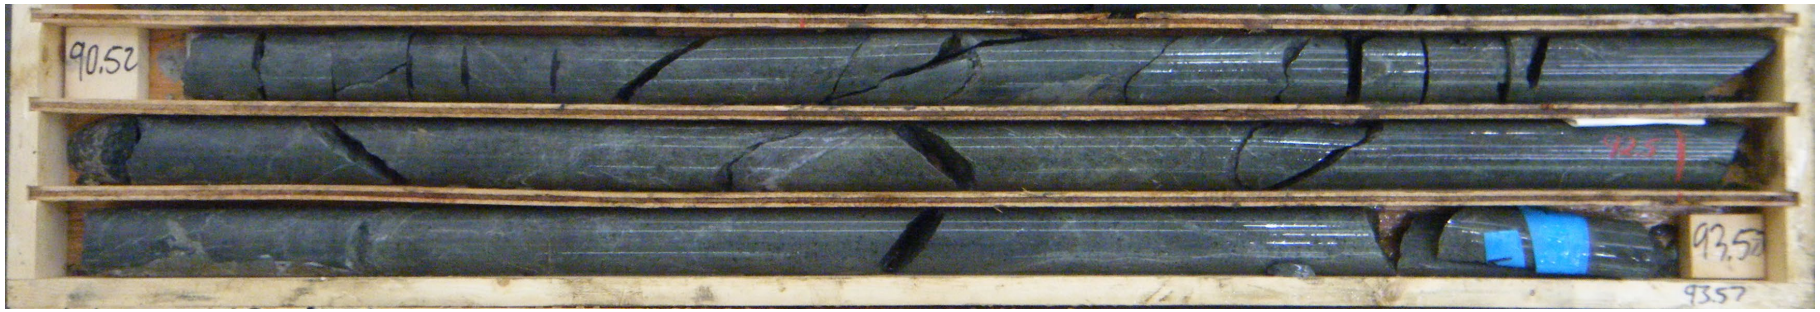
**Monzonite Dyke, WX-10-16:** 377.85 m to 380.08 m



**Diorite, WX-11-53:** 483.05 m to 487.52 m

**Diorite, WX-10-37:** 537.27 m to 541.63 m

# Typical Mafic Dyke



**C2-11-86:** 153.76 m to 158.04 m

**WX-11-49:** 173.79 m to 176.06 m

**WX-10-35:** 90.52 m to 93.57 m

# Typical Faults

**WX-11-55:** 342.41 m to 345.66 m

**WX-11-49:** 502.35 m to 504.26 m

**WX-10-35:** 146.10 m to 148.99 m

**APPENDIX F**

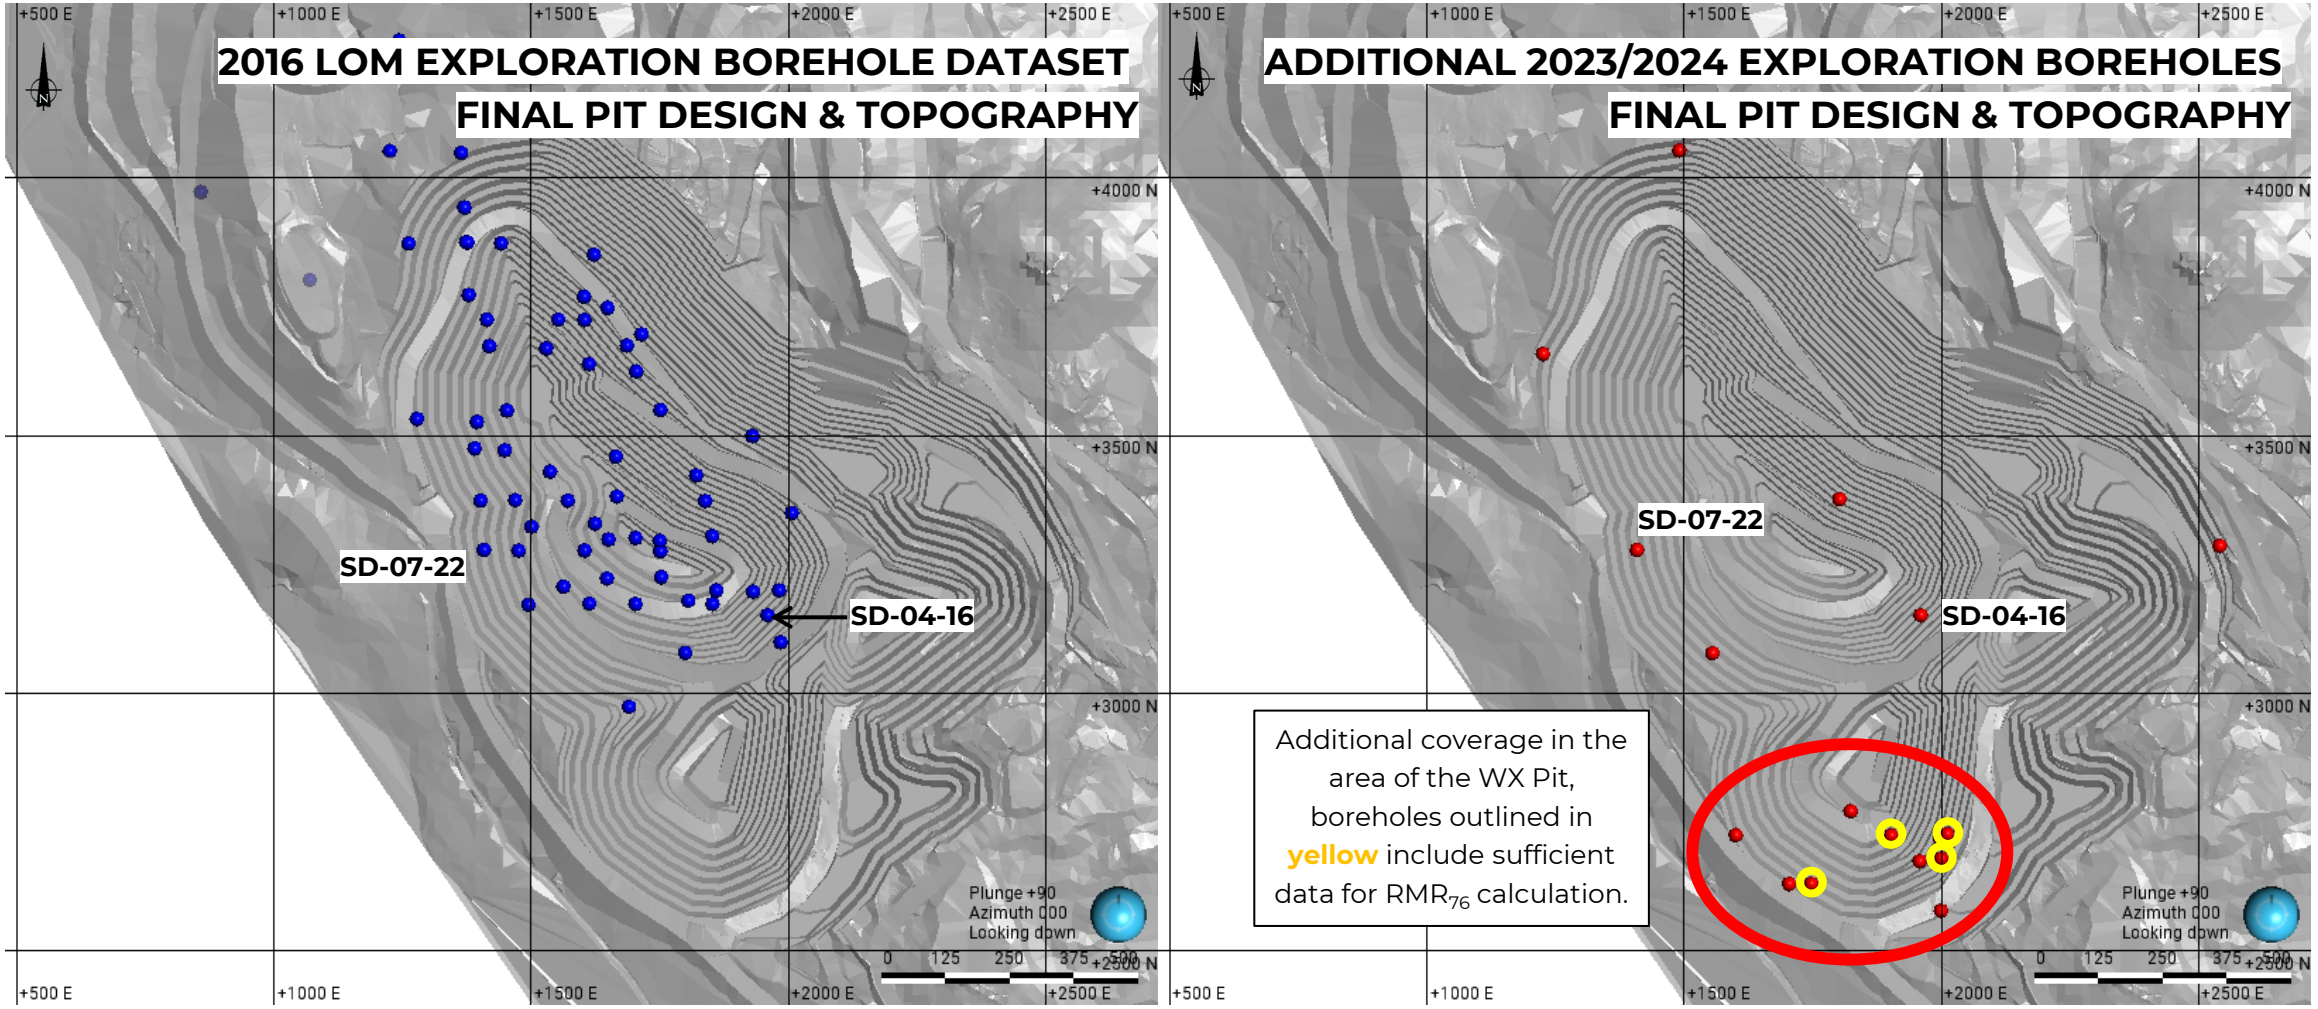
# Rock Quality and Strength Review

# $RMR_{76}$ Review Summary

A database, including 65 boreholes, provided by MPMC was used in the review of Rock Mass Rating ($RMR_{76}$) for the 2016 LOM assessment (Golder 2016). Seventeen additional holes were provided by MPMC in late 2023 and early 2024. Of the 17 boreholes provided, 15 boreholes were added to the overall database (two were the same as the 2016 LOM assessment database). Four of the new boreholes included enough information to calculate RMR.

Minimal QAQC was completed on the dataset, i.e., duplicates and blanks were removed.

This presentation summarizes the review of exploration borehole logging data used to calculate $RMR_{76}$.



A total of 69 borehole logs were used to review the following:

- Differences in geology and $RMR_{76}$ defined zones
- RMR of all lithology groups by length
- RMR of individual lithology groups by percent

Downhole plots of the exploration borehole logs  provided in late 2023 and early 2024 are presented in Appendix E.

# 2016 LOM Exploration Borehole Database vs. New 2024 LOM Exploration Boreholes Provided

*Plan Views*

# Comparison of Geotechnical and Geological Intervals

*Application of Geology to Geotechnical Units*

- Intervals logged geotechnically and geologically do not always match.
- Geological logging was completed at a higher level of detail, including smaller dykes and geological intervals less than 25 cm thick. Contacts were also more accurate than those recorded in the geotechnical logging.
- Intervals less than 25 cm thick are not considered in the $RMR_{76}$ calculation as there are no unique geotechnical parameters logged for them.
- There are slight differences in the depths of some lithologies.

**Geological Intervals**

# ISRM Strengths from Exploration Borehole Logs

*Minimum and Average Strength Values*

In some boreholes, there are instances where the geotechnical interval was assigned more than one ISRM value (see example below).

The lower value ISRM strength was selected and applied to each interval.

| BH ID | From (m) | To (m) | Length (m) | Lithology | Lithology Group | Recover (m) | Recovery - Length (m) | Percent Recovery (%) | Recovery > 100%? | RQD (m) | Percent RQD (%) | RQD > 100% ? | Fracters (per run) | Fractures (per run) corrected | Fracture Spacing (m) | Strength | empty | Alteraation | Comments | Fracture Condition | R0 | R1 | R2 |

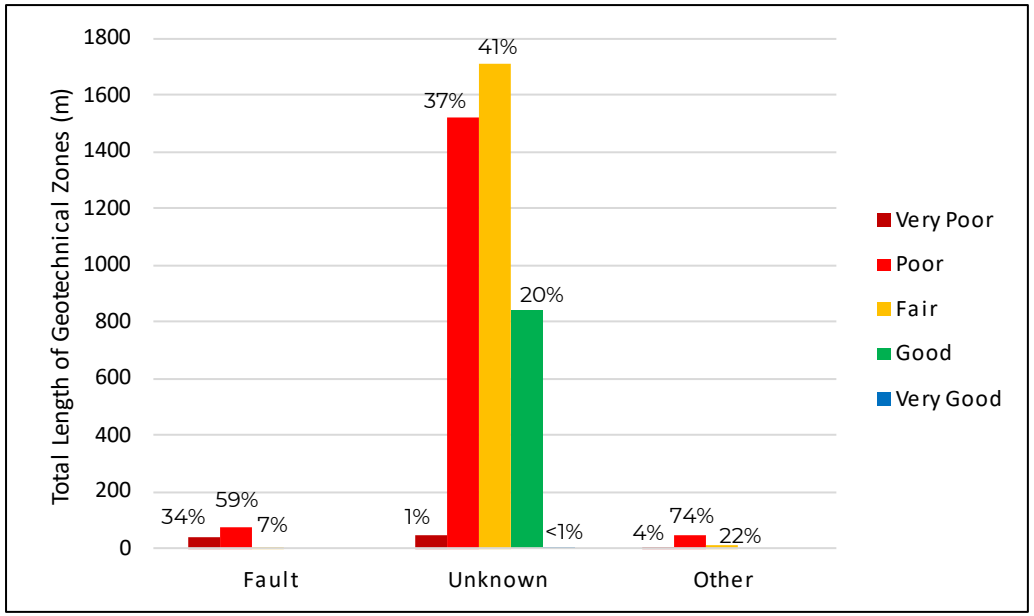
# Lithological Groupings



Lithologies logged within the exploration boreholes were grouped according the major lithologic units identified in the geologic map by Rees 2013.

| Description | Lithology Grouping (based on Rees 2013) | Description | Lithology Grouping (based on Rees 2013) |
|---|---|---|---|
| Breccia | **Breccia** | Diorite Dyke | **Dyke** |
| Magnetite Breccia | | Quartzite | |
| Volcanic Breccia | | Altered Diorite or Quartz Diorite | |
| Intrusive Breccia | | Monzodiorite Dyke | |

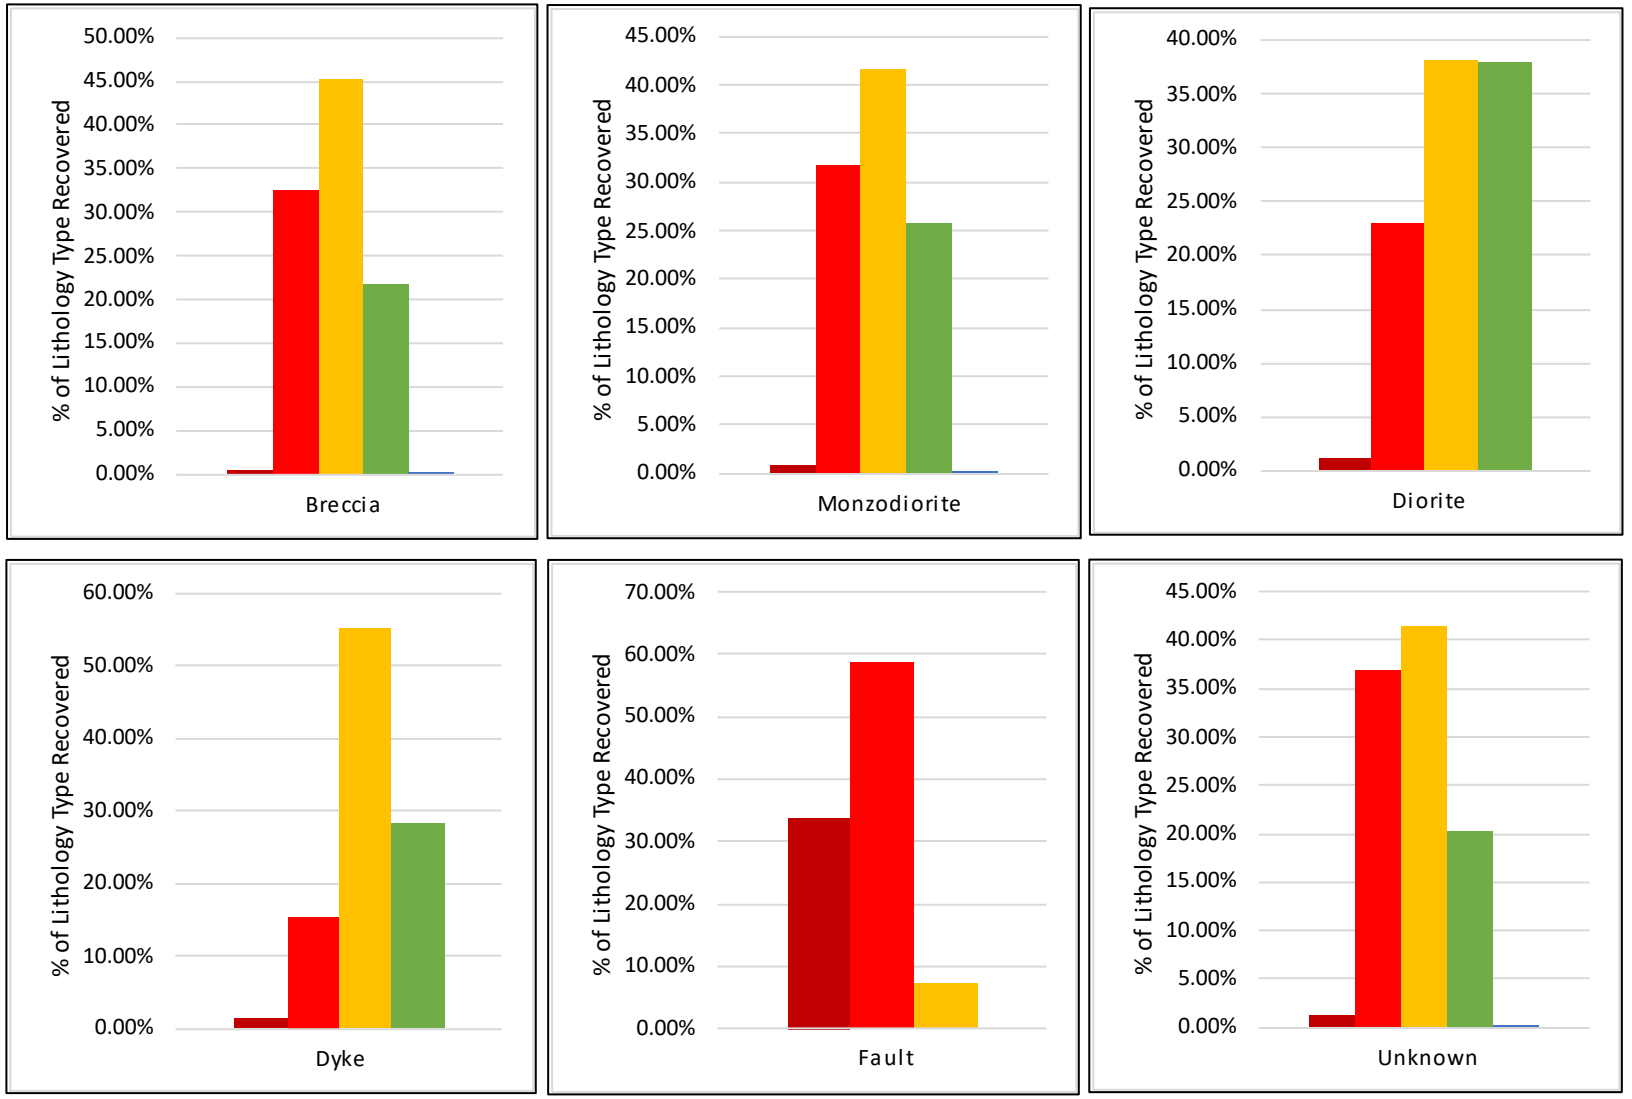
# Minimum $RMR_{76}$ Displayed by Total Length Logged

*Filtered by Lithology Group*



| $RMR_{76}$ Description and Corresponding Value Range |
|---|
| Very Poor Rock (0 - 20) |
| Poor Rock (21 – 40) |
| Fair Rock (41 – 60) |
| Good Rock (61 – 80) |
| Very Good Rock (81 – 100) |

# Minimum $RMR_{76}$ Displayed by Percent Lithology Recovered

*Shown by each Lithology Group*

Values using the minimum field estimate rock strength indicate that rock strength is Poor to Good quality.

# 2016 LOM vs. 2024 LOM Assessment of $RMR_{76}$

Overall, the $RMR_{76}$ values calculated using the updated dataset are similar to those calculated for the 2016 review (Golder 2016).

| Rock Group | Average RMR from Exploration Boreholes 2016 LOM | Average Minimum RMR 2024 LOM |
|---|---|---|
| Breccia | 55 (Fair Rock) | 49 (Fair Rock) |
| Diorite | 57 (Fair Rock) | 53 (Fair Rock) |
| Monzodiorite | 53 (Fair Rock) | 49 (Fair Rock) |
| Dykes | Not Reviewed | 53 (Fair Rock) |
| Faults | Not Reviewed | 24 (Poor Rock) |

The review and comparison of the $RMR_{76}$ assessment indicated the following.

- The Breccia group exhibits poor to good rock mass quality.
  - Although the average value calculated for Breccia was lower in the 2024 review, the rock group is still within the fair rock quality range.
- The Diorite rock exhibits fair and good rock mass quality.
  - Although the average value calculated for Diorite was lower in the 2024 review, the rock group is still within the fair rock quality range.
- The Monzodiorite group exhibits poor to good rock mass quality.
  - Although the average value calculated for Diorite was lower in the 2024 review, the rock group is still within the fair rock quality range.

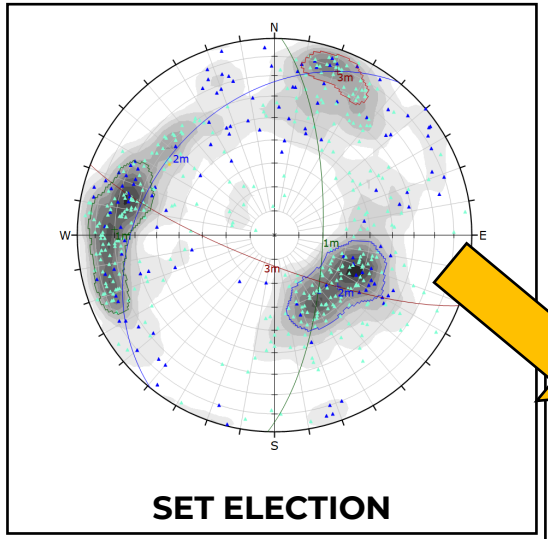
The results of the $RMR_{76}$ assessment indicate a similar distribution of $RMR_{76}$ values between the major rock groups, i.e., ranging between poor to good rock mass quality with fair rock quality being dominant. However, data from the Diorite and Dyke rocks indicate mostly fair to good quality, and therefore indicating a comparatively better rock mass quality. As expected, the faults exhibit poor rock quality.

**APPENDIX G**

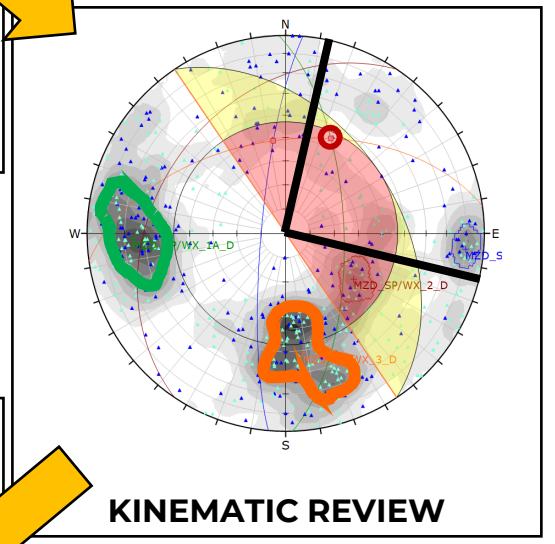
# Kinematic Analyses

# Presentation Summary

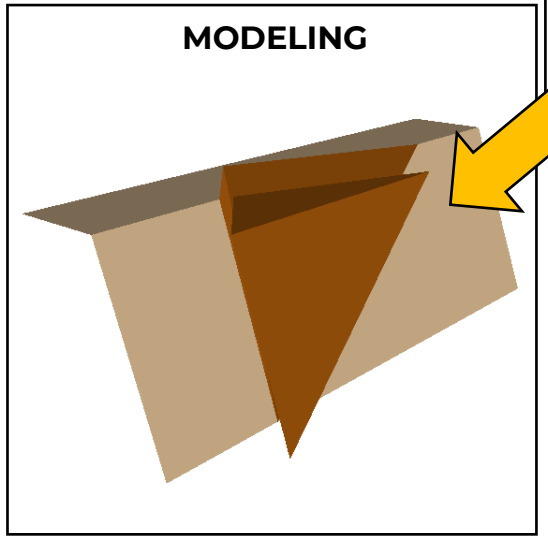
*Kinematics Workflow*



- Mapping data was compiled and flagged for feature scale (discontinuous versus continuous) and lithology.
- Sets were chosen using DIPS (RocScience) as presented in Appendix C.
- The DIPS software was then used to review the kinematic admissibility of planar, wedge, and toppling failure mechanisms for each of the lithology and wall orientation combinations.
- Admissible mechanisms were selected then modelled using RocScience's Swedge and RocPlane.
- As there are no available laboratory tests completed on structural features at Mount Polley Mine, the Barton-Bandis relationship for discontinuity strength was used based on the compiled mapping data from 2008, 2009, 2010, 2014, 2015, and 2023.
- Single and double bench configurations were reviewed for the proposed ultimate pit design.
- Modelling structural set names were assigned as follows:



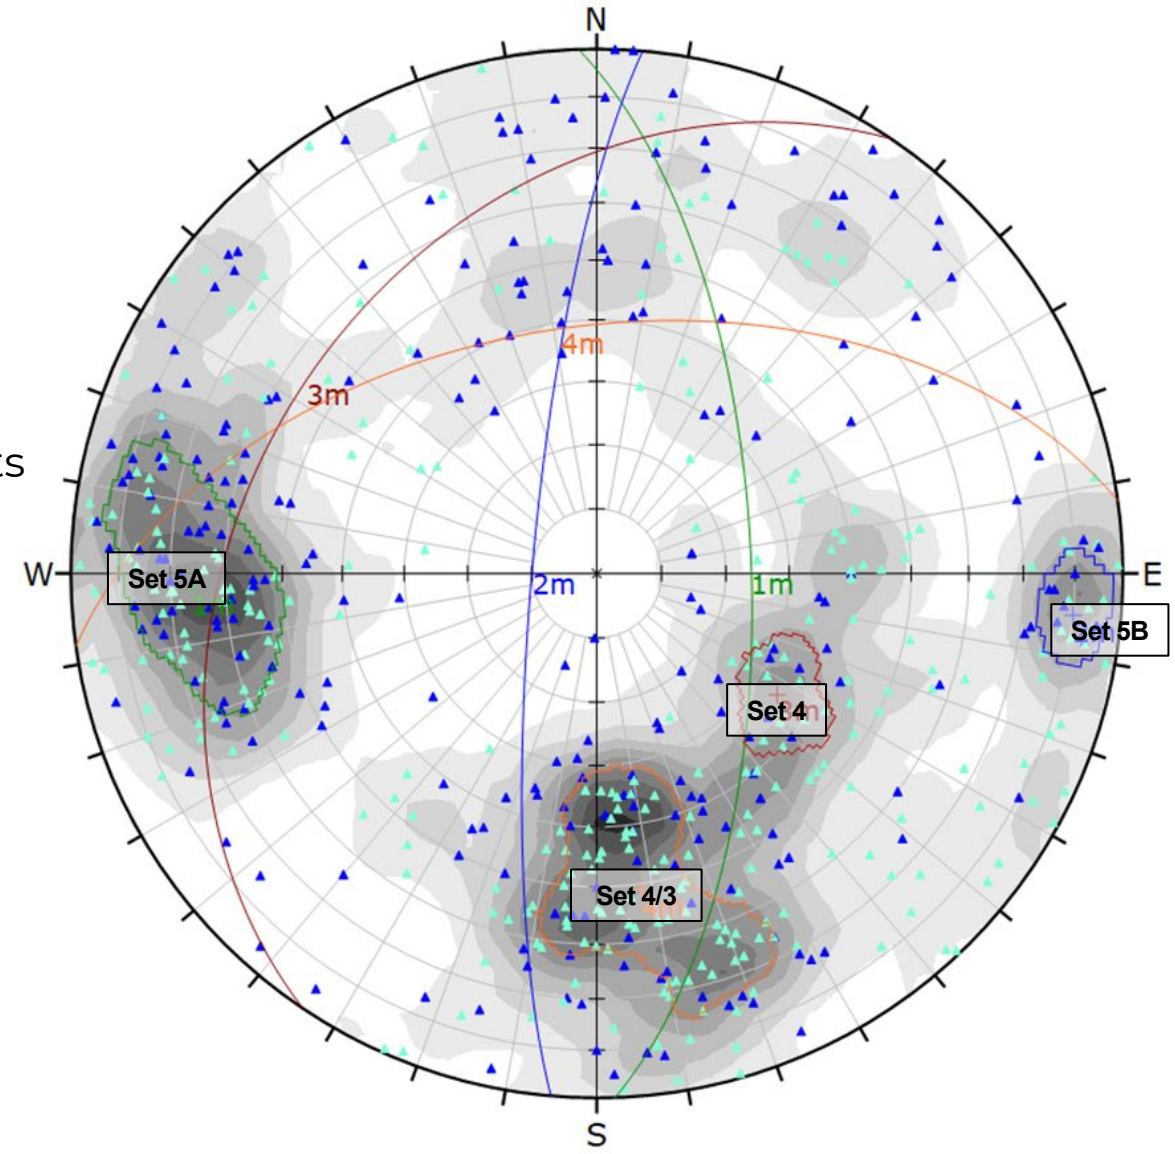
***Key:***



*Rock Type_Pit_Set Differentiator_Feature Scale (Discontinuous or Continuous)*

***Example:***

*MZD_SP/WX_1A_D*



# Springer & WX Pits

*Monzodiorite Discontinuous*

Discontinuous sets within the Monzodirite for the WX and Springer Pits are moderate to steeply dipping.

There are 4 wall orientations within the Springer and WX Pits that will be reviewed kinematically for these sets.

Based on the data available, planar, wedge, and toppling failures are possible.

# Springer Pit

*Diorite Discontinuous*

Discontinuous sets within the Diorite for the North Wall of Springer Pit have variable orientations.

Based on the data available, wedge failures are likely not of concern.

There is a steep southwest dipping set that may be of concern for planar and toppling failures.

# Springer Pit

*Diorite Continuous*

Continuous sets within the Diorite for the North Wall of Springer Pit are dipping into or oblique to the wall.

Based on the data available, planar failures are likely not of concern.

There is one wedge mechanism that may be of concern.

# Cariboo & C2 Pits

*Monzodiorite Discontinuous*

Discontinuous sets within the Monzodirite for the C2 and Cariboo Pits are steeply dipping.

There are 3 wall orientations within the C2 and Cariboo Pits that will be reviewed kinematically for these sets.

Based on the data available, wedge & planar mechanisms are not likely to be problematic. Toppling failures may be possible for the 320-degree wall direction.

# Kinematic Analyses

*Model Inputs*

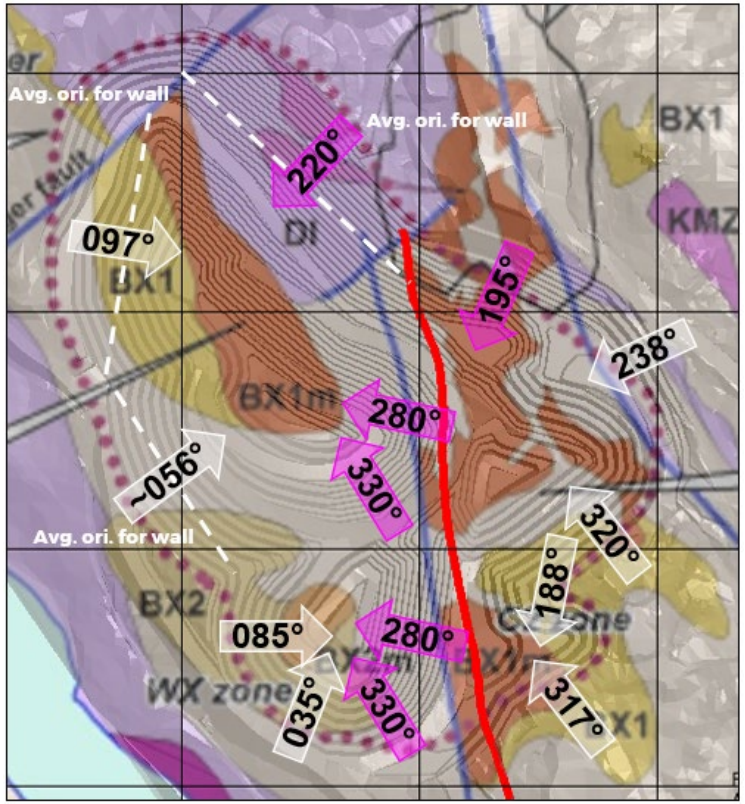
Rocscience SWedge, RocPlane, and RocTopple were used for probabilistic kinematic analysis.

Model inputs are summarized in the tables at right.

Unit weight, bench widths, and bench heights were used from the 2016 LOM assessment and proposed ultimate pit design provided by MPMC.

As a conservative approach, small (ubiquitous) spacing was used for all features.

As it is expected that pore water pressures will dissipate at the bench-scale, all models were analyzed under dry conditions.



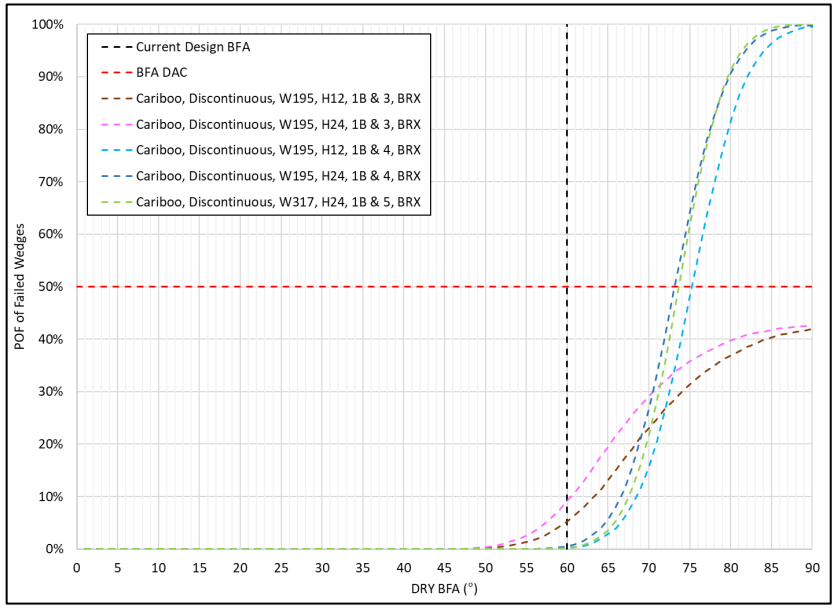
| Model Inputs | |
|---|---|
| Bench Height (m) | 12 or 24 |
| Bench Width (m) | 8.5, 11.5, or 12 |
| Bench Length (m) | 3 x bench height |
| Unit Weight (MN/m³) | 0.026 |
| Minimum Wedge Size (MN) | 0.104 |
| Feature Persistence | Small (Ubiquitous) |
| Models were assessed under dry conditions. | |

| Discontinuous Features | |
|---|---|
| Cohesion (kPa) | 0 |
| Friction Angle (degrees) | 42 |
| **Continuous Features** | |
| Cohesion (kPa) | 40 |
| Friction Angle (degrees) | 28 |

# Single-Bench Kinematic Results Summary

Critical limiting mechanisms affecting single bench configurations for each of the analyzed wall directions are summarized.

All models have been run with small (ubiquitous) feature spacing.



| Pit | Lithology | Wall Direction (Degrees) | Bench Height (m) | Structure Scale | Critical Mechanism | Set(s) | BFA @ P[FOS<1]=50% |

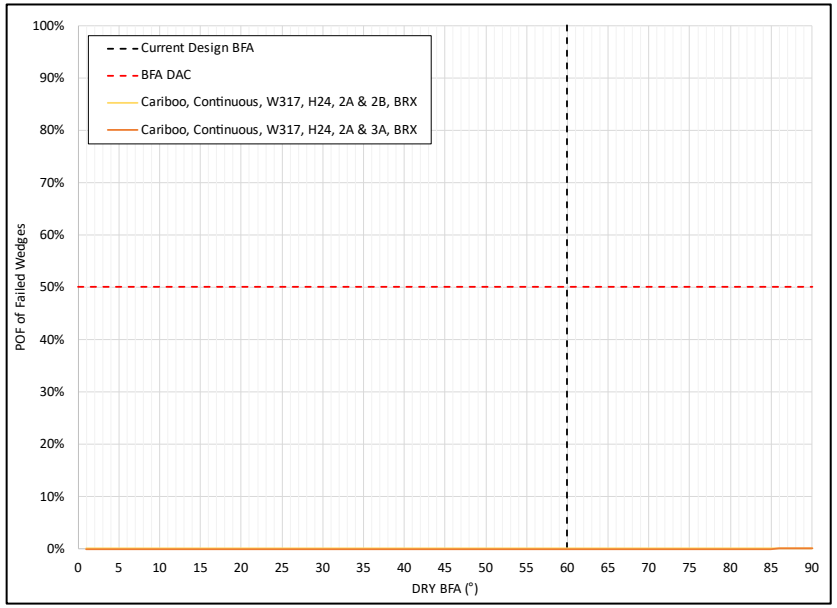
# Double-Bench Kinematic Results Summary

Critical limiting mechanisms affecting double-bench configurations for each of the analyzed wall dip directions have been highlighted in the table at right.

All models have been run with small (ubiquitous) feature spacing.



| Pit | Lithology | Wall Direction (Degrees) | Bench Height (m) | Structural Scale | Critical Mechanism | Set(s) | BFA @ P[FOS<1]=50% |

# Inter-ramp Kinematic Results Summary

Saturated models in RocPlane were completed using plane water, 33% filled slopes, with peak pressure applied at the toe of the slope.

All models have been run with small (ubiquitous) feature spacing.

# Summary of Previous Recommendations by Wall Orientation

The figure on the left presents deign recommendations from the 2016 LOM assessment (Golder 2016).

The figure on the right presents results from kinematic analyses completed for the 2024 LOM assessment.

- Values from the 2024 kinematic analyses resulting in BFAs lower than the 2016 recommendations or are incorrect are highlighted in red, BFAs equal to or above the 2016 recommendations are highlighted in green.

Within 000 Single-Bench orientation but appears double benched.

# 1. INTRODUCTION

## 1.1. Report Overview

This Mine Plan and Reclamation Program Update 2022 (2022 MRP) is submitted to the Ministry of Energy, Mines, and Low Carbon Innovation (EMLI) in compliance with condition E.13 of *Mines Act* Permit M-200 amendment "*Approving Return to Full Operations and Use of Tailings Storage Facility*" for the Mount Polley Mining Corporation (MPMC) Mount Polley Mine (Mine Site). This document is an update to the "*Mine Reclamation and Closure Plan Update November 2017*" (2017 MRP) dated 15 November 2017.

The first year of mining and milling at the Mine Site occurred in 1998. Following approximately three years of operations, the Mine Site went into care and maintenance in October 2001 due to low metal prices, and subsequently resumed operations in 2004. The Mine Site operated without interruption until August 2014. On 4 August 2014, a Tailings Storage Facility (TSF) embankment breach caused MPMC to suspend operations. Following this, the Mine Site returned to restricted operations from 2015 to 2016. Full operations resumed in the latter portions of 2016, and occurred uninterrupted until 2019, when the Mine Site was again placed in care and maintenance due to poor commodity prices. In recent years, prices have improved, and the Mine is now actively preparing to come out of care and maintenance. Activities related to resuming operations include dewatering the Cariboo-Springer Pit and preparations for mining and milling ore. Further details of MPMC's historical and planned operations are outlined in Section 1.2 and Section 2.

The Mine Site's currently permitted mine plan was originally approved in 2016, and was scheduled to continue until 2022. However, given the delays due to temporary shutdown, operations under the mine plan are now expected to conclude in September 2024. As such, the 2022 MRP incorporates the planned disturbance and corresponding reclamation requirements for disturbances created to Q3 2024. MPMC is approved for tailings deposition in the Mine Site's TSF to the 970 metre (m) elevation. Conditions set on the current mine plan are provided in the corresponding *Mines Act* Permit M-200 amendment application submitted to EMLI on 6 November 2015 (MPMC 2015a).

This 2022 MRP provides an overview of planned mine operations and reclamation and closure objectives and strategies for all permitted Mine units, and associated liability cost estimates for their execution. The MPMC reclamation program is designed to meet the environmental protection and reclamation requirements of all applicable provincial and federal legislation, including:

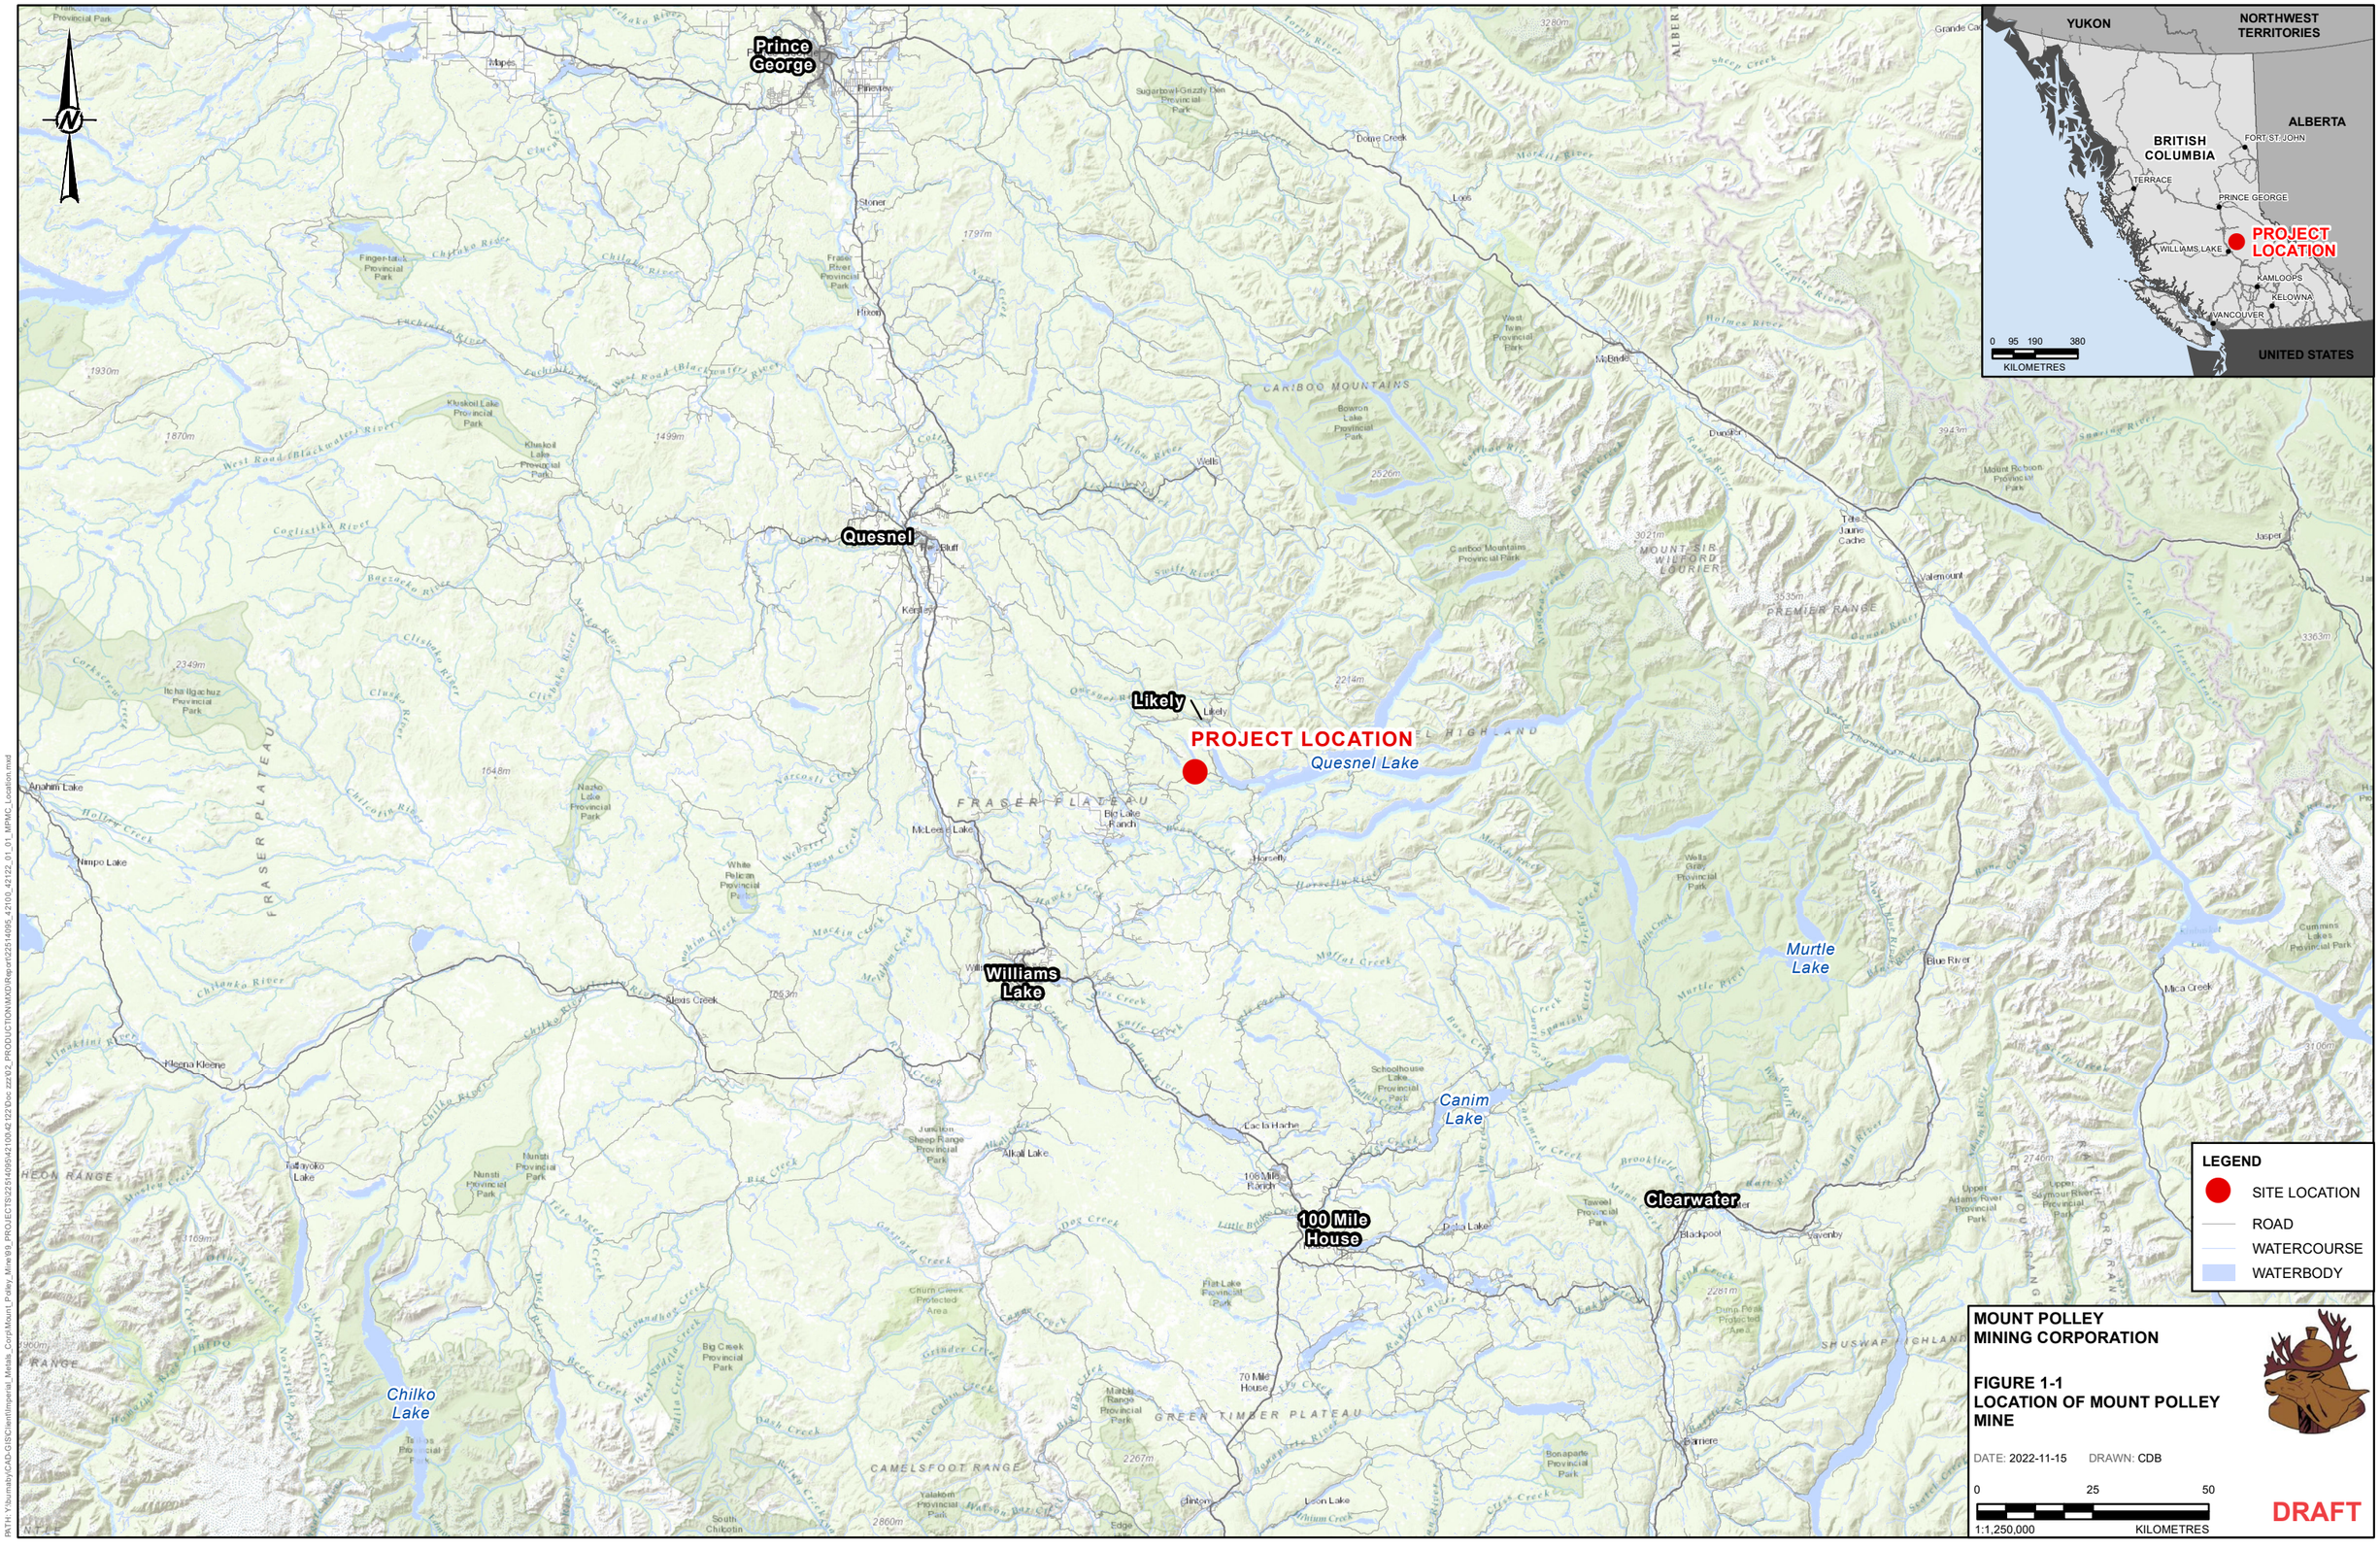
- the *British Columbia (BC) Mines Act*
- the *Health, Safety and Reclamation Code for Mines and British Columbia*
- the *Environmental Management Act* (EMA)
- the *Canadian Fisheries Act* (including the annexed *Metal and Diamond Mining Effluent Regulations*; MDMER).

Included in the 2022 MRP and presented in the subsequent sections are:

- a summary of the project background, permits, and biophysical setting (Section 1)
- an overview of mining and milling operations and site water management (Section 2)
- a description of the designated end land uses and capability objectives (Section 3)
- an overview of MPMC's reclamation approach and update on progressive reclamation and reclamation research (Section 4)
- descriptions of MPMC's reclamation strategies and management plans for achieving their reclamation objectives (Section 5)
- reclamation plans for the major disturbance units at the Mine Site (Section 6);
- projected post-closure monitoring requirements (Section 7)
- the conceptual Mine Site reclamation schedule (Section 8)
- reclamation liability costing (Section 9)
- an overview of relevant consultation and engagement activities since the last Mine Plan and Reclamation Program update (Section 10)

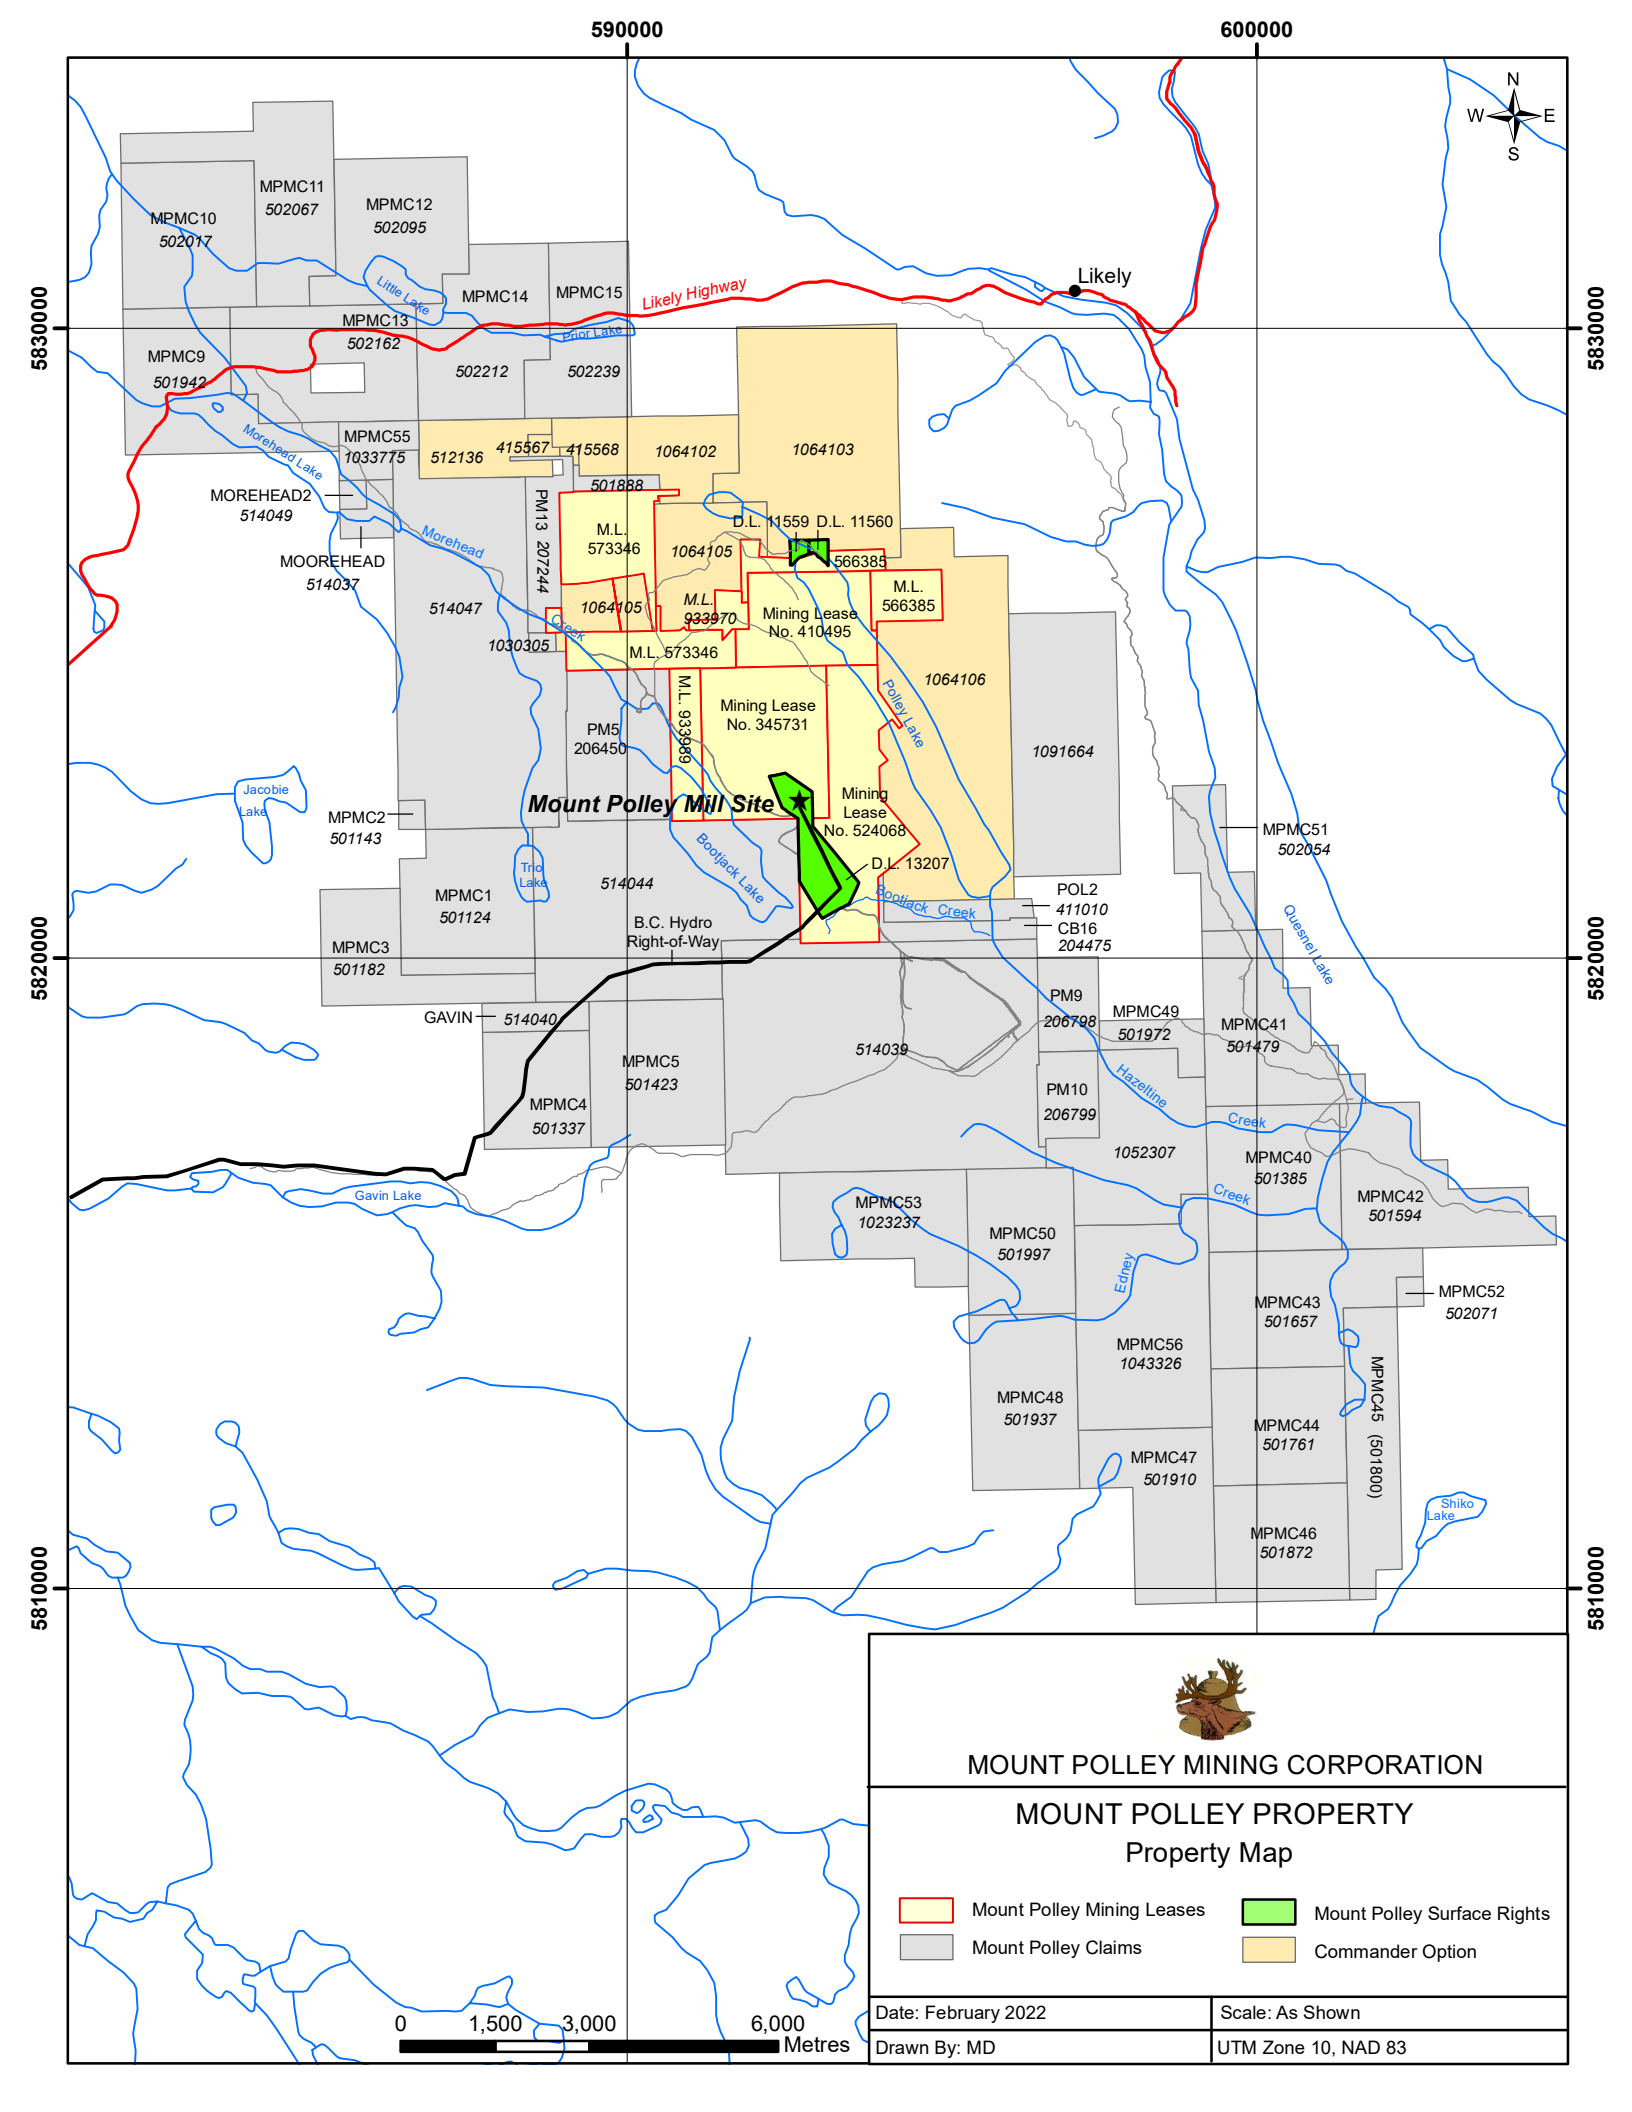
The three main phases in the Mines life cycle used in this MRP are defined as follows:

- **Operations:** The phase when mining, milling, and tailings deposition are occurring. The mine is actively producing finished products (e.g., concentrate) or is working towards this overarching goal. Reclamation activities are those required for erosion prevention (e.g., temporary reclamation), or are conducted in areas that are no longer required for mine operations (e.g., progressive reclamation).
- **Active Closure:** The phase when all operational (e.g., mining and milling) activities have ceased, and efforts to return disturbed areas to the proposed end land uses are in progress. Mine infrastructure not required for post-closure is removed, the landscape is recontoured to blend with the surrounding landscape, where possible, and coversoil placement and revegetation occurs.
- **Post-Closure:** The phase immediately following the conclusion of all active closure activities. The Mine Site is in its final configuration. Monitoring and maintenance activities continue to confirm the receiving environment is protected and vegetation communities on the disturbed areas are on a growth trajectory towards meeting end land use goals.



## 1.2. Project Summary

The Mine Site, operated by MPMC (a wholly owned subsidiary of Imperial Metals Corporation, is an open pit copper/gold mine with an underground component located in south-central British Columbia. It is located eight kilometres (km) southwest of Likely and 56 km (100 km by road) northeast of Williams Lake, British Columbia (BC; Figure 1-1). The Mine Site has the capacity to process 20,000 to 22,000 tonnes per day (tpd) of ore when in normal operations. The mine property covers 24,077 hectares (ha), consisting of seven mining leases totaling 2,007 ha, and 51 mineral claims encompassing 22,070 ha (Figure 1-2; MPMC 2022a). Concentrates from the Mine Site are trucked to facilities at the Port of Vancouver, then shipped to overseas smelters or transported by rail to smelters in North America.



### 1.2.1. *Project History*

Clearing of the site and construction of the facility began in 1995, with the mill commissioned in June 1997. In May 1997, the Mine received a British Columbia Ministry of the Environment, and Climate Change Strategy (ENV) Effluent Permit, Environmental Management Act (EMA) Permit 11678, issued under the provisions of the provincial EMA. This permit authorized the discharge of concentrator tailings, mill site runoff, mine rock runoff, open pit water, and septic tank effluent to a TSF, from where limited volumes of dam filtered water could be discharged to Hazeltine Creek (MPMC 2014). Approval of the original Mine Site Reclamation and Closure Plan by the EMLI resulted in the issuance of *Mines Act* Permit M-200 in July 1997 (Hallam Knight Piesold 1996; EMLI 2020). The first full year of mining and milling at the Mine Site took place in 1998. The Mine suspended operations in October 2001 due to low metal prices, then reopened in December 2004, with mill production commencing in March 2005. Between 1999 and 2009 the Wight Pit was mined (excluding the 2001 care and maintenance period). Following this, the pit was backfilled with potentially acid generating (PAG) rock from the Southeast Zone Pit (SEZ Pit). Mining of the Cariboo and Springer Pits also occurred during this time, until 4 August 2014.

On 4 August 2014, a breach occurred in the Perimeter Embankment of the TSF. The TSF embankment breach released tailings, water, and embankment construction materials to the downstream environments of Polley Lake, Hazeltine Creek, and Quesnel Lake. As a result, ENV issued MPMC a Pollution Abatement Order (PAO) 107461, dated 5 August 2014, ordering MPMC to attend to the environmental impacts of the TSF embankment breach. Mining and milling operations at the Mine were immediately suspended, along with previously authorized water discharge to Hazeltine Creek through EMA Permit 11678.

Following the issuance of PAO 107461, the focus of the Mine Site's operations shifted to monitoring and remediation work at the TSF, around Polley Lake, and down the Hazeltine Creek corridor to Quesnel Lake. Immediately following the TSF embankment breach, MPMC implemented a remediation strategy that focused on stabilization and containment of the breach and the tailings that remained in the TSF (approximately 75 to 80% of pre-breach volume). As part of this effort, a temporary upstream rock fill berm was constructed to retain tailings solids during low flow conditions. The short-term emergency response to the TSF embankment breach included:

- addressing health and safety concerns
- containment to prevent further release of materials from the TSF
- water quality monitoring
- removal of woody debris on Quesnel Lake
- lowering of the Polley Lake water level (which had been increased by the event)
- assessment of the physical stability of the sediment deposited at the outlet of Polley Lake
- implementation of sediment and erosion control measures in the Hazeltine Creek corridor.

Detailed information of work undertaken is provided in the 2019 Remediation Plan (Appendix A).

After initial containment of the breach, an alternative method was required to contain mine-affected materials, water, and sediment for the 2015 freshet event. MPMC applied for, and received an amendment to their *Mines Act* M-200 Permit titled "*Approving TSF Breach Repair and Perimeter Embankment Buttress Design for 2015 Freshet*" which was issued on 17 December 2014 (EMLI 2014). Through the winter of 2014/2015, MPMC constructed a breach repair incorporating a cut-off wall, under the design, engineering, and construction monitoring services of Golder Associates Ltd. (Golder). Other remediation activities included the construction of sediment control ponds, construction of a new creek channel, implementation of erosion control measures, and ecological remediation work. Then, MPMC applied for a joint *Mines Act* Permit M-200 and *EMA* Permit 11678 amendment on 12 January 2015 to allow the Mine to return to restricted operations, with tailings being deposited in the Springer Pit. The corresponding permit amendments were received in 2015, and allowed for restricted restart (including milling) for a period of one year, up to a maximum throughput of 4,000,000 t of ore.

Restricted operations commenced on 4 August 2015, with tailings being deposited in the Springer Pit. While restricted operations were authorized for a one-year period, ore reserves indicated approximately 10 more years of viable mine life. Additionally, as Springer Pit had a finite storage capacity, and a water discharge authorization was not in place at that time, MPMC applied to ENV to amend *EMA* Permit 11678 to allow short-term (maximum two years) discharge of treated Mine contact water to Quesnel Lake via the Hazeltine Creek channel, which was not fish bearing and was undergoing rehabilitation. MPMC installed all required infrastructure for water treatment and temporary discharge. On 23 June 2016, authorizations allowing return to full operations and deposition of tailings in the TSF were issued by EMLI and ENV. As such, the Phase 4 Cariboo-Springer Pit mine plan was adopted and implemented by MPMC.

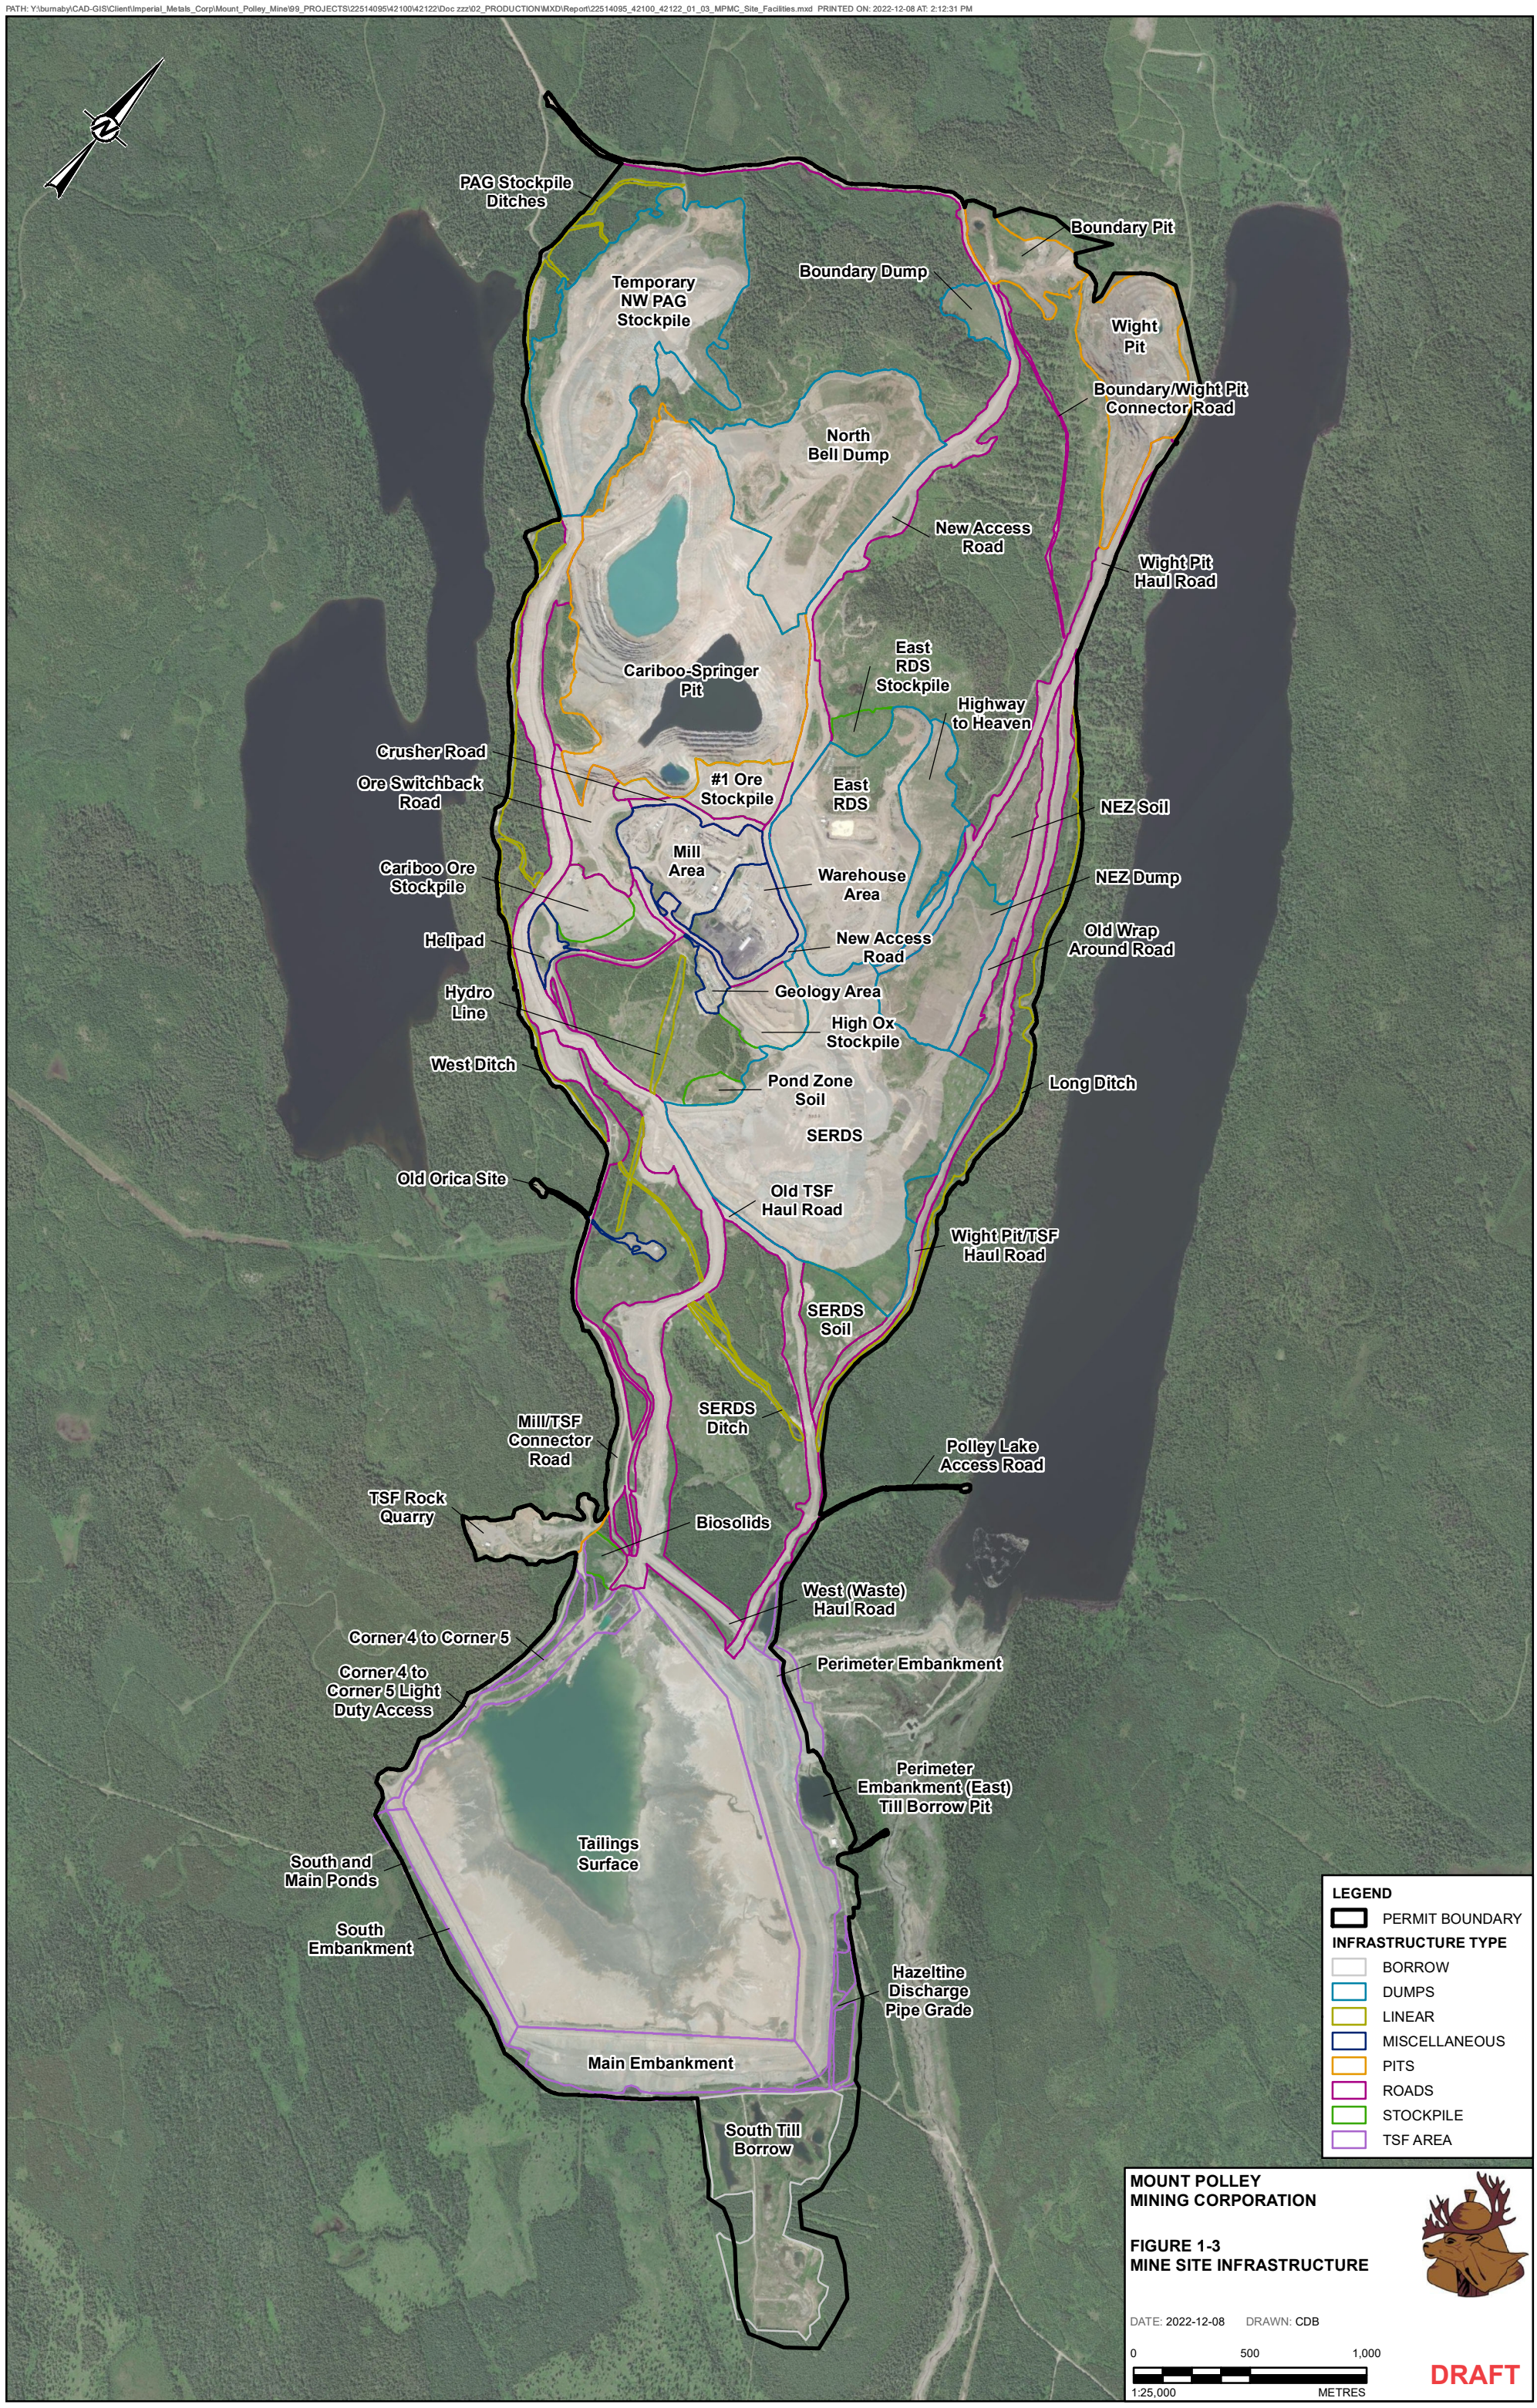
The Mine Site continued operating and executing the Phase 4 Cariboo-Springer Pit mine plan from 23 June 2016 onwards to 31 May 2019. On 31 May 2019, the Mine Site again entered care and maintenance citing poor metal prices. During care and maintenance, MPMC committed to continue environmental monitoring and sampling, and other commitments as required in the permits and Comprehensive Environmental Monitoring Plan (CEMP; MPMC 2019).

#### 1.2.2. *The Test Heap Leach*

From 2006 to 2008, approximately 11,000 $m^3$ of sulphur was procured to generate sulphuric acid for the heap leach trial (SRK 2022a). Between 2007 and 2012, different layering and blending techniques of ore and sulphur were tested to optimize leaching and collection of metals from low grade ore. In 2012, the Test Heap Leach Facility was placed into care and maintenance due to economic considerations, but was not fully decommissioned prior to shut down, and approximately 7,000 $m^3$ of ore mixed with elemental sulphur remain on the leach pad (SRK 2022a). A sulphur stockpile (approximately 23,000 t of sulphur) also remains within the footprint, along with an estimated 30,000 t of contaminated soil. Full details of materials present within the leach pad footprint can be found in SRK (2022b), and within Appendix B (B-3: Test Heap Leach Decommissioning), along with details regarding its partial decommissioning.

Currently, leachate from within the lined heap leach pad facility is managed by treatment with lime at the plant and subsequent conveyance to the TSF. A copper recovery system using Sodium Hydrosulfide (NaHS) to precipitate copper sulfide in the tailings thickener is being developed by MPMC within the concentrator building. Details related to steps required for active closure of the Test Heap Leach can be found in Section 6.3.

#### 1.2.3. *Current Project Status*



In the years following the Mine Site's 2019 care and maintenance status, metal prices have improved significantly. On 25 August 2021, MPMC provided a Mine Restart Notice to EMLI to return to operations and resume the 2016 mine plan. Currently, the Mine Site is authorized for:

- open pit mining of the Phase 4 Cariboo-Springer Pit
- milling of up to a maximum of 8,200,000 t of ore per year with deposition of tailings in the TSF
- construction and operation of the TSF up to an elevation of 970 m

Existing project infrastructure consists of the mill site and two active rock disposal sites (RDSs) – the SERDS and the Temporary Northwest (NW) PAG Stockpile, as well as a TSF. Ancillary infrastructure includes access roads, powerlines, drainage collection systems, sediment/seepage control ponds, and a water discharge system (Figure 1-3).

While the Mine Site is permitted for full operations, activities have been primarily focused on restarting production. Due to initial mill maintenance, there was an early lack of processing capacity, and the discharge of tailings has only been resumed recently (July 2022). As part of water management, treated mine water is discharged into Quesnel Lake through two underwater diffusers, as permitted under EMA Permit 11678.

PATH: Y:\burnaby\CAD-GIS\Client\Imperial_Metals_Corp\Mount_Polley_Mine\99_PROJECTS\22514095\42100\42122\Doc zzz\02_PRODUCTION\MXD\Report\22514095_42100_42122_01_03_MPMC_Site_Facilities.mxd PRINTED ON: 2022-12-08 AT: 2:12:31 PM

MPMC resumed mining production in November 2021, mining the saddle between Springer Pit and Cariboo Pit. The Cariboo Pit contains water which will be removed during mining of Phase 4. The crusher and concentrator were refurbished, milling operations began June 2022.

MPMC is currently pursuing further operational permits, and is progressing towards lowering the phreatic surface within the tailings that were deposited in the Springer Pit in 2015/2016. Ore reserves are located beneath the tailings, which are expected to provide an additional 2 years of production.

Since the initial method of tailings removal (e.g., dredging) was only successful in removing 1/3 of the tailings, MPMC is exploring the use of a truck and shovel method to remove the remaining tailings from Springer Pit. As part of these efforts, a causeway was constructed, and three dewatering wells were installed in Springer Pit that are currently dewatering the tailings. This dewatering activity in combination with plating the tailings with waste rock is expected to facilitate movement of the material using haul trucks in 2023. Tailgates are not currently anticipated to be needed to support this process; however, the possibility may be revisited during operations based on conditions.

The Wight Pit is no longer in production and is being used to temporarily store mine contact water. The Wight Pit Portal (located within the pit) was partially secured with loc-blocks prior to flooding; a small amount of PAG waste rock backhauled into the pit is submerged. The current elevation of the Wight Pit Lake is at 915.97 m. Prior to flooding, the underground infrastructure and equipment were removed, however, some power cables, piping, and part of the lift are still in place (G. Holmes, pers. comm. 2022).

### 1.3. Summary of Regulatory Permits and Requirements

Provincially, all phases of the mine life (construction, operation, decommissioning, and reclamation) are regulated under the *EMA* and the *Mines Act*, as well as the *Water Sustainability Act* and other legislation implemented by the BC Ministry of Land, Water, and Resource Stewardship (MLWRS). A summary of existing Mine Site permits under these regulations is presented in Table 1-1. Table 1-2 provides a list of amendments to *Mines Act* Permit M-200 (issued by EMLI [formerly MEM]) that have been received throughout the mine life.

Permit 11678, issued by the ENV, authorizes discharge of effluent under the *EMA*. Table 1-3 lists amendments to *EMA* Permit 11678 that have been issued over the course of the mine life.

Federal regulation is primarily through the *Fisheries Act*, which is to protect fish habitat by prohibiting the entry of deleterious substances into fish-bearing waters, as well as the disruption or disturbance of fish habitat without the necessary approvals. Protection of fish habitat also includes the MDMER (annexed under the *Fisheries Act*) which regulate deposition of mining waste (effluent) into fish-bearing waters.

**Table 1-1 Current Mine Site Permits**

| Ministry | License/Permit/Approval No. (Date Issued) | Project Component/ Activity Approved |
|---|---|---|
| Interior Health | Drinking Water Permit Facility No 14-098-00199 (March 31, 2009) | Permit to operate drinking water system 14 or less connections. |
| ENV | Approval AE-14591 (June 21, 1996) | Discharge treated mine water runoff from sediment ponds between 1 July 1996 and 30 September 1997. |
| ENV | Conditional Water License 111741 (Dec 6, 1996) | Diversion of water from Polley Lake for dust suppression and industrial purposes. |
| ENV | Conditional Water License 101763 (Original: December 6, 1996) (Amended: January 17, 1997; June 14, 2002) | Diversion of water from Polley Lake to the tailings pond for storage and use in mining (processing of ore) purposes. |
| ENV | License BCG-01559 (Original: July 16, 1997) (Amended: Oct 23, 2012) | Special waste consignor, in accordance with Section 44 of Special Waste Regulation. |
| ENV | Permit PR 14590 (Original: March 18, 1997) (Amended: June 26, 2007; June 21, 2019) | Discharge of refuse to the land (landfill operation on site) from a copper-gold mine and mill. |
| ENV | Permit PA 15087 (Original: August 7, 1997) (Amended: June 26, 2007) | Discharge of air contaminants from mill and crusher. |
| ENV | Approval AE 15554 (May 29, 1998) | Discharge effluent (biosolids) to the land for the purposes of establishing reclamation test plots. |
| ENV | Permit PE 15968 (Original: December 13, 1999) (Amended: June 26, 2007) (Active Version: July 3, 2014) | Current major authorization components: Discharge of biosolids to tailings and waste rock disposal locations for the purpose of reclamation. |
| ENV | Permit PE 11678 (Multiple Received) | See Table 1-2. |
| Fisheries and Oceans Canada (DFO) | File No 8450-10 (September 25, 1996) | Authorization for works or undertakings affecting fish habitat from development and operation of a copper/gold open pit mine, as outlined in the Habitat Compensation Agreement dated 25 September 1996. |
| DFO | Habitat Compensation Agreement (September 25, 1996) | Construction of a dam on the southeast end of Bootjack Lake. |
| DFO | File No A54120 (February 17, 2005) | Culvert installation at North Drainage Creek and diversion of unnamed drainage north of the Wight Pit. |
| DFO | File No 8450-10 (October 5, 2005) | Removal of existing culvert and installation of bottomless log culvert. |
| DFO | Authorization 13-HPAC-PA7-00276 (Original: August 8, 2013) (Amended: February 27, 2014) | Authorization for works, undertakings or activities affecting fish habitat near Mine Drainage Creek. |

**Table 1-1 Current Mine Site Permits**

| Ministry | License/Permit/Approval No. (Date Issued) | Project Component/ Activity Approved |
|---|---|---|
| DFO | License WL14-154619 (September 5, 2014) | Authorization concerning the movement of live fish (Bootjack Creek to Bootjack Lake). |
| DFO | License XHAB 125 2015 (September 21, 2015) | Authorization for fish salvage in Hazeltine Creek sediment ponds prior to draining. |
| Ministry of Agriculture and Lands | License No 515696 (July 7, 2007) | Electrical distribution to supply power to adjacent properties to Mount Polley. |
| Ministry of Agriculture and Lands | License No 515696 (November 30, 2015) | Construct outfall structures along shoreline and land covered by water at Quesnel Lake. |
| MFLNRO | Road Use Permit 01-5654-96 (June 1, 1996) | Construct, modify, use and maintain Morehead-Bootjack Road. |
| MFLNRO | License to Cut (Multiple Received) | Timber harvesting. |
| MFLNRO | *Water Act* File A5004120 (February 21, 2005) | Changes in and about a stream on unnamed watercourses in the vicinity of Mineral Lease 41095 near Polley Lake; instream work to be completed by 31 March 2005. |
| MFLNRO | *Water Act* File A5004119 (March 18, 2005) | Changes in and about a stream, to install a discharge pipe into Polley Lake. |
| MFLNRO | *Water Act* File A5-4397 (August 8, 2012) | Changes in and about a stream, to install a discharge pipe into Hazeltine Creek. |
| MFLNRO | License No 516031 (October 2, 2012) | Construct pipeline for Hazeltine Creek discharge system. |
| MFLNRO | License No 516186 (April 25, 2014) | Construct impoundment to install a small generator and propane tank to operate water monitoring and communication system at Hazeltine Creek. |
| MFLNRO | License No 516217 (June 25, 2014) | Construct pipeline from water treatment plant to discharge structure in Polley Lake. |
| MFLNRO | Conditional Water License C132360 (August 10, 2015) | Storage of water from Hazeltine Creek and its tributaries. |
| MFLNRO | License of Occupation 516364 File No. 5407795 (November 30, 2015) | Improvements necessary for pipeline and diffuser and for telecommunications equipment necessary for the operation of the system in Quesnel Lake. |
| MFLNRO | Occupation of Crown Land Permit No 28205 | Occupation of a portion of Crown Land and the disturbed area along Hazeltine Creek; for works and flooding having a total area of 134.8 hectares. |

**Table 1-1 Current Mine Site Permits**

| Ministry | License/Permit/Approval No. (Date Issued) | Project Component/ Activity Approved |
|---|---|---|
| MFLNRO | *Water Act* File 76930-40/Mount Polley order 006 variance 3 (September 28, 2016) | 1. Collect and remove such debris from Hazeltine Creek, Quesnel Lake and Polley Lake, resulting from the Mt Polley tailings pond failure.<br>2. Maintain the Lake level of Polley Lake in a manner that prevents further mass movement of material from Polley Lake and Hazeltine Creek.<br>3. Undertake habitat remediation work on Edney Creek, Hazeltine Creek, Quesnel Lake, and Polley Lake. |
| MFLNRO | *Water Act* File No. 76910-20/5002485 (October 15, 2015) | Section 9 Approval for discharge pipeline into Quesnel Lake. |

**Table 1-2 Mines Act Permit M-200 Amendments**

| Date | Amendment Title |
|---|---|
| 13-Jun-1996 | Name Change |
| 23-Sep-1996 | Approval to Construct Tailings Storage Facility to Elevation 934 m |
| 11-Jul-1997 | Amended Reclamation Permit, Approval to Construct Open Pits and Waste Dumps, and Traffic Control Plan |
| 7-Apr-1998 | Approval to Construct Tailings Storage Facility to Elevation 940 m |
| 13-Jun-2000 | Approval to Construct Tailings Storage Facility to Elevation 944 m |
| 2-Aug-2000 | Approving Tailings Storage Facility and Amended Metal Leaching and Acid Rock Drainage Conditions |
| 30-May-2001 | Approval to Construct Tailings Storage Facility to Elevation 945 m |
| 16-Feb-2004 | Approving Milling of Ore and Tailings Deposition from the International Wayside Bulk Sample |
| 1-Nov-2004 | Approving Mining and Reclamation Program for the Northeast Zone and Approving Mine Restart |
| 25-May 2005 | Approving Tailings Storage Facility Stage 4 Construction |
| 2-Aug-2005 | Approving Haulage Road Construction from the Northeast Zone to TSF |
| 24-Nov-2005 | Approving Mining of Southeast Zone |
| 2-Aug-2006 | Approving Change of Name and Deletion of Requirement to Monitor Blasting |
| 2-Aug-2006 | Approving Tailings Storage Facility Stage 5 Construction |
| 29-Mar-2007 | Approving Northeast Zone Dump Expansion |
| 29-Mar-2007 | Approving Copper Oxide Test Heap Leach Facility |
| 31-Aug-2007 | Approving Boundary Road |
| 5-Dec-2007 | Approving Wight Pit High Wall Rehabilitation |
| 19-Feb 2008 | Approving Tailings Storage Facility Stage 6 Construction |
| 6-Mar-2008 | Approving Transfer of Road Use, Maintenance, and Reclamation |
| 8-Jul-2009 | Approving Pond Zone |
| 15-Aug-2011 | Approving Mining of C2 and Boundary Zone Pits |
| 29-Jun-2012 | Approving Tailings Storage Facility Stage 8 Construction |
| 15-Oct-2012 | Approving Tailings Storage Facility Stage a Construction |
| 25-Mar-2013 | Approving Boundary Zone Underground |
| 22-Apr-2013 | Approving Processing of 15,000 Tonnes of Ore from Dome Mountain |
| 25-Jul-2013 | Approving Northwest PAG Dump Expansion and South Haul Road |
| 9-Aug-2013 | Approving Tailings Storage Facility Stage 9 Construction |
| 17-Mar-2014 | Approving Cariboo Phase 4 Expansion |
| 27-Mar-2014 | Approving Change to Reclamation Security Schedule |
| 24-Jun-2014 | Approving Waste Rock and Tailings Comingling Research Project |
| 17-Dec-2014 | Approving TSF Breach Repair and Perimeter Embankment Buttress Design for 2015 Freshet |
| 9-Jul-2015 | Approving Return to Restricted Restart of Operations |
| 22-Oct-2015 | Approving Main Embankment Buttress |
| 25-Feb-2016 | Approving Upstream TSF Construction and 2016 Freshet Water Management |
| 26-Mar-2016 | Approving Springer Pit Lake Elevation Increase |
| 29-Apr-2016 | Approving Extension to Restricted Operations and Corner 1 Buttressing |
| 23-Jun-2016 | Approving Return to Full Operations and Use of Tailings Storage Facility |

**Table 1-2 Mines Act Permit M-200 Amendments**

| Date | Amendment Title |
|---|---|
| 22-Jul-2016 | Approving TSF Upstream Drain Design Modification |
| 29-Jun-2017 | Approving Security Schedule |
| 10-Dec-2020 | Approving Reclamation and Closure Plan |
| 18-Mar-2022 | NoD for Water Storage in Wight Pit |
| 02-Nov-2022 | NoD for C2 Backfill |

**Table 1-3 EMA Permit 11678 Amendments**

| Date | Scope of Amendment |
|---|---|
| 30-May-1997 | Original permit |
| 20-Oct-1997 | Amended authorized tailings discharge rate (10,000 tpd increase) |
| 12-Jun-1998 | Amended reporting requirements |
| 8-Sep-1999 | Amended monitoring requirements |
| 1-Feb-2000 | Amended authorized tailings discharge rate (4,500 tpd increase) |
| 7-Feb-2002 | Approval to discharge effluent from the Perimeter Embankment Seepage Collection Pond (PESCP) and MESCP; approval to store TSF supernatant and Mine contact water in the Cariboo and Bell Pits |
| 4-May-2005 | Amended authorized tailings discharge rate (5,000 tpd increase); discharge of groundwater to Polley Lake; updates to reference analytical procedures and monitoring program |
| 17-Apr-2009 | Amended monitoring, water level and supernatant characteristic requirements for the Cariboo and Bell Pits |
| 7-Nov-2012 | Approval to discharge to Hazeltine Creek |
| 7-Jun-2013 | Sulphate guidelines and milling of contaminated soils |
| 9-Jul-2015 | Tailings discharge to the Springer Pit |
| 29-Nov-2015 | Approval to discharge to Hazeltine Creek |
| 4-Apr-2016 | Discharge of additional tailings to the Springer Pit |
| 9-Sep-2016 | Hazeltine Creek discharge total suspended solids limit change |
| 7-Apr-2017 | Direct pipeline from water treatment plant to Quesnel Lake |
| 2-Oct-2018 | Amendment to Sections 1.2.3, 1.2.6 and 2.7 of existing 11678 permit |
| 14-Mar-2019 | Amendment to revisions for November 9, 2018, CEMP approval letter conditions including 3, 4, 8, 9, 11, 14 and 15 |
| 15-Jul-2019 | Amendment to Section 6.14 of the approved August 15, 2018, CEMP |
| 1-Feb-2020 | Amendment to Sections 1.2, 1.2.5, 1.2.6, 2.7, 2.8, 2.8.1, 2.8.3, 2.9 2.10, 3.3, 3.5, 3.5.5 and 4.1.4 of existing 11678 permit |
| 18-Sep-2020 | Consent Order amendments to Sections 2.8, 2.9, 2.10, and 4.2.1 of existing 11678 permit |
| 31-Dec-2020 | Approved and amended Permit 11678 |

## 1.4. Biophysical Setting

### 1.4.1. *Physiography*

The Mine Site is located near the eastern edge of the Fraser Plateau physiographic subdivision, approximately 10 km west of its boundary with the Quesnel Highland subdivision, as defined by Holland (1976). Within the Mine Site, the plateau has somewhat stronger relief, with the Mine Site rising approximately 300 metres (m) above the surrounding terrain. Topographically, the Mine Site area consists of north–south trending ridges of moderate elevation and relief. Local elevations range from 922 masl at Polley Lake to 1,266 masl at the top of Polley Mountain. The area is within the Quesnel Highlands Ecosection as described by Demarchi et al. (1990), and the area has been previously glaciated, which has resulted in the over-deepened Polley and Bootjack lakes.

### 1.4.2. *Geological Characterization*

The Mine Site is located within the Quesnel Terrane, a belt of mafic to intermediate volcanic rocks, which are mostly of Upper Triassic to Lower Jurassic age. The Mine Site's mineral body is hosted within an alkali intrusive complex. Most of the Mine Site is covered by blankets and veneers of glacial tills, but there are also small inclusions of alluvial, lacustrine, colluvial, and organic landforms.

The Mount Polley deposit is classified as a porphyry copper gold deposit (BC MINFILE No. 093A 008) hosted within Jurassic – Triassic Polley Stock that intrudes the Nicola Group volcanic rocks. The Polley Stock is a northwesterly elongated body approximately 5 km long and extends from Bootjack Lake to Polley Lake in the east–west direction. The Polley Stock is a multi-phase pluton with composition ranging from diorite to monzodiorite to monzonite. It is variably altered and brecciated. Felsic (plagioclase phyric) and mafic (augite phyric) dykes occur as late-stage intrusive phases. Late brittle faults offset lithologies, alteration, and mineralization.

The Mount Polley deposit has been mined from several different mineralized zones, which have common features (SRK 2015):

- The host rocks for porphyry mineralization are intrusions into the Nicola Volcanics varying in composition from diorite to syenite;
- Alteration is potassic (secondary biotite and pink orthoclase) and propylitic (calcite-epidote-chlorite-pyrite);
- Sulphide mineralization consists mainly of chalcopyrite ($CuFeS_2$) and pyrite ($FeS_2$), with lesser bornite ($Cu_5FeS_4$), covellite (CuS), and digenite ($Cu_9S_5$);
- Carbonate mineralization is principally calcite, with occurrences of malachite ($Cu_2CO_3(OH)_2$). Iron carbonates have not been reported; and
- Oxidized copper mineralization is present at approximately 50% of the 0.3% total copper in the upper portions of the ore body, primarily as the silicate chrysocolla ($(Cu,Al)_2H_2Si_2O_5(OH)_4 \cdot nH_2O$) and the carbonate malachite ($Cu_2CO3(OH)_2$) in equal proportions (Henry 2009).

#### 1.4.2.1. Lithologies

The following lithologies are present at the MPMC Mine Site:

- **Volcanics:** These volcanic and volcaniclastic rocks are the oldest on the Mine Site, form part of the Nicola Group, and are Upper Triassic in age. They consist mainly of andesitic basalt or augite phyric alkali basalt, and volcanic breccias. Volcanic rocks do not make up a significant component of material from the pits.

- **Diorite:** The diorite occurs mainly in the eastern section of the Springer Pit and is bluish grey, fine to medium grained, and equigranular to weakly porphyritic. Phenocrysts are plagioclase, minor augite, and occasional magnetite, biotite, calcite, and apatite.

- **Monzonite:** The monzonite unit is brown to pinkish grey or greenish grey, medium to coarse-grained, and equigranular to weakly feldspar phyric. Predominate feldspars are orthoclase and albite. Accessory minerals include magnetite, augite, biotite, calcite, apatite, and epidote. This unit is variably flooded with potassic alteration, and is variably brecciated with copper/gold mineralization.

- **Potassium feldspar phyric dykes:** These dykes are pinkish orange to orangish grey. The matrix is fine to medium grained, orangish grey and composed largely of potassium feldspar. The phenocrysts are elongated subhedral to euhedral plagioclase laths up to 10 millimetres (mm) long. These dykes are often planar, occurring in various orientations and filling fractures of the brecciated monzonite. They vary in width from fractions of 1 m to 5 m wide.

- **Augite phyric dykes:** These dykes are distinctive dark green with a fine- to medium-grained mafic matrix and scattered up to 3 mm augite phenocrysts (up to 8% of rock) and occasionally up to 2% euhedral magnetite phenocrysts. Dykes are generally planar in form and tend to fill fractures and faults. They occasionally exhibit orange potassic alteration.

#### 1.4.2.2. Alteration and Mineralization

Brecciation and hydrothermal alteration variably affected the Polley Stock and the surrounding Nicola Group volcanics. Alteration can be described in terms of a potassic core enveloped by a propylitic zone. In the core of the system, intense potassic alteration is accompanied by variable strong albite, magnetite and actinolite alteration. Propylitic alteration (calcite – chlorite – minor pyrite) occurs near the perimeter of the system. In the Springer Pit, alteration is generally characterized by veins of actinolite, epidote, and magnetite, which cut across the earlier potassium feldspar and albite flooding in the breccia.

Mineralization is variable, but strongly associated with brecciation and alteration. In the Springer Pit, chalcopyrite is the dominant copper sulphide, with local accumulations of bornite in the higher-grade areas. Sulphides occur disseminated to finely blebbed within potassium feldspar, albite, magnetite, and actinolite alteration. In the southern portion of the Springer Pit, pyrite occurs strongly disseminated in both ore and waste rock. The pyritic waste generally constitutes PAG rock, with sulphur values up to 3%. This pyritic zone extends south to encompass the neighbouring WX Zone, where gold values are typically higher.

#### 1.4.2.3. Structures

Faults recognized to date are late and brittle. Two dominant fault sets have been recognized. One is a north-northeast trending, steeply dipping set. The other is a west-northwest trending, also steeply dipping set. Both fault sets offset and terminate the ore.

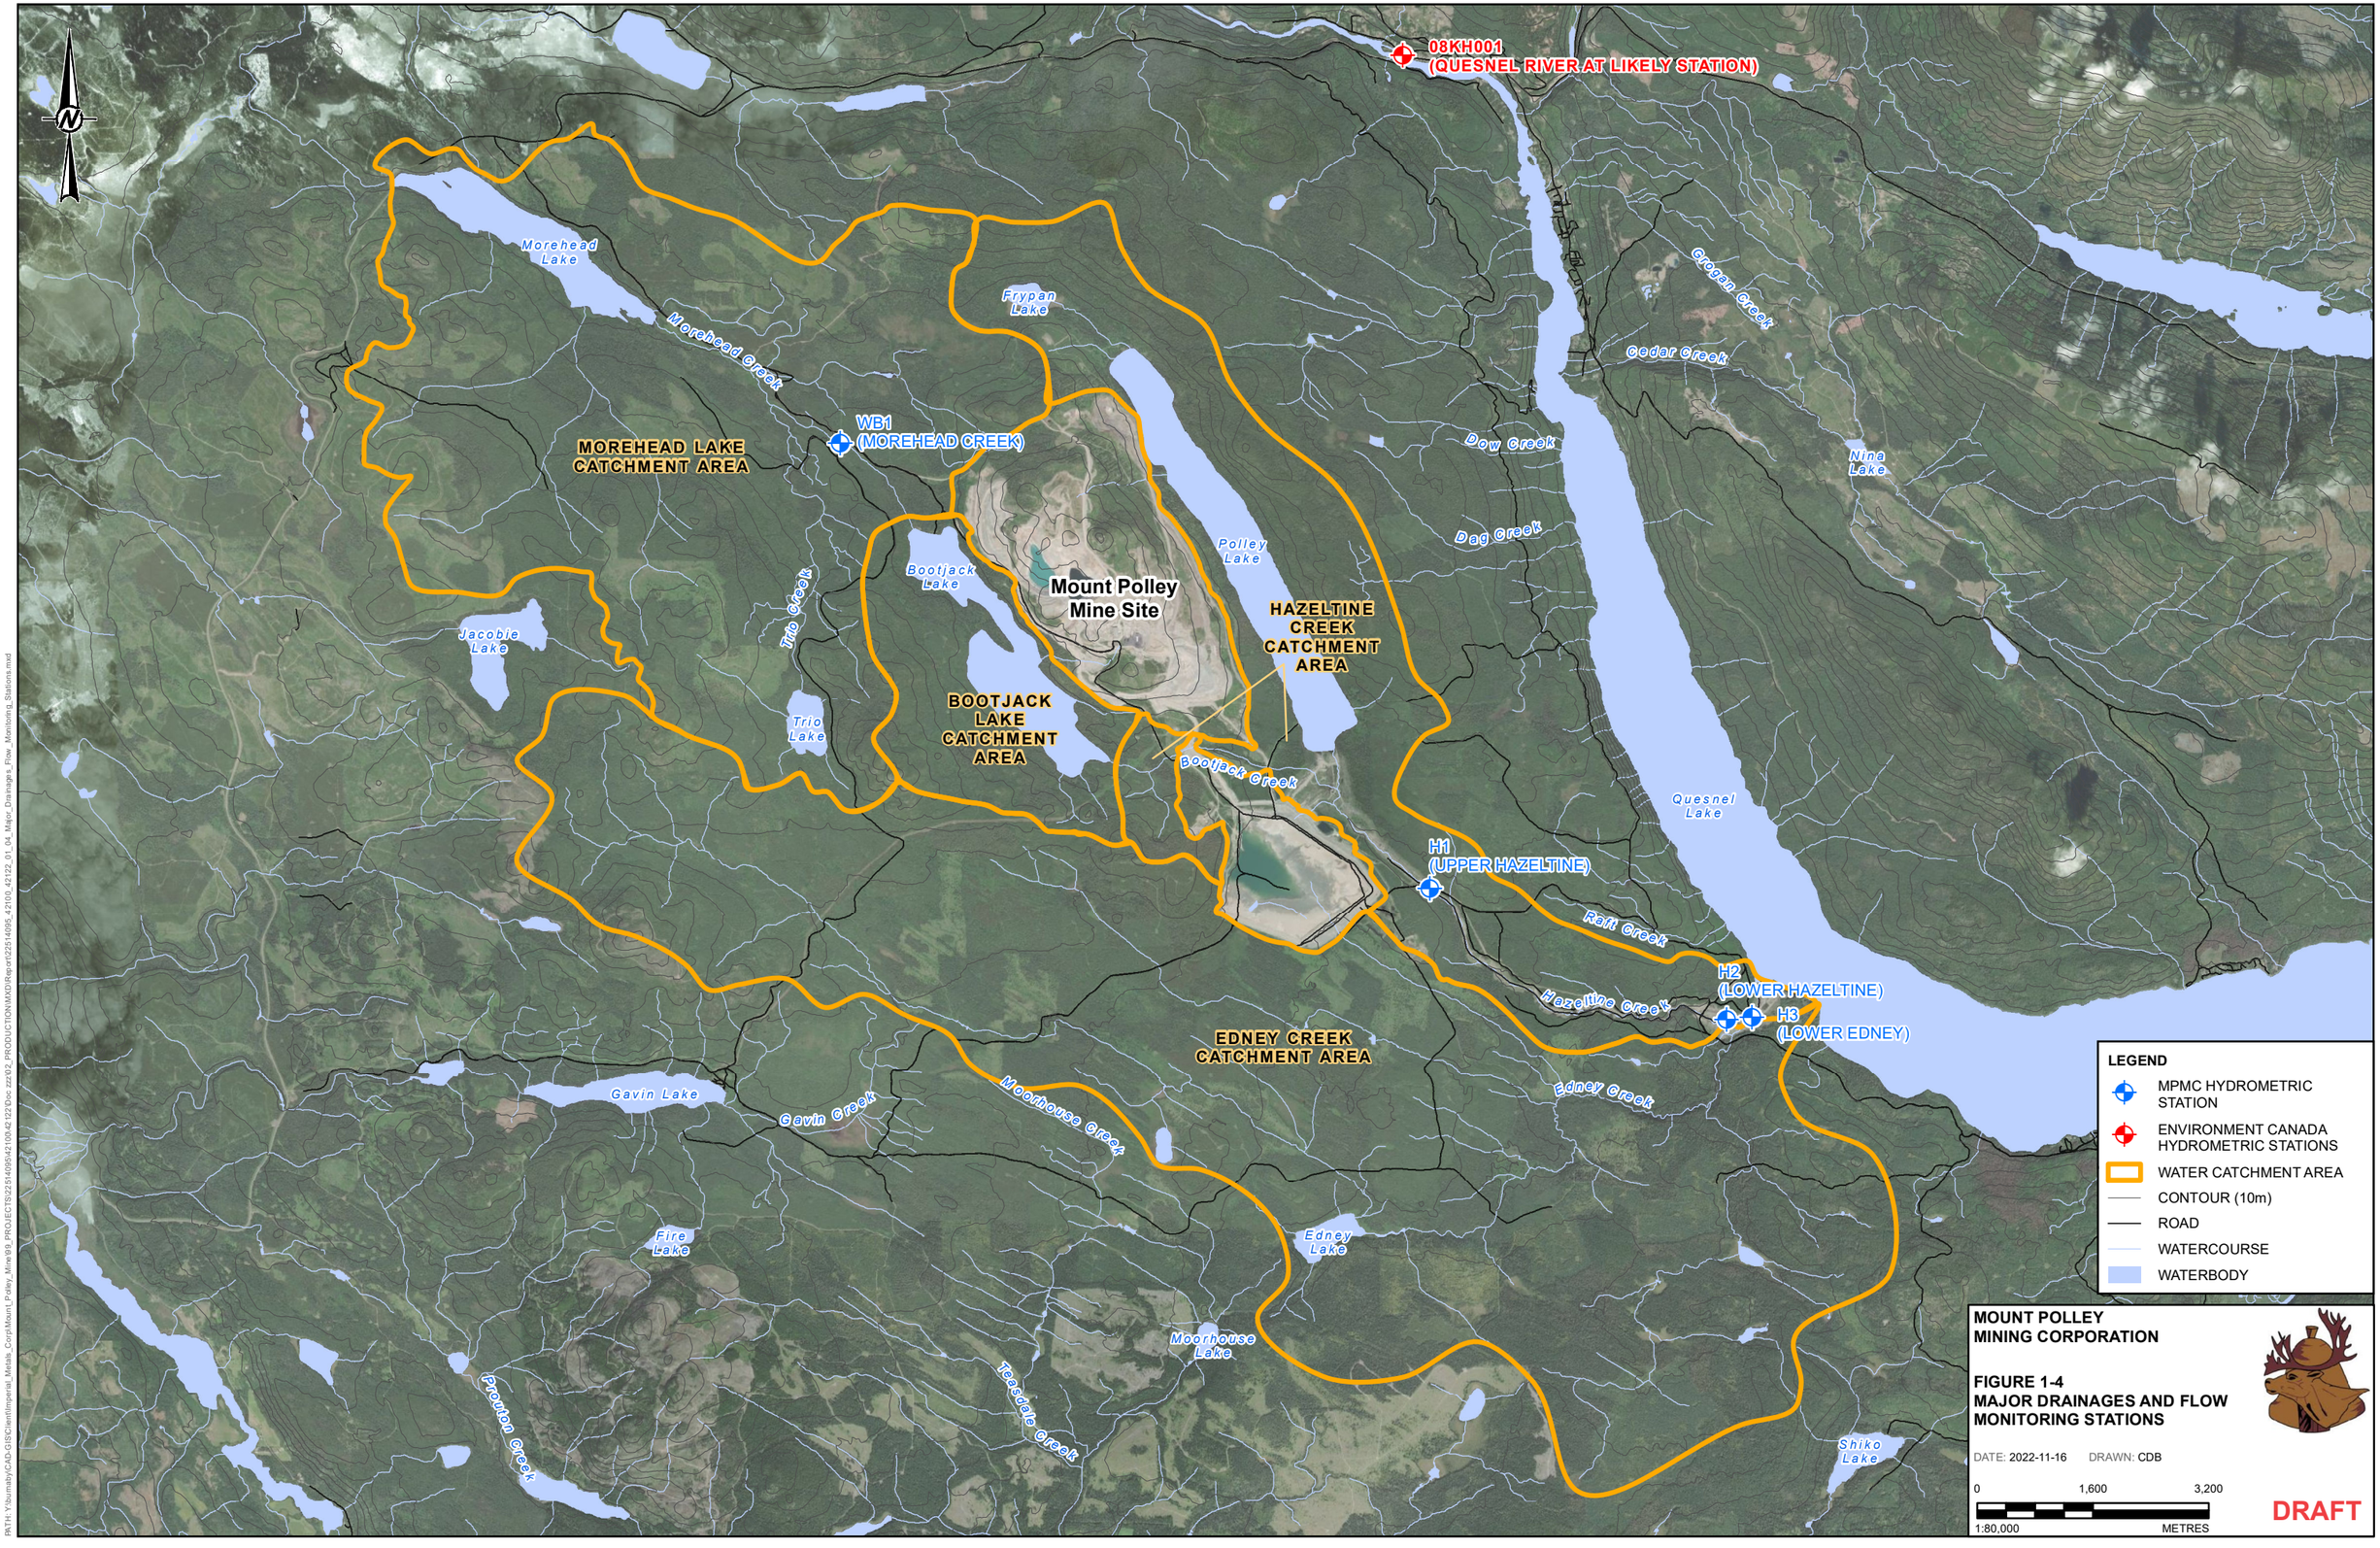
### 1.4.3. *Soils*

The following description is based on Meister (2010). Most soils at the Mine Site are derived from morainal deposits overlying bedrock. The soils are typically loam to sandy loam in texture and contain 15% to 35% (by volume) coarse fragment content (>2 mm diameter). The pH of the parent material ranges from 6.0 to 7.5 ($CaCl_2$ solution). This reflects the calcareous nature of the underlying bedrock. The calcareous horizon occurs generally at 120 to 150 centimetres (cm) in depth. The organic matter content of the mineral soil is low. The dominant soil development process is the downward translocation of clay particles, resulting in a Bt horizon (characterized by the accumulation of clay) and the development of Brunisolic Gray Luvisol soils. In areas where the Luvisolic soil development is weak, soils are therefore classified as Orthic or Eluviated Eutric Brunisols, reflecting a weaker rate of soil formation. In more acidic areas, the soils are classed as Dystric Brunisols.

Detailed soil descriptions and terrain classification from inventories carried out for the Mine Site are provided in Appendix C.

### 1.4.4. *Vegetation and Wildlife*

Biogeoclimatic maps of the Cariboo Forest Region indicate that the Mount Polley site is located within the Horsefly Moist Cool variant of the Interior Cedar-Hemlock Biogeoclimatic Zone (BEC zone; ICHmk3), which occurs between Quesnel and Horsefly Lakes, in the valley of McKinley Creek, and near Canim Lake. ICHmk3 site series are provided in Appendix C. The dominant trees on upland sites in the ICHmk3 BEC zone are Douglas-fir (*Pseudotsuga menziesii*), Western red cedar (*Thuja plicata*), hybrid spruce (*Picea glauca x engelmannii)*, and subalpine fir (*Abies lasiocarpa*). Lodgepole pine (*Pinus contorta*), trembling aspen (*Populus tremuloides*), and paper birch (*Betula papyrifera*) are also present in the early stages of forest succession. The forests in lower valley bottoms are often dominated by hybrid spruce and black cottonwood (*Populus trichocarpa*). Field surveys of the Mount Polley site have found that the dominant trees in mature and old growth stands are Western red cedar, Douglas-fir, and subalpine fir. Subalpine fir usually dominates the seedling regeneration in mid-seral, mature, and old forests. Black cottonwood dominates the early stages of forest succession after logging, while trembling aspen and paper birch are usually secondary species. Western hemlock (*Tsuga heterophylla*) is present in the area, but rare. Large portions of the project area have been selectively logged to remove the largest Douglas-firs and Western red-cedars, and some clearcut sites have been replanted with lodgepole pine seedlings. Hybrid spruce occur sparingly on lower, middle and upslope positions in the Mount Polley site area, and is most common near streams and lakeshores.



Wildlife species present are listed in Appendix C, and include species such as Western toad (*Anaxyrus boreas*), common nighthawk (*Chordeiles minor*), and grizzly bear (*Ursus arctos*), which are identified as species at risk.

#### 1.4.5. *Watersheds*

The Mine Site is located on the divide of two sub-watersheds within the Quesnel Lake watershed. The western watershed, which includes drainage from Bootjack Lake, discharges to the Quesnel River via Morehead Creek and drained approximately 60% of the Mine Site area prior to Mine construction. The eastern watershed includes Polley Lake, which discharges to the east via Hazeltine Creek, Edney Creek, and the West Arm of Quesnel Lake. The Hazeltine Creek and Edney Creek watershed areas at Quesnel Lake are approximately 30.2 square km ($km^2$) and 87.4 $km^2$, respectively (Figure 1-4). Approximately 10.5 $km^2$ that historically reported to this watershed is now within the Mine contact water runoff collection system catchment.

Bootjack Creek is a small tributary of Hazeltine Creek downstream of Polley Lake. Historically, Bootjack Lake discharged into Hazeltine Creek via Bootjack Creek. However, in 1913 a dam was constructed at the south end of Bootjack Lake and the flow direction was reversed to direct water into Morehead Lake for hydraulic mining of Bullion Pit and recently hydropower production. This resulted in 14 $km^2$ being diverted from the Hazeltine Creek catchment. The old Bootjack Lake Dam was upgraded by MPMC in 1997 as fulfillment of a Fish Habitat Compensation Agreement signed between MPMC and the regulating federal and provincial agencies. The Bootjack Lake watershed area is 11.2 $km^2$. Approximately 2.3 $km^2$ that historically reported to this watershed is now within the Mine contact water runoff collection catchment. Currently, Bootjack Creek reports to Polley Lake.

The regional topography, water bodies, and pre-mining watersheds are shown in Figure 1-4. Refer to Section 2.4.2 for more information on Mine Site water collection systems and catchment areas.

### 1.4.6. *Climate*

The following is a summary of the climate characteristics in the area of the Mine; additional details can be found in the climate baseline update (Appendix D).

Local climate characterization for the Site was completed using climatic data recorded at the Mine and nearby Environment and Climate Change Canada (ECCC) climate stations. The ECCC climate stations included Likely, Spokin Lake, Williams Lake, Barkerville, and Quesnel, and were selected for their proximity to the Site, length of record, elevation range, and concurrent time period with Site records. In addition, the ECCC Prince George climate station was added to support the characterization of expected incoming solar radiation at the Site. Table 1-4 summarizes the station metadata used in the local climate characterization.

**Table 1-4 The Mine Site and Regional Climate Stations**

| Station Name | Northing (m N)[1] | Easting (m N)[1] | Elevation (masl) | Sensors | Period of Record[2] |
|---|---|---|---|---|---|
| Mill site | 5822420 | 592495 | 1,181 | R, T | 1995 – 2012 |

| Prince George A | 5971423 | 521103 | 691 | P, R, S, T, RH, SR | 1973 - 1995 |

1) UTM Coordinate system – Zone 10U

2) Length of record from start year to end year may not reflect the number of complete years of data

3) ECCC provided provisional data only for the period between January 2016 and December 2021

4) Station still in operation

5) Combined record from Quesnel A and Quesnel Airport Auto stations. Stations are located at the same location.

masl = metres above sea level

P = Precipitation; R = Rainfall; S = Snowfall; T = Temperature; RH = Relative Humidity; SR = Solar Radiation; E = evaporation; WS = wind speed; WD = wind direction.

In winter, snow course surveys are carried out at the Mine Site to generate snowpack depth measurements, with higher frequencies during heavy snowfall months. A summary of the snow course survey station locations and periods of record is provided in Table 1-5. A map of the weather station and snow course locations is provided in Figure 1-5.

**Table 1-5 The Mine Site Snow Courses**

| Station Name | Northing (m N)[1] | Easting (m N)[1] | Elevation (masl) | Period of Record[2] |
|---|---|---|---|---|
| #1 (near mill) | 5823182 | 592792 | 724 | 1997 – 2010, 2015 – 2021[3] |
| #2 (near TSF) | 5819976 | 594092 | 1,181 | 1997 – 2021[3] |
| #3 | 5823895 | 593632 | 1,171 | 2012 – 2021[3] |
| #4 | 5823537 | 590835 | 964 | 2015-2021[3] |

#### 1.4.6.1. Temperature

Air temperature statistics for the MPMC Mine Site were developed using historical data from the nearby ECCC climate station in Likely, approximately 9 km northeast of the Site. The historical Likely data set was adjusted to the average elevation of the Mine Site by applying a regional monthly lapse rate. Data gaps were infilled using data from the regional ECCC climate stations in a prioritized sequence and applying the monthly temperature lapse rate to adjust for elevation.

The estimated mean annual temperature varies between 1.7°C and 6.3°C, with a long-term mean of 3.9°C. Mean monthly temperatures vary between -6.7°C in January and 15.1°C in July. The historical daily maximum and minimum air temperature from the derived long-term data set for the Site was 38.1°C in June 2021 (measured at the Site) and -39.8°C in December 1996, respectively. Mean monthly air temperatures generally turn positive in April and negative in November. Monthly and annual air temperature statistics for the MPMC Mine Site (1974 to 2021) are presented in Table 1-6.

**Table 1-6 Monthly Average, Minimum, and Maximum Temperatures for the Mine Site (1974 to 2021)**

| Month | Average Temperature (°C) | Minimum Temperature (°C) | MaximumTemperature (°C) |
|---|---|---|---|
| January | -6.7 | -16.0 | -0.3 |
| February | -4.8 | -13.0 | 0.7 |
| March | -1.0 | -6.7 | 3.2 |
| April | 3.7 | -0.7 | 12.0 |
| May | 8.5 | 5.2 | 13.1 |
| June | 12.2 | 8.6 | 15.5 |
| July | 15.1 | 11.8 | 21.2 |
| August | 14.6 | 11.0 | 17.1 |
| September | 10.0 | 6.8 | 14.2 |
| October | 4.1 | 0.8 | 8.7 |
| November | -2.4 | -13.7 | 2.6 |
| December | -6.6 | -13.7 | -1.2 |
| **Annual** | **3.9** | **1.7** | **6.3** |

#### 1.4.6.2. Precipitation

Long-term precipitation time series representative of the climate conditions at the Mine Site was derived using the long-term regional data from the ECCC Likely station (1974 to 1993) and available local data from the three on-site climate stations (1995 to 2021; Golder 2022). The data set was infilled using historical data from the regional climate stations and adjusted for orographic effect. The Mine Site experiences high summer precipitation due to summer storms, with the lowest precipitation occurring in February. Precipitation typically occurs as snowfall starting in November, and accumulates until March. Average annual precipitation at the Mine Site is estimated to be 692 mm. A frequency analysis of the long-term precipitation time series was undertaken to estimate the variability in monthly and annual precipitation of the Mine. Estimated wet and dry values for 1-in-25-year and 1-in-200-year return periods are shown in Table 1-7.

The average monthly snowpack for the winter months from data collected at the Mine Site and recorded as snow-water equivalent (SWE) since 1995 is shown in Table 1-8.

**Table 1-7 Long-term Monthly and Annual Precipitation Frequency Analysis for the Mine Site (1974 to 2021)**

| Month | Precipitation (mm) | | | | |
|---|---|---|---|---|---|
| | 1:200-Year Dry | 1:25 Year Dry | Average | 1:25 Year Wet | 1:200-Year Wet |
| January | 12.4 | 17.5 | 49.4 | 117 | 207 |
| February | 4.7 | 8.3 | 35.8 | 101 | 185 |
| March | 5.0 | 9.6 | 29.7 | 57 | 71 |
| April | 4.3 | 8.7 | 44.7 | 118 | 199 |
| May | 9.4 | 17.8 | 49.9 | 88 | 104 |
| June | 7.7 | 18.9 | 70.8 | 131 | 152 |
| July | 2.4 | 7.7 | 63.6 | 172 | 254 |
| August | 5.7 | 11.8 | 50.6 | 120 | 178 |
| September | 3.1 | 9.5 | 52.3 | 111 | 133 |
| October | 10.7 | 19.6 | 58.1 | 111 | 141 |
| November | 4.7 | 11.0 | 49.8 | 110 | 146 |
| December | 14.3 | 20.5 | 57.6 | 135 | 232 |
| **Annual** | **349** | **421** | **612** | **836** | **960** |

**Table 1-8 Month End Average Snowpack Levels Recorded as SWE at the Mine Site (1995 to April 2021)**

| Month | Snowpack [SWE] (mm) |
|---|---|
| November | 17 |
| December | 102 |
| January | 147 |
| February | 182 |
| March | 185 |
| April | 33 |

#### 1.4.6.3. Wind

Prevailing winds are from the north-northeast and the south-southwest near the TSF, and from the northwest (and to a lesser extent from the southeast) near the mill site, with a predominance of winds designated as calm (below 3 metres per second [m/s]; Golder 2015).

#### 1.4.6.4. Relative Humidity

Relative humidity data are available for the Mine Site (from 2019 to 2021), Quesnel (1953 to 2021) and Williams Lake (1961 to 2021). Relative humidity data from the MPMC climate stations are insufficient for characterizing relative humidity at the Mine Site due to the short period of record. Therefore, data from Quesnel and Williams Lake stations were reviewed and analyzed to define a representative long-term relative humidity data set for the MPMC Mine Site.

Statistics for the derived historical relative humidity time series (1974 to 2021) are presented in Table 1-9. Mean annual relative humidity is 68.1%. Monthly values vary between 57.7% in April to 82.2% in December.

**Table 1-9: Derived Monthly and Annual Relative Humidity Statistics for The Mine Site (1974 to 2021)**

| Month | Relative Humidity (%) | | | | | |
|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25th Percentile | 50th Percentile | 75th Percentile |
| January | 69.2 | 81.3 | 90.1 | 78.9 | 81.7 | 84.0 |
| February | 65.5 | 75.0 | 84.8 | 72.0 | 75.6 | 77.8 |
| March | 55.4 | 64.9 | 76.2 | 61.0 | 64.0 | 68.3 |
| April | 47.9 | 57.7 | 69.4 | 54.9 | 57.4 | 60.5 |
| May | 45.6 | 58.1 | 70.3 | 54.1 | 57.8 | 61.5 |
| June | 44.2 | 60.4 | 72.4 | 54.4 | 60.2 | 67.7 |
| July | 42.2 | 59.0 | 72.9 | 52.6 | 58.6 | 65.9 |
| August | 48.4 | 60.2 | 81.2 | 55.0 | 58.8 | 63.6 |
| September | 47.5 | 66.4 | 79.1 | 61.3 | 66.1 | 71.3 |
| October | 54.3 | 72.3 | 86.7 | 69.7 | 72.0 | 76.1 |
| November | 61.4 | 80.1 | 87.8 | 77.6 | 80.4 | 83.5 |
| December | 70.8 | 82.2 | 89.3 | 78.9 | 82.6 | 85.0 |
| **Annual** | **54.4** | **68.1** | **80.0** | **64.2** | **67.9** | **72.1** |

#### 1.4.6.5. Solar Radiation

Solar radiation data are available from MPMC climate stations from 2001 to 2003 and 2019 to 2021, and ECCC climate stations Williams Lake (1961 to 2001) and Prince George (1973 to 1995). Solar radiation data from the MPMC climate stations is insufficient for characterizing incoming solar radiation at the Mine Site due incomplete data. In addition, the data are not concurrent with either ECCC climate station as the data recorded in 2001 is incomplete. Solar radiation statistics for the Mine Site area were determined from the ECCC Williams Lake data. Missing values were infilled with adjusted Prince George records.

Table 1-10 presents the results and statistics of the long-term solar radiation time series (1974 to 2001) representative of the Mine Site. Mean annual solar radiation is 136 watts per metre squared ($W/m^2$), with a minimum of 127 $W/m^2$ and maximum of 148 $W/m^2$. Mean monthly solar radiation varies between 20 $W/m^2$ in December to 257 $W/m^2$ in July.

**Table 1-10: Estimated Solar Radiation Statistics for The Mine Site Based on Infilled Williams Lake Records (1974 to 2001)**

| Month | Solar Radiation ($W/m^2$) | | | | | |
|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25th Percentile | 50th Percentile | 75th Percentile |
| January | 16 | 27 | 40 | 23 | 27 | 32 |
| February | 37 | 60 | 86 | 54 | 61 | 67 |
| March | 85 | 114 | 152 | 108 | 113 | 123 |
| April | 143 | 180 | 215 | 161 | 179 | 201 |
| May | 196 | 230 | 275 | 214 | 227 | 250 |
| June | 192 | 246 | 302 | 228 | 244 | 267 |
| July | 211 | 257 | 318 | 234 | 258 | 276 |
| August | 158 | 225 | 261 | 211 | 228 | 248 |
| September | 99 | 152 | 188 | 139 | 149 | 168 |
| October | 55 | 79 | 103 | 71 | 79 | 86 |
| November | 23 | 33 | 50 | 28 | 32 | 37 |
| December | 12 | 20 | 27 | 18 | 20 | 23 |
| **Annual** | **127** | **135** | **148** | **132** | **135** | **140** |

#### 1.4.6.6. Evaporation

Evaporation monitoring data are available from the MPMC climate stations from 2019 to 2021, although the data are not continuous, and the length of record is not sufficient for characterizing the evaporation conditions at the Mine Site. Therefore, a mathematical model (Morton 1983) was applied to calculate evaporation and evapotranspiration (actual and potential) based on long-term synthetic records for air temperature, relative humidity, and solar radiation. The calculated evaporation rates are reflective of potential shallow lake evaporation rates; that is, there is no thermal impact of deeper water volumes on evaporation.

Calculated evaporation at the Mine Site shows a typical seasonal profile, with little to no evaporation in the winter months and maximum evaporation in the summer months. Table 1-11 to Table 1-13 present the long-term mean annual and monthly statistics for shallow lake evaporation, potential evapotranspiration, and actual evapotranspiration, respectively, for 1974 to 2001 as calculated using the Morton Model. The mean annual evaporation rate is estimated to be 673 mm, varying between 606 mm and 762 mm. Mean monthly evaporation rates varies between 0 mm in December to 138 mm in July.

**Table 1-11: Estimated Monthly and Annual Shallow Lake Evaporation Statistics for the Mine Site Based on Infilled Williams Lake ECCC Records (1974 to 2001)**

| Month | Shallow Lake Evaporation (mm) | | | | | |

#### 1.4.6.7. Air Quality

The location of the Mine Site is remote, but the air quality is subject to impacts from seasonal pollen, as well as fugitive dust and particulate matter from the logging industry, forest fires, recreational traffic, and nearby wood-burning stoves. The slightly undulating terrain around the Mine Site permits unobstructed atmospheric exchanges and prolonged inversions. Major storm tracks are from the west off the Pacific Ocean. A monthly dust fall monitoring program was initiated at the Mine Site in 1995 to establish baseline dust fall data on total deposition amounts of fugitive dust (particles) during the non-winter months (June to September). The dust fall collectors were set up at seven locations on the Mine Site and collected monthly. Monitoring results did not exceed 3.95 milligrams per decimetre squared per day (mg/dm$^2$/d) (Hallam Knight Piesold 1996b).

# 2. MINE OPERATIONS

## 2.1. Access and Transportation

Primary access to the Mine Site is via the Likely Highway. The route from Williams Lake involves driving 14 km south on Highway 97 to the Horsefly/Likely Road turnoff and continuing on this road 4.3 km, then turning left onto the Likely Road and continuing 66 km to the Bootjack Forest Service Road (FSR). Shortly after the Morehead Lake Resort, a turnoff to the right connects the Likely Road to the Bootjack FSR. The Bootjack FSR is a radio controlled (frequency RR-25) industrial road operated and maintained by MPMC. All Mine personnel, supplies, and concentrate trucks use this access road, with additional use by the forest industry and recreational users. Most non-mine traffic is related to people accessing the Bootjack Lake forestry campsite, which is located at 8.5 km along the Bootjack FSR. There are also several private properties that are accessed via the Bootjack FSR. After the turnoff to the Bootjack Lake forestry campsite at 8.5 km, the road continues, and the remaining 6 km of road to the Mine Site are private. There is a gatehouse at the entrance to the Mine Site that controls access. All other access points to the Mine Site are controlled by locked gates.

To access the Mine Site, MPMC personnel use the Likely Highway from areas north and south of the Bootjack FSR. Employees live in many communities along this secondary highway, including 150 Mile House, Big Lake, Beaver Valley, Morehead Lake, Little Lake, Hydraulic, Likely, and Horsefly.

The Likely Highway has seasonal load restrictions imposed in springtime by the MoTI. The Bootjack FSR is monitored by the MLWRS and loads are seldom restricted. Concentrate and other supplies are hauled year-round. MPMC is responsible for the maintenance of the Bootjack FSR year-round, including grading, repairs, dust suppression, and clearing of snow. The Likely Highway is maintained under contract by the MoTI.

## 2.2. Mill and Processing Plant Description

The flow sheets outlining the processes of the Mount Polley mill and processing plant are included in Appendix E.

### 2.2.1. *Primary, Secondary, Tertiary Crushing and Ore Handling*

Ore is crushed in three stages to produce a 16 mm product for the grinding circuit, which is stored in a 60,000 t stockpile. Sized rock for the pebble mill is removed from the secondary crusher feed and stored in a 10,000 t surge pile.

### 2.2.2. *Grinding*

Rod mills receive the crusher product from storage and reduce it to ball mill feed size at a rate of approximately 915 t per hour. Product from the ball mills is fed to the pebble mills, where it is reduced to flotation feed sized (65% passing 200 mesh). Slurry is pumped to hydrocyclone packs and classified to the required product size.

### 2.2.3. *Flotation*

A combination of column and mechanical cells recover rougher and scavenger concentrates for regrinding and subsequent cleaning to produce high-grade concentrates. The circuit has been designed with sufficient flexibility to accommodate operational variations in the head grade and oxidation of the ore.

### 2.2.4. *Concentrate Dewatering*

The concentrate from the flotation circuit is thickened and stored in a stock tank that provides surge capacity between thickening and filtering. Two pressure filters reduce the moisture content of the final concentrate to 8% for shipment. A conveyor deposits the filtered concentrate in a concentrate storage shed accessible to a front-end loader in the truck loading area. A new horizontal filter will be installed in 2023 to increase concentrate dewatering reliability.

### 2.2.5. *Concentrate Handling and Transport*

The Mine's concentrate is transported to the Port of Vancouver by Arrow Transportation Systems Inc. and shipped to overseas smelters. The principal market for the Mine Site concentrate is Asia. Concentrate has also been trucked to rail for delivery to smelters in North America.

### 2.2.6. *Mill Reagents*

Table 2-1 summarizes the types and estimated amounts of reagents currently used in mill processing. Depending on the type, mill reagents are shipped to the Mine Site in bags or drums as solids or as liquids. Mixing and storage tanks, which are heated as necessary, provide up to 48 hours of supplies of reagent ready for feeding by metering pumps. A spare system is provided for trials of experimental reagents. A ventilation system ensures that there is no build-up of noxious fumes in the area.

**Table 2-1 Reagent Types and Quantities Used in the Mount Polley Mill**

| Reagent | Rate of Use (g/t) |
|---|---|
| Potassium amyl xanthate collector | 12 |
| W22C frother | 20 |
| Flocculant | 0.13 |
| Lime | 70 |

### 2.2.7. *Instrumentation and Control Philosophy*

The entire processing operation is controlled through a central programmable logic controller (PLC). This PLC and its principal auxiliary components are in a control room in the concentrator building and it communicates with the remote input/output stations at the freshwater pump house, the water head tanks, the reclaim water pump barge, and the reclaim water booster pump house, among other components, by way of an overhead data highway cable.

An on-stream analyzer (OSA) provides up-to-date information on the ore feed and operating results by measuring assays for five streams. This enables flotation operators to control recovery and concentrate grades. The OSA minimizes the requirements for personnel who would otherwise be required to provide these control assays. The OSA package includes an X-ray analyzer (which has an X-ray tube and spectrometer) and computer hardware and software for data collection and analysis. The sample streams to the OSA are used for shift composite samples for metallurgical accounting purposes, along with five other hand-cut samples from other streams.

### 2.2.8. *Processing History*

A summary of the history of processing at the Mine Site is provided in Table 2-2.

**Table 2-2 History of Mill Processing at the Mine Site**

| Year of Production | Ore Processed (t) | Tailings Produced (t) | Grinding Circuit | Sources of Tailings | Changes and Geochemical Considerations |
|---|---|---|---|---|---|
| Mine Start (1997) | 2,346,829 | 2,333,186 | 2 rod, 2 ball, 3 pebble mills. | Three tailings streams: (1) sand scavenger; (2) oxide; and (3) cleaner tails from cyclone overflow. All streams combined for disposal in the impoundment. | NaHS used to float copper oxide minerals. |
| 1998 | 5,828,358 | 5,788,498 | | | |
| 1999 | 7,051,212 | 6,986,932 | | | |
| 2000 | 6,948,339 | 6,883,317 | | | |
| 2001 | 5,385,796 | 5,328,581 | | | |
| 5-year shutdown | | | | | Consolidation of the tailings in the impoundment. |
| 2005 | 4,814,083 | 4,758,757 | 2 rod, 2 ball, 3 pebble mills | Two streams; rougher and scavenger tails. Both streams combined for disposal in the impoundment. | Higher proportion of sulphide ore and lower NaHS addition. |
| 2006 | 6,235,221 | 6,133,088 | | | |
| 2007 | 6,444,112 | 6,346,640 | 2 rod, 3 ball, 3 pebble mills. | | Addition of third ball mill to increase production from 6.4 to 7 million t per year. |
| 2008 | 6,848,983 | 6,735,444 | | | |
| 2009 | 7,045,737 | 6,977,681 | | | |
| 2010 | 7,894,596 | 7,825,178 | 2 rod, 3 ball, 3 pebble mills and flash flotation. | | Addition of flash flotation for remainder of operations to date with the potential to lower sulphide content in the tailings. |
| 2011 | 7,716,856 | 7,663,577 | | One stream combined. | More oxidized ore and higher NaHS addition. |
| 2012 | 8,121,878 | 8,056,496 | | One flotation stream and addition of circuit to remove magnetite. | Addition of magnetite removal circuit. Tailings produced after 2012 would contain lower amounts of magnetite. |
| 2013 | 7,956,738 | 7,882,625 | | | |
| 2014 (to 4 August 2014) | 4,486,121 | 4,440,700 | | | |

**Table 2-2 History of Mill Processing at the Mine Site**

| Year of Production | Ore Processed (t) | Tailings Produced (t) | Grinding Circuit | Sources of Tailings | Changes and Geochemical Considerations |
|---|---|---|---|---|---|
| 1 year shutdown | | | | | |
| 2015 (5 August to December 31) | 1,781,799 | 1,765,955 | 2 rod, 3 ball, 3 pebble mills and flash flotation. | One flotation stream and addition of circuit to remove magnetite. | Tailings deposition in the Springer Pit. |
| 2016 (up to June 26) | 3,240,819 | 3,214,965 | | | |
| 2016 (June 27 to December 31) | 3,444,005 | 3,420,710 | | | Tailings deposition in the TSF. |
| 2017 | 6,723,188 | 6,686,158 | | | |
| 2018 | 6,195,760 | 6,166,566 | | | |
| 2019 (January 1 to May 31) | 2,231,119 | 2,224,146 | | | |
| 2019 (May 31 to December 31) | 0 | 0 | Care and maintenance . | No Deposition of Tailings. | |
| 2020 | 0 | 0 | | | |
| 2021 | 0 | 0 | | | |

## 2.3. Current Permitted Mine Plan

The current mine plan accounts for the existing operational period of the mine, as well as a one-year restricted operating period which was completed in 2016. Because of the delays in its execution (Section 1.2.1), the current mine plan will complete the mining of Phase 4 Springer Pit by 2024. Under the currently authorized mine plan, approximately 16,900,000 t of material will be mined over the next two years, which will yield 17,500,000 t of tailings; the bulk of which will report to the TSF (MPMC 2022b). Currently the TSF has a minimum elevation of 968 m and does not have the capacity to accommodate all of the tailings that will be generated through the remainder of the authorized mine plan (MPMC 2022b). To help alleviate this, MPMC is in the process of executing work to raise the TSF elevation to that currently approved under the M-200 *Mines Act* permit (970 m). When complete, the associated work will provide an additional 14,000,000 t of tailings capacity to the TSF (MPMC 2022b). As this additional capacity is not enough to accommodate all of the tailings generated from the mining of Phase 4, MPMC is also pursuing permitting to raise the TSF to 984 m; however, as this raise has not been approved, the 2022 MRP (e.g., this document) excludes discussion on the use of the additional capacity related to the 984 m TSF.

The active closure period will occur after completion of mining of the Phase 4 Cariboo-Springer Pit. Prior to this, stockpiled ore will be processed, to prepare the Mine Site for active closure. The exact volume of stockpiled ore to mill during this period will depend on the volume of ore generated prior to this point and space available in the 970 m TSF.

Following the processing of ore stockpiles, approximately 33,920,000t of PAG rock from the Temporary NW PAG Stockpile will be rehandled into the Cariboo-Springer Pit for long-term subaqueous disposal (MPMC 2015b). This will occur as haulage capacity allows, over a period of at least two years. Generation of acid rock drainage (ARD) from the PAG rock is not a concern during the rehandling phase, or prior to completion of mine closure, as the onset times for potential acid generation are in the order of 100 years and greater due to its inherently high carbonate content (MPMC 2015b).

### 2.3.1. *Material Handling*

A summary of expected quantities of different material types generated and handled during the current mine plan (including those associated with the restricted operation period) is provided in Table 2-3. Referenced locations are shown in Figure 2-1, which shows their expected footprints during active closure. Of note, underground mining has been removed from the approved mine plan.

During active closure, non-acid generating (NAG) waste rock will be placed at the SERDS or, alternatively, used for on-site projects. PAG rock will continue to be characterized according to the current acid-base accounting (ABA) sampling regime, and placed on the Temporary NW PAG Stockpile before being rehandled into the pits for final subaqueous disposal. Section 5.2.2 provides additional details on metal leaching (ML) and ARD characterization and associated material management, including handling of PAG material.

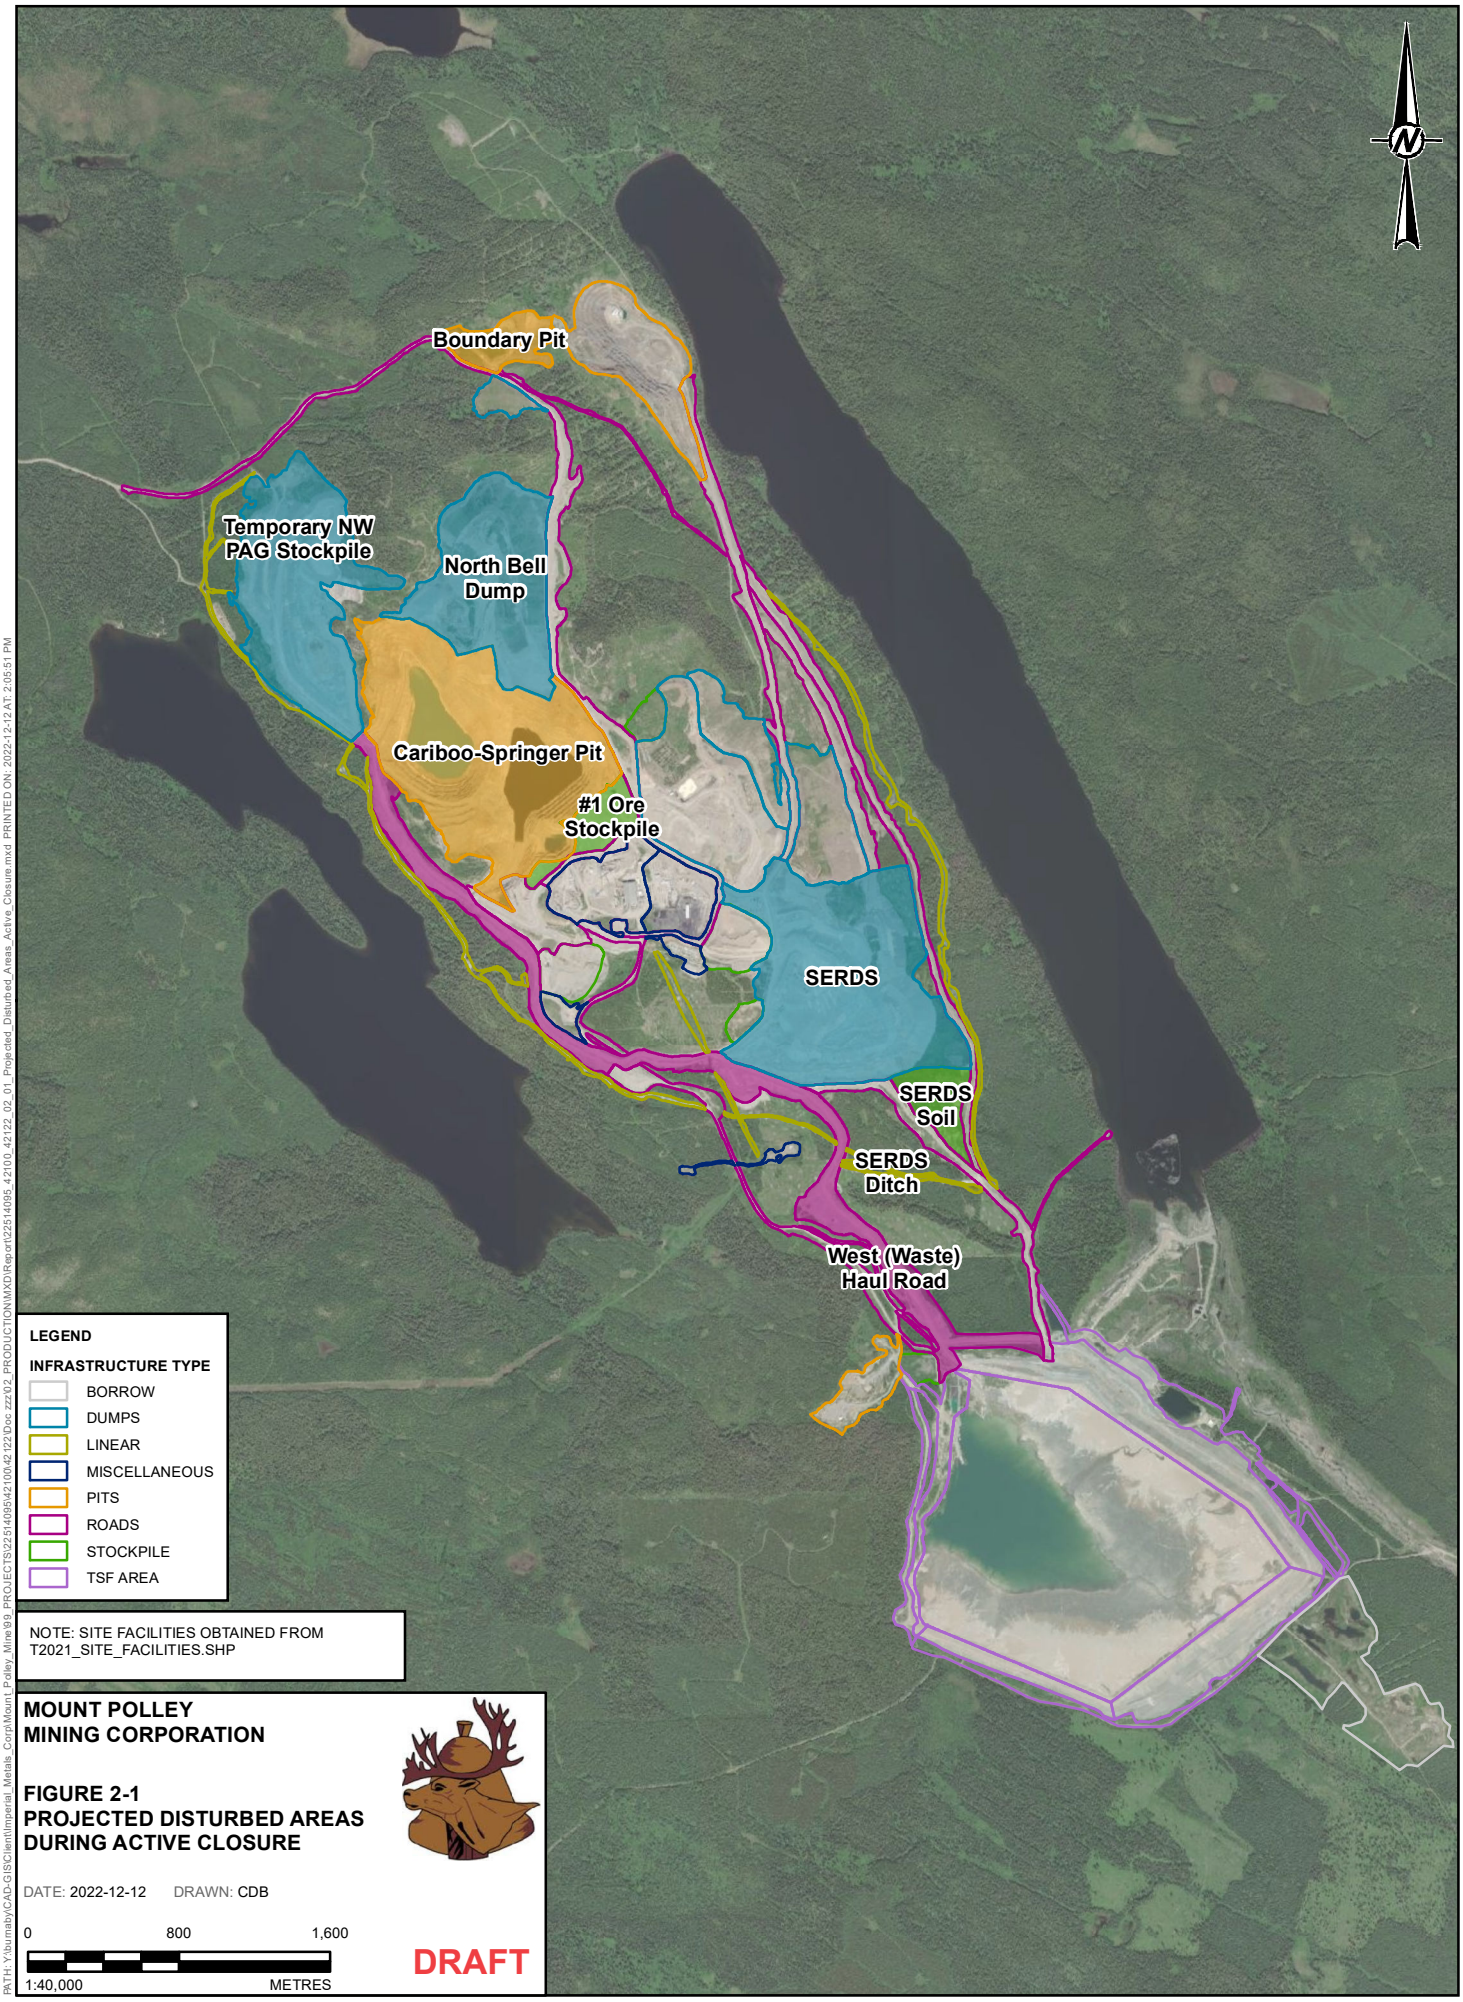

**Table 2-3 Mine Plan Material Tonnages (Including the Restricted Operations Interval)**

| Material Type | Quantity (t) |
|---|---|
| NAG waste rock | 51,700,000 |
| Tailing to be moved from the Springer Pit to the TSF or for co-disposal at SERDs[1] | 4,000,000[2] |
| Phase 4 PAG waste rock stockpiled | 8,170,000 |
| Total PAG waste rock rehandled during active closure | 33,920,000 |
| Ore directed to mill from pits | 24,600,000 |
| Phase 4 ore stockpiled | 3,550,000 |
| Stockpiled ore processed over entire period | 5,310,000[2] |
| **Total ore processed** | **29,910,000** |

Notes:

1) contingent on approval of SERDS co-disposal application.

2) denotes material to be deposited in the TSF for the 970 m configuration.

PATH:Y:\Burnaby\CAD-GIS\Client\Imperial_Metals_Corp\Mount_Polley_Mine\09_PROJECTS\225140954210042122\Doc zzz\02_PRODUCTION\MXD\Report\225140954210042122_02_01_Projected_Disturbed_Areas_Active_Closure.mxd PRINTED ON: 2022-12-12 AT 2:05:51 PM

### 2.3.3. *Area of Disturbance*

The current area of disturbance at the Mine Site is 1,219.49 ha as reported in the 2021 Annual Reclamation Report (MPMC 2022a). The areas are organized by mine features and disturbance type (Table 2-4). These disturbed areas are shown in Figure 2-1 in their final configuration. Areas designated as undergoing progressive reclamation are discussed and shown on a map in Section 4.2.

The projected disturbance footprint that will be reclaimed is 1,311.06 ha; this is an anticipated increase of 91.57 ha from the December 2021 disturbance footprint. This increase in disturbance is the result of the development of components under the authorized mine plan, including pits, SERDS and Temporary NW PAG Stockpile development, and projected development of the West Haul Road; construction of the West Haul Road will depend on haulage efficiencies and economics to be determined by MPMC. Area changes in specific features associated with the approved mine plan are summarized in Table 2-5 and the projected disturbance footprint is shown in Figure 2-1.

Table 2-4 also includes the area that will require reclamation following the execution of the approved mine plan (1,131.94 ha). Areas shown in Table 2-4 represent the final configurations of these components prior to material rehandling, and inform reclamation activities (e.g., placement of coversoil) in active closure.

* Areas for the SERDS and Temporary NW PAG Stockpile represent final configurations prior to PAG subaqueous disposal and resloping; areas for the Boundary Pit and Cariboo-Springer Pit represent areas prior to flooding.

** Not all areas are new disturbance; some are transfers of areas between site components.

## 2.4. Water Management

### 2.4.1. *Water Discharge Background*

The Mine Site has a positive water balance, (i.e., an accumulation of water year over year). As the Mine Site footprint has expanded, the annual surplus water has increased over the life of the project. During the early 2000s, the Mine was in care and maintenance due to low metal prices, and excess water accumulated in the TSF, and was subsequently discharged to Edney Creek under *EMA* Permit 11678. In November 2011, MPMC received an amendment to *EMA* Permit 11678 that allowed for discharge of dam-filtered water into Hazeltine Creek. However, permit restrictions on the quality and quantity, water source, and season of discharge prevented the Mine from fully discharging the surplus water that was accumulating in the TSF. At the time of the TSF embankment breach, the Mine was actively pursuing permit amendments for a short-term discharge system to manage the surplus water, while a long-term plan for water management was developed.

Following the TSF embankment breach, MPMC had no permitted discharge due to a PAO (issued by ENV), and all Mine contact water was stored in the Springer Pit. However, the Mine Site continued to have a positive water balance, and Springer Pit possessed a finite storage capacity (overflow elevation of 1,050 masl; Golder 2015b). Modelling by Golder following the breach indicated that once the pit water elevation reached approximately 1,030 masl, water would exfiltrate to groundwater and discharge towards Bootjack Lake (Appendix F). Therefore, there was a need to develop a system for treatment and discharge of Mine contact water. In July 2015, after the development of a long-term water management strategy, MPMC was provided approval by EMLI to return to restricted operations for a one-year period using the Springer Pit for tailings deposition. The Springer Pit received tailings and contact water until 2016 when the TSF was repaired and authorized for use under *Mines Act* Permit M-200 and *EMA* Permit 11678.

In 2016, a Technical Assessment Report (TAR) was submitted to British Columbia Ministry of Environment and Climate Change Strategy (ENV). The main objective of the TAR was to identify water management practices that would limit further accumulation of contact water at the Mine Site and prevent unplanned discharge to the environment. The TAR included an assessment of the effluent discharge during operations, and recommended using an active treatment system and a pipeline to discharge treated mine water at depth in Quesnel Lake. These recommendations were implemented, and in May 2016, a direct pipeline from the Springer Pit to the Water Treatment Plant (WTP) was installed. Work towards water discharge continued, with a pipeline and diffusers installed at depth in Quesnel Lake. On 23 June 2016, MPMC was approved by EMLI to return to normal operations and discharge treated water to Quesnel Lake. This discharge is currently permitted until 30 June 2025 under *EMA* Permit 11678.

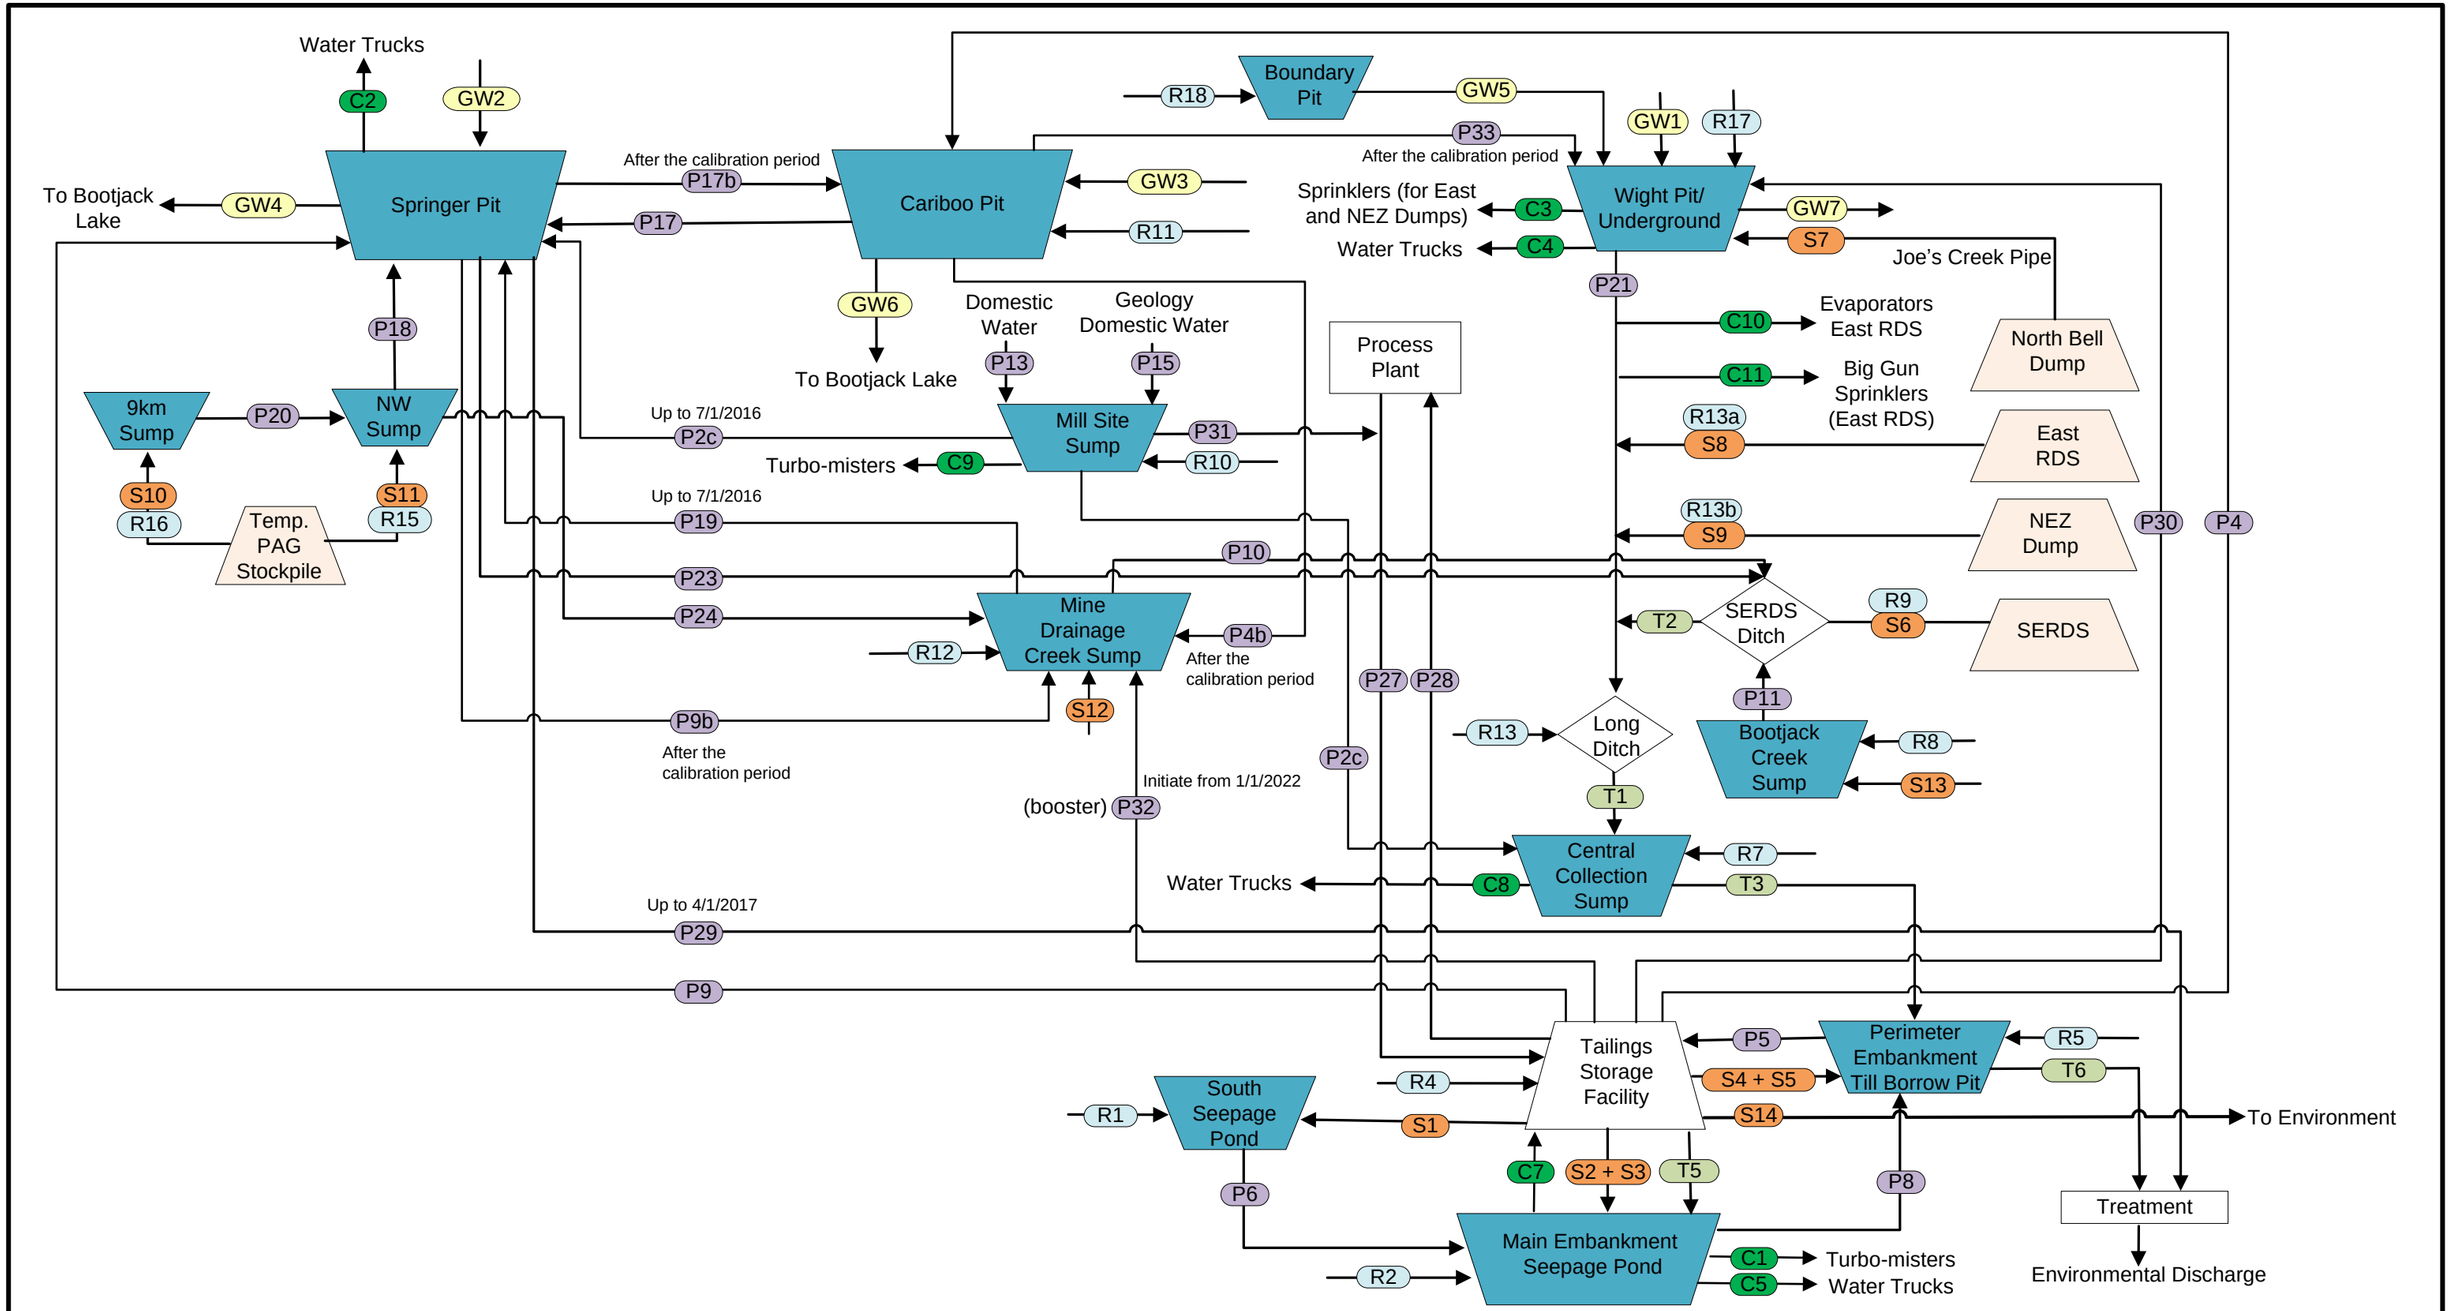
Following the 2016 *EMA* Permit 11678 approval, normal operations resumed, including the continued dewatering of Springer Pit and the transferring of 5,000,000 t of tailings from Cariboo-Springer Pit to the TSF. From 2016 to 2019, the Mine Site operated at full capacity, but was again placed in care and maintenance due to slumping metal prices. Currently, dewatering of the Springer Pit has been completed, and the tailings removal is expected to be finished by the end of 2022. Dewatering of the Cariboo Pit is still ongoing, with approximately 1,000,000 $m^3$ of water remaining.

### 2.4.2. *Current Water Management System Overview*

As with most mines, water management at the Mine Site is integral to limiting potential impacts on the environment. Currently on the Mine Site, a network of channels, ponds, and pumps are used for managing surface water. Contact and non-contact (e.g., clean) water systems are managed with the objective of avoiding the mixing of these two types of water sources. Because of the extensive infrastructure and the multiple sources of water that require management (e.g., precipitation inputs, seepage, runoff), water management at the Mine Site is complex. Figure 2-2 provides an overview of water management systems at the Mine Site for existing and future operations. Figure 2-3 provides a detailed breakdown on how water is managed and treated at the Mine Site, while Figure 2-4 shows environmental monitoring locations that are associated with mine operations.

In general, non-contact water management systems consist of channels to divert runoff (originating from undisturbed areas) away from the Mine Site; thus, preventing the generation of additional contact water. Conversely, contact water from within the Mine Site is actively managed using the infrastructure shown in Figure 2-2, with the contact water ultimately destined for one of the following:

- use in operations (e.g., milling) or dust management
- conveyance to the TSF
- transport to the Perimeter Embankment Till Borrow Pond (PETBP), which functions as the influent pond for the WTP
- transmission to the WTP for treatment, and then subsequent release to the surrounding environment



For information on existing water treatment, see Section 2.4.2.5.

Currently, most contact water at the Mine Site is collected along two collection-ditch systems that run north to south along the western and eastern edges of the site: namely, the West Ditch system and the Long Ditch system (Figure 2-2). The contact water is conveyed to the TSF or the PETBP for re-use as part of mine operations or for treatment and subsequent discharge.

Site water management is designed to meet the TSF quantitative performance objectives set by the TSF engineer of record (Golder 2020a), including TSF pond size, freeboard, and beach width. Due to large freshet water volumes, it is necessary to utilize the TSF for temporary detention of contact water. However, the fundamental basis of the water management plan is to not accumulate water on site by treating and discharging water, and to not carry over surplus water inventory year-to-year even under extreme weather conditions.

A summary of the water management infrastructure is provided in the following subsections (Sections 2.4.2.1 to 2.4.2.5). See Figure 2-2 for clarity, as infrastructure is discussed in detail within the following sections.

#### 2.4.2.1. West Ditch System

The West Ditch system collects contact water from the west side of the Mine Site and extends from the Junction Zone Seepage Collection to SERDS Sump (as shown on Figure 2-2). The West Ditch system comprises the following (from upstream to downstream) series of open-flow ditches and sumps:

- **Junction Zone Seepage Sump** collects seepage from the Temporary NW PAG Stockpile and is pumped into Junction Zone Ditch
- **Junction Zone Ditch** collects contact water runoff from the Temporary NW PAG Stockpile and flows by gravity to the 9K Sump
- **9K Sump** collects contact water from Junction Zone Ditch and runoff from the Temporary NW PAG Stockpile, and is pumped to the NW Sump
- **NW Sump** collects contact water from 9K Sump and runoff from the Temporary NW PAG Stockpile. There are two pumping options for NW Sump:
    - the primary option is to pump to the north portion of Mine Drainage Creek Ditch
    - the secondary option is to pump to Springer Pit
- **Mine Drainage Creek Sump and Ditch** collects contact water runoff from the West Haul Road and Mill Site Area, and at times pumps flow from the NW Sump. Mine Drainage Creek Sump is pumped to the south branch of Mine Drainage Creek Ditch and flows by gravity into Lower West Ditch.
- **Lower West Ditch** collects contact water runoff from the West Haul Road and flows by gravity into SERDS Ditch.
- **Bootjack Creek Sump** collects contact water from the east side of the Tailing Access Road and pumps into SERDS Ditch.
- **SERDS Ditch** collects contact water runoff from the SERDS Catchment and conveys water by gravity from Lower West Ditch and Bootjack Creek Sump to SERDS Sump.
- **SERDS Sump** is the terminus of the West Ditch system. Water collected at SERDS Sump flows by gravity feed pipeline to the Central Collection Sump (CCS). An overflow system consisting first of a 24” HDPE pipeline conveys flow to Lower Long Ditch Sump, and then overflowing water is conveyed over the haul road to Upper Long Ditch Sump.

#### 2.4.2.2. Long Ditch System

The Long Ditch system collects contact water from the east side of the Mine Site and extends from below the site access road to the Long Ditch Sump (as shown on Figure 2-2). The Long Ditch system comprises the following (from upstream to downstream) series of open-flow ditches and sumps:

- **Joe's Creek Coffer Dam** collects seepage from North Bell Dump and conveys flow by gravity feed pipeline to the north end of Long Ditch, or directs it to Wight Pit
- **Wight Pit** is currently being dewatered. Water from Wight Pit is pumped via a series of pumps and booster tanks to the north end of Long Ditch
- **Long Ditch** collects contact water from Joe's Creek Coffer Dam and Wight Pit Dewatering, and conveys it by gravity to Upper Long Ditch Sump
- **Northeast Zone (NEZ) Sump** collects contact water from NEZ Seep 1 and NEZ Seep 2 and conveys water by gravity feed pipeline to the Booster tank where it is then pumped to the mill for treatment. Overflow from this booster tank flows into the Wight Pit
- **Upper Long Ditch Sump** collects contact water from Long Ditch and is conveyed by gravity feed pipeline to the CCS

#### 2.4.2.3. Central Collection Sump (CCS)

The CCS receives water from the Long Ditch and West Ditch systems, as well as contact water from local runoff. Depending on water management needs, water may be pumped to the TSF or allowed to overflow into the PETBP.

#### 2.4.2.4. Perimeter Embankment Till Borrow Pond (PETBP)

The PETBP receives contact water from the immediate area via runoff and seepage. The PETBP also serves as a storage pond for the West Ditch and Long Ditch systems with overflow coming from the CCS. Water from the PETBP provides influent for the WTP or is recirculated (via pumps) for use in other areas of the site.

#### 2.4.2.5. Mill Process Water

Mill process water is currently, and will continue to be, primarily sourced from the TSF. The TSF will receive water from a variety of locations depending upon the season and site water management considerations. Any required mill water will be pumped from the TSF to the booster station and from the booster station to the mill process water tank. From the mill process water tank, water will then be directed to the mill, with surplus water returned to the TSF. A TSF free water (pond) volume between 1.0 and 1.7 $Mm^3$ will be targeted for processing requirements. This volume range also allows for adequate tailings beaches (operating objective of a minimum of 100 m) to be maintained. Appendix E includes mill process flow diagrams that detail mill water use.

#### 2.4.2.6. Water Treatment and Discharge

Currently, the Mine Site's water management infrastructure allows for the cycling of water through the mill and back to the TSF or PETBP, which allows for mill components to provide lime pre-treatment (as needed) to precipitate metals (mainly high instances of copper). The Mine Site operates with an existing WTP design capacity of 0.23 $m^3/s$. Additional temporary treatment capacity of 0.07 $m^3/s$ has been recently added in 2022 to assist in treating and discharging surplus contact water currently on-site. Under *EMA* Permit 11678, the allowable maximum annual discharge volume from site is currently 10.59 $Mm^3$/year (which equates to an average of 0.33 $m^3/s$), while the design capacity of the WTP effluent pipeline and diffusers is 0.6 $m^3/s$ (equivalent to the permitted maximum daily instantaneous rate). Modeling predictions for total copper, total selenium, and total suspended solids (TSS) indicates that these parameters will require treatment during the remainder of operations; however, actual monitoring data over several years shows that selenium treatment has not been required during operations. Operation of the WTP has been shown to effectively treat both TSS and total copper for the majority of operating conditions.

In preparation for closure of the Mine Site, MPMC has been proceeding with a program of evaluating and developing passive, semi-passive, and active water treatment technologies for their possible use during mine closure to support the goal of distributing discharge back into the pre-mining configuration. Two treatment options are considered the BAT for treatment during closure and post-closure: Option A - distributed passive/semi-passive treatment systems (applied to select sources), and Option B – pit-lake treatment followed by the centralized Actiflo WTP. Option B is the current assumption for water treatment during closure/post-closure, but MPMC has also been progressing technology evaluations to support Option A. Further detail on research conducted to further progress BAT water treatment is provided in Section 4.4, while the most recent information on water treatment is provided in Appendix G.

# 3. LAND USE AND CAPABILITY OBJECTIVES

Prior to the development of the Mine Site, the key land uses within the Mine Site footprint were commercial forestry and wildlife habitat. Portions of the Mine Site footprint were also used for cattle grazing, recreational activities, hunting, and trapping. There was no agriculture in the area, and in baseline assessments, the Mine Site was determined to have poor agricultural capability. Detailed baseline land capability and historical land use information is provided in Appendix C, and summarized in Section 1.4.

## 3.1. Reclamation Objectives

### 3.1.1. *End Land Use Objectives*

The main objective of the reclamation program is to return all areas that have been disturbed by mining operations (except pit walls) to equivalent or greater land capability than existed prior to mining, on an average property basis. To help achieve this overarching goal, an End Land Use Plan (Section 5.3) has been developed, which focusses on ecosystem rehabilitation as the main goal with a target towards ecosystems that occurred prior to disturbance (Section 1.4).

The End Land Use Plan also estimates shifts in the end land use objectives over time as the ecological trajectories of the ecosystem evolve. This allows for end land use planning to be considered over the long-term and considers that a variety of end land uses can occur on the landscape over different temporal scales. To achieve successful closure of the Mine Site, the following objectives must be achieved:

- long-term stability of engineered structures, including the RDSs, TSF and open pits, as well as all exposed erodible materials
- removal and proper disposal of access roads, structures, and equipment not required after the Mine Site closes
- sufficient coversoil (e.g., reclamation material) to achieve the desired target ecosystems on the post-closure landscape
- geochemical stability of WRDs, open pits, the TSF, and all other major components of the Mine Site in the post-closure landscape
- long-term preservation of water quality within and downstream of decommissioned operations
- a water balance that meets the requirements for a functional landscape that aligns with the targeted end land use
- natural integration of disturbed lands into surrounding landscape, and restoration of the natural appearance of the area after mining ends, to the extent practicable

- self-sustaining vegetation covers established, consistent with the end land uses and desired ecosystems

- use of reclaimed ecosystems by their desired stakeholders (e.g., recreational users, wildlife, and traditional use practitioners)

Once these aspects are in place, flexibility exists to modify ecosystem composition, patch size, and vegetation mosaic and to provide additional structural components, as desired. By reclaiming disturbed land to stable, functioning, and locally appropriate ecosystems that can reasonably be expected to thrive on a specific landform or location, a variety of end land use objectives can also be met.

#### 3.1.2. *Success Criteria*

To track progress towards closure objectives and overall adherence with the End Land Use Plan, Success criteria, which are more specific than closure objectives, were developed. These success criteria are used as milestones that indicate progress to achieving specific land use objectives. The success criteria include parameters such as:

- landform stability

- erosion control

- visual and functional integration into the surrounding environment

- establishment of self-sustaining native vegetation consistent with target site series

- vegetation quality

- presence of culturally important and rare or listed species

The general approach for measuring reclamation success is described in Section 7.4.

#### 3.1.3. *Towards Sustainable Mining Program*

As a member of the Mining Association Canada, Imperial Metals Corporation is a participant in the Towards Sustainable Mining (TSM) program. TSM is a set of guiding principles and performance elements that address key activities of companies in all sectors of the mining and mineral-processing industry, and the program works to promote corporate social responsibility. Protocols of relevance to reclamation and closure are Aboriginal and Community Outreach, Tailings Management, and Biodiversity Conservation Management.

Historically, Imperial Metals Corporation has worked to advance TSM objectives for the MPMC Mine Site. TSM activities were postponed during care and maintenance, but Imperial Metals Corporation intends to resume TSM activities in the future.

# 4. RECLAMATION APPROACH

## 4.1. Reclamation Approach

To achieve the closure and end land use objectives outlined in Section 3, MPMC has developed strategies to promote physical stability, water quality and watercourse protection, sediment retention and erosion control, appropriate soil handling, suitable revegetation, and invasive species management.

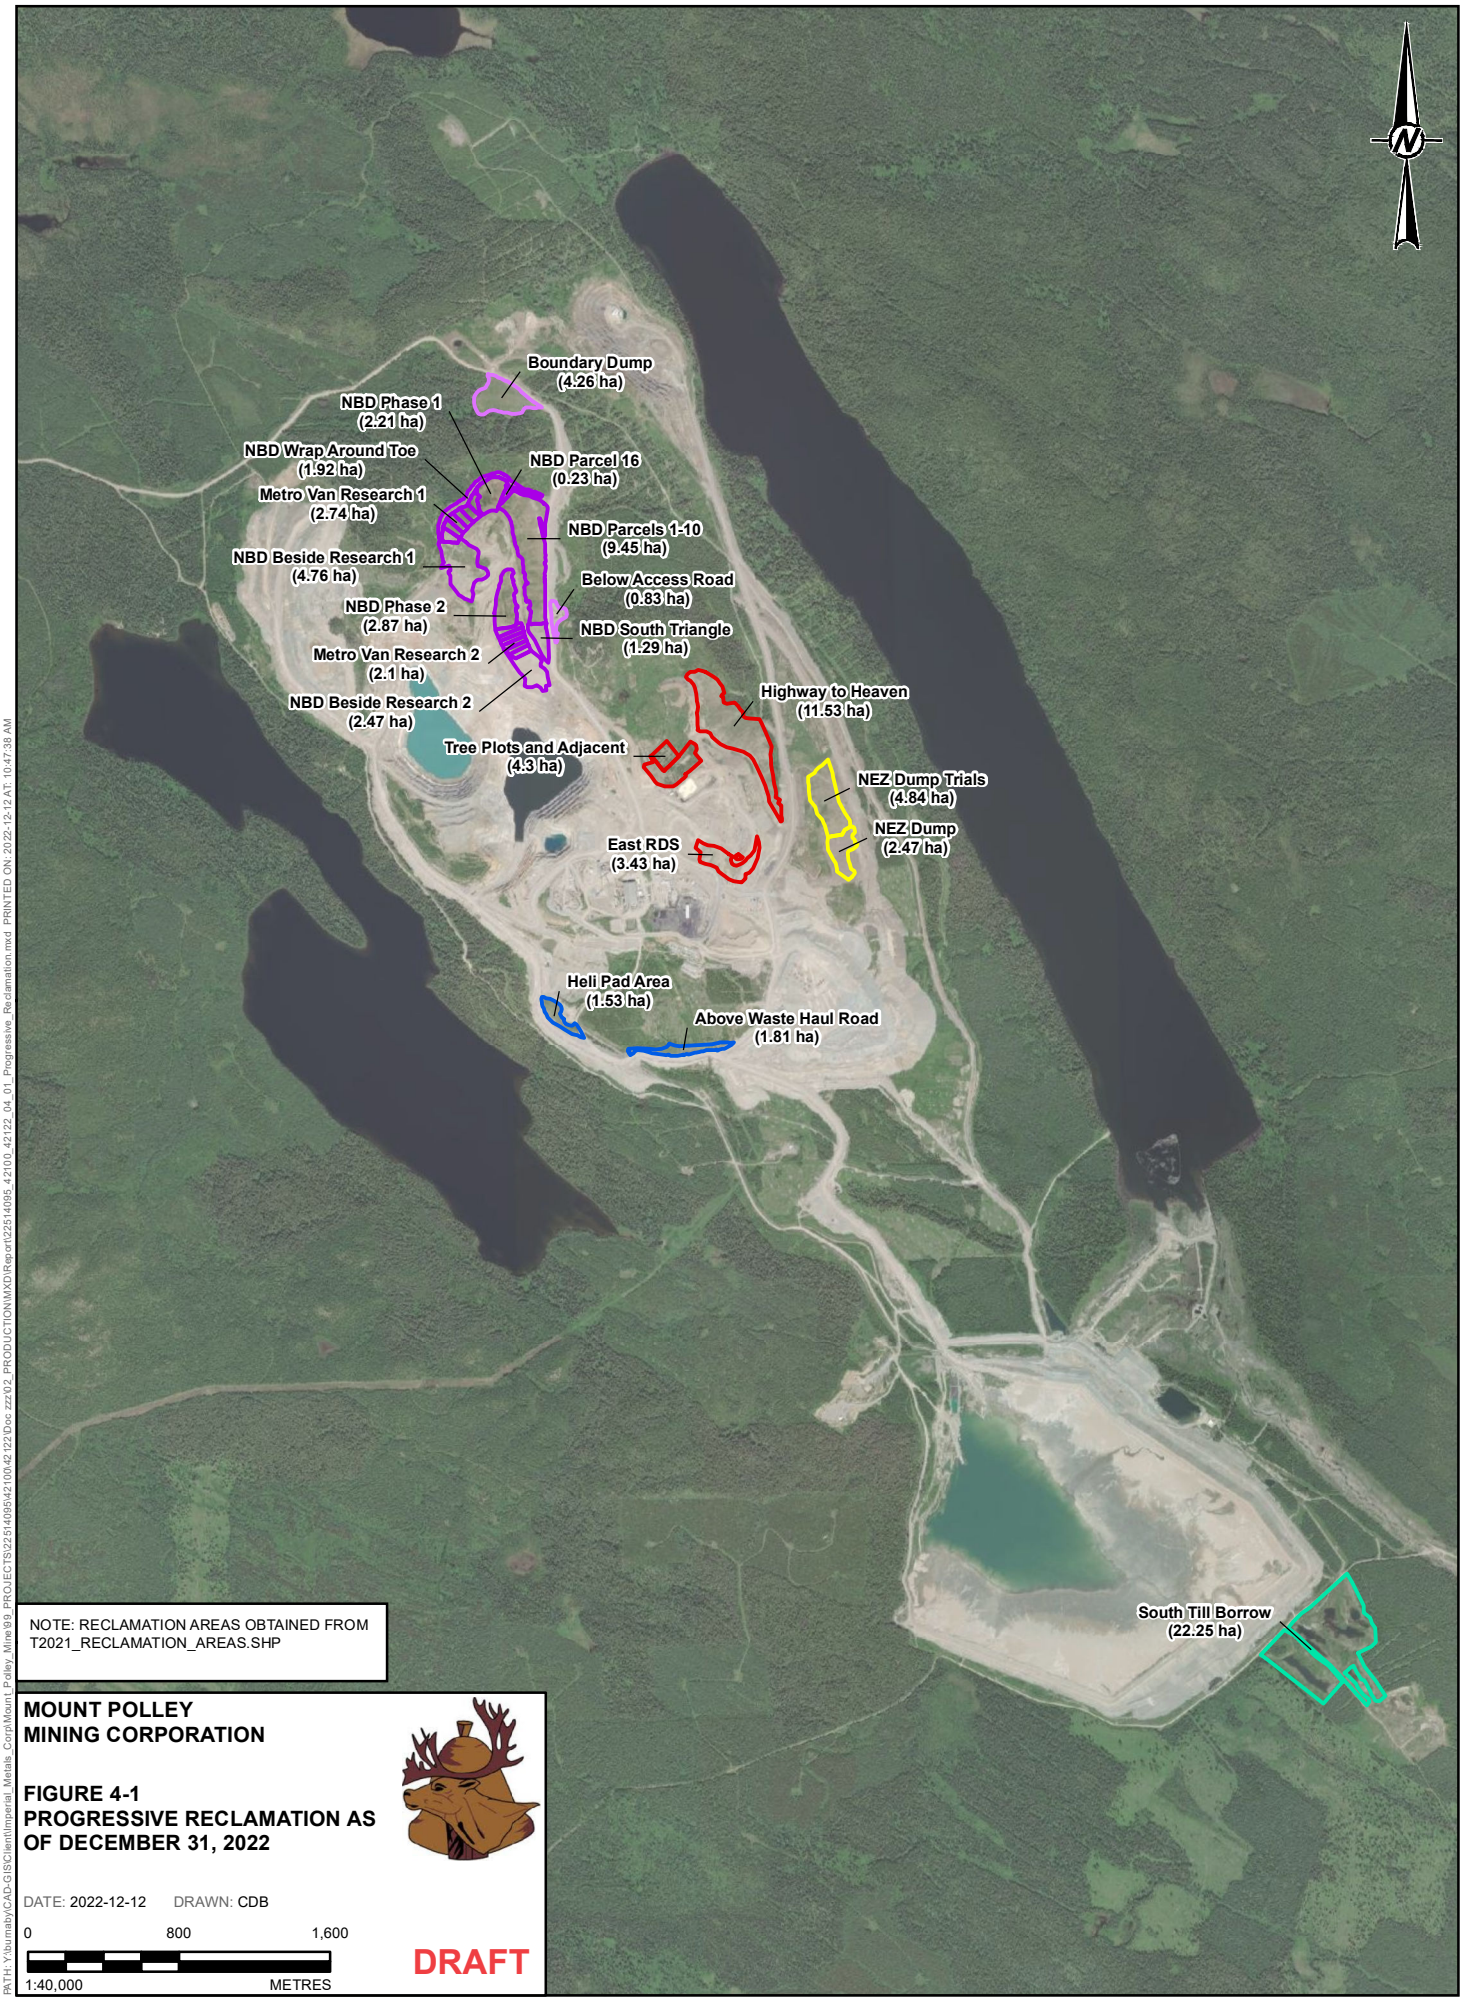
Mine Site reclamation and active closure is still partially in the conceptual phase. Reclamation and closure strategies are designed to be adaptable and evolve based on findings from progressive reclamation, site monitoring and research, and advancements in engineering and science. The following sections outline progressive reclamation and research activities MPMC is currently undertaking, the results of which will continue to influence active closure and post-closure. Section 5 describes MPMC's reclamation strategies and prescriptions in detail.

## 4.2. Progressive Reclamation

### 4.2.1. *Geomorphic Design*

One key strategy used in MPMC's reclamation approach is the concept of geomorphic design. A geomorphic design attempts to replicate natural conditions in engineered environments. The objective is to construct a dynamic system of landforms and watercourses that is adaptable and does not erode more than natural systems or cause unacceptable environmental impacts. An engineered landscape based on the geomorphic approach can be subject to periodic changes without accelerated erosion characteristic of many constructed systems. Because of this, geomorphically designed systems more closely resemble natural systems than traditional engineered landforms, improving post-closure aesthetics and replication of natural ecosystems. As part of progressive reclamation and overall closure efforts, MPMC employs geomorphic designs for various post-closure landforms (namely RDSs). To assist in geomorphic design of post-closure landforms (e.g., reclaimed RDSs), two geomorphic guidance documents were created (Golder 2017a; Golder 2019). Best management practices and information from these guidance documents will be used in realizing a reclaimed landscape that meets the end land use objectives outlined in Section 3.

### 4.2.2. *Current Progressive Reclamation Status*



Currently, progressive reclamation sites at the Mine Site are treated as large-scale research projects, with outcomes influencing future reclamation plans and prescriptions. Much of the progressive reclamation achieved at the Mine Site occurred in the 2010's. Many of the monitoring programs associated with progressive reclamation have been executed as planned or have been put on hold due to the Mine Site's recent care and maintenance status. Detailed information on historical results of these trials can be found in the 2017 MRP (MPMC 2017).

More recent progressive reclamation included salvage of approximately 7,838 $m^3$ of soil from Cariboo Pit Access and subsequent placement of the salvaged soil at SEZ-1 and Mill Site 1 in 2017. In 2018, approximately 3,691 $m^3$ of till was placed in the Breach Zone (Lower SERDS-1 to Corner 1 Buttress), the NEZ Dump, and the 9 km Wetland. Tree planting also occurred in 2018 on the North Bell Dump (MPMC 2018).

Table 4-1 and Figure 4-1 shows the areas that have been re-contoured, received fertilizer or biosolids, and have been seeded and/or planted as of 2021 (MPMC 2022a). Detailed reclamation prescriptions for all reclamation and research sites within the Mine Site are also provided in Table 4-2 , and their locations are shown in Figure 4-1. Areas that were seeded for sediment retention and prevention of invasive species establishment are not included in Table 4-2 and Figure 4-1 as these are temporary reclamation areas, and may later be disturbed.

**Table 4-1 Summary of Completed Progressive Reclamation at the Mine Site (as of 31 December 2021; (MPMC 2022a)**

## 4.3. Reclamation Research Program Update (Terrestrial Reclamation)

In addition to decommissioning portions of the Mine Site, progressive reclamation also acts as a research tool. The reclamation research program at the Mine Site commenced in 1998. Since this time, many research trials have been established at various locations around the Mine Site. Progressive reclamation sites provide monitoring results and information on which treatments and vegetation strategies are most successful, and provide insight into considerations for scaling up reclamation prescriptions for large-scale implementation. Historically, reclamation research focused on improving coversoil quality (e.g., using biosolids). However, since the TSF embankment breach, most research has focused on post-closure water quality.

The Mine Site has an extensive record of reclamation research experience that was presented in the 2017 MRP Update (MPMC 2017). The following subsections provide a summary of findings of historical research conducted at the Mine Site, along with ongoing reclamation research (mainly water treatment technologies).

### 4.3.1. *East RDS, NEZ Dump, and North Bell Dump Trials*

The East RDS Reclamation Research Trial was established between 1998 and 2000 and has since concluded. The trial was designed to test the effect of coversoil placement thickness on grass and conifer seedling performance, while amending coversoil with biosolids. The NEZ Dump Trial also investigated the amendment of coversoil (biosolids and fertilizer “tea bags”) and revegetation prescriptions. The North Bell Dump trial also investigated coversoil amendment with biosolids sourced from Metro Vancouver (see Figure 4-1 for application areas, and a general overview of reclamation trial areas). Key findings from these trials have been used to inform current reclamation prescriptions.

**Coversoil Placement Findings:**

- direct placement of stripped soil is an effective way to maintain soil nutrients
- placement of 15 cm of coversoil is adequate for tree survival and growth
- trees at the Mine Site require a minimum rooting depth of 25 to 30 cm for normal root development and this can be provided by overburden (till) or a combination of overburden (15 cm or greater) and waste rock
- tailings combined with overburden and biosolids provide a suitable root growing medium, equivalent to overburden
- a rate of 50 dt/ha of biosolids provided a similar degree of rooting enhancement as 15 to 30 cm of overburden
- 20 cm of overburden with ~100 dt/ha of biosolids is sufficient for establishment of vigorous conifer seedlings

- biosolids in combination with 15 cm of overburden substantially increased the rooting depth on plots located on upper slopes and crests (McDougall 2015)
- biosolids accelerated LFH development on reclaimed sites (McDougall 2015)
- amendment of soil with biosolids improved tree growth, but has a limited period of effect (less than 15 years)
- sites that received biosolids demonstrated soil chemistry to be within acceptable ranges for plant growth

**Revegetation Findings:**

- native species will grow from the seed bank within directly placed soil; fully or partially negating the need for seeding of ground cover
- plant growth is improved on reclamation areas with surface roughening and coarse woody debris
- seedling mortality on reclaimed areas is high, likely due to the exposed locale and harsh climate and should be mitigated through overplanting
- selection of trees and shrubs should consider site-specific conditions, specifically hot, dry conditions on south and west facing slopes
- timely establishment of overstory vegetation (primary successional trees and shrubs) is important for preventing establishment of invasive and non-native species
- natural ingress of diverse native species is occurring in reclaimed areas, including shrubs/trees such as raspberry (*Rubus idaeus*), elderberry (S*ambucus spp.*), cottonwood (*Populus trichocarpa*), and willow (*Salix* spp.)
- lodgepole pine (*Pinus contorta*) had greater survival than Douglas fir (*Pseudotsuga menziesii*) in most treatments
- other species, such as woods rose (*Rosa woodsia*), black cottonwood (*Populus trichocarpa*), willow (*Salix spp.*) and alder (*Alnus glutinosa*), performed more successfully than paper birch (*Betula papyrifera*), trembling aspen (*Populus tremuloides*) and saskatoon (*Amelanchier alnifolia*)
- the application of biosolids can increase grass growth leading to competition with woody species and forbs (McDougall 2015)
- increased grass layers can provide habitat for rodents who can impact tree survival through girdling of seedlings

- The growth of conifers was higher on the parcels amended with biosolids compared to control parcels

- the understory on biosolids-amended soils should be seeded at low seeding rates with native forbs to promote the highest conifer survival rate while still providing erosion and invasive plant control

#### 4.3.2. *Tailings Beaches*

At many mine sites throughout Canada and elsewhere, the growth of vegetation directly on tailings has been observed, either because of direct planting programs, or through the propagation of volunteer species over the tailings. While tailings are variable in grain size, they typically have moisture-retaining properties that can attract vegetation growth. They are, however, commonly limited in nutrients, which may limit the initial propagation of vegetation. Observations and informal trials at the Mine Site in the early 2000s have demonstrated that tailings can support plant growth and revegetation efforts, and that tailings are NAG and non-toxic to plant growth (SRK 2017).

#### 4.3.3. *Trace Elements in Soils and Uptake in Vegetation*

Reclamation research led by MPMC has included an ongoing series of interrelated studies that address concerns related to the possible presence of trace elements in soils above background concentrations. This research also investigated trace element uptake into vegetation, with the possible risk scenario of the concentrations in vegetation leading to impacts on human health or the environment. Additionally, vegetation metal uptake monitoring at the Mine Site has included baseline monitoring programs in 1989, 1995, and 1996, complemented by monitoring of reclaimed areas in 2007, 2012, and 2014. The purpose of this monitoring is to evaluate if vegetation growing on reclaimed areas at the Mine Site has different levels of metal uptake when compared with baseline and reference site data, and to assess if elevated metal concentrations (if encountered) are of concern for grazing and wildlife species or humans. Monitoring of metal concentrations in natural soils stockpiled for reclamation use, and monitoring of trace element concentrations in soil/biosolid mixtures have also been evaluated. More recently, as part of the Hazeltine Creek environmental impact assessment, a formal terrestrial ecological risk assessment (TERA) was conducted for metal uptake into vegetation that grows directly in the tailings (Golder 2017b). In 2022, an ecological risk assessment was also conducted and investigated metal uptake in revegetated areas. Of the metals analyzed, only copper was shown to have higher than reference site concentrations; however, hazard quotients (HQs) were less than 1, indicating that risks to ungulates was low (Golder 2022b).

#### 4.3.4. *Geomorphic Landform Design*

Geomorphic landform designs (defined in Section 4.2.1) improves long-term physical stability, landform aesthetics, and promotes greater biodiversity than traditional approaches to closure (Toy and Hadley 1989; Hopkinson et al. 2014). A geomorphic reclamation design guidance document was produced that provided guidance for specific channel characteristics, which related

stream slope, terrain type, bankfull width and depth, and stream density to basin area (Golder 2017b; MPMC 2017). Results of the geomorphology assessment include the following:

- The stream networks on the Mine Site were observed to contain both radial and rectilinear drainage patterns. Organization of streams into similar radial and rectilinear patterns should be followed in line with the stream.
    - Drainage from residual high spots should be organized with streams radiating away from the high spot.
    - Drainage from approximately planar terrain surfaces should be rectilinearly organized with streams oriented approximately parallel to each other.
- Since terrain type influences stream gradient, it should be considered during stream reclamation:
    - In a typical, natural, stream channel, elevation drops can be managed in the upper reaches of the watershed.
    - In a regionally significant flat-over-steep terrain, the catchment areas should be kept small in the upstream, lower gradient regions to prevent high volumes of water passing through the downstream steeper portions of the channel or an engineered conveyance channel should be considered if catchment areas cannot be kept small.
- Results of the assessment indicate that bankfull width and bankfull mean depth increase with increasing basin area.
- Analyzing the relationship of stream density to drainage area indicates that surface drainage should form at least one stream per approximately 10 to 20 ha of drained area.

A slope guidance document was also developed in 2019 (Golder 2019), while additional research on geomorphic landform design was conducted as part of the 2020 Water Management Plan (Mine Operations) (Golder 2020). The purpose of this work was to develop a definition for a landform at the Mine Site so that contact water volumes could be reduced; contact water is defined as any water that encounters mine infrastructure (e.g., WRDs). This landform definition work involved:

- a literature review, which looked at how landforms are classified globally
- a review of erosion rates
- development of criteria for the proposed landform definition
- numerical modeling to estimate new contact water generation rates

### 4.4. Reclamation Research Program Update (Water Treatment)

To facilitate the transition from centrally managed and treated water (as envisioned by the LTWMP) to distributed, passive or semi-passive systems, additional studies for water treatment have been identified by MPMC as an important component of reclamation and closure planning optimization.

Like terrestrial reclamation, MPMC has evaluated various water treatment technologies. Some of these studies have been concluded, and are not discussed herein. Details regarding historical water treatment research are outlined in the 2021 ARR (MPMC 2022a) and the 2017 MRP Update (MPMC 2017). A summary of technology being actively researched is provided Appendix G. Currently passive treatment research is being advanced in parallel across multiple fronts.

Table 4-3 provides a summary of the technologies that have been researched and tested for active-closure and post-closure water treatment. Further information on the respective water treatment technologies can be found in Appendix G.

**Table 4-3: Treatment Technology Inventory and Stage of Development**

| Technology / Stage of Development | Targeted COCs | Proof-of-Concept Bench-Scale Testing | Detailed Bench-Scale Testing | Pilot-Scale Testing | Demo-Scale Testing | Full-Scale Execution | Work Completed |
|---|---|---|---|---|---|---|---|
| Actiflo | TSS, total copper | | | | | → | Bench and full-scale testing. |
| Lime Treatment | Dissolved copper | | | | | → | N/A |

Implemented → Under Consideration → — Eliminated/Paused

N/A = not applicable.

# 5. RECLAMATION STRATEGIES

To promote successful reclamation and closure of the Mine Site (i.e., achieve the reclamation objectives outlined in Section 3.1), MPMC has developed protocols and plans related to the following topics:

- physical stability
- water quality and watercourse protection
- soil management
- revegetation prescriptions
- invasive plant management
- fugitive particulate management
- waste management
- contingency plans

These plans and protocols are discussed in detail in the following subsections (e.g., Section 5.1 through to Section 5.10)

## 5.1. Physical Stability

Physical stability is a fundamental building block of terrestrial reclamation and mine closure. This section describes the methods used by MPMC to promote physical stability of Mine Site landforms for reclamation.

### 5.1.1. *Waste Dump Stability*

Consideration of physical long-term stability of RDSs begins prior to dumping of waste rock, continues through the construction phase, and is completed after reclamation activities are implemented and the revegetated plant community is on a trajectory to meet the target end land use. A chronology of events to support RDS stability for reclamation is as follows:

- A Qualified Professional (QP) conducts a footprint stability assessment to determine if any special construction techniques are required to promote the long-term stability of the RDS. This includes a review of available information on the foundation soils beneath the planned RDS.
- The salvageable soil (e.g., coversoil) within the footprint of the RDS is removed and stockpiled for use in future reclamation. Soil salvage prior to dumping improves the stability of the waste dump by being constructed on competent ground, such as till and bedrock.

- When the RDS is under construction, a QP conducts annual (at a minimum) visits to determine if the construction technique being used is consistent with long-term stability objectives.

- When the RDS is complete, it is re-sloped from an angle of 37° to 26.5° (from the angle-of-repose to a slope ratio of 2H:1V).

- Implementation of geomorphic design features (e.g., Section 4.3.4) on RDSs.

- Final reassessment of the stability of the completed RDS, and possible modifications to final dump configuration, as needed.

Examples of geomorphic design being used at the Mine Site are the North Bell Dump over top of the Bell Pit, and the SERDS over top of the Pond Zone. Greater long-term physical stability can be achieved at locations where excavated pits are backfilled with waste as compared to RDSs being constructed exclusively on flat to gently sloping terrain. Following the implementation of the geomorphic design, the surface will be prepared for coversoil placement, and revegetated.

#### 5.1.2. *Pit Wall Stability*

During the excavation of the pits, stability of the surrounding surfaces and pit walls is a priority, as this is necessary for the safety of workers. Pit stability (physical and geochemical) is also desirable for terrestrial reclamation and mine closure. A chronology of events to promote long-term stability is as follows:

- The pit walls are excavated with overall slope angles that have been recommended by a qualified professional engineer. The selected overall slope angles are chosen to ensure the stability of the pit walls throughout the excavation phase, as well as for their long-term stability.

- Routine inspection of pit walls and benches is conducted, and maintenance is continued as required (i.e., wall scaling and bench cleaning). A formal annual (at minimum) stability review of the pit walls is conducted by a registered professional engineer.

- Prior to the excavation of benches below the top surfaces, soil and till materials are removed and pulled away from the area immediately surrounding the maximum boundary of the pits. This is conducted to prevent the sloughing of loose materials down onto the pit walls.

- During active closure, pits are backfilled with PAG waste rock from the Temporary PAG Stockpile for subaqueous disposal, as outlined in Section 6. Backfilling of the pits will promote geochemical stability of the deposited PAG rock, and effectively buttress the pit walls, further promoting long-term physical stability.

- Pits that are not intended to receive PAG waste rock are converted into pit lakes or other post-closure infrastructure (e.g., in-situ pit lake treatment facility). Access to inactive pits is restricted.

Currently, pits at the Mine Site will yield pit lakes during active and post-closure. Terrestrial reclamation is not expected, except around the shores of some pit lakes, like those of the Boundary Pit.

#### 5.1.3. *Road Stability*

The large access roads and haul roads at the Mine Site are constructed with NAG waste rock and are essentially RDSs. During active closure, their long-term stability will be achieved using techniques like those employed for the RDSs. A chronology of events to achieve long-term stability objectives is as follows:

- prior to development, the salvageable soil (e.g., coversoil) from within the footprint of roads is stripped to create adequate foundation conditions for stability; salvaged soil is later used in reclamation

- culverts that were used in the construction of the road and have potential to affect fish-bearing streams will be removed and water bars will be dug across the roads to continue to facilitate the movement of water past the structure to the downstream slopes

- when roads are no longer needed, if possible (without encroaching on watercourses or sensitive undisturbed areas), road edges will be re-sloped from an angle of 37° to 26.5° (e.g., from the angle-of-repose to a slope ratio of 2H:1V)

#### 5.1.4. *TSF Reclamation Stability*

During active closure, the TSF embankment slopes will be recontoured from angle of repose to 2H:1V slopes. Achieving 2H:1V slopes may require additional material placement. After recontouring, and prior to coversoil placement, an assessment will be conducted to determine which species can successfully revegetate the TSF embankments without penetrating the till core, filter, or transition zone, as root penetration of these components may negatively affect TSF stability. This assessment will also investigate which species and revegetation/reclamation techniques will maximize overall coversoil stability and minimize erosion and future maintenance requirements. Following recontouring and coversoil placement, the TSF will be revegetated (projected to be an ICHmk3_01 site series). A spillway, sized with capacity for the probable maximum flood, will also be constructed during active closure, so that a desirable long-term pond level will be maintained.

#### 5.1.4.1. TSF Reclamation Stability Monitoring

Ongoing monitoring through operations and active closure will be conducted. Visual inspections will be performed at regular intervals (e.g., seasonally), with additional inspections following major rainfall events (e.g., those defined with return intervals). Inspections will note signs of pedestalling stones, rilling, gullying, slope creep/failure of the coversoil, and sheet erosion. Should poor stability of the placed coversoil be observed, contingencies such as rough mounding, placement of coarse woody debris, use of cover crops, and evaluation and subsequent amendment of the coversoil will be implemented.

### 5.1.5. *Underground Stability*

For the overall successful closure of underground mine works, stability and potential for subsidence are a key concern. At some mine sites, subsidence may be caused by the collapse of underground mine voids, leading to movement of the ground surface. As documented in the MPMC analysis in Appendix J, the risk of subsidence at the Mine Site is minimal due to the depth and size of the voids below ground surface and the quality of the rock. The only additional closure work planned for the active closure of the underground mine will be backfilling of the Alimak Raise, which will be done primarily for access control, and is described in Section 6.11.2. Given the stability of the underground, and because underground mining has been removed from the life of mine, underground stability issues are unlikely to develop during the remaining operation period of the Mine Site or during post-closure.

## 5.2. Water Quality and Watercourse Protection

To protect water quality and watercourses in the receiving environment, MPMC uses the following approaches, which are described in further detail in subsequent sections:

- prevention of erosion and sediment into watercourses
- waste rock characterization and management
- collection of contact water (previously described in Section 2.4)
- monitoring of seep and contact water chemistry and flows to improve the understanding of site geochemistry and hydrology
- water quality and quantity monitoring of downstream environments to verify if water management strategies are working, and to support water discharge planning
- overall closure water management planning based on a predictive water quality and quantity model

### 5.2.1. *Sediment Retention and Erosion Control*

Development of an open pit mine and associated works creates surface disturbances that may result in erosion. Erosion prevention strategies for construction activities and active closure are outlined in MPMC's Sediment and Erosion Control Management Plan (Appendix K).

Erosion control is key to preventing sediment transport and negative impacts on the environment, and promoting geotechnical stability of structures. Revegetation is a highly effective and permanent erosion control measure; thus, disturbed areas are seeded and planted at the earliest opportunity. Re-sloping is another important erosion control measure used by MPMC. Typically, re-sloping involves site preparation and creation of microtopography and the direction of surface flow away from slope faces to minimize surface water erosion, where possible.

In addition to the measures described in the Sediment and Erosion Control Management Plan, a geomorphic approach is incorporated, where practicable, as an overall strategy for active closure design.

#### 5.2.2. *Material Characterization and Placement*

In a mine setting, ML/ARD can have negative and lasting effects on water quality if not properly monitored and managed. Active monitoring of ML/ARD potential in Mine Site waste rock is part of an established protocol, and is detailed in MPMC's ML/ARD Management Procedure Manual (Appendix L). This is a "live" document that is routinely updated to reflect changes in Mine Site conditions or protocols. The manual encompasses procedures for material characterization, segregation, disposal (including subaqueous disposal of PAG waste rock in pits during active closure), and monitoring.

Prior to placement, material at the Mine Site, including ore that will be stockpiled, is sampled. In 2015, MPMC retained SRK to conduct an assessment of ML/ARD potential from ore stockpiles (SRK 2015). Findings indicate that the ore stockpiles have low ARD potential and that contact water chemistry from the stockpiles is expected to be similar to waste rock, although selenium may be more leachable, depending on the mineralogical association (Appendix B-2). In 2022, the Mine Site's geochemical source terms were reviewed by SRK, as a basis for extending MPMC's *EMA* 11678 permitted discharge period. SRK found that no update to the source terms was required (Appendix B-4). The SRK memo indicated that seepage from RDSs has been mostly stable for key parameters over the monitoring period, except for localized influences from sulphuric acid water likely originating from the Test Heap Leach.

#### 5.2.3. *Water Quantity and Quality Monitoring*

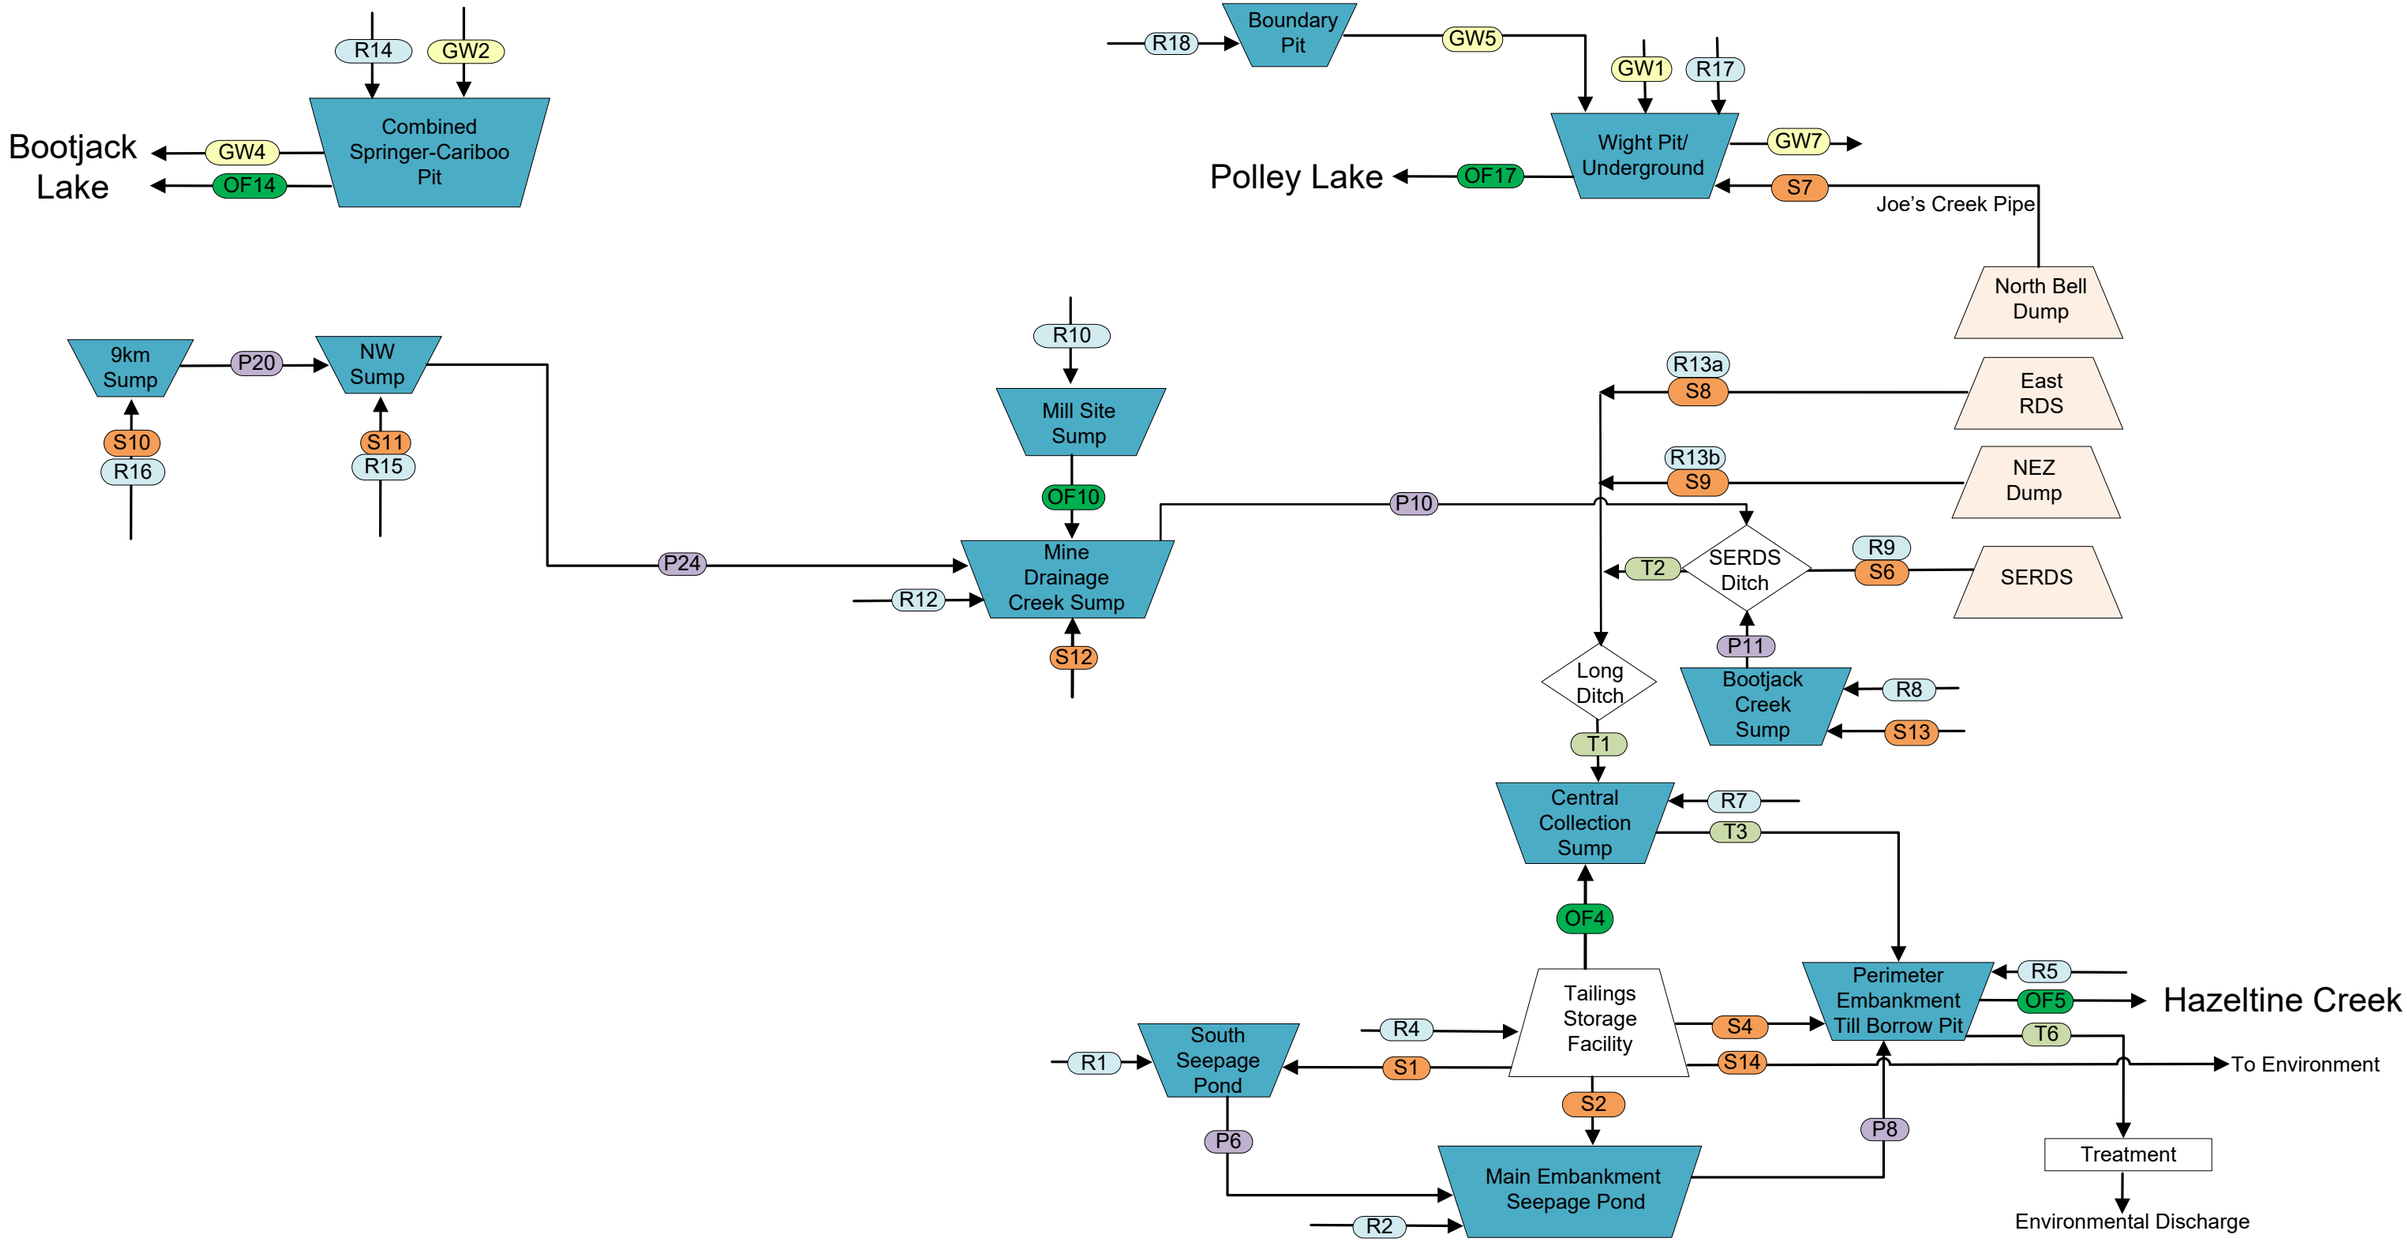
Two important components of determining the overall chemical stability of a mine are water balance (quantity) and water quality. Water balance modeling is used to determine the amount of mine contact water that is generated, and informs overall water management and water treatment strategies at the Mine Site. To this end, hydrological and meteorological monitoring are conducted.

The Comprehensive Environmental Monitoring Plan (CEMP), required under *EMA* Permit 11678, encompasses chemistry and flow monitoring of receiving environment waters, groundwater, and meteorological monitoring. Biological monitoring of aquatic receiving environments (primarily associated with effluent discharge points) is also included in the CEMP, and is consistent with federal MDMER (Canada 2022) requirements. The 2019 CEMP (MPMC 2019) outlines monitoring program details including locations, frequency, parameters, and QA/QC procedures. Results are presented each year in the Annual Environmental Report (AER; MPMC 2022c) and ARR Report (MPMC 2022a).

Updates to the CEMP occur every three years at minimum, and are based on the results of detailed three-year monitoring program interpretive reports. As per the mechanisms described in the CEMP, written notice of proposed CEMP changes will be provided to ENV. First Nations and stakeholders will also be notified, as per MPMC's Communication Plan, should the CEMP change.

While some effluent monitoring sites are included in the CEMP, more comprehensive monitoring of mine contact water chemistry and flow is conducted under *Mines Act* Permit M-200 through sampling of waste dump seeps and runoff collection infrastructure. The more comprehensive mine contact water monitoring program is included as part of the OMS Manual (MPMC 2021), which is a "live" document that is routinely updated to reflect Mine Site conditions. The OMS Manual provides sample locations, frequencies, parameters, and QA/QC procedures. Similarly, monitoring results associated with OMS Manual sample collection are also presented each year in the AER.

Figure 2-4 provides an overview of monitoring conducted at the Mine Site, reflective of the plans outlined in the CEMP and OMS Manual. Note that some far-field monitoring sites are not included in the Figure 2-4, as to provide a high-resolution overview of monitoring conducted within, and in the immediate vicinity of, the Mine Site.



#### 5.2.4. *Closure Water Management*

The Mine Site's water management system for runoff from RDSs, roads, and other disturbed areas is presented in Section 2.4. Current and planned methods of treating and discharging the water from the Mine Site are detailed in Section 2.4.2.5. Appendix H discusses active and post-closure water management in detail, while Appendix I provides comprehensive information on water quality for the same mine life cycle intervals.

The post-closure water quality modeling to date indicates that most parameters of concern (e.g., metals) are not anticipated to negatively affect water quality when water is released to the environment (Appendix G and Appendix I). This is due to the relatively low abundance of PAG rock at the Mine Site as indicated by Golder and SRK (Golder 2016b; SRK 2016; SRK 2022a). However, copper and selenium are predicted to exceed water quality guidelines, and require treatment during active and post-closure. Appendix G, Table 2 provides further detail on active closure and post-closure water quality. Given that water treatment will be required during active and post-closure, MPMC is working towards the development of water treatment technologies that will meet their overall closure needs.

Currently, one objective for the active and post-closure phases of the Mine Site's life cycle is the development and implementation of a decentralized passive/semi-passive water treatment system. Given that the Mine Site was developed on a watershed divide, it is desired that such a system returns water to its respective pre-development watersheds – an objective consistent with the Environmental Assessment and input from local communities and First Nations. Ultimately, this decentralized system will be achieved using passive/semi-passive technologies developed through bench scale and pilot testing. The status of current research towards this end is discussed in Section 4.4.

While a distributed system is desired for active and post-closure, there are several challenges that will need to be overcome. For instance, the ability of the receiving environment to accommodate the post-closure flows needs to be carefully assessed. Given that runoff from disturbed areas is higher than runoff from forested areas (the pre-mine case), the flow volumes during early post-closure may be too great to be accommodated without damaging the existing receiving environment and their associated habitats. Further, water quality receiving environment targets are likely to become more stringent, given the lower assimilative capacity of these receiving environment. Although distributed passive/semi-passive treatment and discharge is a desired closure outcome, these technologies have not yet been fully developed to full scale and face permitting uncertainty. The assumed treatment configuration for active and post-closure is pit lake pre-treatment followed by centralized Actiflo treatment (one the closure BAT options identified (Golder 2016c). Figure 5-1 and Figure 5-2 provide the current models for active closure and post-closure water management. Appendix H and Appendix I provide discussion on predicted water balance, water management, and water quality at closure. Figure 5-3 shows the anticipated catchments for the post-closure environment.

### 5.2.5. *Closure Water Management Planning*

A key component for overall successful closure water management lies in planning. Specifically, the projections of active and post-closure water quality and quantity. To this end, MPMC has retained Qualified Professionals to project long-term water chemistry and quantity for the Mine Site during operation, active closure, and into post-closure The Site Wide Water Balance Model (SWWBM) and the Site Wide Water Quality Model (SWWQM) were both created in GoldSim, in 2017 for the 2017 MRP Update, and have been revised to project water quality and quantity from 2024 to 2124.

The updated SWWBM simulates the site water circuitry (the logic driving water transfers and flows on site) during the closure and post-closure phases. The closure phase will commence on 1 September 2024 and will include closure and reclamation activities as identified in the Mine Reclamation and Closure Plan Update. The post-closure phase will commence on 1 September 2034 and extends to September 2124. In updating the model, Springer-Caribou Pit was added with its stage-storage curve as Springer Pit and Caribou Pit combined into one pit in the closure phase. New inflows including direct precipitation, runoff and groundwater flow have been created based on the Springer-Caribou Pit closure design surface provide by MPMC and will be going into the Springer-Caribou Pit from 1 September 2024. A TSF configuration was also added to reflect a 970 m dam crest elevation for the closure phase modelling. Deterministic and stochastic climate inputs, as described in Mount Polley Mine Climate Baseline Update (Appendix D), were used to account for climate change in the closure model.

The SWWQM was updated with the latest RCP and water balance (base case and climate change scenarios) to reflect the closure and post-closure conditions on the mine site from 2024 to 2124. The model was also updated with additional monitoring data for assigned water quality inputs to refine the distribution inputs into the model. The updated model was calibrated against monitoring data from the mine site. During closure and post-closure, discharges from the mine will preferably be returned to their natural watersheds, to the extent possible. Specifically, nine potential mine discharge locations are expected to drain to Polley Lake, Bootjack Lake, Edney Creek, and Hazeltine Creek. Model results were generated for each potential discharge to inform treatment planning for closure and post-closure.

## 5.3. End Land Use Plan

The End Land Use Plan for the Mine is presented in Table 5-1. The table shows how ecosystems are grouped into ecosystem categories. End land use objectives are then assigned for each ecosystem and are defined across a range of structural stages. The end land use objectives are predicted for structural stages, such as mature and old growth forests, with these stages occurring as far out as 250 years in some ecosystems.

The End Land Use Plan is a long-term plan that is designed to adapt to the changing conditions in vegetation communities for the different ecosystems that are targeted. While it will be difficult to remove all uncertainty when working with long timelines, the long-term ecological trajectories that will guide the end land use objectives into the future can be evaluated.

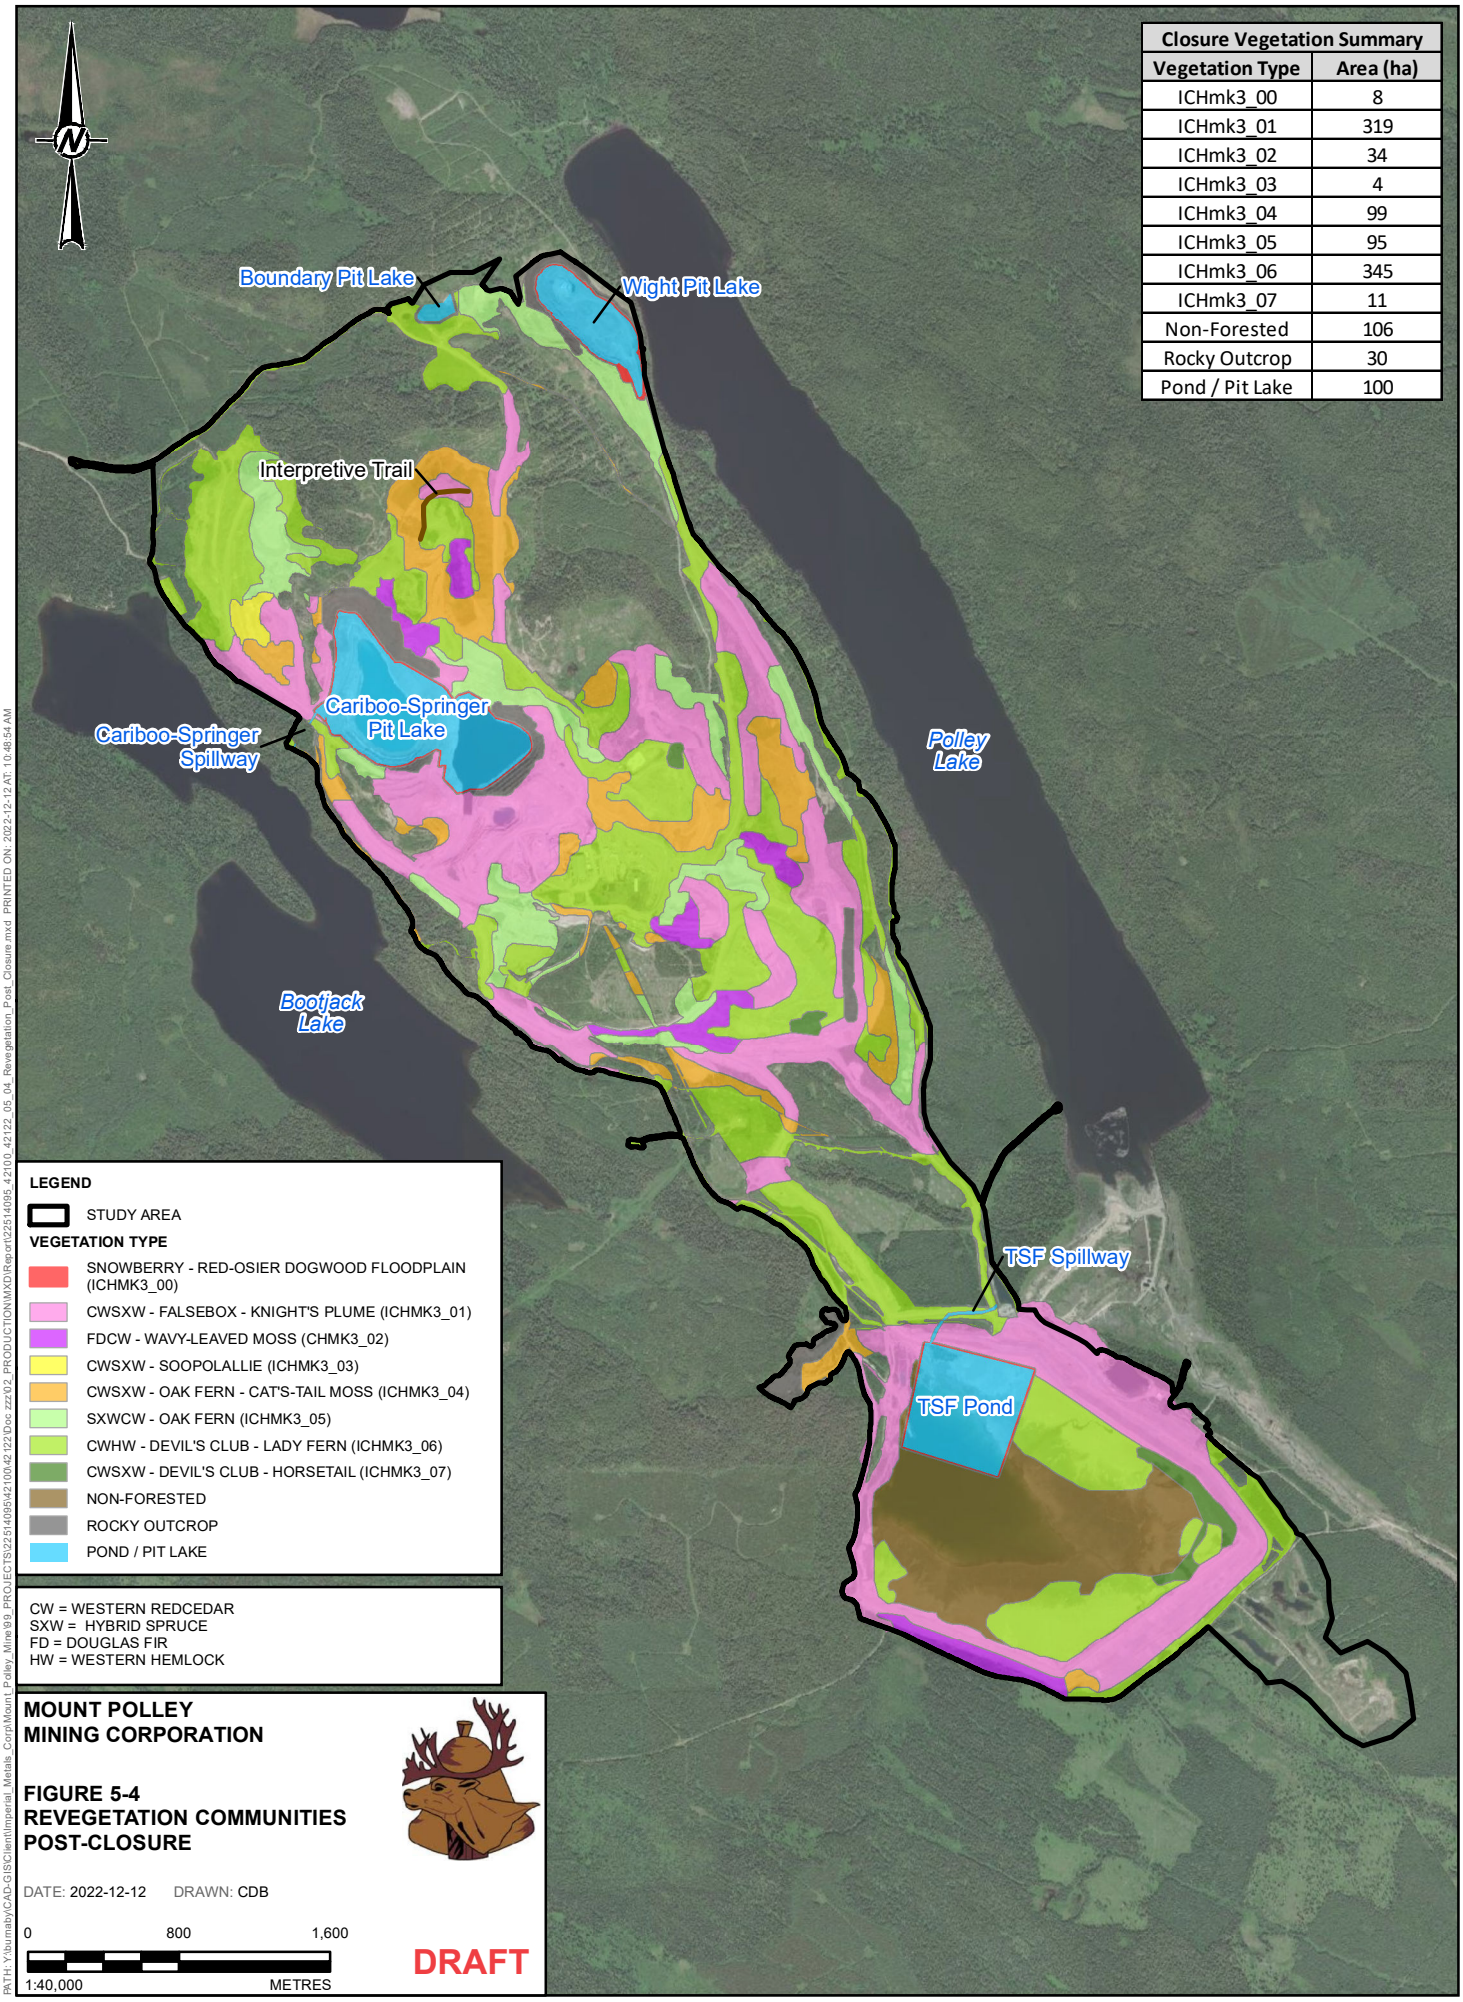

Figure 5-4 shows how the target ecosystems are planned to be distributed over the post-closure landscape. These ecosystems were distributed using GIS to divide the landscape into polygons that are separated by slope, aspect, elevation, slope position, and substrate type. Table 5-2 shows the predicted distribution of vegetation types on the post-closure landscape as compared to pre-disturbance conditions, while Table 5-3 provides methods for recreating wildlife habitat on the post-closure landscape.

The specific strategies for achieving end land use objectives are outlined in Sections 5.4 and the detailed reclamation objectives and plans for each mine unit are outlined in Section 6.

Note: According to Table 2-4 current disturbance = 1,219 ha. This Table 5-2 does not include areas of existing reclamation such as the Southeast Till Borrow (~40 ha). The additional 27 ha of area is likely due to overlapping facilities. Numbers may not add exactly due to rounding.

**Table 5-3 Method of Habitat Creation for Target Wildlife Species in Waste Dump Reclamation**

| Target Wildlife Species | Habitat Creation | Game Species |
|---|---|---|
| Deer mouse | Application of rock piles/boulders and coarse woody debris will provide cover and denning areas. | - |
| Bushy-Tailed woodrat | | - |
| Northwestern chipmunk | | - |
| Marten | | Trapping |
| Long-Tailed weasel | | Trapping |
| Ermines | | Trapping |
| Snowshoe hare | | Trapping |
| Red squirrel | | Trapping |
| Coyote | Will be attracted to reclaimed waste dumps when ungulates and small mammals occupy the area. | Trapping |
| Gray wolf | | Trapping |
| Cougar | | Hunting |
| Red fox | Will be attracted to reclaimed waste dumps when small mammals occupy the area, and grasses/berries are present. They may den if soft substrates are available. | Trapping |
| Fisher | Eventual creation of continuous forest habitats, with the availability of carrion, small mammals, insects, berries, and mushrooms will attract fishers. | Trapping |
| Lynx | Will be attracted to area as snowshoe hare population increases, as they are very dependent on hares as a food source. | Hunting/Trapping |

**Table 5-3 Method of Habitat Creation for Target Wildlife Species in Waste Dump Reclamation**

| Target Wildlife Species | Habitat Creation | Game Species |
|---|---|---|
| Black bear | As vegetation is established, they will be attracted to food sources including berries (saskatoon, raspberries), buds, grasses, shoots and shrubs. Bears will also be attracted by the presence of mammals for prey and carrion. | Hunting |
| Mule deer | Planting native shrubs and woody species including willows, red elderberry, Douglas-fir, western redcedar, and trembling aspen will provide ungulate forage. | Hunting |
| Moose | | Hunting |

## 5.4. Soil Management

MPMC has developed a Soil Management Plan which includes protocols for soil salvaging, stockpiling, and use in reclamation (Appendix M). To collect information for developing the Soil Management Plan, and to guide future reclamation practices, a comprehensive soil quality assessment of Mine Site soil stockpiles was conducted in September 2013. Results are appended to the Soil Management Plan.

### 5.4.1. *Soil Use in Reclamation*

#### 5.4.1.1. Soil Application

MPMC's Soil Management Plan describes coversoil application methods in detail, including strategies for reducing compaction. Figure 5-5 shows the proposed soil profiles to be used in reclamation prescriptions based on slope, aspect, substrate, and target site series. Pre-disturbance soil depths ranged from 0 cm to up to 1 m of salvageable surface soil (i.e., LFH + A Horizon + B Horizon[s]).

The soil profiles in Figure 5-5 are meant to allow for successful ecosystem development using the resources available on site. Trials have indicated that overburden (till) is an effective growth medium for plant roots (McDougall 2015). In addition, initial trials have indicated that tailings can be mixed with till and perform as an effective growth medium. Actual coversoil placement depths will vary based on material availability, landscape, site preparation techniques used, and equipment used for application. Additional soil amendments may be added to the profiles, if required (Section 5.4.1.2). Site preparation of coversoil to create microtopography will be conducted to reduce erosion and promote more diverse microsites, including microsites with improved moisture retention. A variety of site-specific site preparation methods are described in the Soil Management Plan.

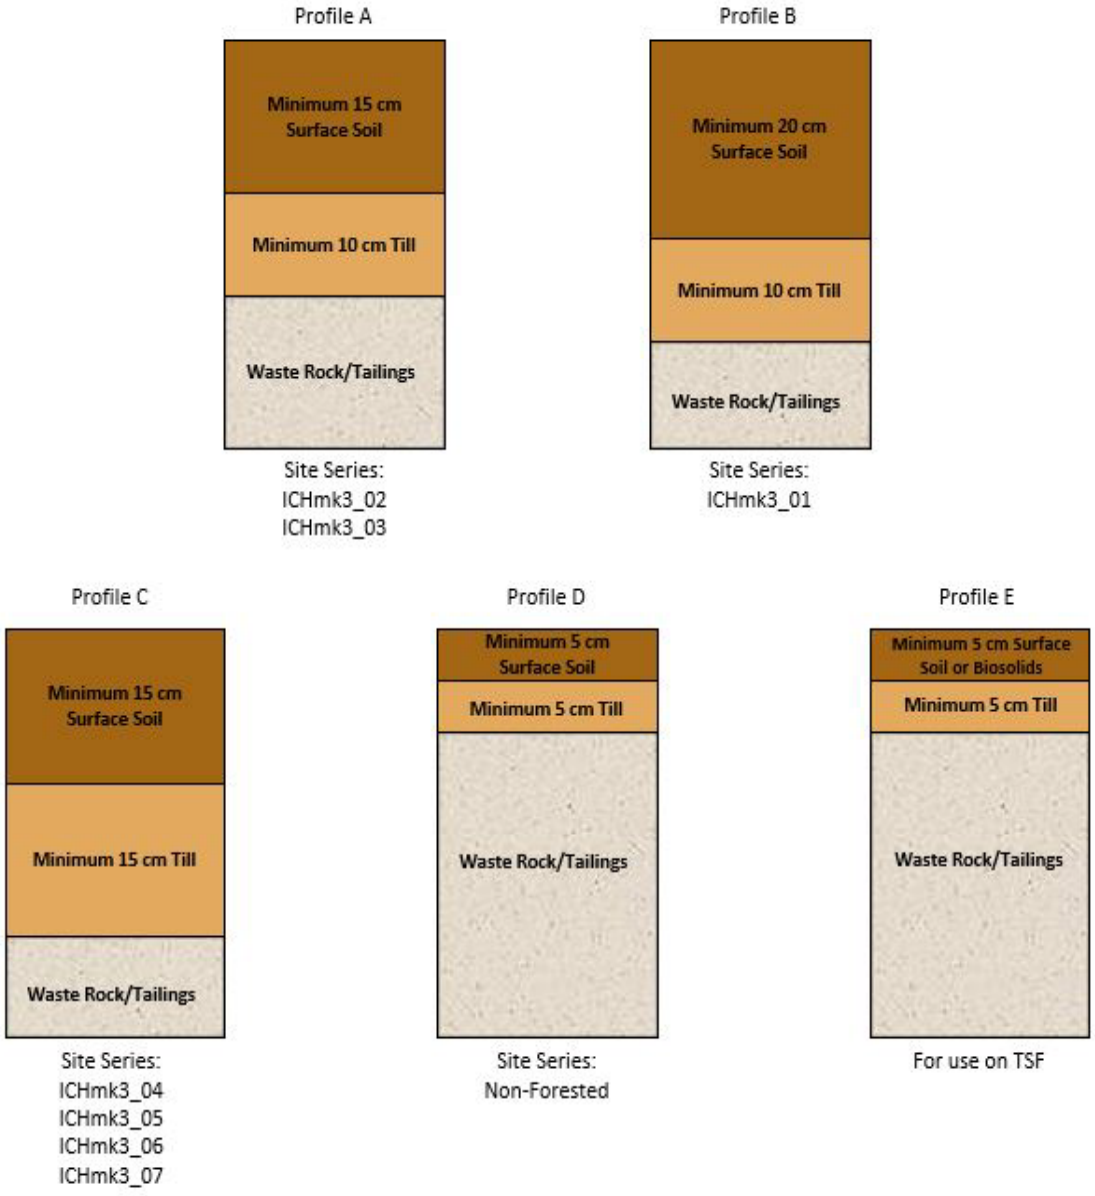

*Figure 5-5 Proposed Coversoil Profiles*

#### 5.4.1.2. Soil Amendments

Soil amendments can be any additional materials that are added to reclamation sites to increase soil fertility, improve soil structure, provide better growing conditions for vegetation, or provide enhanced habitat features for target wildlife species.

Soil amendments may be used if there is a shortage of surface soil, if there are insufficient nutrients to support plant growth, or if the soil texture requires modification. Where possible, on-site soil amendments will be used to reduce costs, make use of waste, and prevent potential ingress of non-native species through importing soil from off site. Researched soil amendments are detailed comprehensively in the 2017 MRP Update (Section 4.3.2**;** MPMC 2017) and summarized within this MRP (Section 4.3) as well as below. Results from ongoing site-specific research will continue to provide guidance on when soil amendments are necessary, and what types and quantities to use. This will include long-term considerations, as soil amendments are typically only a short-term nutrient source.

**Biosolids**

Biosolids have been studied on research plots since 1998. Biosolids are available in large quantities for use on the Mine Site. The overall findings are that biosolids can be effective in encouraging initial tree establishment and root development. Biosolids can even act as a replacement for standard growth mediums in some cases. Overall, biosolids have been shown to be an effective soil amendment, at least with regards to establishing desirable vegetation.

**Tailings**

Initial trials have been conducted into seeding grasses directly into tailings and mixing tailings with till as a growth medium. Seeding grasses into tailings has generally been successful, and initial trials to combine tailings with till and biosolids have been successful (McMahen and Simard 2018). However, evidence from the TSF embankment breach terrestrial ecosystem assessment has indicated that in some cases tailings can be too fine, resulting in poor drainage, excess water retention, and decreased oxygen in the rooting zone, resulting in die off of vegetation.

**Fertilizer**

Contrasting with biosolids, fertilizer has not been found to be an effective soil amendment. “Tea bag” packages planted with trees were actually found to reduce long-term growth, and broadcast fertilizer can result in heavy ground cover (grass) development, which provides competition for target tree and shrub species . Results from ongoing site-specific research will continue to provide guidance on when soil amendments are necessary, and what types and quantities to use. This will include long-term considerations, as soil amendments are typically only a short-term nutrient source.

**Woody Debris**

Following soil application, woody debris (if not already incorporated into soil) should be placed, if available, to enhance microsite diversity and habitats, retain moisture, contribute to long-term soil organic matter, and improve catch of native seeds. If woody debris is not available, boulders or rock fragments can be placed in piles and individually. Although rocks are not a source of nutrients, over time, like woody debris, they can increase moisture retention, promote plant microsite diversity, provide habitat, and reduce soil erosion. Application of boulders or small rock piles will also continue to be carried out as a method of creating varied habitats on reclamation sites. Coarse woody debris and/or rock piles and boulders are important in creating wildlife habitats (Table 5-3) and contribute to meeting wildlife-related end land use objectives.

### 5.4.2. *Estimated Soil Balance*

No stockpiling occurred from 2017 to 2020. In 2021, 18,100 $m^3$ of reclamation material was salvaged at Springer Pit and stockpiled in the SERD-3 and Upper Cariboo Stockpiles (G. Holmes, pers. comm.). Table 5-4 provides the estimated soil balance for the site. Additionally, Table 5-5 provides the site soil stockpile inventory (updated as of December 2021), and Figure 5-6 provides the locations of all site stockpiles. The estimated soil volumes required for reclamation are based on the coversoil profiles (Figure 5-5) developed for the site. Currently, there is 1,219 ha of disturbed land; 1,020 ha of which will require coversoil placement either through progressive reclamation or at the time of active closure. The current soil balance estimates indicate that there is 1,694,010 $m^3$ of coversoil available to complete effective reclamation for all disturbed areas on the Mine Site (a surplus of 47,490 $m^3$). Additionally, there is a 1,101,330 $m^3$ shortage of till material. These calculations were developed using the soil and landform data as shown in Appendix C, with the soil stockpile inventory and disturbed areas provided from MPMC.

MPMC acknowledges that coversoil volumes may not be exactly as indicated due to losses through handling and erosion, as well as changes in bulk density. If it is found that there is insufficient coversoil available to implement the planned reclamation prescriptions contingencies will be explored such as:

- using soil amendments (Section 5.4.1.2); biosolids present on site (Table 5-4) are enough to address the coversoil shortage discussed above, and have had good results in reclamation trials
- borrowing additional till material from the borrow areas around the TSF, and/or
- mixing tailings in with till if further research shows it is a viable growth medium

**Table 5-4 Coversoil Balance as of December 2021**

| Vegetation Type | Area Requiring Coversoil[(1)] [ha] | Average Coversoil Placement Depth [cm] | Required Coversoil Volume [$m^3$] | Average Till Placement Depth [cm] | Required Till Volume [$m^3$] | Available Biosolids Volume[(2)] [$m^3$] | Available Coversoil [$m^3$] | Available Till [$m^3$] |
|---|---|---|---|---|---|---|---|---|
| ICHmk3_00 | 8.36 | 5 | 4,182 | 10 | 8,364 | 0 | **1,694,010** | **140,895** |
| ICHmk3_01 | 318.96 | 20 | 637,911 | 10 | 318,955 | 0 | | |
| ICHmk3_02 | 33.66 | 15 | 50,486 | 10 | 33,657 | 0 | | |

## 5.5. Revegetation Prescriptions

Ingress of native species has been observed at the Mine Site (e.g., South Till Borrow), and is expected to continue. To support natural colonization, active planting of native vegetation is conducted to promote development of desirable post-closure ecosystems. Planting vegetation prevents erosion, avoids establishment of invasive species, and initiates the process of natural succession. Vegetative growth increases soil organic matter, provides native seed sources, and begins to create microsites that will, in time, be appropriate for growth of secondary successional species. For instance, early seral stage conifers used in the logging industry (lodgepole pine and Douglas-fir) are planted at the Mine Site, with climax woody species such as Western red cedar, subalpine fir, and hybrid spruce expected to ingress naturally when microsite conditions are appropriate. Ultimately, revegetation efforts promote end land use and closure objectives, such as wildlife values and biodiversity.

### 5.5.1. *Species Selection*

Development of MPMC's revegetation prescriptions for the Mine Site are discussed herein, while Section 5.5.2 provides discussion on planting strategies for the revegetation prescriptions. Appendix C describes the BEC zone and site series that were present on the Mine Site prior to development.

Historically, MPMC has planted diverse native species across the Mine Site. To this end, MPMC has developed a method for refining vegetation selection to identify species best suited for revegetation on the different site series that are targeted for reclamation. The species identified generally have a high potential to meet the conditions present in the various reclamation prescriptions (e.g., Figure 5-4), and are easy to procure through collection or purchase.

The approach for revegetative species selection is based on the BEC system. Identification of the site series of a specific area considers slope, elevation, and aspect assessed using a GIS model. This is further informed by site-specific substrate characteristics that suggest soil moisture and nutrient conditions. A generalized GIS matrix is used to aid in identifying the most appropriate treatment for an area. This approach is not designed to be rigid, and flexibility will be maintained to allow for alternative treatments or trials on designated sites, as well as based on professional discretion in localized areas. Table 5-6 shows general prescriptions by target site series for reclamation of disturbed surfaces on the Mine Site, which includes the mill and explosive sites, RDSs, roads, and the TSF embankments. The respective site series are shown in Figure 5-4. Specific reclamation considerations for specialized areas, including riparian and wetland areas, are described in Section 6, which individually discusses each reclamation unit at the Mine Site.

**Table 5-6 Reclamation Prescriptions**

| Site Series | | Moisture | Gradient (%) | Slope Position | Aspect | Soil Profile Type[7] | Grasses/Forbs[1,2] | Deciduous Trees[3] | Coniferous Trees[4] | Shrubs[5] 200 – 500 sph |

Notes:
1) Grass and forb seeding rate should be reduced (5 to 10 kg/ha) if amendments such as biosolids or fertilizer are used.
2) Grass and forb mixture shown in Table 5-8.
3) Species chosen based on BC Forest Development Stocking Standards (ICHmk3 biogeoclimatic subzone).
4) Species chosen based on BC Forest Development Stocking Standards (ICHmk3 biogeoclimatic subzone).
5) Later successional species to be considered for underplanting after primary canopy is established.
6) Shrub species to be selected appropriate for each site based on research and availability.
7) Refer to Figure 5-5, Section 5.4.1.1 for profile descriptions.
8) Juniper will be targeted for drier sites.
sph = stems per hectare.

MPMC's method goes through several steps to determine the species selected. In general, candidate species are assessed based on ecological conditions and then are further evaluated for social and economic considerations. As such, input from First Nations consultation and vegetation documented in a traditional use study of the area (Table 5-7) are also used to aid in species selection. To date, three species of traditional importance have been tested in small-scale trials at the Mine Site:

- huckleberry (Vaccinium ovatum)
- common juniper (Juniperus)
- soopolallie (Shepherdia canadensis)

Due to promising results, these species are now new additions to the general site reclamation prescription.

MPMC's selection process is iterative, and refinement is ongoing. Further, MPMC has had the opportunity to reclaim several areas on the Mine Site and continues to use the learnings from those reclaimed areas to refine and adjust reclamation prescriptions. The steps included in this process are:

1. determine which species are locally common to each site series and those that existed on the landscape prior to development
2. review government regulations for reforestation guidelines and dominant overstory and understorey species for each target site series
3. determine which species are commercially available, or easily harvested on the Mine Site
4. work with First Nations and local communities to determine species that are important for traditional use and support target wildlife species
5. add selected species to the newly reclaimed sites (e.g., immediately after coversoil placement)
6. monitor the progress of reclamation sites to determine which species (or combination of species) are performing well and at which locations (site series)
7. adapt reclamation prescriptions to incorporate learnings from monitoring results
8. incorporate refined prescriptions into progressive reclamation and reclamation research activities to further develop best practices for establishment of high priority target species
9. continue to adapt prescriptions and research trials as new information is gathered and additional target species are identified

**Table 5-7 Incorporation of Traditionally Important Species into Reclamation Prescriptions**

| Species Common Name | Species Scientific Name | MPMC Comment |
|---|---|---|
| Lodgepole pine | *Pinus contorta* | Incorporated into revegetation prescriptions. |
| Western redcedar | *Thuja plicata* | A later successional species – underplanting of reclamation sites may be required if natural ingress is not observed. |
| Balsam fir | *Abies balsamea* | This species is only present east of the Rocky Mountains. |
| Paper birch | *Betula papyrifera* | Incorporated into revegetation prescriptions. Moderate performance to date. |
| Chamomile | *Matricaria* sp. | Not native to the area (species introduced and is only found to naturally occur in southwestern BC). |
| Black huckleberry | *Vaccinium membranaceum* | Difficult to establish, but a trial was planted in 2014. Poor performance to date. |
| Blueberry | *Vaccinium myrtilloides* | Difficult to establish, consider based on outcome of huckleberry trial. |
| Highbush cranberry | *Viburnum edule* | Not documented in the baseline vegetation survey – consider in future reclamation of wet areas. |
| Raspberry | *Rubus idaeus* | Strong natural ingress observed on reclamation sites. |
| Saskatoon | *Amelanchier alnifolia* | Incorporated into revegetation prescriptions. Moderate performance to date. |
| Red elderberry | *Sambucus racemosa* | Natural ingress into reclamation areas observed; incorporation into revegetation prescriptions being considered. |
| Wild strawberry | *Fragaria virginiana* | Incorporation into revegetation prescriptions to be considered if a seed or plant source is found. |
| Soapberry | *Shepherdia canadensis* | A trial plot was planted in 2014. Has performed well in trials to date. |
| Cow parsnip | *Heracleum lanatum* | Expected to naturally ingress at late stages of natural succession in moist areas. |
| Common juniper | *Juniperus communis* | Not native to the area; however, a trial plot was planted in 2015 on a hot dry reclamation site. Has performed well in trials to date. |
| Kinnikinnick | *Arctostaphylos uva-ursi* | Not documented in the baseline vegetation survey – a trial is being considered for a dry site if a seed or plant source is found. |
| Falsebox | *Paxistima myrsinites* | Expected to naturally ingress at late stages of natural succession in moist areas. |
| Labrador tea | *Ledum groenlandicum* | Consider in future reclamation of non-forested organic site (wet areas). |
| Devil's club | *Oplopanax horridus* | Expected to naturally ingress at late stages of natural succession in established conifer forests. |
| Yarrow | *Achilles millefolium* | Included in the forb mixture used in Metro Vancouver trial plots. |
| Tiger lily | *Lilum columbianum* | Not documented in the baseline vegetation survey – lake margins reported to grow this species in the traditional use study will not be disturbed by the Mine. |
| Wild potatoes[(a)] | - | Not documented in the baseline vegetation survey. |
| Mosses | Moss spp. | Expected to naturally ingress at late stages of natural succession in moist areas. |
| Fiddlehead ferns | Fern spp. | Expected to naturally ingress at late stages of natural succession in moist areas. |

(a) Additional consultation regarding this species is planned.

### 5.5.2. *Planting Strategies*

To achieve desired ecosystems on the post-closure landscape, conifer species are planted at a roughly uniform density, while targeting ideal, moist, protected microsites. In turn, deciduous tree and shrub species are planted in a similar manner. Variable land surfaces with diverse macro- and microtopography are important to improve vegetation establishment and biodiversity. Land features, such as depressions, on recontoured landscapes, may be supported through targeted plantings, such as densely planted biodiversity islands of deciduous trees and shrubs, or possibly collection and spreading of seeds of more diverse species. Additionally, timing of planting has been shown to affect overall revegetation success. Fall seeding of grass species has been successful on the Mine Site, while tree and shrub planting in the spring is more favourable than during other seasons. The seeding method used also influences revegetation success, with hand seeding being more cost-effective compared to hydroseeding with equally successful results.

Revegetation prescriptions will be slightly adapted in areas identified to be reclaimed with livestock grazing as a secondary end land use objective (Table 5-1). As such, these areas will be seeded with the native grasses/forbs mixture and provide grazing areas during earlier successional stages before a closed canopy is established (Table 5-8). Roadsides will act as long-term grazing areas. In selected agroforestry areas, lower densities of deciduous trees and shrubs will be planted, and conifers will be planted at minimum reforestation stocking targets (500 to 700 stems per hectare [sph]) using techniques such as cluster or corridor planting. This will allow for up to 30 years of good forage production (Forest Renewal BC 2001). Precautionary measures will be taken, including planting trees adjacent to obstacles to prevent seedlings from being trampled.

**Table 5-8 Mount Polley Native Species Grasses and Forbs Seed Mix**

| Species | % (by weight) | % (by seed count) |
|---|---|---|
| Mountain brome (*Bromus carinatus*) | 20 | 8.61 |
| Native red rescue (*Festuca rubra)* | 10 | 17.81 |
| Rocky mountain fescue[1] (*Festuca saximontana*) | 15 | 28.94 |
| Bluebunch wheatgrass[1] (*Pseudoroegneria spicata*) | 25 | 10.76 |
| Blue wildrye[1] (*Elymus glaucus*) | 25 | 3.34 |
| Junegrass[1] (*Koeleria macrantha*) | 3 | 17.81 |
| Ticklegrass (*Agrostis scabra*) | 1 | 11.87 |
| Big leaf lupine (*Lupinus polyphyllus*) | 0.97 | 0.07 |
| Fireweed (*Chamaenerion angustifolium*) | 0.03 | 0.81 |

Reclamation materials are locally sourced where possible. Current sources are:

- **Seed:** Premier Pacific Seed and on-site collection (alder, elderberry, cow parsnip)
- **Seedlings:** Peel's Nurseries (deciduous), NATS Nursery (deciduous), and PRT growing services (coniferous)
- **Soil amendments:** Metro Vancouver (biosolids); 153 Mile Fertilizer (fertilizer)

In case of emergency, alternative local (provincial) suppliers are available for seed and seedlings, such as Tipi Mountain Native Plants. In addition to the biosolids currently stockpiled on site, Metro Vancouver has verified their continued interest in providing biosolids for reclamation activities, if they are selected for use. Fertilizer is also readily available in commercial quantities, as it is routinely used in the agriculture industry. However, the natural succession approach applied to reclamation at the Mine Site does not rely on these amendments and suppliers. After the TSF embankment breach, MPMC was able to use a variety of sources to get large quantities of native trees and shrubs at short notice with little difficulty. In addition, MPMC is experimenting with local seed collection of high priority target species and commercially less available species to ensure a more secure source of reclamation materials in the future.

#### 5.5.3. *Alignment with End Land Use*

Because the end land use objectives selected for the Mine Site align with pre-mining land uses, species used in revegetation promote wildlife use and the development of conifer species for commercial forestry in the area (Table 5-9; BC Ministry of Forests, Forest Development Plan 2021). Additionally, to incorporate a secondary land use of livestock grazing (Section 3.1), a native grasses and forbs seed mix was developed for use at the Mine Site by consultant Moss Giasson, P.Ag., (Montane Environmental Services) and was based on recommended native grazing forage species for the area in the British Columbia Rangeland Seeding Manual (Dobb and Burton 2012; Table 5-8). MPMC is considering the use of an annual groundcover species (for example, fall rye) for future use at the Mine Site. This approach aims to provide erosion control and organic matter inputs in the short-term while trees and shrubs are being developed, without being competitive to the trees and shrubs in the long-term, thus promoting natural revegetation succession.

**Table 5-9 BC Forest Development Plan Stocking Standards (ICHmk3 biogeoclimatic zone; BC Ministry of Forests 2021)**

### 5.6. Environmental Risk Assessment

To address *Mines Act* permit M-200 condition D.15, MPMC conducted an environmental risk assessment (ERA; Appendix N). Eighteen sampling locations were selected within the Mine Site's permit boundary. Twelver were selected in areas that were revegetated and six were selected in undisturbed reference locations. Paired soil and vegetation samples were collected between 13 and 16 September 2022 and submitted to ALS Environmental (ALS) for analysis of nutrient, physical and chemical parameters (soil only), metals, and moisture content. Plant parts that are edible to wildlife were selected to allow the assessment of the potential risk to ecological receptors from ingestion of terrestrial vegetation. The sampling program targeted the main vegetative lifeforms (e.g., grass, forb, tree, and shrub [e.g., berry]), based on availability at each sampling location.

The results of the ERA are summarized below:

- The initial step of the ERA involved screening soil concentrations against soil screening criteria protective of lower-trophic-level receptors (i.e., plants and soil invertebrates) (BC CSR standards) and wildlife (Canadian Council of Ministers of the Environment Soil Quality Guidelines [CCME SQGE]).
    - Measured concentrations of parameters of potential concern (POPCs; selenium, sodium, copper) in coversoils exceeded soil screening criteria and in some cases were also elevated compared to reference soil concentrations
    - Selenium concentrations in coversoils were marginally elevated at 2 of 18 sampling locations, which were spatially separated across the Mine Site. The average selenium concentration met the CSR screening criterion for toxicity to soil invertebrates and plants (TSIP) and none of the coversoils exceeded the CCME SQGE. Given the isolated exceedances, impacts to plant communities are not expected and, on this basis, selenium was not retained as a POPC for further evaluation in the ERA.
    - Sodium soil concentrations at 14 of 18 stations were elevated compared to the CSR screening criterion for TSIP. Adverse effects from the salinity levels at the Mine Site were not expected, as other parameters (electrical conductivity [EC] and sodium adsorption ratio [SAR]) which are indicators of sodicity were low. Therefore, sodium was not retained as a POPC for further evaluation in the ERA.
    - Copper was retained as a POPC for further evaluation in the ERA for both plants and wildlife as concentrations within coversoils exceeded ecological screening criteria across the Mine Site and exceeded reference concentrations.

- Copper is an essential element in both plants and animals. Detrimental effects can be observed in plants and animals with copper deficiency as well as with excess copper. No signs of plant distress were observed by field staff during the tissue sampling event. Measured tissue concentrations of copper in reclaimed area grass, forbs, berries, and leaves were generally within the "normal" range of concentrations required to meet the nutritional needs of a plant (4-20 mg/kg dry weight reported by Hochmuth et al. 2015).

- Plant tissue concentrations were generally lower across the southern sites compared to the northern sites, where a select number of samples at northern sites were reported at copper concentrations greater than 20 mg/kg dry weight.

- Hochmuth et al. (2015) reports that copper is not highly mobile in plants, but some copper can be translocated from older to newer leaves. Fresh growth was targeted during tissue sampling, representing what would be considered areas of highest copper within the tissues.

- The isolated, elevated concentrations of copper within plant tissues at northern sample sites on the mine are not expected to impact the viability of the plant community.

- With respect to potential risk to birds and mammals through soil and food (plant) consumption, the ERA concluded that there is negligible risk to plant-eating wildlife based on the conservative food chain assessment, which considered that receptors of concern (ROCs) feed exclusively from the Mine Site, in the area of maximum copper concentrations. Hazard quotients (HQs) for ruffed grouse, meadow vole, and deer were all equal to or below 1, indicating minimal risk.

### 5.7. Invasive Plant Management

To promote natural succession, invasive plants on the Mine Site must be managed such that they do not inhibit growth of native species (both planted and naturally encroaching). To address this issue, MPMC maintains and implements an Invasive Plant Management Plan (Appendix O). Invasive plants found on the Mine Site are managed in accordance with the Cariboo Chilcotin Coast Invasive Plant Council Regional Strategic Plan and the BC *Weed Control Act* (RSBC 1996).

### 5.8. Fugitive Particulate Management

Under *EMA* Air Permit 15087, MPMC is required to suppress fugitive dust from the operations area and monitor dust fall in areas adjacent to the Mine Site. MPMC's regulatory threshold is 2.9 mg/dm$^2$/d (milligrams per decimetre square per day). To meet these requirements, MPMC has a Dust Management Plan (Appendix P) for the Mine and TSF areas which uses a "Plan, Do, Check, Act" management approach. The plan includes:

- identification of sources of fugitive dust emissions associated with the Mine

- a description of how fugitive dust can be controlled from each significant source and the best management practices in place or planned
- a description of how the plan will be implemented, including the training of personnel
- a description of inspection and maintenance procedures
- a description of methods of monitoring and appropriate response actions to feed back into refining management actions, as needed, based on monitoring and inspection results

This program will continue to be implemented through the operations and active closure of the mine, until monitoring results indicate that further mitigation measures and monitoring are no longer necessary.

### 5.9. Waste Management

The Mine Site operations uses potentially hazardous chemicals, reagents, and other products that are subject to waste disposal procedures. From 2019 to 2021, limited hazardous waste was generated. In 2019, Sumas Environmental routinely removed and disposed of waste products compliant with relevant regulations. Waste from 2020 was stored on site temporarily due to the small quantities produced during the Mine Site's care and maintenance status. Starting 2021 and continuing to the present, Sumas Environmental Services Ltd. resumed the disposal of waste products, as waste production picked up in conjunction with the ramp-up to operations. Materials that are routinely segregated and removed include aerosol cans; contaminated gasoline and diesel; waste oil (in drums); waste oil filters; waste grease fuel or oil-soaked rags, debris; and leachable liquid toxic waste, such as glycol/anti-freeze mix. The bulk waste oil tanks are emptied, and the oil removed from site by GFL Environmental. MPMC is registered with ENV under the Hazardous Waste Regulation (BC 1988) for generation and temporary storage of these materials.

A summary of current on-site waste management segregation practices and disposal locations is provided in Table 5-10. MPMC Environmental Department staff conduct routine (typically weekly) inspections of waste management disposal areas at the Mine Site to verify that correct waste segregation is being conducted. These practices will continue to be carried out through the operating and active closure phases of the mine life until such a time when these materials are not used or present at the Mine Site. Discussions on removal of fuels, reagents, and toxic materials, and removal of structures and equipment during active closure are provided in Section 6.1.3 and Section 6.1.4, respectively.

**Table 5-10 MPMC Waste Management Matrix**

| Item | Correct Disposal Location(s) |
|---|---|
| Food waste | Lunchroom garages, bear-proof garbage cans (fuel islands, parking lot), and Admin Building entrance garbage cans |
| Drink containers | Recycling bins: lunchrooms, Admin Building entrances/2nd floor/ 3rd floor, Warehouse, Purchasing and Planning Trailers, Control Room, and Fuel Island<br><br>(Proceeds from returns donated to local charities) |
| Cardboard | Warehouse, Pit Shop (east side), front of Admin Building |
| Paper | Small blue bins in offices/big bin outside Admin Building |
| 5-gallon pails (oily) | Warehouse 5-gallon pail disposal bin (beside Light Vehicle Fuel Island) |
| Oily/greasy rags, used spill pads, motor oil containers, etc. | Black enviro barrels designated for oily waste at the fuel islands, pit shop, crusher, and maintenance laydowns. |
| Scrap metal | Warehouse scrap metal disposal site (separate according to signs) |
| Aerosol cans (including brake clean) | Black enviro barrels designated for aerosols at the Warehouse (beside light vehicle fuel island), pit shop, crusher, and maintenance laydowns |
| Large batteries | Warehouse bin (beside Light Vehicle Fuel Island) |
| Small batteries | Box inside Warehouse at counter, Admin Building 3rd floor hallway |
| Paint cans (not empty) | Warehouse disposal bin |
| Lamps, ballasts, and fixtures | Bin on Mill second floor (near electrical shop) |
| Engine oil | Waste oil tank at Pit Shop or black enviro barrels at laydowns (to be emptied into waste oil tank) |
| Engine coolant | Black enviro barrels in maintenance areas |
| Electronic waste | Bin under stairs on 1st floor of the Admin Building (mill side) |
| Wood, plastic, rages (not oily), and any other products not listed above | Landfill |

## 5.10. Contingency Plans

Risks to successful closure will be partially mitigated through adaptive planning and decision-making. Reclamation is an important piece of the mining life cycle and is critical to the overall closure planning process. The underlying strategy for reclamation is that it is founded on a management approach that is iterative based on monitoring results, research findings, and changes to best practice and regulation (Figure 5-7).

Progressive reclamation activities allow opportunities to test, monitor, and adapt reclamation strategies where required. MPMC will use ground-based sampling programs as an effective method to measure success of reclamation (see Section 7). The goal is to establish a means to determine parameters and criteria for monitoring and judging the success of reclamation efforts. The monitoring program can be used to help support an adaptive management approach to reclamation by identifying areas for mitigation and improvement in reclamation design.

Results may highlight areas for improvement or indicate aspects of the design that are working well and may be implemented elsewhere on the landscape.

Maintenance is planned for, and is included, in MPMC's long-term reclamation planning. Long-term monitoring and maintenance will be conducted until the Mine Site is ready for certification. If, during monitoring, sites are found that are not performing as expected, mitigations may be applied, including: infill planting, fertilization, mulching, weed control, pest control, watering, and, where required, further investigation into soil and foliar chemistry. Where uncertainty remains about the performance of reclamation activities, adaptive management strategies will be used to formulate an appropriate response.

As part of adaptive management, results from research programs will be incorporated where opportunities exist. MPMC relies upon experience, topic specific experts, and research findings to identify methods for achieving reclamation and closure objectives.

Specific contingency plans can be found throughout this document, including:

- contingencies for coversoil shortages (Section 5.4.2)
- contingencies for acquiring revegetation materials in large volumes and/or with short notice (Section 5.5.2)
- contingency options if Springer Pit seepage is adversely affecting the receiving environment (Section 6.4.2)
- contingencies for the ore stockpiles (condition D.3.(c)(iv) of M-200) (Section 6.7)

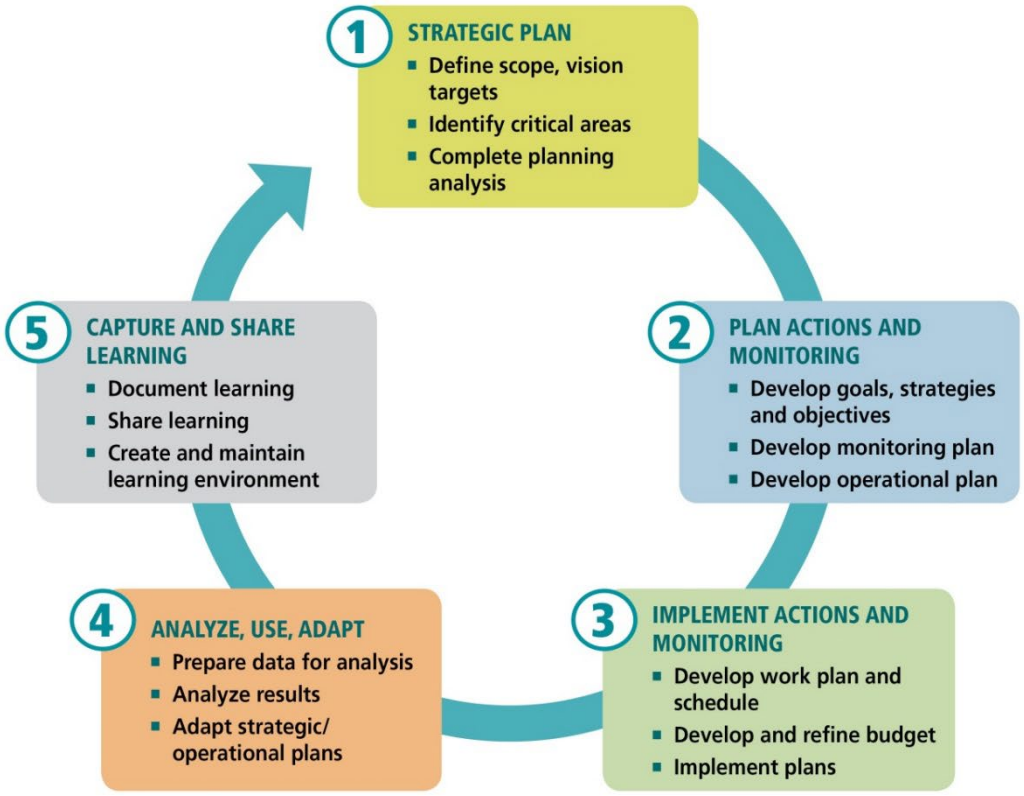

*Figure 5-7 Adaptive Management Cycle*

# 6. RECLAMATION UNITS

Reclamation units represent the various mine features that will be reclaimed once mining ends. A description of the reclamation units and specific considerations are provided in the subsequent subsections. Reclamation prescriptions for areas scheduled to be reclaimed in the latter portion of the active closure phase, as per the conceptual schedule (Section 8), may be refined based on results from progressive reclamation.

## 6.1. Mill and Plant Area

The mill and plant site area will comprise 36.58 ha at the onset of active closure, and will encompass nearly all the structures and equipment that exist at the Mine Site, including the:

- crusher and stockpile facilities
- mill
- magnetite recovery plant (operated by Craigmont Industries Ltd.)
- concentrator
- electrical substation
- maintenance shops
- warehouse
- offices
- assay laboratory
- fuel storage facilities
- potable water systems
- exploration geology buildings and core shacks

#### 6.1.1. *Mill Reclamation Plan*

MPMC owns the surface rights to most of the mill and plant area, and interest has been expressed from local stakeholders for leaving some of the buildings and associated infrastructure (i.e., power supply) in place during the decommissioning of the Mine Site. This approach is supported by MPMC for all non-salvageable components of interest. In this scenario, MPMC would transfer ownership of the facilities to a third party, if an interested group can be identified at the time of active closure. During the first operation period from 1997 through 2001, the potential to convert the mill building into a truck repair shop or other industrial complex was discussed with ENV officials. The mill building has offices, electricity, telephones and all the other requirements of an industrial complex, and is located near forest industry activity in the surrounding areas, as well as communities that are connected to the industry.

For the purposes of scheduling in this MRP, it assumed that all mill and plant area infrastructure will be demolished and decommissioned, with the former plant area fully reclaimed. Careful planning of activities will be needed so that site services are not disrupted prematurely, and are available to support other overall closure and reclamation activities. Offices, power, sewage, and domestic water systems will be required for employees overseeing overall closure activities. During the active closure, the mill and plant area footprint will be decompacted (as needed), and coversoil will be placed in accordance with the reclamation and revegetation strategies shown in Figure 5-4, Figure 5-5, and discussed in Sections 5.4 and 5.5.

#### 6.1.2. *Decommissioning Work Sequence*

All buildings, overhead structures, water management infrastructure, and pipelines will be catalogued, and their potential for salvage or other uses will be determined. Any infrastructure not required for future use will be dismantled and removed from the site. Core shacks may be left on site pending a decision that will be made in collaboration with EMLI.

Water intake systems and all above-ground pipework will be lifted and removed from the site. Underground pipework, such as fire, sewage and communication lines, will remain buried. Groundwater wells, both potable and monitoring, will be decommissioned when they are no longer required.

The proposed decommissioning and demolition approach for all buildings and infrastructure follows the same basic sequence of events. This sequence is summarized in Table 6-1.

**Table 6-1 Decommissioning and Demolition Sequence**

| Item | Task | Description |
|---|---|---|
| 1 | Hoarding | Installation of hoarding (fast fence) around the work site to provide a working environment delineated from other operations at the site. |
| 2 | Cut and remove all utilities from the building | Electrical, fuel lines from tanks, water, sanitary sewer, storm sewer, data cables, telephone. |
| 3 | Removal of interior contents | Clean demolition: removal of all contents from inside the building without damaging any designated substances identified. |
| 4 | Abatement of hazardous building materials or process substances | Recovery, removal and recycling of products that may be hazardous to the environment and a Contaminated Sites Assessment (Section 6.1.3).<br>Prior to demolition of any building, all hazardous building materials or process substances will be removed from the building. Upon completion of the removals, access to be restricted to those trades involved in the demolition. |
| 5 | Structural demolition to grade | Structural demolition of buildings and structures using excavators equipped with tools in a top-down, out-in approach.<br><br>It is assumed that the fleet of heavy equipment will be brought to site to perform the demolition (if equipment on site is not suitable) and process the waste streams for shipment to designated waste disposal facility or facilities. Waste streams will be segregated. |
| 6 | Removal of slabs and foundations | Breakup and removal of concrete slabs and foundations, footings, and floor slabs of buildings with basements. Foundations to be demolished to ground surface, or a maximum of 600 mm below grade surface if needed to allow for backfilling and grading of the site to a self-draining condition. Floor slabs to be processed and hauled to a RDS or another designated site for final disposal. |
| 7 | Backfilling/site grading | Backfilling of basements with inert waste rock or overburden from the site in 300 mm lifts, nominally compacted to approximately 95% standard Proctor maximum dry density.<br><br>Bulldoze and grade all site areas to a self-draining condition, with re-contouring of site to mimic surrounding natural landscape and restore drainage patterns towards Mine Drainage Creek (the Mill Site Sump and Ditch will be removed when no longer required and when water quality meets discharge guidelines). |
| 8 | Final cleanup | Removal of any final small debris (75 mm or larger) such that reclamation activities can be undertaken so the area can naturalize. |
| 9 | Reclamation | Site preparation and re-distribution of stockpiled overburden, incorporating amendments as per Section 5.4.1.<br>Revegetation using early successional species and diverse habitat enhancements for wildlife and forestry values as per the prescriptions in<br>Section 5.5. |
| 10 | Post-reclamation monitoring | Monitoring of reclamation success, as per Section 7. |

### 6.1.3. *Removal of Fuels, Reagents, and Toxic Materials*

All tanks and fuel storage facilities will be emptied of their contents before they are removed from their foundations. Tank residues will be transferred by a proven and reputable waste oil reprocessing company or waste recycling company, as appropriate. This will follow similar procedures that have been in place throughout the operating period of the Mine (Section 5.9). Unused reagents and laboratory chemicals will be repackaged and shipped to other authorized users, or to an appropriate waste disposal facility. Any contaminated soils will be collected and stockpiled for treatment or disposed of in an approved manner.

A conceptual plan for a Contaminated Sites Assessment under the BC Contaminated Sites Regulation has been developed for the Mine Site (Appendix Q). The conceptual plan focussed on areas that stored or dispensed hydrocarbons, chemicals, blasting products (the Orica Site), and stockpiled materials (ore and PAG). Associated cost estimates have been incorporated into the liability bond costing calculations.

### 6.1.4. *Waste Streams*

All waste streams resulting from the decommissioning and demolition of the Mine Site will be recycled where possible, or landfilled. Given the complexity of the Mine Site, and the diversity of the associated waste generated, waste has been classified into 11 different waste streams. These waste streams are presented in Table 6-2.

**Table 6-2 Typical Waste Classifications**

| Item | Name | Description |
|---|---|---|
| 1 | Total metal (recyclable) | Structural steel (heavy, light, shred), non-ferrous (copper, aluminum). |
| 2 | Wood/plywood/mixed wood | Interior wall partitions, wood structures and sheds, exterior wood cladding, shelving, core boxes, interior finishes. |
| 3 | Painted/laminated/wood | Counters, wooden and laminate office furniture and lab installations, cabinets, etc. |
| 4 | Plastic | Anything plastic within contents of buildings. A significant portion of the contents were observed to have plastics as the primary material. |
| 5 | Particle board/tile | Interior finishes and bathrooms. |
| 6 | Concrete | Steel reinforced cast in place concrete structures, foundations, footings, interior and exterior slabs, core slabs, cast in place structure elements. |
| 7 | Concrete Masonry Units | Concrete masonry units – block walls, etc. |
| 8 | Brick (clay based) | Terracotta block, speed block, clay-based exterior brick veneers. |
| 9 | Mixed debris/demolition waste | Mixed waste generated from the demolition of the structures, and is combination of small pieces of recyclables, concrete, wood, insulation, and other demolition debris. |
| 10 | Interior contents | Interior contents of buildings which are removed prior to structural demolition, and segregated from demolition waste and building debris. Recyclables will be removed from this waste stream as practical. |
| 11 | Sulphur stockpiles | Excess elemental sulphur stockpiled before use as sulphuric acid in copper ore leaching process |

Near the date of mine closure, detailed estimates of waste stream volumes and corresponding landfill capacity and design will be prepared. Details on the disposal of various waste categories are provided below:

- **Non-salvageable, non-combustible, and non-recyclable materials:** these materials will be buried within the onsite landfill, covered with waste rock, and reclaimed to match the end land use of the surrounding area(s), as per the BEC site series. Any materials that would require the landfill to have an engineered cover will be disposed of offsite.

- **Combustible, non-salvageable materials**: these materials will be burned pending receipt of a refuse permit, and the burned residues will be buried in the onsite landfill.

- **Structural steel, heavy gauge, shred, ferrous, and non-ferrous metals:** these will all be segregated and sheared to scrap metal industry sizing.

- **Concrete rubble:** this material may be used for filling in basements and regrading surfaces in the mill area. For the entire Mine Site, it is assumed that concrete rubble will be pulverized using a heavy excavator equipped with a pulverizing jaw attachment. The pulverized concrete rubble collected from each area will be stockpiled until the end of the demolition phase of the overall closure work. Once the demolition phase is complete, the pulverized concrete rubble can be placed in an RDS or other suitable location. Alternatively, it may be preferable to process the concrete rubble through a crushing plant to obtain a 2-inch (50 mm) minus crushed material. This material can be used as cover material for other aspects of demolition (e.g., cover material for foundations) during active closure.

### 6.2. Power Lines

Removal of power infrastructure will depend upon the power requirements for post-closure (particularly water treatment) and on other potential power users in the region. When no longer required, overhead power lines and infrastructure on the Mine Site will be removed by a specialty contractor. Salvageable materials will be sold, recycled, or disposed of using an approved method. Buried cables will remain in the ground, as they do not pose a risk to humans or the environment. Postholes will be backfilled, and reclamation will be carried out in a manner consistent with adjacent reclamation units. As a ground cover already exists in power line rights of way, revegetation will only include planting of trees and shrubs, if not already naturally regenerating.

### 6.3. Test Heap Leach

The Test Heap Leach Facility is located on top of the East RDS and includes the lined heap leach pad, operations building, and former sulphur stockpile footprint (see Section 1.2.2). Remaining materials and their volumes are presented in Table 6-3.

**Table 6-3 Test Heap Leach Materials Estimates (SRK 2022a)**

| Material | Location | Estimated Tonnage (t, $m^3$)[1] |
|---|---|---|
| Ore mixed with elemental sulphur | Stored on the leach pad | 7,000 $m^3$ |
| Elemental sulphur | Stored on top of leached ore on leach pad<br>Stored in layers between ore on leach pad | 23,000 t<br>Unknown amount |
| Leached waste rock from below the sulphur stockpile | Stored on top of leached ore on leach pad | 9,200 t |
| Leached ore | Stored on top of leach pad | 19,000 t |
| Crushed rock (waste rock) | Stored on leach pad (surrounding and underneath contaminated soils) | 20,000 t[1] |
| Metal contaminated soils | Stored on top of leached ore on leach pad | 30,000 t |
| Anchor rock (for liner) | Outside of leach heap footprint | 5,400 t[1,2] |
| Berm | Around leached ore on leach pad | 22,000 t[1] |
| Drainage material | Drainage rock above and between liner layers | Unknown |
| Till liner | Underneath heap leach facility | Unknown |
| Liner[3] | Bottom of heap leach pad | - |

1) Estimated based on volume.

2) Stored outside of leach pad footprint.

3) Liner comprises of two plastic liners that are 19,000 $m^2$, with one geonet placed between them.

The Mount Polley Heap Leach Decommissioning Plan (SRK 2022a) determined that submergence of stockpiled elemental sulphur, leached waste rock, leached ore, crush rock, contaminated soils, and berm materials in the TSF was the best option for the disposal of these items. Submerged disposal is expected to arrest oxidation but will rapidly leach the soluble acidity. This acidity may be neutralized by contact with tailings or with the addition of lime during disposal. The method of disposal of anchor rock will depend on its ML/ARD classification. If surface disposal is desired the anchor rock may require amendment. Alternatively, this material could also be disposed of within the TSF. To allow sufficient time for generation of tailings to cover the anchor rock in the TSF and sufficient blending with neutralizing amendments, disposal is recommended to be started during operations and completed before the last year of processing (SRK 2022a).

## 6.4. Open Pits

### 6.4.1. *General*

Approximately 231 ha of the Mine Site is projected to be open pits at the onset of active closure, which includes the Boundary Pit, the Wight Pit, the Cariboo-Springer Pit, and the TSF Rock Quarry. Once pit lakes form in the Boundary, Wight, and Cariboo Pits, approximately 164 ha is projected to remain above the elevation of the pit lakes. The total area of the pit lakes at active closure is expected to be approximately 67 ha. The balance of the pit area is lost in the flooded pits.

Public safety is paramount during the reclamation of the open pits. When mining of the pits is complete, berms and signage will be installed around the perimeter of the pits. Efforts will be made to revegetate the rims of pits visible from Bootjack Lake and Polley Lake to minimize visual impact. Remaining exposed pit walls will have a slope ranging between 40° and 50° and are exempt from reclamation pursuant to Section 10.7.13 of the *Health, Safety and Reclamation Code for Mines in British Columbia* (EMLI 2021). The unvegetated pit walls have potential to add to the post-closure landscape's biodiversity by providing microhabitats that did not exist prior to the Mine Site's development. Cliff faces, particularly those with ledges, boulder piles, crevices, and overhangs, may provide nest sites for a variety of cliff nesting birds, such as the common raven (*Corvus corax*), birds of prey, cliff swallows (*Petrochelideon pyrrhonota*), barn swallows (*Hirundo rustica*), and Say's phoebe (*Sayornis saya*). Cavities in boulder piles can provide nesting and denning habitat for bats (*Chiroptera*), the bushy-tailed woodrat (*Neotoma cinerea*), deer mice (*Peromyscus* spp.), the northwestern chipmunk (*Tamias minimus*), and other small mammals.

Ramps down to the level of flooding will be decompacted with heavy equipment and reclamation will occur as outlined for ICHmk3_02 BEC series (Table 5-6 and Figure 5-4). Flooded pits will create isolated water bodies that have little potential as fish habitat. The surface waters of the ponds have potential to support aquatic invertebrates, and may provide useable spawning habitat for western toad and spotted frog. To promote aquatic habitat, species including duckweed (*Lemna spp.*), pond weed (*Potamogeton spp.*), yellow pond lily (*Nuphar variegata*), water sedge (*Carex aquatilis*), beaked sedge (*Carex utriculata*), common cattail (*Typha latifolia*), and river horsetail (*Equisetum fluviatile*) will be considered in revegetation. Floating species help build up organic matter, creating potential habitats for riparian species to be introduced over time. Such plants may also help remediate pit water quality through microbial activity, while the pit lakes may have the potential to act as a drinking water source for wildlife, depending on water quality and access.

Water quality modelling indicates that the water in pit lakes will be suitable for wildlife and livestock; predicted concentrations are below applicable guidelines. Predicted concentrations (Section 5.2.4) are below the screening level for livestock and wildlife of 10 mg/L for molybdenum, and selenium will be managed in response to measured water quality, through measures such as carbon addition to reduce selenate and precipitate selenite, if necessary. The need for this mitigation will be confirmed by monitoring the actual water quality observed in the active closure and post-closure periods.

### 6.4.2. *Cariboo-Springer Pit*

#### 6.4.2.1. Post-Closure Water Balance

At the onset of active closure, PAG material will be placed in the Cariboo-Springer Pit to an elevation of 1,004 masl (Appendix H). The active closure and post-closure water balance model assumes uniform deposition across the Cariboo-Springer Pit. Under the mean condition, the combined Springer-Cariboo Pit Lake is estimated to start overflowing in 2054. Under the 90th percentile condition, the combined Springer-Cariboo Pit Lake is estimated to start overflowing in 2050. Under the 99.5th percentile condition, the combined Springer-Cariboo Pit Lake is estimated to start overflowing in 2049. It is expected that the pit overflow for the 99.5th percentile condition will occur the soonest compared to the mean and 90th percentile conditions. Peak daily discharge and annual discharge volume to Bootjack Lake is expected to remain constant from 2051 to 2124.

The post-closure water balance (Appendix H) Indicates that, under natural accumulation conditions, the Cariboo-Springer Pit will fill to an elevation of 1,030 masl in January 2038 (following drawdown for mining and subsequent placement of PAG material) and an elevation of 1,050 masl in 2050. The post-closure surface area of the combined pit lake is projected to be 50 ha at 1,050 masl. Depending on water management requirements and Mine Site objectives, water may be directed (i.e., pumped) to the Cariboo-Springer Pit to advance this filling schedule. A summary of projected long-term water chemistry for the Cariboo-Springer Pit during active closure and post-closure is provided in Appendix I. This projected chemistry will determine treatment requirements and inform selection of treatment options for development of the closure water management plan.

A geotechnical assessment of the slope stability of the southwest wall of the Springer Pit (the wall between the Springer Pit and Bootjack Lake) was conducted (Appendix S). Findings from the assessment indicate that adequate long-term slope stability conditions are expected to be achieved, as results of the analyses exceeded the minimum recommended factor of safety (FoS) of 1.3.

#### 6.4.2.2. Cariboo-Springer Pit Spillway

As part of the post-closure design for the Cariboo-Springer Pit, a conceptual level spillway design was prepared (Appendix R). The spillway is intended to operate after the active closure of the Cariboo-Springer Pit and its purpose is to safely discharge overflow caused by storm water runoff and other inflows from the surrounding catchment. The spillway channel has also been sized with constructability and vehicle passage along the existing haul road as main considerations. The wide channel base and gradually sloped banks allow for vehicles using the existing haul road to cross the spillway channel safely when no water is flowing. The spillway channel has been sloped towards the Cariboo-Springer Pit to eliminate the risk of normal runoff from the haul road discharging into the environment. Design flows for several, rainfall scenarios were considered at regular intervals, with the spillway invert at 1050.5 masl.

#### 6.4.2.3. Hydrogeology

A hydrogeological assessment of the Cariboo-Springer Pit is provided in Appendix F. This assessment predicts the formation of a pit lake at closure and potential exfiltration of pit lake water to groundwater (flowing in the direction of Bootjack Lake). Currently, modeling, which assumes no mining of the inter-pit saddle, indicates that once pit lake elevations are above approximately 1,028 masl, the pit lakes in the Springer Pit and Cariboo Pit merge and form a single pit lake. Results indicate that seepage to groundwater will occur when the lake level reaches 1,030 masl, with seepage at the spillover elevation (1,050 masl) projected to be approximately 420 $m^3$/d (combined seepage of 400 $m^3$/day from the Springer Pit and 20 $m^3$/day from the Cariboo Pit; (Golder 2016b).

In 2016, an additional well was installed downgradient of the Cariboo Pit, to monitor both water quantity and quality during operations, active closure, and post-closure. Groundwater quantity and quality modeling evaluated conditions during active closure and post-closure with the spillway elevation at 1,050 masl. Seepage water data was fed into a three-dimensional lake model that considered an initial dilution zone within Bootjack Lake. The model results were considered in an aquatic effects assessment, which concluded there would be no likely adverse effects on Bootjack Lake as a result of pit lake seepage (Golder 2016c). The assessment was carried forward to an application to the ENV for an *EMA* Permit 11678 amendment that would allow the seepage to occur under a “no discharge” contingency scenario. These results are also applicable to closure of the Cariboo-Springer Pit.

Despite these predictions, if results from ongoing groundwater and receiving environment monitoring indicate that seepage to groundwater is negatively impacting the receiving environment, mitigation options include decreasing the spillover elevation, installing a low-permeability barrier, and/or constructing a passive seepage collection system.

### 6.4.3. *Wight Pit*

The Wight Pit is no longer actively mined and is being used to store mine contact water. An adit to the former underground operations located within the pit is below the flood level. MPMC plans to construct a spillway toward Polley Lake This spillway will follow the same concept and design basis as the Springer Pit spillway, with an invert elevation of 926 masl. The Mine Site’s closure water balance modelling (Appendix H) indicates that Wight Pit Lake is projected to start overflowing in 2027, at which point the PAG the PAG material currently deposited in the pit will be entirely submerged. Overflow from the Wight Pit Lake will discharge to Polley Lake. Annual discharge volume to Polley Lake is expected to remain constant from 2029 through 2124. The reader is directed to Appendix H for more detailed information, including discharge rates. Once filled, the pit lake is expected to have a surface area 14.61 ha.

A hydrogeological assessment by Golder (Appendix T) projects that at spillover elevation (926 masl), seepage to groundwater towards Polley Lake will occur at approximately 500 $m^3$/d, with groundwater seepage into the pit lake of approximately 600 $m^3$/s. The hydrogeological assessment recommended that old borehole wells be reconditioned, or new wells installed to collect data to refine the model. MPMC conducted investigations associated with the recommendation, and two dewatering wells near the Wight Pit were converted into monitoring wells in 2016.

#### 6.4.4. *Boundary Pit*

The Boundary Pit is a small pit, and observations through the operating period of the Mine Site indicate that the water within the pit exists in a roughly steady state (i.e., does not overflow). Modelling indicates that a seasonal pond will develop in the Boundary Pit, and the pond is not expected to overflow during the modelling period of 1 September 2024 to 1 September 2124. Seepage from the Boundary Pit is assumed to contribute to inflow to the Wight Pit. During post-closure, the Boundary Pit is expected to have a water elevation of approximately 1,070 masl and a projected surface area of 2.74 ha.

A groundwater characterization and modelling assessment (Appendix U) indicates that the water level in the Boundary Pit could rise to 1,073 masl, resulting in a pit lake with a maximum depth of 5 m. The modelling indicates that groundwater seepage from this area would flow towards the Wight Pit at a rate of 59 $m^3$/d. Accessible disturbed areas of the pit's footprint will be reclaimed as outlined in Section 6.4.1, and the reclamation prescriptions shown in Table 5-6.

#### 6.4.5. *TSF Rock Quarry*

When the TSF rock quarry is no longer active and available for reclamation (e.g., following recontouring efforts associated with the TSF's closure prescription), coversoils will be applied to accessible areas and revegetation will take place as outlined in Section 5.5, and the reclamation prescriptions shown in Table 5-6 and Figure 5-4, with the pit walls remaining in their current state.

#### 6.4.6. *Water Management Infrastructure*

Water management in post-closure is crucial to overall success of the closure of the Mine Site. Pit lake post-closure conditions are discussed in Section 6.4.; however, other components are accounted for within this section. Table 6-4 shows a summary of details related to estimated overflow dates. Table 6-5 shows projected discharge locations. Figure 5-1 and Figure 5-2 provide detail on water management infrastructure and how water will be managed in active and post-closure.

**Table 6-4 Overflow/Discharge Dates of Post-Closure Water Management Components**

| Component | Projected Date of Overflow/Discharge |
|---|---|
| PETBP | 2024 |
| SESCP | 2044 |
| MESCP | 2045 |
| 9K Sump | 2034 |
| NW Sump | 2025 |
| Mine Drainage Creek Sump | 2025 |
| Long Ditch/SERDs Ditch | 2034 |

Note: SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment.

**Table 6-5 Discharge Locations for Post-Closure Water Management Components**

| Water Management Infrastructure | Discharge Destination |
|---|---|
| Wight Pit | Polley Lake |
| SERDS/ Long Ditch | |
| Perimeter Embankment Till Borrow Pond | Hazeltine Creek |
| Main Embankment | |
| South Seepage Pond | Edney Creek |
| 9K Sump | Bootjack Lake |
| NW Sump | |
| Springer-Cariboo Pit | |
| Mine Drainage Creek Sump | |

As the mine moves into closure and post-closure, the objectives of water management in the closure plan for the mine are to return the impacted land to pre-mining land functions. As the mine is constructed across a watershed divide, it is desired that during the post-closure period, drainages will be distributed back to their natural watersheds (i.e., to Bootjack Lake, Polley Lake, and Hazeltine Creek), provided that this can be achieved in an environmentally appropriate and permittable manner. No additional water infrastructure will be constructed for closure and post-closure.

Overall, water management infrastructure in active closure will be a more simplistic version of that currently in place during operations. Notable differences in active closure include that the Cariboo-Springer pit will no longer be connected to the rest of the water management system, and that a passive/semi-passive treatment system will be in place. During post-closure, water management infrastructure will be broken up into segments (e.g., decentralized), and main site features (e.g., TSF) will not receive water from other segments of the mine. For instance, water from the East RDS will no longer ultimately reach the PETPB, but will report to the Long Ditch, and then overflow to Polley Lake.

### 6.5. Waste Dump Reclamation

The Mine Site is projected to have 356.87 ha of waste dumps prior to active closure (Figure 2-1), including areas that are currently undergoing progressive reclamation. All RDSs that will remain as permanent structures at closure contain NAG rock. The reclamation and closure approach for the NAG RDSs is focused on creating geotechnically stable landforms that not only support revegetation and reclamation efforts but also reduce the visual impacts from Bootjack and Polley lakes, in compliance with condition E.9.(b) of M-200 permit. PAG waste rock generated during operations (which has not already been backhauled into exhausted pits) will be segregated and temporarily stored in the Temporary NW PAG Stockpile. The reclamation of that stockpile is discussed separately in Section 6.6.

### 6.5.1. *Reclamation Approach*

During active closure, RDS slopes will be recontoured to 2H:1V or less, to promote long-term physical stability (Section 5.1.1). Recontouring efforts at closure will consider landform design and aesthetics to promote natural integration of reclamation sites into the surrounding landscapes. Landform design will also consider the pre-mining drainage pathways shown in  and conceptual closure drainages discussed in Section 5.2.4. Additionally, designs for the RDSs will consider scales ranging from micro-topography to regional landscapes, and minimize erosion and the long-term visual impact from Polley and Bootjack lakes.

Engineering design guidelines for RDS closure morphology were prepared in 2019 (Golder 2019). This work evaluated the design approach for drainage over the surface of the RDSs, with the intent of developing a reclaimed landform that conveys surface runoff in a form that is analogous to the drainage on surrounding landforms.

Following recontouring, RDSs will be covered with coversoil, and revegetated with early successional species and wildlife habitat enhancements to promote forest establishment and encourage wildlife usage. Agroforestry practices will be implemented in select areas to allow for livestock forage in young forests and open canopy forests. Procedures for soil handling and application to reduce compaction and create microsites, along with placement of coarse woody debris and other habitat features on the RDSs, are outlined in Section 5.4.

End land uses are discussed in Section 5.3, and revegetation prescriptions are provided in Section 5.5. The recreation end land use could potentially include interpretive walking trails and picnic areas to promote outdoor recreation and public education. A possible location is the North Bell Dump, which overlooks the Mine Site and Polley and Bootjack lakes. This location would offer views over the reclaimed mill and Temporary NW PAG Stockpile sites, as well as over the pit lake that will form in the Cariboo-Springer Pit.

### 6.5.2. *Visual Assessment*

The closure design of the RDSs was assessed for aesthetic value and visual impact from Bootjack and Polley lakes to comply with condition E.9 in *Mines Act* permit M-200. The visual simulations of the RDSs were created as panoramic photocompositions. Panoramic images consist of multiple photos stitched together to create a wide field of view, allowing the resulting image to depict a large site. Photocompositions are combinations of site photos taken in the field and modelled views of the closure landscape, which are superimposed onto the site photos.

The visual simulations were created for four viewpoints, two located on Bootjack Lake and two located on Polley Lake (Appendix V.1). A series of photos were taken on 18 August 2022 at each viewpoint, covering a field of view large enough to encompass the entire Mine Site. The GPS location of each viewpoint and the specifications of the photos taken (i.e., height above ground, direction, focal length) were recorded.

A 3D model of the current landscape in and around the Mine Site was created in a 3D software suite (Autodesk 3ds Max 2021 with the Forest Pack extension). A digital elevation model (DEM) of the Mine Site and surrounding area (topography as of 2019) was added to the 3D landscape model. The changes to the landscape at closure were then modelled by applying textures to the

DEM (e.g., to represent grassland at closure where currently no visible vegetation exists) and by adding trees (to represent the growth of forest where currently none exist). The height, density, and species composition of the post-closure vegetation communities was modelled for the individual site series as presented on Figure 5-4.

For each of the viewpoints, a series of cameras were added to the 3D landscape model, each representing the parameters (e.g., location, direction, field of view) of one of the photos taken from the viewpoint. The closure landscape was then rendered in the 3D model from these cameras, allowing for the closure landscape features to be depicted exactly as they would appear from the viewpoints on Bootjack and Polley lakes (i.e., position and size of the closure landscape). The rendered post-closure landscape (including grasslands and forests) was then superimposed onto the site photos in Adobe Photoshop 2022. Rendered post-closure landscape features that were blocked by foreground elements visible in the photos (e.g., existing trees along the shoreline) were removed. The resulting photocompositions were then stitched together into panoramic images (Appendix V.2).

The photocompositions demonstrate that following reclamation and closure of RDSs, the dumps will appear as revegetated hills similar to the surrounding undisturbed landscape. The aesthetic values held by recreational users of Bootjack and Polley lakes will be protected. The only visible feature post-closure will be the Springer-Cariboo Pit high wall.

### 6.6. Temporary NW PAG Stockpile

At the end of mine life, all PAG material from the Temporary NW PAG Stockpile will be relocated to the bottom of the Cariboo-Springer Pit and submerged. This will reduce the risk of these materials generating acid in the long-term. Subaqueous disposal of PAG materials is considered an effective methods for limiting ARD generation at sites where it is possible to comply with key design constraints, such as positive water balance, satisfactory physical stability of the final storage facility, and sufficient long-term water depth (INAP 2009; MEND 2015). The disposal of the PAG waste rock will be physically stable, as no buttressing, berms, or dams will be needed to maintain water cover over the pit-disposed waste rock. As referenced in the Cariboo-Springer Pit hydrogeological assessment (Appendix F), sufficient space will exist after mining ends such that PAG waste rock at maximum elevation 1028 masl will be covered by 22 m of water when the pit lake reaches the spillover elevation of 1050 masl after closure. Water quality in the Cariboo-Springer Pit has been modelled with the submerged PAG material, as described in Sections 5.2.4, and Appendix I. Accelerated filling of the Springer Pit to meet water management (quantity or quality) objectives is an option by directing additional flow (i.e., pumping) to the Cariboo-Springer Pit. The accelerated filling scenario was also assessed.

A sampling program will be developed prior to closure, and submitted to the EMLI Chief Inspector at least 60 days prior to the commencement of material rehandling. Waste rock will be excavated to a minimum of 1 m beyond the surveyed PAG/NAG boundary. Once PAG waste rock is removed, the underlying NAG pad will be sampled and analyzed to confirm removal was complete. If any PAG waste rock remains, additional rock will be removed, and this process will continue until only NAG waste rock remains. The NAG pad will then be re-sloped and revegetated following reclamation prescriptions outlined in Section 5.5.2.

### 6.7. Ore Stockpiles

Once ore is removed, decompaction of the stockpile footprints may be necessary, and will occur prior to the placement of coversoil on the footprints of #1 Ore Stockpile and Cariboo Ore Stockpile. Revegetation efforts will target a revegetated mosaic of forested site types that tie into the surrounding post-closure landscape (Figure 5-4 and Table 5-6).

### 6.8. Road Reclamation

Two types of roads exist at the Mine Site: light vehicle roads (often old forestry roads that pre-date mine operations) and large haul roads made from NAG waste rock (often built up, and are essentially linear RDSs). Roads scheduled for reclamation will be reclaimed to target the adjacent end land uses (generally wildlife habitat and forestry), as shown in Figure 5-4 and Table 5-6. A total of 220.83 ha of roads are projected to exist at closure, with 104.81 ha of this reflecting the potential additional West Haul Road construction.

#### 6.8.1. *Light Vehicle Roads*

Roads required for monitoring reclamation success and geotechnical stability will be retained. Additional roads may be preserved for logging and forestry use, for ranchers to reach their grazing cattle, and for recreation, guide-outfitting, hunting, and trapping. These roads and roadsides will be seeded with the native grasses and forb mixture in Table 5-8 to provide forage for wildlife and livestock.

Roads not necessary for access will be identified and reclaimed. Culverts will be removed and replaced with cross-drainages where required to minimize long-term maintenance and re-establish natural surface drainage patterns. Surface runoff channels will be improved to accommodate closure design capacity flows, and cleared of debris, to prevent new channels from interfering with newly reclaimed areas.

Roads that will not be required post-closure will be “ripped” (scarified) to a minimum depth of 30 cm, and side-cast material and cutbanks will be recovered and spread over the road surface. This material can be supplemented with stockpiled soil to reach an appropriate depth for vegetation. Cutbanks will be re-contoured to below the angle of repose to reduce future slumping. Surface preparation will be carried out as per Section 5.4.1. The surface will then be planted according to the prescriptions in Section 5.5, with any adjustments made to match the end land uses designated in Figure 5-4 and Table 5-6.

#### 6.8.2. *Haul Roads*

Site haul roads include the Waste Haul Road, Tailings Access Road, New Access Road, Wight Pit Haul Road, Wight Pit TSF Haul Road, and the Old TSF Haul Road. These roads are essentially linear NAG waste dumps, and the sides will be sloped to 2H:1V or flatter, to the extent possible. There are some limitations to achieving this slope related to water body crossings (for example the Tailings Access Road crossing of Bootjack Creek) and proximity to sensitive undisturbed land. Re-sloping will incorporate landform design and geomorphic considerations, consistent with those described for RDSs, with wildlife passage pathways being a key feature. Culverts will be removed and replaced with cross-drainages as appropriate. Surface runoff channels will be improved to accommodate design capacity flows, and cleared of debris, to prevent new channels from interfering with newly reclaimed areas.

Roads not required for access during closure will be fully reclaimed to match their end land use designations following the coversoil application and revegetation approaches for waste dumps, as described in Sections 5.4.1 and Section 5.5, respectively. Roads required for access will be partially reclaimed (edges re-sloped and revegetated as discussed above), with light vehicle and/or equipment access maintained.

### 6.9. Watercourses

Consistent with the closure water management plan (Section 5.2.4), contact water will be collected and treated prior to discharge to the receiving environment, as required to avoid adverse effects on the receiving aquatic environments. Collection system ditches that remain in perpetuity (e.g., the SERDS Ditch and Long Ditch as per the conceptual long-term plan) will be further armoured as required, with the banks and adjacent areas revegetated with riparian species, such as black cottonwood, willow (plugs or wattles and live stakes), and Sitka alder. At closure, habitats for riparian species and aquatic life will be established that will also provide forage for wildlife in wetland and riparian areas.

### 6.10. TSF Area Reclamation

The TSF contains NAG tailings and will remain as a permanent structure post-closure and will be reclaimed to productive land use. The post-closure ecosystems are shown in Figure 5-4, and their corresponding land uses are provided in Table 5-6. The final configuration of the TSF will include a small permanent pond and wetland area on the surface, with maximum 2H:1V embankment slopes, and a spillway for pond water level control.

The principal activities for the reclamation of the TSF will be as follows:

- removal of all infrastructure (Section 6.10.1)
- re-sloping and reclamation of embankments (Section 6.10.2)
- spillway construction (Section 6.10.3)
- revegetation of tailings surface (beach and pond; Section 6.10.4)
- reclamation of till borrow pits, as required (Section 6.10.5)

#### 6.10.1. *TSF Infrastructure*

Upon Mine closure, surface facilities on the TSF will be removed in stages, salvaged, and sold or disposed of as per the procedure outlined in Section 6.1.4. The tailings conveyance systems will be removed and sold or disposed of following the end of tailings production. The seepage collection infrastructure and recycle pumps will be retained after closure until monitoring results indicate that the water quality from the TSF is suitable for direct release to the environment. The monitoring piezometers in the TSF will be maintained as long-term monitoring devices. Water management infrastructure will be maintained or decommissioned and removed in accordance with the closure water management plan (Section 5.4.2).

### 6.10.2. *TSF Embankments*

The TSF embankment consists of a till core with filter and transition layers and a free-draining rock shell (made up of NAG run-of-mine waste rock) on the downstream side. The TSF includes one embankment that is approximately 4.8 km in length. The embankment is subdivided into three sections, referred to as the Perimeter, Main, and South Embankments (Figure 1-3) that reach a maximum elevation of 970 m at closure. At the end of construction and long-term, each of these embankments will have a minimum static FoS of 1.5, and pseudo-static FoS of 1.0 (as per Canadian Dam Association [CDA] 2013, *Mines Act* Permit M-200 and *Health, Safety, and Reclamation Code for Mines in BC* [EMLI 2022]), meeting closure criteria requirements.

At closure, the downstream embankment slopes will be sloped to a maximum 2H:1V ratio, which will not negatively affect overall stability. It is anticipated that additional material will be required to achieve the desired slope design because cut-and-fill cannot be used in all areas of the embankment. The re-sloped embankments and the 2H:1V buttress slopes will then be reclaimed and revegetated as per Section 5.4.1, Section 5.5, respectively and target an ICHmk3_01 site series, which will be planted over 20 cm coversoil underlain by 10 cm of till.

At some closed sites, there are concerns with volunteer tree species growing on reclaimed TSF embankment slopes. These concerns center on the possibility that mature trees may fall over at some point, lifting soil associated with the root ball, which could in turn concentrate erosion with possible impacts on embankment stability. As the resloping for the MPMC TSF embankment will result in the placement of excess material to infill and create the 2H:1V slope, it is unlikely that erosion generated locally by such a mechanism could impact the deeper rockfill that is needed to maintain long-term embankment stability. While having the TSF align with the surrounding ecosystems and landscape is desirable, its overall post-closure stability and function are the priority.

### 6.10.3. *TSF Spillway*

Prior to active closure, the TSF pond will be reduced to about 250,000 $m^3$ of water. During the active closure and post-closure phases, the TSF pond will vary seasonally, but will be limited by the spillway invert (which occurs at 965.7 m) to a maximum volume of approximately 260,000 $m^3$ during passage of water through the spillway (Appendix H). As part of active closure, the spillway will be constructed at the north abutment near Corner 5 (Figure 1-3) Detailed information is provided in Appendix R. This spillway will consist of a riprap lined channel sized with sufficient capacity to handle the probable maximum flood considering storm water runoff and other inflows from the surrounding catchment, with considerations for maintaining appropriate freeboard. The spillway will be designed to limit the maximum pond size so that it does not exceed approximately 15% of the tailings surface area. Discharge from the spillway will be directed towards CCS water management channels. The final tailings surface will provide a positive gradient towards the spillway invert (Golder 2015c). The positive gradient will be achieved by management of the deposition of tailings slurry prior to closure.

### 6.10.4. *TSF Tailings Surface*

The largest component of the TSF disturbance is the TSF basin (approximately 214 ha). The Mine Site's tailings have been characterized to be NAG (SRK 2015), thus issues associated with PAG tailings are not a concern.

During operations, tailings have been deposited in the TSF basin from spigot points located along the embankment crest and form an average subaerial beach slope of approximately 1% and a subaqueous slope of approximately 3% (Golder 2015c). During normal operations, a minimum beach length of 100 m is to be maintained between the TSF pond and the embankment (Golder 2015c). In the final year of operation prior to active closure, the TSF pond will be pushed against the north abutment (Corner 5; Figure 1-3; Golder 2015c). The tailings deposition points will be moved out onto the tailings beach to reduce the tailings beach slope to about 0.5% (Golder 2015c). Discharge of tailings directly into the pond may be required to reduce the pond depth. The total area of the pond will fluctuate with seasonal and annual climate variations, but as indicated in Section 6.10.3 the pond has been designed to occupy a maximum of 15% of the total tailings surface, with the maximum elevation controlled by the spillway invert (Golder 2015c).

The NAG tailings will have variable levels of saturation during active and post-closure. Geochemical source terms were developed for both saturated and unsaturated tailings in the TSF (Appendix B-1). These source terms were included in the 2022 water quality model, as well as active closure and post-closure predictions (Appendix I). The source terms were reviewed in 2022 (Appendix B-4) by SRK, who found that an update of the source terms was not required.

Ongoing seepage from the TSF is expected following the active closure of the facility, and predictions of seepage direction, quantity, and quality have been developed (Appendix F). Seepage control measures during active closure and post-closure will consist of passive capture and collection in drainage sumps, which are presently routed through the WTP. Plans are progressing toward a distributed system with passive treatment (Section 4.4) that will subsequently return these waters to Hazeltine Creek and/or Edney Creek.

Overall, the target of reclamation of the TSF surface is to create a patchy mosaic of deciduous trees and shrub thickets with a gradual transition towards a wetland and pond near Corner 5 (Figure 1-3 and Figure 5-4), with dominant focus on the ICHmk3_06 and ICHmk3_07 site series. The end land use target consists of multiple uses as the ecosystem matures, including wildlife habitat and traditional use (Section 5.5.3).

The drier upland portions of the TSF will be covered with 5 cm of till and overlain with 5 cm of coversoil and/or a layer of biosolids at 65 dt/ha (currently in storage at the TSF biosolids stockpile). This cover material and fast-growing vegetation will assist in minimizing wind erosion. Artificial refuges (rock piles) will be created to allow for a more diffuse transition to the pond area, and provide diversity in wildlife habitat (e.g., edge effects). Unused woody debris (e.g., logs from log decks) may be scattered on the surface or placed as standing debris on the TSF beaches to create perching habitat for raptors.

Areas closer to the pond may not be immediately accessible due to low trafficability of the saturated tailings. As pond size reduces over time, till will be placed closer to the pond and revegetated. Land closer to the pond will be revegetated with deciduous species, including black cottonwood, willow (plugs or wattles and live stakes), and Sitka alder. Red osier dogwood may also be considered. Turfs, offsets, stolons, cuttings, and winter buds of aquatic plants will be collected from local sources, such as the wetland adjacent to the Mine Site, and planted in the pond. Water sedge, beaked sedge, common cattail, river horsetail, yellow pond lily, and narrow-leaved bur-reed are all present in Bootjack Lake, Polley Lake, and small wetlands in the surrounding area.

The key wildlife species anticipated to use the reclaimed TSF tailings surface include:

- Columbia spotted frog
- Pacific northwestern toad
- mallard
- green-winged teal
- bufflehead
- common snipe
- common yellowthroat
- Lincoln's sparrow
- muskrat
- moose

#### 6.10.5. *TSF Till Borrow Pits*

The till borrow pits adjacent to the TSF were mined to obtain material for constructing the embankments' core. After reclamation, this landscape will include low-lying wetlands surrounded by riparian habitats and upland vegetation. This combination of ecosystems will provide a variety of habitat requirements for a diverse group of wildlife species including birds, small mammals, ungulates, and carnivores. The access to water and open riparian areas could also provide good grazing conditions for cattle. Additionally, this area should be well suited to traditional use activities and recreation (Table 5-1).

At the Southeast Till Borrow area, 22.25 ha has been re-contoured, treated with applied biosolids (12 ha), and revegetated. The wetland areas that have developed in low-lying depressions have several emergent grasses, bull rush, and beaked sedge growing. The dry land areas have a robust grasses and forb cover, with some early successional species (black cottonwood) encroaching. The cover of grasses forbs have been observed to provide range lands for the livestock that currently graze in this area. Monitoring is ongoing to determine requirements for additional planting. If additional tree and shrub planting is required, it will occur, as per Section 5.5, with consideration for agroforestry.

Some till borrow areas still require recontouring. Revegetation will follow the prescriptions in Section 5.5 for upland areas (ICHmk3_02 and ICHmk3_03 BEC series). Low-lying areas (ICHmk3_01, ICHmk3_05, and ICHmk3_07 site series) will focus on planting of deciduous species, including black cottonwood, willow (plugs or wattles and live stakes), Sitka alder, and potentially red osier dogwood. Potential transplants and seeding of wetland species could be carried out using vegetation already growing in the Southeast Till Borrow area, or from Bootjack Lake, Polley Lake, and neighbouring areas where species such as water sedge, beaked sedge, common cattail, river horsetail, yellow pond lily, and narrow-leaved bur-reed are found. Like the TSF tailings surface, this will be done through collection of turfs, offsets, stolons, cuttings, and winter buds of aquatic plants from local sources, and similar wildlife species are anticipated for post-closure use.

## 6.11. Underground Reclamation

As discussed in Section 1.2.3, the underground workings at the Mine Site are closed, and the Wight Pit Portal is secure. The following subsections describe the final decommissioning and active closure of the underground workings and mine openings.

### 6.11.1. *Decommissioning*

Due to the Mine Site's 2019 care and maintenance status, the underground was allowed to flood. Prior to flooding, most equipment and infrastructure were removed, along with fuels and reagents. Currently, only inert materials remain underground, thus, no further decommissioning of the underground is required at this time. MPMC may consider re-opening the underground in the future to access additional mineral resources.

### 6.11.2. *Mine Openings*

There are two openings associated with the underground mine, the Wight Pit Portal, and the Alimak Raise. The Wight Pit Portal was secured with loc-blocks, and then submerged under water as the Wight Pit flooded.

At the Alimak Raise, various capping options have been considered, including the construction of a simple concrete slab cap, and construction of a locked steel gate cover. To minimize long-term needs for monitoring and maintenance, and to minimize the risk of access to the raise, the raise will be backfilled with unconsolidated waste fill. The fill will be selected with from NAG material that is sufficiently coarse that drainage can pass through the rock if needed, and to not be at risk of liquefaction (which could theoretically cause the loss of fill material into the underground openings). An estimated 18 $m^3$ of ready-mix concrete will be used to seal the top of this backfill with a permanent cap. The ground surface in the immediate area of the former raise will be reclaimed following the coversoil and vegetation prescriptions applicable for the surrounding areas, as described in Section 5.

Little or no maintenance is anticipated to be required for the reclaimed areas after active closure, beyond what is planned for monitoring at the Wight Pit and other reclaimed areas. Periodic inspections of the closed Alimak Raise will include visual checks to confirm the integrity of the raise cap and surrounding ground surface, and that there are no signs of subsidence. As discussed in Section 5.1.6, there is little risk of subsidence caused by the collapse of underground voids at this site.

# 7. POST-CLOSURE MONITORING

Post-closure monitoring is an important aspect in achieving successful closure and includes:

- inspections and maintenance of geotechnical structures
- monitoring water chemistry and aquatic effects
- water treatment and discharge
- reclamation monitoring
- final decommissioning of site infrastructure that was left in place to support monitoring efforts

Requirements associated with these activities are described in the following subsections.

## 7.1. Inspections and Maintenance of Geotechnical Structures

The inspection and monitoring of the TSF will be aligned with the recommendations of the CDA for tailings facilities that cannot be decommissioned (CDA 2014). For the purposes of the 2022 MRP, it has been assumed that the TSF will undergo a dam safety inspection, carried out annually following mine closure by a qualified geotechnical engineer, with additional extra inspections possible after extreme events (such as rainfall exceeding a selected design return period). The inspections will focus on any conditions that could adversely impact the long-term function and stability of the structure. Annual inspection reports will be submitted to EMLI for review. TSF management in active closure will continue to follow the procedures outlined in the OMS Manual (Appendix W). Post-closure (approximately 10 years following end of operations), it is anticipated that the monitoring frequency may be reduced, potentially supplemented by remote monitoring of site instrumentation.

## 7.2. Water Quality and Aquatic Effects Monitoring

### 7.2.1. *Surface Water Quality Monitoring*

Surface water quality monitoring will continue during active closure for the same parameters monitored during operations (total and dissolved metals, nutrients, physical parameters, ions, and dissolved organic carbon), with QA/QC sampling procedures to continue. Sampling locations are shown in Figure 2-4.

Mine contact water will continue to be produced while reclamation is occurring (e.g., 10 years into active closure). During this time, and at ENV permit locations, water quality will be analyzed to understand changes in geochemistry of the Mine Site waste dumps and to confirm the accuracy of the long-term effluent quality predictions. Monitoring frequencies will follow the CEMP and the OMS Manual. Following the 10-year active closure phase sampling frequency can be reduced to annually or an alternative approved frequency if the receiving environment and mine contact water results are stable and meet applicable water quality

guidelines. Water quality monitoring stations are shown in Figure 2-4 and a summary of the monitoring schedule is provided in Table 7-1. Monitoring at some stations may be more frequent if water discharge is occurring, as discussed in the next section. During water quality sampling events, the associated water management infrastructure will be visually inspected. Current water quality modeling indicates that discharge at nine potential mine discharge locations, higher water quality concentrations are anticipated during the active closure phase compared to the post-closure period (Appendix I).

**Table 7-1 Conceptual Closure Water Quality Monitoring Schedule (MPMC 2017)**

| Site Type | Site Name | Active Closure (Years 1-10)[1] | Post-Closure (Years 10-15) [1] | Post-Closure (Years 15+)[1] | Notes |
|---|---|---|---|---|---|
| Receiving Environment | North Dump Creek (W4a) | Quarterly | Annually | Annually | |
| | Bootjack Creek (W5) | Quarterly | Annually | Annually | |
| | Upper Edney Creek (W8) | Quarterly | Monthly | Quarterly | Downstream passive discharge to SESCP and MESCP |
| | Hazeltine Creek (W7/HAC-05) | Quarterly | Monthly | Quarterly | Downstream of Polley Lake (multiple inputs) |
| | W20 Creek (W20) | Quarterly | Annually | Annually | |
| | Mine Drainage Creek (W3a) | Quarterly | Monthly | Quarterly | Downstream of passive discharge from Mine Drainage Creek Sump |
| | Morehead Creek (W1) | Quarterly | Monthly | Quarterly | Downstream of Bootjack Lake (multiple inputs) |
| | 6 km Creek (W12) | Quarterly | Annually | Annually | |
| | Bootjack Lake (B1, B2) | Bi-annually | Bi-annually | Bi-annually | Multiple passive discharge inputs |
| | Polley Lake (P1, P2) | Bi-annually | Bi-annually | Bi-annually | Multiple passive discharge inputs |
| Mine Water Collection System | TSF (E1) | Quarterly | Annually | Annually | |
| | MESCP (E4) | Quarterly | Monthly | Quarterly | Passive discharge to Edney Creek |
| | Cariboo Pit (E8) | N/A | N/A | N/A | Cariboo and Springer Pits will merge during operations, and passively discharge to Bootjack Lake |
| | Springer Pit (E11) | Quarterly | Monthly | Quarterly | |
| | Boundary Pit | Quarterly | Annually | Annually | No surface discharge; groundwater flow towards Bootjack Lake |
| | Wight Pit | Quarterly | Monthly | Quarterly | Passive discharge to Polley Lake |
| | NW Sump (E13) | Quarterly | Monthly | Quarterly | Passive Discharge to Bootjack Lake |
| | Mine Drainage Creek Sump (E14) | Quarterly | Monthly | Quarterly | Passive Discharge to Bootjack Lake |
| | Bootjack Creek Sump (E15) | Quarterly | Annually | Annually | |
| | 9 km Sump (E17) | Quarterly | Monthly | Quarterly | Passive discharge to 6 km Creek |
| | CCS (E18) | Quarterly | Monthly (at PETBP) | Quarterly (at PETBP) | Passive discharge to Hazeltine Creek |
| | SESCP | Quarterly | Monthly | Quarterly | Passive discharge to Edney Creek |

1) Sampling frequency increases to align with anticipated implementation of full-scale passive treatment and discharge systems; frequency to be decreased over time, when water quality becomes more stable.

### 7.2.2. *Groundwater Monitoring and Characterization*

A review of the groundwater monitoring program at the Mine Site was conducted (Golder 2016b). The outcomes of this review, found that monitoring during active closure and post-closure will likely consist of:

- sampling of the Springer Pit wells quarterly and measurements of water levels daily until conditions are stable and appropriately characterized, and then reducing monitoring frequency to annual monitoring for approximately five years
- sampling of a nested pair of monitoring wells near the Cariboo Pit, which would follow a similar monitoring pattern as described for the Springer Pit wells
- sampling of reconditioned wells adjacent to the Wight Pit, which would follow a similar monitoring pattern as described for the Springer Pit wells
- continued bi-annual (i.e., every six months) monitoring of wells adjacent to other facilities until trends are stable and the water chemistry and flow patterns are appropriately characterized, at which point the monitoring frequency will be reduced

Existing groundwater monitoring wells are shown in Figure 2-4. Contingency measures, such as lowering pit lake levels, installation of low-permeability barriers, treatment, and/or implementation of passive interception systems will be used if it is determined that the water quality in the pit lakes and associated seepage quantities are of concern. Detailed evaluations of these options will be developed as part of the ongoing water quality and water balance assessments for long-term water management planning.

### 7.2.3. *Water Discharge Aquatic Effects Monitoring*

Until the passive/semi-passive treatment system (Section 4.4) has been demonstrated to be able to be scaled up and implemented (and permitted), mine contact water will continue to be managed through the centralized system (e.g., WTP) with a single discharge to Quesnel Lake. Monitoring of this discharge will occur according to a monitoring plan (the CEMP) that will require ENV approval, and will likely be similar to the monitoring plan for operational water discharge. As the Mine Site transitions to distributed discharges, each point of discharge will be subject to monitoring requirements under *EMA* Permit 11678, and these requirements are anticipated to continue into post-closure.

During post-closure, the monitoring plan will consist of weekly water quality samples of the effluent at the discharge points (described in the water balance report; Appendix H), which over time will decrease to monthly samples. Routine (likely monthly) sampling in the receiving environment is also anticipated, along with biological monitoring (fish population and fish tissues, sediment chemistry, and benthic invertebrate monitoring). Biological monitoring will continue every three years as per the MDMER (Canada 2022), with the frequency of all monitoring decreasing as results stabilize (for example quarterly sampling and biological monitoring every six years), until such time when treatment of Mine Site runoff is not required, or passive systems are deemed to be sufficiently effective and not requiring long-term monitoring. MPMC will apply to become a closed mine under the MDMER (Canada 2022), which includes conducting a final biological monitoring study.

## 7.3. Hydrological Monitoring

The existing hydrometric stations (Figure 1-4) on receiving water creeks (Table 7-2) will continue operations during active closure and post-closure. Continuous water level monitoring equipment (pressure transducer and data logger) will continue to be operated at each site during non-freezing periods, and the rating curves will be updated and maintained, as required.

While hydrometric stations are only currently present at receiving locations, water levels will be measured quarterly in the TSF pond, and the Cariboo-Springer, Wight, and Boundary pits during post-closure.

**Table 7-2 Conceptual Closure Hydrology Monitoring Schedule (MPMC 2017)**

| Station | Parameter | Type |
|---|---|---|
| Upper Hazeltine (H1) | Water Level/Flow | Continuous |
| Lower Hazeltine (H2) | Water Level/Flow | Continuous |
| Lower Edney (H3) | Water Level/Flow | Continuous |
| Morehead Creek (W1b) | Water Level/Flow | Continuous |
| 6 km Creek (W12) | Water Level/Flow | Continuous |
| TSF Pond | Water Level | Quarterly |
| Cariboo-Springer Pit | Water Level | Quarterly |
| Wight Pit | Water Level | Quarterly |
| Boundary Pit | Water Level | Quarterly |

## 7.4. Revegetation Monitoring

### 7.4.1. *Revegetation Assessments*

Reclamation monitoring and inspections of progressive reclamation sites will continue into closure. Monitoring is typically completed in the summer or early fall when plants are most easily identifiable. A general schedule for reclamation assessments is as follows:

- post-application visual inspections (e.g., soil test pits) after placement of coversoil to assess placement depth and to verify if recommended reclamation methods described Section 5.4.1 and the Soil Management Plan (Appendix M) were appropriately implemented
- assessment of revegetated areas following the first growing season to determine species composition (including presence of invasive species) and cover, as well as documentation of any areas of erosion
- observations of wildlife or grazing occurrences and usage;
- survival surveys of planted trees and shrubs immediately after planting (for quality control purposes)

- survival surveys of planted trees and shrubs following their first growing season
- periodic assessments of tree survival/growth and ground cover vegetation, decreasing in frequency over time (e.g., years two, five, and ten)

Monitoring will continue with additional reclamation activities occurring in an adaptive management process until performance criterion for these assessments provided in Table 7-3 have been met.

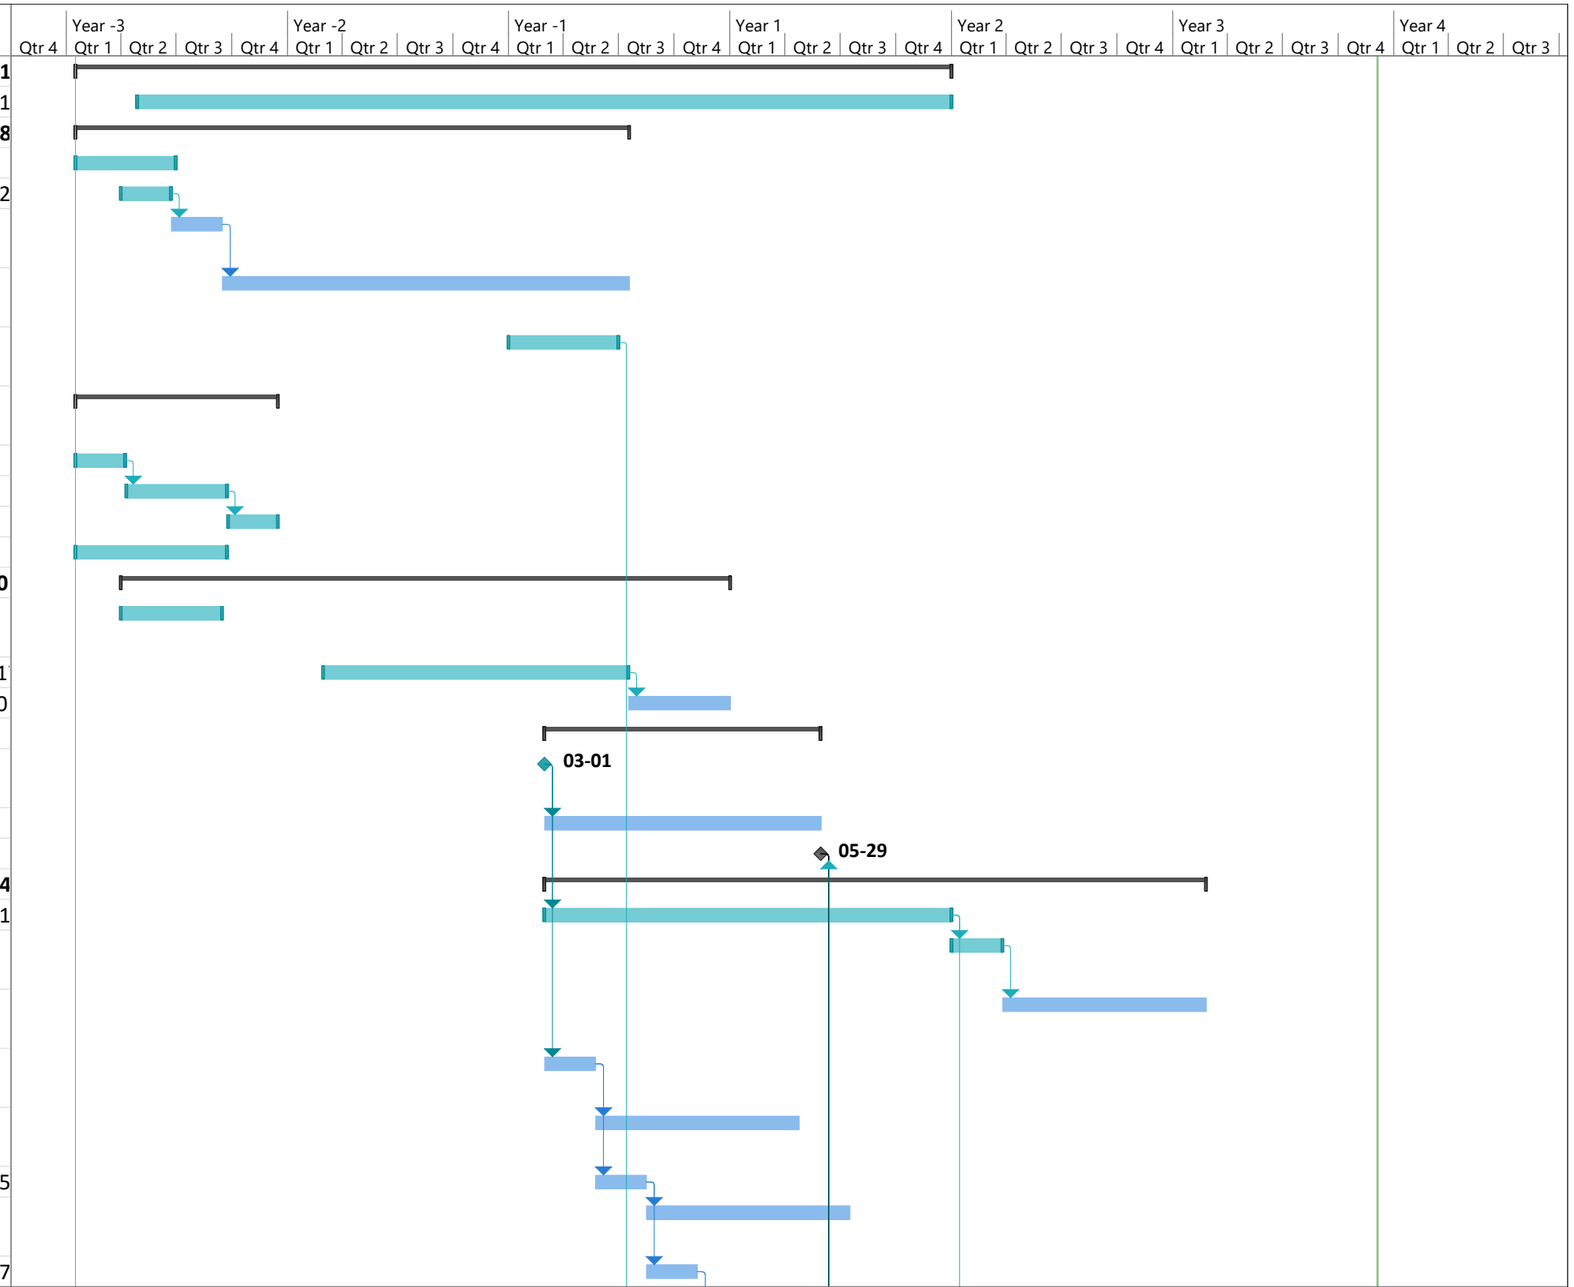
The proposed post-closure monitoring program for determining terrestrial reclamation success, is divided into a Goal-Objective-Criterion-Indicator hierarchy (Table 7-3). Each indicator consists of a measure, measurement method and a threshold value. Each objective (e.g., those presented in Section 3.1) has a set of criteria with measurable indicators associated with them as a means of determining whether the objective has been met. The premise is that if the criteria and objectives are achieved, the reclamation is trending towards meeting the goal, and subsequently, fulfilling the regulatory requirements of equivalent land capability. Where possible, reclaimed sites will be compared against pre-disturbance conditions or a comparable ecological benchmark in the natural landscape as part of post-closure monitoring. Additionally, this framework is designed to allow for continuous improvement through ongoing incorporation of new knowledge, technology, and stakeholder input.

**Table 7-3 Reclamation Monitoring Criteria**

| Criteria | Indicator | Measure |
|---|---|---|
| **Landform Function** | | |
| Landforms have geotechnical stability | Geotechnical stability | Visual inspection for the presence/absence of subsidence, erosion, deposition of sediment in low lying areas, ponding, gullying, rilling or slumping, including bank stability round watercourses and waterbodies |
| Landscape enhancements are appropriate to the ecosystem and increase the diversity of the landscape | Landscape enhancements | Presence of rocks, coarse woody debris, brush piles, snags, bird/bat boxes, etc. |
| **Water** | | |
| The Mine Site's water balance meets the needs of the post-closure landscape | Successful function of the TSF and Cariboo-Springer Pit Spillways | Assessment of water levels in the TSF and Cariboo-Springer Pit<br><br>No signs of instability of the TSF, or the TSF and Cariboo-Springer Spillways |
| | Water quality parameters | Water quality parameters support discharge of water to the receiving environment |
| | Pit lake elevation | Pit lake elevations align with projected modeling<br><br>Pit lake elevations successfully cover PAG material |
| **Soil** | | |
| Reclamation materials are placed appropriate to the landform | Soil depth | Average placement depth (m) |
| | Soil pH | Soil pH |
| | Soil moisture regime | Soil texture/particle size analysis (percent sand, percent silt, percent clay), placement depth, topography |
| **Vegetation** | | |

**Table 7-3 Reclamation Monitoring Criteria**

| Criteria | Indicator | Measure |
|---|---|---|
| Terrestrial and aquatic vegetation common to the surrounding area is established | Plant community composition (terrestrial, riparian and, marsh/aquatic) | Presence, percent cover, distribution of noxious and prohibited noxious weeds |
| | | Species inventory and percent cover by layer and species. Include damage codes (e.g., insect, browse) |
| The reclaimed landscape provides commercial forest (where designated as an end land use within the reclamation plan) | Regeneration of trees (commercial stocking) | Stocking (the percentage of a polygon that contains acceptable tree regeneration) (Information gathered to support this includes height, diameter at breast height (DBH) and age for potentially commercial tree species) |
| | Mortality of trees | Percent mortality between planting and ten years after planting |
| | Insects and disease | Percent of trees with signs of chewing, spots, eggs, nests or galls |
| | Browsing pressure | Percent of trees with signs of browsing on new shoots, bark damage |
| | Limitations to vegetation growth | Percent of trees with signs of chlorosis, stunting, unusual formations |
| **Emergent Properties** | | |
| The reclaimed landscape provides for biodiversity | Patch size and shape | Patch sizes (ha) |
| | Food vegetation species | Food species for target wildlife species are present |
| | Plant community composition – diversity, richness, evenness and abundance | Species inventory, percent cover and density (stems/ha) |
| Traditional Ecological Value | Wildlife habitat that supports traditional use | Derived from Plant Community Composition |
| | Biodiversity that supports traditional use | Derived from Plant Community Composition and incidental wildlife observations |
| | Vegetation that supports traditional use | Derived from Plant Community Composition |



### 7.4.2. *Soil and Vegetation Metal Uptake*

Section 5.6 and Appendix N discuss the 2022 ERA program for evaluating potential pathways for uptake of metals by ecological receptors at the Mine Site. Preliminary results indicate that there is minimal risk of metal uptake from reclaimed soil into vegetation and wildlife. However, copper was identified as a potential parameter of concern, and retained for further evaluation. MPMC plans to continue consultation with the Williams Lake Indian Band, Xatśūll First Nation, and ENV.

# 8. RECLAMATION AND CLOSURE SCHEDULE

MPMC's conceptual schedule for the Mine Site's active closure and post-closure periods are presented in Table 8-1, including the schedule for research leading up to the implementation of closure and reclamation works. This schedule is indicative and can be expected to evolve based on findings of reclamation research and progressive reclamation projects. It is also subject to change in accordance with changes to the mine plan.

| ID | Task Mode | Task Name | Duration | Start | Finish |
|---|---|---|---|---|---|
| 1 | | **Operations and Research** | **1034 days** | **Mon 17-01-1** | **Thu 20-12-31** |

# 9. RECLAMATION COST ESTIMATE

The reclamation cost estimate was prepared by MPMC and provided under separate cover.

# 10. CONSULTATION AND ENGAGEMENT

In 2012, MPMC implemented Participation Agreements with both First Nations groups that have interest in the area: Xat'sull Cm'etem (Soda Creek/Deep Creek First Nation) and the T'exelc (Williams Lake First Nation). Through these respective Participation Agreements, Implementation Committees were formed to facilitate open dialogue between both Nations and MPMC for discussing environmental, social and economic matters related to Mine development, operation, reclamation and closure (i.e., Mine updates, permitting, environmental protection, reclamation, employment opportunities, and potential joint ventures).

Consultation and engagement activities were reduced while the mine was on care and maintenance status. Mine restart activities in 2021 renewed interest in renegotiation of expired Participation Agreements. Williams Lake First Nation and MPMC signed the Revised Participation Agreement in April 2022. Talks are advancing between Xat'sull First Nation and MPMC at time of writing.

# 11. CLOSURE

This MRP reflects the planned mining, construction, environmental monitoring, and reclamation activities for the Mine Site. Consultants and Qualified Professionals were retained to conduct work considered outside the expertise of in-house personnel, as outlined in Table 11-1. Work by consultants to MPMC is primarily included as appended reports or technical memos. The information presented in this MRP is consistent with the level of care and skill normally exercised by professional scientists and engineers, or similar, currently practicing under similar conditions. Results, conclusions, and recommendations are based on information known at the point of report publication, and are based on any described assumptions. These results, conclusions, and recommendations may change with the availability of additional information.

**Table 11-1 Qualified Professionals (retained and in house) Responsible for Completing Components of MPMC's Mine Plan and Reclamation Program 2022**

| Report Component | Qualified Professional(s) |

# Executive Summary

This executive summary provides a high-level overview of the Remediation Plan (RP); however, because it is a brief summary, it should not be read in isolation of the full report.

## Overview

The Mount Polley Mine, located in south-central British Columbia, 56 km northeast of Williams Lake near Likely, BC is an open-pit and underground copper and gold mine. On 4 August 2014, the failure of a glacial lacustrine layer beneath the Perimeter Embankment of the Tailings Storage Facility (TSF; "the breach") resulted in the release of a slurry of water, tailings, and dam construction material. The material released from the breach and the resulting debris flow resulted in physical impact to Hazeltine and Edney Creeks, Polley Lake, and Quesnel Lake. Approximately 1.36 $km^2$ of the breach area was scoured of forest and topsoil (floodplain zone). Tailings were also deposited on top of relatively undisturbed forest floor across an additional 100 hectares (ha; equivalent to 1.0 $km^2$) at the breach area. It is estimated that approximately 12.8 million $m^3$ (M $m^3$) of tailings was discharged to Quesnel Lake (plus an additional 5.8 M $m^3$ of native soil and TSF water) where some of that material settled in the West Basin over an area of approximately 1.81 $km^2$; and that an additional 1.6 M $m^3$ of tailings were deposited in the Polley Flats area and the Hazeltine Creek corridor.

Following the TSF breach an adaptive remediation framework was developed to guide and communicate the process of investigation, pollution abatement measures and remediation of areas affected by the breach. The strategy used a phased approach, focusing first on the immediate needs of establishing safe work conditions and controlling the further release of the tailings. To control turbidity, considerable erosion control work was carried out involving construction of a new foundational channel in Hazeltine Creek, designed with the foresight of re-establishing the creek as an aquatic and riparian habitat and planting adjacent soils. Habitat features have been installed on top of that foundational channel and though not yet complete, many of these habitat construction works have been advanced considerably and planning for them has been carried out through direct collaboration with environmental agencies and First Nations as well as their respective technical advisors for example, through the Habitat Remediation Working Group (HRWG).

The RP identifies the proposed remedial options and it outlines the rationale to select the preferred options where those have not already been selected during previous or ongoing work (e.g., by the HRWG). The RP is a requirement of the Ministry of Environment & Climate Change Strategy (ENV) Pollution Abatement Order (107461) which requires a RP that:

- Summarizes the remedial planning basis.
- Summarizes remedial actions that have already been carried out, including a description of the process and criteria that were used to evaluate options for remedial work that has been undertaken.
- Identifies the proposed remedial actions based on the results, conclusions and recommendations from the detailed site investigation, the human health risk assessment, and ecological risk assessment as delineated by area as defined in the Update Report: Post-Event Environmental Impact Assessment Report.

- Summarizes consultation on the remedial objectives and how the feedback received from that consultation has been accommodated within the remedial planning basis.
- Provides an implementation schedule.
- Provides a monitoring and reporting framework that will be integrated into the Comprehensive Environmental Monitoring Plan (CEMP) that is required in accordance with Permit 11678.

The remedial plan brings together agency requirements and commitments made by the Mount Polley Mining Corporation (MPMC), studies carried out to identify remedial needs and a roadmap towards compliance with the *Fisheries Act*, the *Environmental Management Act* and the *Water Sustainability Act*.

## Remedial Planning Basis

The remedial planning basis provides a summary of the findings of previous studies that informed the evaluation of human and ecological risks, which in turn form the basis of the remediation that is needed to manage defined risks.

All scientific studies have uncertainties that are part of any scientific measurement. While uncertainty is not a basis for active remediation, such uncertainties do inform the need for monitoring and, if the monitoring results indicate that the objectives are not being met then they are used to identify further remedial actions as appropriate.

The remedial planning basis comes primarily from the human health and ecological risk assessments. The remedial planning basis is detailed by remediation area in the report; however, the impacts that require remediation are physical ones associated with scour and deposition of the breach-impacted water bodies and riparian areas. These physical impacts resulted in ecological effects in the form of fragmentation of water corridors in Edney and Hazeltine Creeks, loss of riparian vegetation, and the effects of those losses on aquatic organisms and riparian wildlife. Transient effects on water quality, mostly due to or associated with turbidity also occurred but these effects have subsided in most water bodies except for occasional increases in Hazeltine Creek, thought to be associated with remedial construction works. Changes to soil in the impacted area (such as a loss of organic carbon, soil nutrients and soil fauna), and changes to sediment (primarily low organic carbon content) particularly in the 1.81 $km^2$ of deposited outwash materials in Quesnel Lake, are also associated with risks for which remediation (or offsets) needs to be considered.

The remedial design basis comes from five outcomes that have connection to remediation. These are:

- Human health risks are acceptable and remediation for that purpose is not required.
- Some ecological risks are acceptable and remediation for that purpose is not required.
- Some ecological risks are acceptable but there is scientific uncertainty in that determination. Remediation is not identified for such risks, but monitoring is a requirement to address that uncertainty. Verification and, if data show it is necessary, then remedial work plans to address those risks would be developed.

- Some ecological risks are uncertain – neither an absence nor clear conclusion regarding risk can be made with current data. In such cases, a specific focused study/monitoring program is carried out as an addendum to the CEMP process. The results of that study will either identify the need for more detailed assessment, identify that risks are absent (compliance) or identify that remediation is required. For the latter finding, a remedial work plan would be developed.
- Remediation is clearly required (e.g., where an environmental effect has been identified without need for clarifying study). Remediation approaches are recommended in later sections of this plan. Because the remediation work is focused on habitat remediation, this includes identifiable physical work that has been completed, in progress, or to be carried out on site and habitat offsets to address impacts and productivity losses (including losses due to the passage of time) resulting from the breach.

# Remediation Plan

## Remediation Plan Components and Linkages

The remediation plan has been developed as information has been obtained from the numerous studies that have been carried out. The plan has connections to those studies, regulatory requirements, outcomes, and specific actions to be taken (e.g., habitat remediation and habitat offsets, monitoring). Figure ES-1 is a process diagram that outlines how risks and residual effects are managed: It outlines:

- The RP components that are identified for specific remedial actions.
- How remedial work is monitored and adjusted (either through repairs or adjustments to offset amounts) based on verification monitoring.
- How risks from tailings constituents in the environment are managed within the context of the various components of the remediation plan and how uncertainty, whether normal scientific uncertainty or uncertainty in whether a risk exists are addressed through the CEMP.
- How the RP is linked to compliance. In addition to standing regulatory requirements under both federal and provincial law, formal and specific regulatory requirements were invoked by ENV through the PAO and the Ministry of Forests, Lands, Natural Resource Operations and Rural Development (FLNR) through an Engineer's Order issued pursuant to the *Water Sustainability Act*. Fisheries and Oceans Canada (DFO) has referred to the general provisions contained in the *Fisheries Act*.

Figure ES-1 is an overview-level diagram and the plan, its components, and specific approaches are detailed in the report itself.

Because the tailings constituent risks are currently being addressed through the CEMP, most of the remediation plan addresses remediation primarily for physical impacts. Additional remedial work plans to address tailings constituent risks may be necessary should monitoring demonstrate such need.

## Creek Habitats

The overall remedial objective for impacted stream habitats is to restore the life history functions of fish, in particular salmonids, by constructing an engineered stream base in the otherwise erodible glacial lacustrine native soils below Hazeltine Creek, with habitat features to support an aquatic ecosystem. Design features will also restore life history functions for wildlife associated with small streams and their riparian environments. Based on the remedial planning basis for the creek habitat, remedial needs for creek habitat are associated with the physical impacts of the breach event.

Creek remediation has been ongoing since it was safe to access the area downstream of the TSF. The process of creek remediation is:

- Habitat objectives for each reach of stream habitat were determined by the HRWG.
- Based on these objectives, channel morphology and habitat characteristics are designed and reviewed with the HRWG before being constructed.
- Following the construction of habitat based on reach-specific objectives, the habitat is evaluated based on pre-determined criteria and residual effects of the TSF breach on fish habitat. The functionality and value of that habitat is evaluated to determine whether habitat offsetting measures to address residual effects is warranted. DFO policy is followed to evaluate, rank and select appropriate offsetting measures.
- All construction and repair is documented and record drawings are produced. Post-construction evaluation may result in adjustments or repair to installed habitat features resulting in another round of implementation and evaluation.

## Lake Habitats

The residual effects in Quesnel and Polley Lakes arise from the physical impacts of the breach outflow and associated materials as well as the low organic carbon content of the tailings and scoured glacial soils underlying the Hazeltine Creek alignment. The ecological risk assessment indicated that altered water quality is no longer an operable pathway of effect and thus the focus of the identification of potential lake remediation needs was on physical effects.

Physical habitat remediation (e.g., of the shoreline) and offsets will be addressed by the HRWG whereas options for remediation of the bed of Quesnel Lake were evaluated in this report. The options considered were dredging, amendment with organic carbon (because addition of organic carbon improved test performance in sediment tests) and monitored natural recovery (MNR). Quesnel Lake benthic organisms are showing signs of recovery but do not yet have similar organism abundance or diversity as the reference location. An evaluation of the net environmental benefits of each of these three options identified MNR as the clearly preferred option because it retains the recovery that has already occurred to date and does not result in new disruption of the lake bed or various other effects from the disturbance associated with the other options. Productivity losses are addressed through offsets.

For Polley Lake sediments, the options evaluation was based on similar considerations although the circumstances of Polley Lake are different in terms of its stage of benthic community recovery (it is already similar in diversity and abundance to the reference lake) making MNR a clearly preferred option for similar reasons. An additional issue, unique to Polley Lake is the age class structure of Rainbow Trout which shows a decreased abundance of juvenile trout, inferred to be the result of the post-breach separation of Polley Lake from the outlet stream (Hazeltine Creek), the location of much of the spawning habitat that supported trout recruitment pre-breach. To help address the reduction in available spawning habitat a trout hatchery was developed. The construction of in-stream spawning habitat in upper Hazeltine Creek occurred in 2017 and Polley Lake trout were re-introduced to the upper reaches of Hazeltine Creek in 2018. The hatchery and re-introduction were both successful with an estimated 4,890 adults spawning in the constructed habitat and producing and estimated 40,000 juvenile trout while the hatchery produced an estimated 18,084 juvenile trout that were also released into Polley Lake.

## Terrestrial Habitats

Terrestrial ecosystems include riparian areas, floodplains and upland areas that are at a higher elevation than even the highest water levels. The residual risks to terrestrial habitats are from the physical impacts of the breach outflow and because the tailings lack the heterogeneity and nutrient processing that is part of a healthy soil or sediment ecosystem. The physical impacts (e.g., undercutting of banks, scour) have in part been addressed through the re-contouring of the slopes along Hazeltine Creek; however, the loss of forest soils is part of the needed remediation.

The terrestrial remediation strategy takes a managed successional trajectory approach to remediation, based on the principles of ecological succession. Site preparation methods can be used to A) mix forest floor, mineral soils and any residual tailings to increase soil porosity, B) create raised microsites that have aerated root zones, and C) create plantable microsites. These approaches have been applied in the breach-impacted terrestrial areas. If monitoring indicates it to be necessary, soil fertility can be further improved in areas with nutrient deficiencies by applying soil amendments such as imported soils, microbial inoculum and fertilizer in planting zones or in each planting hole. In the areas where site preparation has yet to be applied, it is important to preserve the organic matter in situ as much as possible and avoid soil compaction during site work. Effort was made to retain existing forest soil to provide organic carbon and nutrients and, in particular, to provide a source of inoculum for beneficial soil microbes.

Once soil conditions are amenable to seed germination and growth, early successional species will establish, and late successional species will slowly colonize through dispersal from nearby seed sources. To assist this process, extensive planting efforts have been undertaken to establish early-mid successional native species in the TSF breach area.

## Residual Effects and Offsetting

It is expected that additional habitat will need to be provided to offset for the loss of habitat use following the breach and before habitat remediation has been undertaken. The HRWG will have the role of evaluating and prioritizing offsetting options to be constructed. To assist the HRWG in prioritizing offsetting options, residual effects and preliminary offsetting estimates were prepared, and potential offsetting opportunities were identified.

Where possible the residual effects of the breach were estimated for aquatic habitats by first comparing the before and after condition of the Ecological Units (EU) defined by the HRWG to quantify spatial and temporal losses of productive use of the habitat. Habitat Equivalency Analysis (HEA) was then used to calculate the area of habitat that would be required to offset the lost productivity of a given ecological unit from the time it was damaged to the time it was reconstructed. This allows for an accounting of productivity lost over the time since the breach and allows a mechanism to make adjustments based on habitat verification monitoring of remedial or offset habitat construction. A similar approach was also followed for upland terrestrial habitat.

This evaluation resulted in one of the following determinations for each EU:

- No offsetting required: this category was applied to ecological units that were: 1) not physically affected by the breach; 2) access to the habitat was restored before it affected a given ecological function (e.g., spawning, rearing); or 3) the quantum reconstructed habitat was greater than the damaged habitat and lost productivity.
- Offsetting required: this category was applied to EUs for which a spatial or temporal deficit in productivity was quantified. For some EUs this is considered a preliminary determination because further reconstruction activities are either being planned or are underway. The HEA will need to be re-run when the remediation activities are completed to finalize the offsetting requirement.
- To be determined: this category was applied to EUs for which the losses in productivity cannot yet be quantified or where traditional offsetting approaches may not be suitable.

## Monitoring

Monitoring at Mount Polley is carried out under the CEMP which has been approved with conditions and must be updated every three years. The CEMP, which is a required part of MPMC's permits provides an adaptive framework and process for identifying monitoring needs and results across the whole of the mine. The main goal of RP monitoring is to support the successful implementation of the remediation plan and to verify that the remedial objectives have been met. In the event that the objectives have not been met, specific workplans focused on those areas will be developed with the benefit of the data obtained from the monitoring program. Because the technical backgrounds of specialists in monitoring programs that target chemical constituents and those that are focused on habitat construction success are different, the RP proposes that habitat success monitoring and adjustments be carried out through the HRWG. However, a single monitoring program could also work, provided that the necessary components were captured.

# 1.0 INTRODUCTION

## 1.1 Background

The Mount Polley Mine, located in south-central British Columbia, 56 km northeast of Williams Lake near Likely, British Columbia (BC) is an open-pit and underground copper and gold mine operating at a deposit formed approximately 200 million years ago and classified as an alkalic copper-gold porphyry. Primary ore minerals are chalcopyrite and bornite (copper sulfide minerals). Mining commenced in 1997, and produces approximately 22,000 tonne per day and employs approximately 350 persons when fully operational.

On 4 August 2014, the failure of a glacial lacustrine layer beneath the Perimeter Embankment of the Tailings Storage Facility (TSF; “the breach”), that was not appropriately characterized in initial geotechnical site investigations, resulted in the release of a slurry of water, tailings, and dam construction material. The TSF for the Mount Polley Mine is located on the east side of the mine site (Figure 1).

The material released from the breach and the resulting debris flow resulted in physical impact to Hazeltine and Edney Creeks, Polley Lake and Quesnel Lake. Approximately 1.36 $km^2$ of the breach-impacted area was scoured of forest and topsoil (floodplain zone). Tailings were also deposited on top of relatively undisturbed forest floor across an additional 100 hectares (ha; equivalent to 1.0 $km^2$) of the breach area. It is estimated that approximately 12.8 million $m^3$ (M $m^3$) of tailings was discharged to Quesnel Lake (plus an additional 5.8 M $m^3$ of native soil and TSF water), and that 1.6 M $m^3$ of tailings were deposited in the Polley Flats area and the Hazeltine Creek corridor. In areas where the tailings covered the forest floor, air exchange for plant roots and the soil microbial community was impeded causing a hypoxic or anaerobic environment for the plant roots, resulting in tree mortality.

The deposited breach materials exceeded some regulatory standards for soils and sediments (Golder 2016a), though it is noted that some of these standards were also exceeded in non-impacted soils and sediments. In the early post-breach stages, ambient water quality guidelines (WQG) in affected waters were also exceeded. Water quality has since returned to meeting WQG in most water, although exceedances of those guidelines still occur in parts of Hazeltine Creek. The WQG exceedances in Hazeltine Creek may be due to ongoing remediation-related construction activity and are being monitored to confirm expectations from geochemical studies (Kennedy et al. 2016).

Extensive environmental impact studies (MPMC 2015a; Golder 2016a; Nikl et al. 2016; Kennedy et al. 2016; Golder 2017a, b, c) and environmental remediation works (Bronsro et al. 2016; Ogilvie et al. 2018) have been undertaken since the breach. Immediately after the breach, Mount Polley Mining Corporation (MPMC) implemented a remediation strategy (Figure 1, described further below). That strategy included stabilization and containment of the breach and the tailings remaining in the TSF (estimated to be on the order of 75 to 80%), removal of the bulk of the spilled tailings, construction of sediment control ponds, construction of a new creek channel and other erosion control measures as well as ecological remediation (which included applying soil improvement and revegetation techniques to improve functional environmental values in the impacted areas). This work is ongoing and continues to improve the site conditions.

MPMC also developed a strategy following the breach to assist in the process of investigation and remediation of areas affected by the breach. The strategy followed a phased approach, focusing first on the immediate needs of establishing safe work conditions and controlling the release of the tailings. Many of these works have been advanced considerably and planning for them has been carried out through direct collaboration with government agencies and First Nations as well as their respective technical advisors; for example, through the Habitat Remediation Working Group (HRWG).

The original framework for the TSF breach response framework consists of four main phases (Figure 2) and nine identified remediation areas (Figure 1) that break up the breach-impacted areas into smaller management units. Ideally, the remediation framework phases are presented sequentially with the information generated or decisions made in one phase feeding into the planning, actions or definition of information needs for a subsequent phase. However, given the dynamic nature of the response and the environmental and regulatory conditions under which it was implemented, some of the actions required adaptive sequencing, but are nevertheless consistent with the intent of the framework (see for example Nikl et al. 2016). Some changes to the framework have occurred during implementation; for instance, the performance verification plan was replaced by the Comprehensive Environmental Monitoring Plan (CEMP).

Government and MPMC recognized that an adaptive response was required for an incident of this nature. The regulatory instruments (e.g., Pollution Abatement Order [PAO] 107461 [the Order], and the instructions issued pursuant to the Order) were themselves adaptive. Amended orders were issued by government during the response as physical works progressed, more data became available and government identified the need to adjust/update the contents of the order. The Remediation Plan (RP) lays out the basis for remediation such that the breach area is on a trajectory of self-sustaining ecological processes that result in productive and connected habitats for aquatic and terrestrial species.

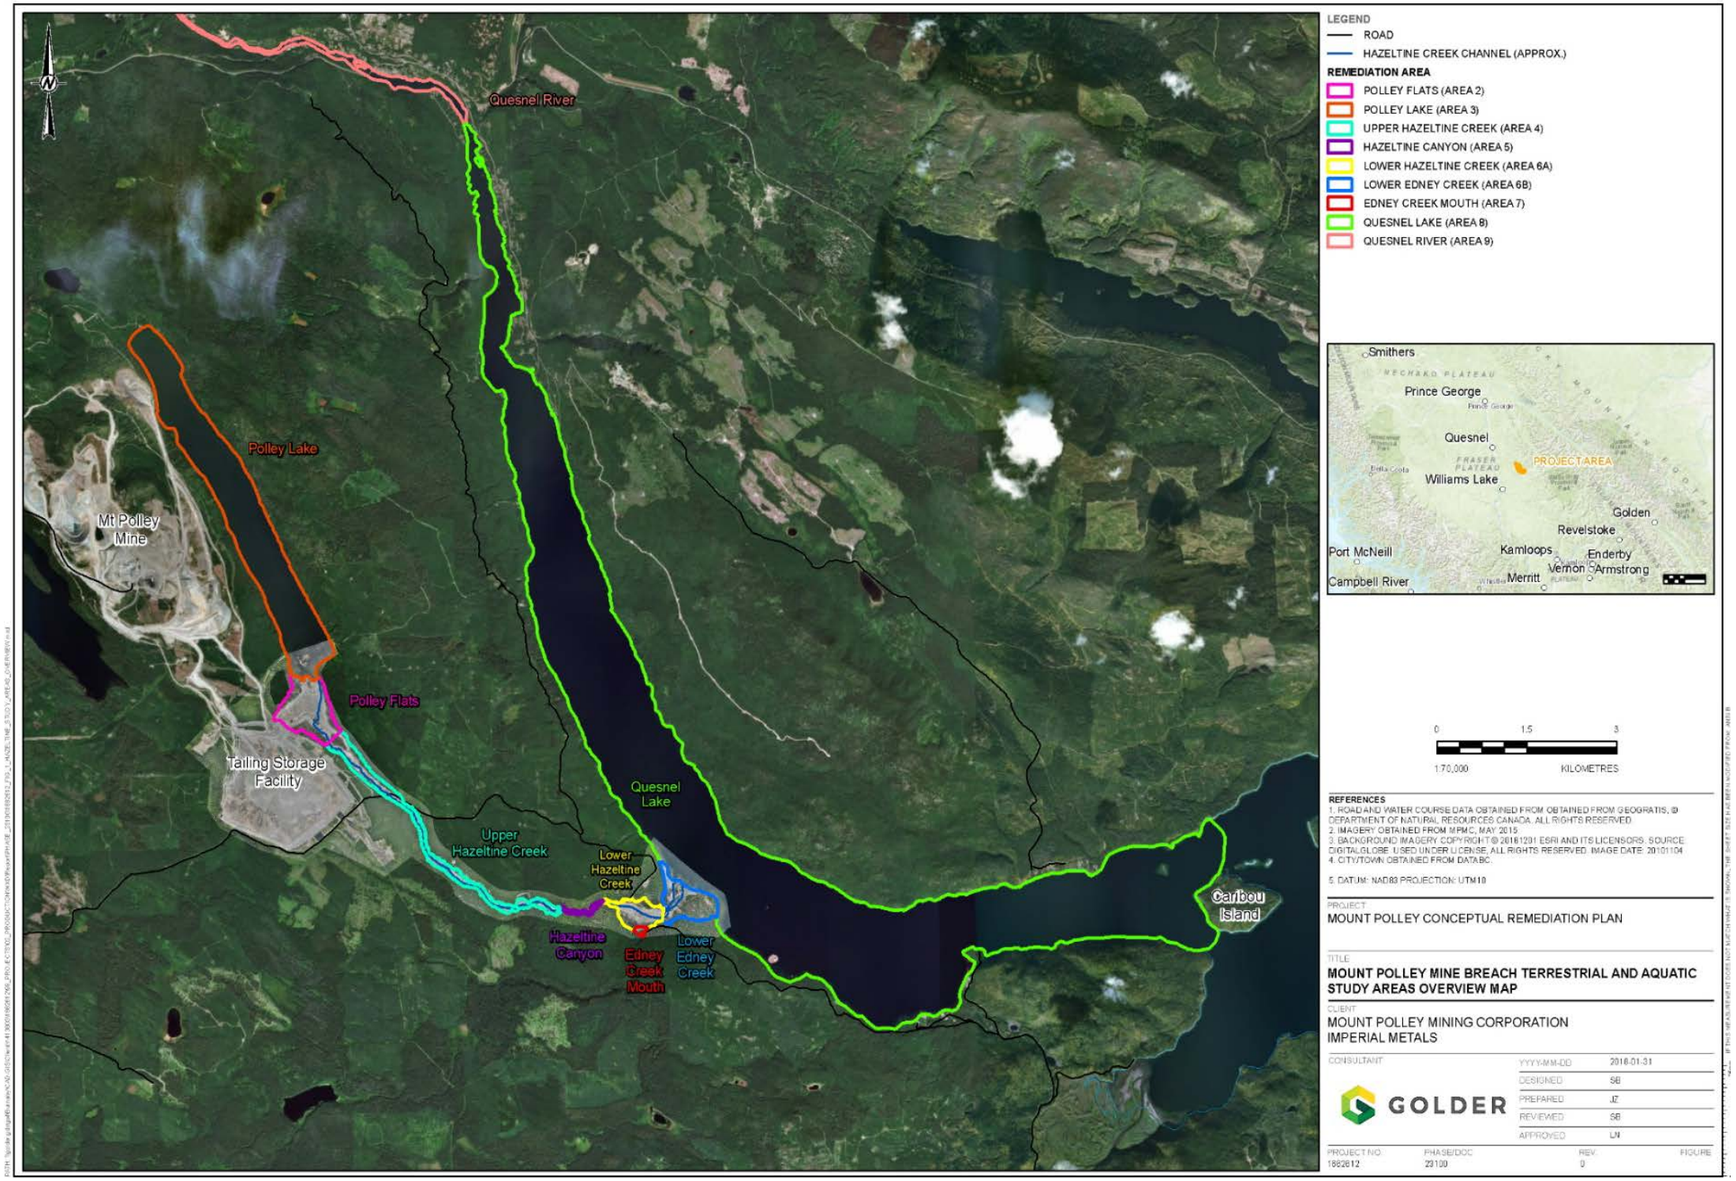

**Figure 1: Mount Polley Mine Breach Terrestrial and Aquatic Remediation Areas Overview Map**

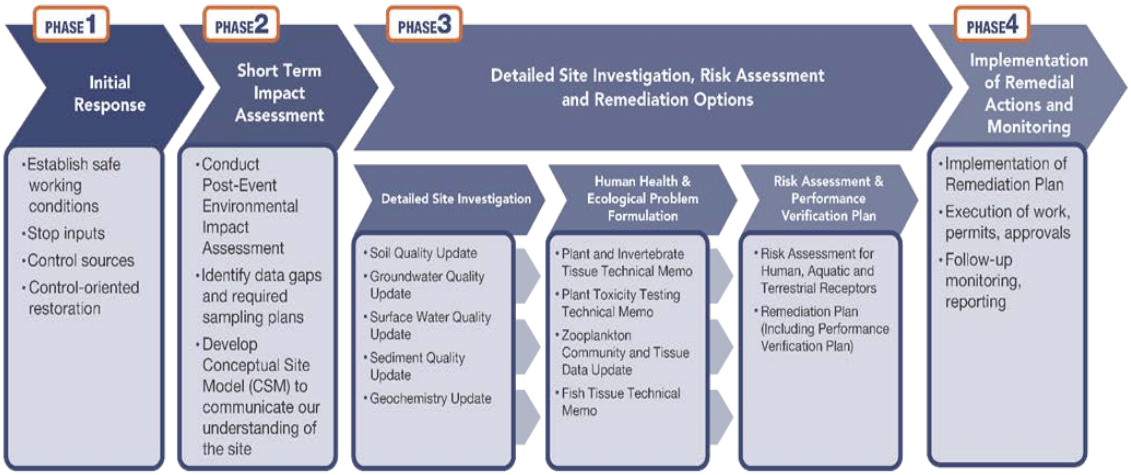

**Figure 2: Mount Polley Tailings Storage Facility Breach Response Remediation Framework (this report represents the last element in Phase 3)**

This RP was prepared for application to the area impacted by the 2014 TSF breach. Currently, remedial actions related to the breach are in the implementation or planning stages, depending on the specific area. This document describes the RP for the TSF breach-impacted area and identifies important issues that need to be considered so that further remediation can be undertaken in an efficient and compatible manner to maximize improvement of local ecosystems and fish habitat. Monitoring is an important part of the RP to assess the success of remediation and minimize risks and uncertainty. The verification monitoring program identified in this RP will become part of the CEMP. which includes breach-related monitoring carried forward to address uncertainties identified in the Ecological Risk Assessment (ERA) (Golder 2017c) and monitoring relating to permit conditions and other mine activities.

The RP follows common remediation practice as adapted for the specific circumstances of this site, though certain steps have necessarily been asynchronous, due to the adaptive response required (see above). Therefore, there are some differences in the report structure for each of the remediation areas because for some areas, remedial decisions were developed and implemented early in the breach response program (e.g., Upper Hazeltine Channel reconstruction), with options evaluations having taken place through the HRWG during the design-build process. In other areas, such as the profundal zone of Quesnel Lake where tailings material was deposited, an evaluation of remediation options is provided in this document.

## 1.2 Goals and Objectives

The scope of the RP considers the following requirements as contained in Section 3.0 of PAO 107461 (dated 9 June 2017):

i) A summary of the remedial planning basis (Section 3.0).

ii) A summary of remedial actions that have already been carried out, including a description of the process and criteria that were used to evaluate options for remedial work that has been undertaken (Section 4.0).

iii) The proposed remedial actions based on the results, conclusions and recommendations from the detailed site investigation (DSI), the human health risk assessment (HHRA), ERA, delineated by area as illustrated in Figure 1.

iv) A description of consultation completed with local First Nations and with stakeholders on the remedial objectives and how remedial objectives have been refined considering the outcome of such consultation (Section 3.4).

v) An implementation schedule (Section 6.0).

vi) Monitoring and reporting are a common expectation of a remediation plan; however, a monitoring and reporting framework will be integrated into the comprehensive environmental monitoring plan (CEMP) required in Permit 11678 and is therefore not included in this plan. A discussion on the implementation of monitoring for habitat remediation is provided in Section 6.0.

The definition of remedial actions as used here is adopted from the common definition provided by MOE (2015) and which means "…action to eliminate, limit, correct, counteract, mitigate or remove any contaminant or the adverse effects on the environment or human health of any contaminant". In this report, we have adopted remediation to also mean rehabilitation which has been used in the breach response program to refer primarily to the rehabilitation of ecological function due to physical impacts from the breach event. These definitions are sufficiently similar to expectations of Fisheries and Oceans Canada (DFO) and Ministry of Forests, Lands, Natural Resource Operations, and Rural Development (FLNR) such that this remedial plan is intended to provide a plan suitable for all environmental agencies. The regulatory and policy framework is further described in Section 2.0.

The remedial planning basis, which draws on the DSI, the HHRA and the ERA and outlines linkages between chemical and physical stressors, how these are being remediated and linkages to regulatory compliance requirements is provided in Section 4.0. Section 5.0 sets out specific remedial objectives and actions for each remediation area and identifies the impacts in need of remediation and offsetting amounts, based on available information at time of writing. Environmental remediation actions described in the RP integrate a range of technical disciplines including geotechnical and river engineering, geochemistry, aquatic and terrestrial ecology and ecological and human health risk assessment. The remediation actions described here incorporate input from the HRWG which includes representatives of MPMC and its consulting team, government and the local First Nations. The HRWG were also involved in the development of the reports that form the remedial planning basis.

This RP seeks to:

- Outline the remediation activities that MPMC have conducted and outline how those remedial decisions were made.
- Outline the basis (rationale) for remedial planning and decisions.
- Outline the components of the remedial plan and their linkages between physical remedial works such as for damaged habitats and how metal contaminants are addressed through risk management, additional study where risks are uncertain or monitoring where there is uncertainty and, where monitoring studies show that risk management is insufficient, the development of focused remedial work plans to address those.
- Identify areas and amounts where further remediation is needed.

- Identify options for remediation where applicable.
- Discuss advantages/limitations of remediation options.
- Make recommendations for remediation where needed.
- Develop a plan and schedule for remediation of additional areas where needed.
- Identify monitoring components that are applicable to the RP such that there is a logical linkage between the RP and the CEMP (also as noted above to address uncertainties in risk assessments).

Detailed workplans and designs are not typically provided within a RP. The detailed workplans will be developed within the context of the RP but external to the RP, for instance as guided by the outputs of the HRWG (see Section 3.3).

## 1.3 Remediation Areas

Remediation areas were defined early in the breach response. The areas were numbered approximately in the order of the event propagation and were defined based on distinct physical and biotic differences in the downstream area when compared to the upstream area. These remediation areas start at the TSF (Area 1), and continue on to Polley Flats (Area 2, which includes the previously named “Polley Plug” area), Polley Lake (Area 3), Upper Hazeltine Creek (Area 4), Hazeltine Canyon (Area 5), Lower Hazeltine Creek (Area 6 – which includes Lower Edney Creek), Edney Creek Mouth (Area 7), Quesnel Lake (Area 8) and Quesnel River (Area 9) (Figure 1). The areas were defined to better manage interim assessment and remediation efforts, and to define knowledge gaps to be addressed by subsequent studies. The remediation areas and interim remediation plan, originally produced as a table, were also developed to enable communication of the work and direction of future work to agencies, the local community and First Nations. Detailed descriptions of these areas are provided in Section 4.0.

For planning and execution of the habitat remediation work, Hazeltine Creek is further described by six stream reaches based on several attributes including dominant valley and stream types, stream order and tributary confluences, major infrastructure, and vegetation characteristics. Stream reaches are delineated in Figure 3 and described in the Section 4.0.

Aquatic habitat has also been divided into aquatic ecological units (EUs), based on fish community and the nature of disturbance, as part of the outputs of the HRWG (Figure 4). Edney Creek was split into three ecological units (E1 to E3), Hazeltine Creek was split into two EUs (H1 and H2), Quesnel Lake was split into three EUs (Limnetic, Littoral, and Benthic[1] zones), and Polley Lake and Quesnel River are each their own ecological unit (similar to the remediation area definitions). Additional information on these ecological units and how they are used is provided in Section 4.0. The ecological units approximately correspond to the remedial areas. The assessment and delineation of tailings and tailings constituent contamination has been delineated using the remedial areas (Figure 1 and Figure 3) whereas the EU delineations are more directly applicable to the remediation of aquatic habitats (Figure 4). In the text descriptions, we have attempted to cross reference each of these approaches to remedial areas.

[1] Also known as the “profundal” zone

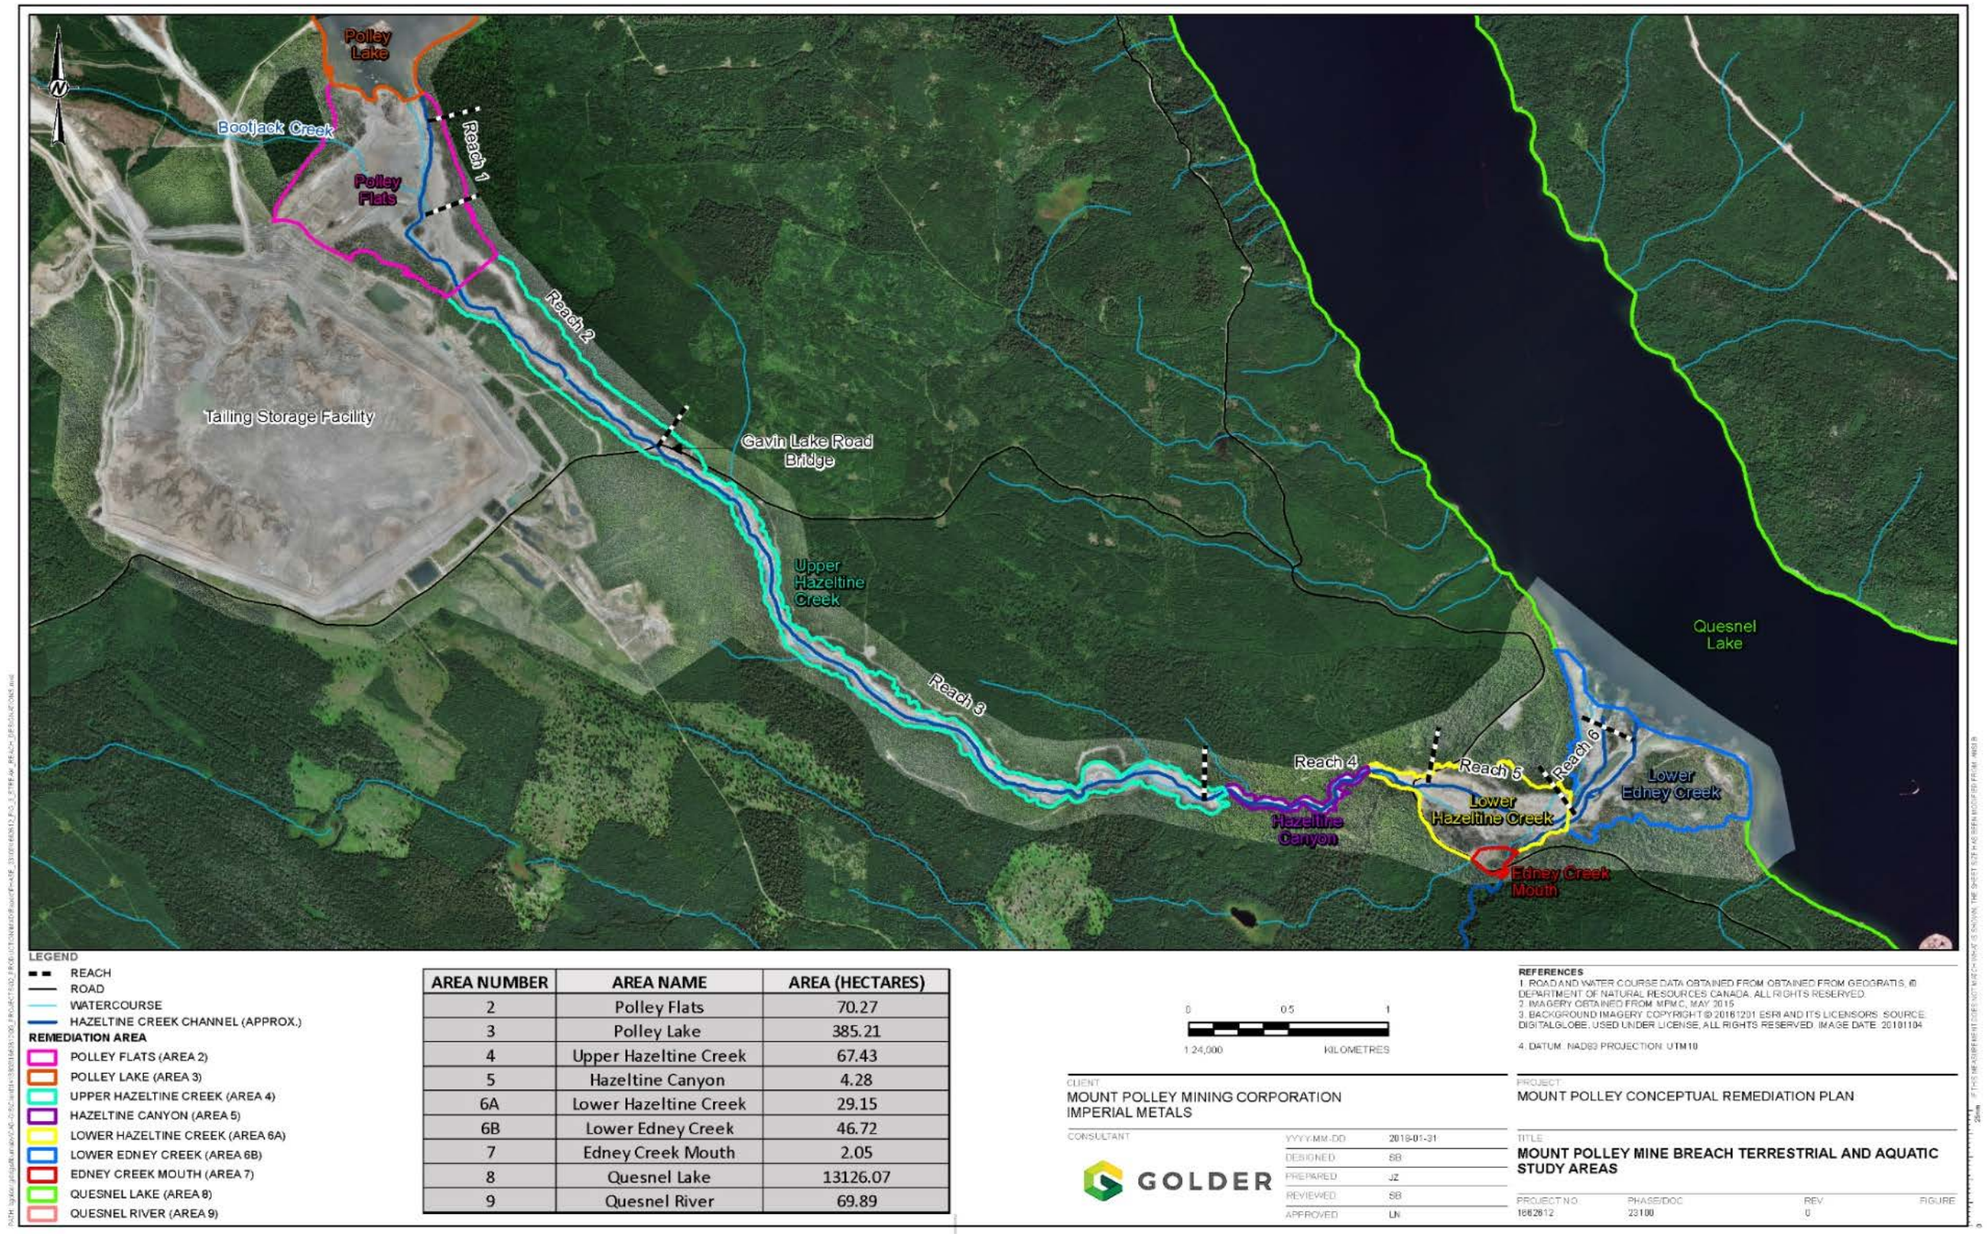

**Figure 3: Overview of Stream Reach Designations**

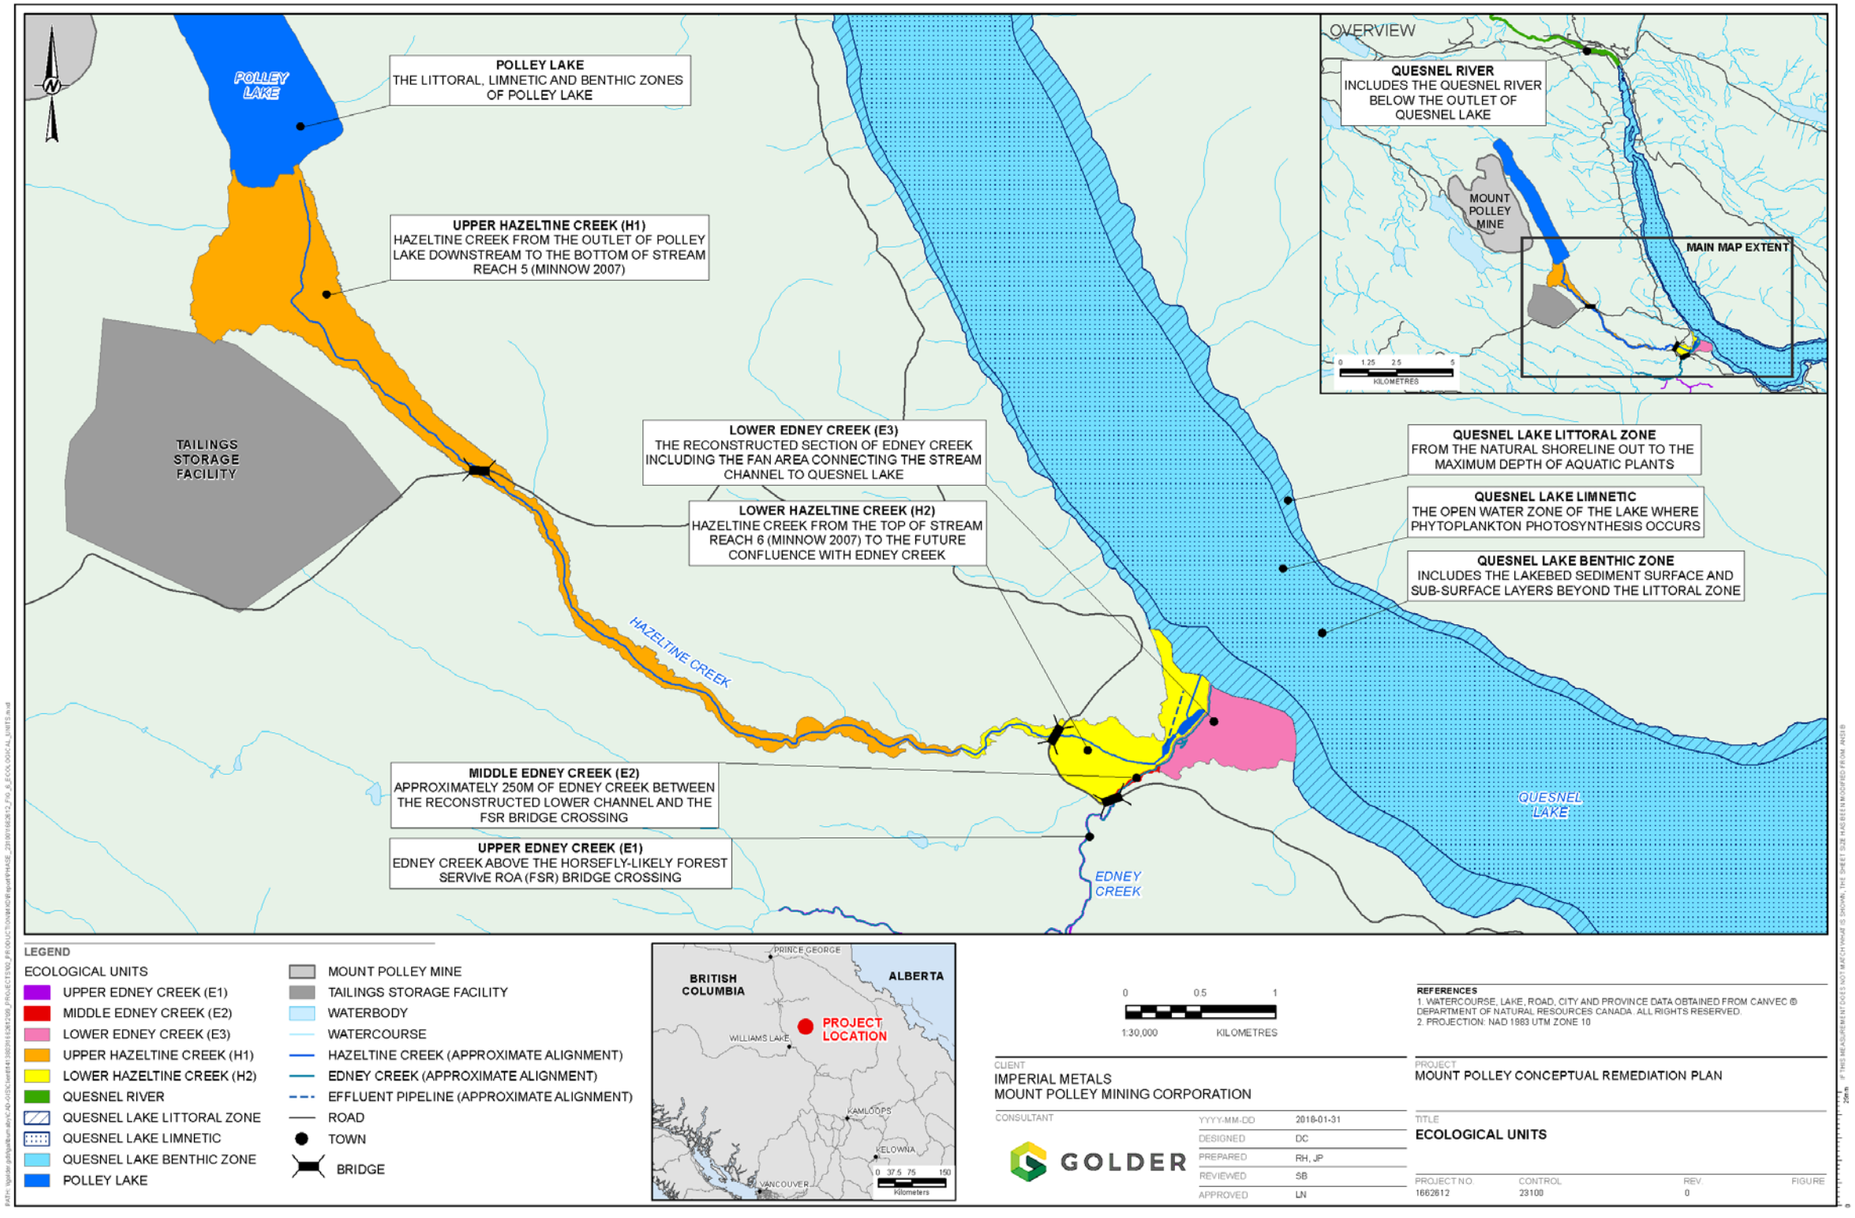

**Figure 4: Map Showing the Ecological Units as Used by the Habitat Remediation Working Group**

# 2.0 REGULATORY AND POLICY FRAMEWORK

This section articulates the regulatory requirements that form the basis of this RP. MPMC has obligations under PAO 107461 issued on 9 June 2017 (amending and consolidating previous Orders) pursuant to Section 83 (1c) of the *Environmental Management Act* (EMA). This overview is limited to remediation of the breach response event which is the subject of this RP; however, it is noted that the Mount Polley Mine is subject to other regulatory and policy drivers such as various operational permits, and the federal Metal and Diamond Mining Effluent Regulation (MDMER)[2].

While the repairs to the damaged portion of the perimeter embankment was part of breach response, those repairs, while ultimately environmental in outcomes, are of an engineering nature and have been regulated externally to PAO 107461 by BC Ministry of Energy, Mines and Petroleum Resources (EMPR). The breach repair and additional subsurface investigations and structural upgrade work has been completed and has been reviewed and inspected by government and by an Independent Expert Review Panel (IERP). It is not the subject of the RP which primarily deals with environmental matters.

## 2.1 Federal

Federal legislation and policy that applies to the breach response and remediation comes from the general provisions of the *Fisheries Act* regarding “Fisheries Protection and Pollution Prevention” (Sections 35 through 38). Early in the response, it was determined by DFO that an Authorization under the *Fisheries Act* was not required to remediate Hazeltine Creek (DFO 2014); however, that determination came with recommendations by DFO and reciprocal desire by MPMC to develop a framework for establishing habitat remediation objectives for each of the impacted areas and a recommendation that provincial agencies and First Nations be included in the development of such objectives. The resulting process was the establishment of what is presently called the HRWG that provides a collaborative process including federal and provincial agencies and First Nations that collectively contribute to the establishment of remedial objectives, an evaluation of the habitat design options to deliver those objectives and monitoring to verify objectives attainment. This collaborative process also provides a means by which agency mandates are met (e.g., *Fisheries Act* – S.38, BC *Water Sustainability Act* – Engineer’s Order (EO), see below).

It is noted that while the Mount Polley Mine is subject to the MDMER because it is an operating metal mine, the remedial plan addresses the breach response and not mine operations which are addressed separately by MPMC.

The Fisheries Protection Program (FPP) of DFO administers the fisheries protection provisions of the *Fisheries Act*. The FPP manage impacts to commercial, recreational, and Aboriginal (CRA) fish and fish habitat through a set of policies that include the general guidance provided by the Fisheries Protection Policy Statement and the guiding principles related to the creation or enhancement of fish habitat provided by the Fisheries Productivity Investment Policy. DFO is a member of the HRWG and this is currently the main vehicle through which fish habitat remediation is provided direction and has linkages to the provincial requirements as described in the following section.

[2] The MDMER replaced the Metal Mining Effluent Regulations (MMER) in 2018.

## 2.2 Provincial

The main provincial regulatory mechanism applicable to the breach response has been PAO 107461. This PAO and its supporting legislation provides the BC Ministry of Environment and Climate Change Strategy (ENV) with broad powers to compel, among other actions, studies that quantify the impacts of the breach, measures to stop further discharges, identify and implement remediation works and to provide reports related to those measures. The documents that form the remedial planning basis (e.g., Post-event environmental impact assessment reports [PEEIAR], DSI, HHRA, and ERA) were requirements of the PAO and this RP also became a requirement of that PAO. A PAO is issued when ENV believe that "pollution" (as defined in EMA) has occurred, or is occurring, and that measures are needed to abate (decrease) pollution. An example of pollution abatement measures carried out by MPMC included stopping the discharge of turbid flows into Quesnel Lake along Hazeltine Creek. By agreement with the local First Nations, the provincial government exercises its authorities with the participation of the First Nations through a government-to-government (G2G) relationship and full information sharing has been a part of that agreement.

A provincial permit for the discharge of treated water (Permit 11678) primarily deals with matters of mine operation and not breach response; however, a condition of that permit is for an updated CEMP. The CEMP includes not only monitoring related to the permit but also includes monitoring related to the breach. Its inclusion as a permit condition provides ENV with an enduring means to compel breach-related monitoring. The CEMP is a key component of the RP as it is the main vehicle to address scientific uncertainty and situations where risks are uncertain. The CEMP also provides a suitable mechanism to adjust (adapt) the monitoring program to data that are collected in the future.

The *Water Sustainability Act* (WSA), which replaced the recently repealed *Water Act*, governs several activities related to habitat remediation, most directly so with regards to the remediation of Hazeltine Creek where there are works in and about a stream. The FLNR are responsible for the WSA and have issued an Engineer's Order under that Act, dated 31 October 2014, amended 10 August 2015 and varied by way of letter. The underlying premise behind the Engineer's Order arises from Section 46 of the WSA which prohibits the introduction of foreign material into a stream in such quantities that cause adverse impacts to the stream, existing water users, property owners aquifers or the aquatic ecosystem and Section 47 of that Act which sets out the authorities of the Engineer to order works in respect of Section 46.

The authorities available under this order also include consideration of impacts to physical and chemical conditions in the aquatic habitat in the streams, rivers and lakes. That order enabled and required several remedial actions such as Quesnel and Polley Lake debris removal from the lake surface and shorelines, management of Polley Lake water levels for safety purposes (when there was concern about the "Polley Plug"), bridge replacement work (Gavin Lake Road Bridge and Ditch Road Bridge), and habitat remediation work. Additionally, the Order is an enabling document in that the necessary "works in and about a stream", particularly the habitat remediation work can lawfully proceed in accordance with the WSA.

The Engineer's Order contains 3 requirements, which, as noted in the cover letter, are to have works carried out consistent with instructions from other provincial ministries and federal agencies. The 3 requirements are:

- Collect and remove such debris from Hazeltine Creek, Quesnel Lake, and Polley Lake that threaten public safety, road infrastructure and stream channel stability.
- Maintain the lake level of Polley Lake in a manner that prevents further mass movement of material from Polley Lake and Hazeltine Creek.

- In accordance with direction of the Provincial and Federal government officials: undertake habitat remediation work on Edney Creek, Hazeltine Creek, Quesnel Lake, and Polley Lake.

There is an expectation under the WSA that the natural functioning state of the impacted environment be returned (Section 47 (1) (c)). In situations where that is not feasible, or the functioning condition of the environment has been impaired, additional compensatory measures (offsetting) may be ordered by the Engineer as per section 47(2) of the WSA. A temporary water license (5002-458) was also issued by FLNR and this license enables habitat remediation work to be carried out outside of the mine area.

While there are differences between the various federal and provincial environmental requirements and agency specialization, in all cases a return to productive function of the impacted environment, and offsets for the residual effects are shared commonalities. While there may be some minor policy differences in how these requirements could be operationalized, these operational differences can be resolved through dialogue with MPMC and the three main agencies involved (ENV, FLNR, and DFO). At present, the forum for such discussions is the HRWG and the PAO. Although the HRWG primarily has a technical function, its membership includes those with agency authorities. This group will help to determine the point at which the impacts from the breach have been sufficiently remediated and/or offset and the Engineer may choose to accept their advice as a basis for compliance with the Engineer's Order.

# 3.0 REMEDIAL PLANNING BASIS

The remedial planning basis provides a brief review of the various studies (and compilations of studies) that identified the impacts of the TSF breach event and that evaluated the chemical and physical risks to human and ecological receptors, including physical risks affecting aquatic and terrestrial habitats and public safety. For detailed information on those study findings, the reader is referred to those studies directly. Human and ecological risk assessment quantifies whether changed conditions are (or are not) safe for people, plants, and animals. If they are clearly unsafe, those residual effects must be remediated, or the risks must be managed so that following such management, they are no longer a risk.

In addition to identified risks, there are uncertainties associated with all risk assessments. An uncertainty is not a risk that requires remediation, but the delineation of those uncertainties identifies issues that should form part of a monitoring program to verify risk where conclusions may lack adequate certainty. Such components of a monitoring program do not directly trigger a need for physical remediation work but do form part of verification monitoring, in this case carried out through the CEMP, and are part of risk management for those areas where the main concerns are tailings-related contaminants (e.g., copper exceeding soil standards). There may also be circumstances where risks are uncertain and where further study is necessary to resolve a possible risk. The remediation plan (Section 4.0) addresses both types of uncertainty and includes a feedback step for the development of focused remedial work plans should monitoring indicate that action is necessary (Figure 8).

## 3.1 Overview

A detailed description of the physical, chemical, and biological alterations observed following the TSF breach was provided in the 2015 PEEIAR and the 2016 update (MPMC 2015a; Golder 2016a), and in various other publications (Nikl et al. 2016, Bronsro et al. 2016, Kennedy et al. 2016). These information sources provide a quantification of the physical, chemical and biological impacts resulting from the breach. The significance of those impacts, in the specific context of the health of people and ecological impacts, were evaluated in the HHRA (Golder 2017b) and the ERA (Golder 2017c). The assessment of risks identifies the significance of impacts in the form of residual risks that may require remediation. Such residual effects form the basis of the resulting RP.

In summary, the TSF breach resulted in water, tailings and perimeter embankment construction materials (collectively referred to as outwash materials) to be released to Polley Lake, Hazeltine Creek, and Quesnel Lake. This release also eroded the slopes adjacent to Hazeltine Creek, removing the forest vegetation and native soil over an area of approximately 1.36 $km^2$, and depositing outwash material above relatively undisturbed forest floor across an additional approximately 1 $km^2$. Several hundred meters of lower Edney Creek was eroded which led to the lower portion of that creek being incised with a step of a few meters drop, preventing migration of fish from Quesnel Lake to Edney Creek. However, the middle and upper reaches of Edney Creek were unaffected by the breach, and the reconnection of middle and upper Edney Creek with Quesnel Lake was made a priority (Bronsro et al., 2016). A mixture of tailings and scoured native material was transported to Polley and Quesnel Lakes. Approximately 12.8 M $m^3$ of tailings (plus an additional 5.8 M $m^3$ of native soil and TSF water) was deposited to Quesnel Lake (MPMC 2015a). The chemical composition of sediments at the bottom of Quesnel and Polley Lakes and along the Hazeltine Creek corridor, reflect the composition of those tailings and other outwash materials. In particular, copper, was elevated above numeric sediment quality guidelines.

A high-level remediation framework was developed early in the breach response program (Figure 2) and that framework continues to be followed. Although that framework implies sequential steps, some of the impacts described above required early actions (e.g., the mouth of Edney Creek as noted above) and options were considered and evaluated with the input of government, First Nations and stakeholders. As of the time of writing, the status of the remediation framework is as follows:

- Phase I (Initial Response) involved the initial Hazeltine channel reconstruction and armouring to stabilize the channel (Bronsro et al. 2016), and the repair and upgrading of the TSF embankment.
- Phase II (Short-Term Impact Assessment) outputs were included in the PEEIAR (MPMC 2015a) and an update to that report based on subsequently collected data (Golder 2016a).
- Phase III of the remediation strategy, which is an active stage, included the preparation of a DSI, an HHRA and an ERA. This phase of the remediation framework focuses on the long-term conditions that remain following the initial impact and implementation of short-term remedial measures (e.g., channel for Hazeltine Channel/Edney Creek re-constructed and conveying water from the Mine Site to Quesnel Lake). This phase identified that unacceptable risks to human health were not present. The ERA identified either that risks were acceptable, acceptable with uncertainty or, in a few instances, risks were uncertain. Uncertainty is addressed through monitoring activities outlined in the CEMP and uncertain risks are addressed through separate, specific studies designed to answer those questions (as illustrated in Figure 8, Section 4.1). Known risks that require remediation (residual effects) are identified (Section 5.0) and these included physical impacts. The RP provides a quantification of the impacts that require remediation and/or may require offsets, a means to risk manage areas contaminated by tailings, a means to address uncertainty, and a process to verify the adequacy of remediation as it progresses.
- Phase IV of the remediation framework is the implementation of the RP. This will remain an active phase as part of MPMC's Long Term Commitments (Figure 8, Section 4.1) and is expected to draw on the input of the HRWG to address DFO and FLNR requirements and on the CEMP process to address risk management and uncertainty. Linkages contained within the remediation plan are further detailed in Section 4.1.

## 3.2 Previous Reports: Summary of Findings

Numerous reports and studies have been prepared following the TSF breach that discuss the current conditions and proposed remedial actions. A few of these recent reports, which are key background reports to the Remediation Plan are listed below:

- Post Event Environmental Impact Assessment Report (MPMC 2015a).
- Post Event Environmental Impact Assessment Report: Update Report (Golder 2016a).
- Detailed Site Investigation and DSI Addendum (Golder 2017a).
- Human Health Risk Assessment (Golder 2017b).
- Ecological Risk Assessment (Golder 2017c).
- Book of Appendices (used for both the HHRA and the ERA) (Golder 2017b, c).

High level summaries of these reports are provided below, with focus on aspects related to remedial planning. However, the reader should refer to those reports for specific details and data. In some cases, additional work has been conducted and monitoring data have been collected since these reports were submitted to government. It is not the intention of this section to update the reports and studies summarized in this section with newer data. Where relevant to remediation planning, newer data are provided in Section 4.0. The most current data are available in the annual data reports prepared by MPMC.

### 3.2.1 Post Event Environmental Impact Assessment Reports

The objective of the PEEIAR was to provide an assessment of the physical, chemical, and biological impacts of the tailings spill on terrestrial and aquatic environments. Because of the effects of season and studies that were in progress at the time of writing of the PEEIAR in 2015, an update document was produced with additional data collected subsequent to the 2015 PEEIAR. The update document was also intended to address comments from reviewers of the first PEEIAR. These documents also provided data that were used in the subsequent DSI, HHRA and ERA reports and, consistent with the adaptive nature of the breach response, the information developed in the two PEEIAR reports were also used to structure subsequent data collection and the study design of those subsequent reports.

The PEEIAR and its update concluded that the tailings spill resulted in physical impacts to Polley Lake, Hazeltine Creek, the mouth of Edney Creek, and the benthic environment in the West Basin of Quesnel Lake and the communities in those environments (MPMC 2015a, 2016). It also provided an initial delineation of tailings constituent (e.g., copper) concentrations, their distribution in the impacted areas and provided and estimate of the volume of material spilled and toxicity and other testing results. The data contained within the PEEIAR and its update formed part of the dataset used to guide subsequent studies and evaluate human and ecological risks, the results of which form the basis of remedial planning.

### 3.2.2 Summary of Detailed Site Investigation (DSI) and DSI Update

Golder (2016a) carried out a DSI and DSI update to characterize and delineate contamination associated with the TSF breach. A DSI is commonly used to define areas of contaminant concentration and, where concentrations exceed standards, the data are used to support the assessment of those risks in the form of an HHRA or ERA.

The impacted physical environment around Polley Lake, Edney Creek and Hazeltine Creek included approximately 136 ha (1.36 $m^2$) where topsoil was removed and an additional area of approximately 100 ha (1 $km^2$) where tailings were deposited overlying intact topsoil.

In some areas, the tailings settled out in two distinct layers: a grey fine silt and a black-orange sand. The two layers settled out according to particle size and density, generally with the finer material overlying the coarser sand. As the debris flow moved down the Hazeltine Creek alignment, it picked up and mixed with native till and other glacial sediments (fluvial and lacustrine) as well as native organic soils. Approximately 20 M $m^3$ of tailings, native soil, water and debris were deposited into Quesnel Lake where a very fine-grained turbidity plume formed and persisted below the thermocline at approximately 20 to 30 m below surface. The plume is interpreted to have included a significant amount of fine-grained natural lake sediment that became suspended by the debris flow from Hazeltine Creek. Turbidity in Quesnel Lake persisted into December 2014 but decreased over the winter.

Together, the soil, sediment, groundwater and surface water results indicate that while tailings-related metals are present above Contaminated Sites Regulations (CSR) standards in these media, research on impacted site materials has indicated that the leachability and migration potential of metals in these materials is low and that there are secondary geochemical controls on the materials which together suggest the bioavailable phase to be low (Kennedy et al. 2016). However, sampling of seeps has indicated elevated copper and monitoring of the geochemical predictions remains an appropriate component of the CEMP.

Section 7.0 of the DSI Update provides the following information:

- identification of areas of potential environmental concern
- determination of the potential contaminants of concern based on the applicable CSR standards
- delineation of the horizontal and vertical extent of contamination
- confirmation that the contamination at the site is stable or decreasing in concentration and extent over time

Because the remediation of the TSF breach is determined based on risks, the DSI/DSI Update does not directly provide a remedial planning basis (particularly for habitat damage) but does provide some of the information to support the assessment of risks (i.e., HHRA and ERA) and the identification of residual effects which are the drivers for the remediation plan.

### 3.2.3 Summary of Human Health Risk Assessment Findings

The HHRA (Golder 2017b) was conducted based on provincial guidance on the conduct of human health risk assessments and was externally reviewed by consultants retained by government and by First Nations and who have specific experience in the conduct of HHRAs. In response to requests by reviewers, the selection of contaminants of primary concern (COPCs) for the risk assessment was expanded beyond the methods outlined in guidance in order to consider substances not typically regulated under the CSR (i.e., aluminum). No COPCs were identified in soil; however, aluminum, copper and vanadium were conservatively[3] retained for the assessment of the ingestion of berries, traditional plants, wild game fish tissue and cattle pathways as part of a multi-media evaluation.

Risks to the subsistence and traditional land user, hiker/camper, all-terrain vehicle (ATV)/snowmobile user, boater/kayaker, sport fisher, hunter/trapper, Quesnel Lake resident, logger and mine/remediation worker from exposure to aluminum, copper and vanadium were evaluated in the HHRA. Specifically, the following exposure pathways were evaluated:

- Subsistence and Traditional Land User: incidental sediment and soil ingestion, dermal contact with sediment, soil and surface water, inhalation of soil particulates, ingestion of surface water and ingestion of berries, traditional plants, deer meat, deer liver, moose meat, moose liver, fish and grouse.
- Hiker/Camper: incidental sediment and soil ingestion, dermal contact with sediment, soil and surface water, inhalation of soil particulates, ingestion of surface water and ingestion of berries.
- ATV User: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of berries.

[3] Reference to conservatism or conservative approach in this report mean that the approach taken was a cautionary one.

- Boater/Kayaker: incidental sediment ingestion, dermal contact with sediment, ingestion of surface water and ingestion of fish.
- Sport Fisher: ingestion of surface water and ingestion of fish.
- Hunter/Trapper: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of deer, moose, fish and grouse.
- Quesnel Lake Resident: incidental sediment ingestion, dermal contact with sediment and surface water, ingestion of surface water and ingestion of berries, deer, moose, fish, grouse and cattle.
- Logger: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water, and ingestion of fish.
- Mine/Remediation Worker: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of berries and fish.

The hazard indices for these receptors were below the threshold of 1.0. This means that the dose that receptors are exposed to is less than the toxicity reference value, indicating that the conditions are not a risk to human health.

### 3.2.4 Summary of Ecological Risk Assessment Findings

An Ecological Risk Assessment was conducted to evaluate the ecological significance of the altered environmental conditions (physical, chemical, biological) that are present in the study area because of the TSF breach (Golder 2017c). Risk management and remediation activities have been underway since the TSF breach occurred and the physical impacts associated with the initial release are being addressed through a broad and consultative habitat remediation program through the HRWG. The breach response has been an adaptive program in which data collection and evaluation have been conducted on an ongoing basis since the breach to address a wide variety of investigation needs, regulatory requirements and information requests from First Nations and the Public. The data collected have been used to inform the design of subsequent stages of study. The risk assessment evaluates the available data considering the long-term management goal of successfully reintroducing a biologically diverse, functional, self-sustaining, and inter-dependent ecosystem.

The risk assessment was intentionally conservative in its approaches, assumptions, and decision criteria, consistent with relevant guidance and common practice in BC. A problem formulation identified the extent of the study, established the objectives of the risk assessment and formed the basis of the conceptual site model. The conceptual site model articulates the risk assessors understanding of the system under study including the ecological stressors and their sources, receptors of interest, and potentially significant exposure pathways. The conceptual site model considers the site investigation data and the understanding of the physicochemical properties and fate of the COPCs. The ERA drew extensively on not only the DSI and DSI Update but also the PEEIAR and its update and various studies carried out as part of the breach response program. An exposure and effects assessment was conducted using a weight of evidence approach that evaluated different types of data such as chemical measurements, toxicity testing and community structure data as would be present in an integrated assessment. The weight of evidence assessment enabled the articulation of the magnitude of risks for each of the major ecosystem components. The conclusions for individual ecosystem components are provided in Sections 3.5 and 4.9 of the ERA (Golder 2017c) for the terrestrial and aquatic risk assessments, respectively. The following are the main findings of the ERA:

- Copper is the primary contaminant of primary concern (COPC) associated with tailings, irrespective of whether tailings were deposited to land or water. There were no other chemical constituents that were found to be a significant ecological risk that was attributable to the TSF breach. The tailings also have deficiencies in terms of soil structure or nutrient/organic carbon that are important non-contaminant stressors.
- Numerous lines of evidence showed that the copper associated with tailings has low bioavailability. This finding was consistent in sediment, water, and soil. However, some copper uptake was noted in sample results (discussed in more detail in Section 4.7.3 of the ERA) though toxicity testing did not indicate that the degree of bioavailability/exposure was harmful. The relative influence of copper versus physical factors will need to be confirmed through monitoring.
- Assessment of several ecosystem components was made with the benefit of laboratory-based toxicity testing or other tools that allowed for experimental verification that the structural and nutrient deficiencies in the tailings are a cause of reduced performance. The specific attributes contributing to the deficiency varied somewhat by media (e.g., total organic carbon in sediment; plant available nutrients and bulk density in soil) but were broadly related to the fact that the tailings lack the heterogeneity and nutrient processing that is part of a healthy soil or sediment ecosystem. This deficiency is expected to decrease over time as organic carbon and biological function returns to the system (Frouz et al. 2008).
- The balance of evidence from the laboratory studies and experimentation, field observations, and inferences based on case studies or relevant literature is that the adverse effects associated with the structural and nutrient deficiencies in tailings, whether as sediment or as soil will have a larger influence on the speed of recovery/recolonization than the influence of copper. The risks associated with copper are low; where ecological risk levels were considered moderate, these were primarily associated with disruption to the physical substrate. For some components of the risk assessment, the findings were uncertain (e.g., risks to amphibians) and these have been carried forward to specific studies designed to address the uncertainties (see for example Figure 8).

The risk assessment findings by area are further summarized in the following sections and key uncertainties or areas of uncertain risk, as well as monitoring considerations for the CEMP, are summarized in Table 1. The RP is structured around known risks. However, the plan also includes feedback mechanisms from the CEMP and related focused studies (to address uncertain risks). Should monitoring or the results of those studies identify that there is a risk that requires remediation, then specific work plans would be developed to address those risks.

Delineation of areas physically damaged from the TSF breach were provided at a high level in the PEEIAR reports; however, environmental damages specific to the Ecological Units as applicable to quantification of habitat losses and potential offset requirements (of particular relevance to DFO and FLNR requirements) are detailed in Section 5.0.

**Table 1: Key Uncertainties in the Ecological Risk Assessment and Monitoring Considerations (adapted from Golder 2017c)**

| Receiving Environment and Area | Receptor Group | Risk Conclusion | Key Uncertainty | Monitoring to Address Uncertainties (detailed in the CEMP) |
|---|---|---|---|---|
| Terrestrial – All areas | Plants | Low to moderate | Field observations of the plant community re-establishment is positive but in an early state of plant succession. | Field monitoring of plant performance will be incorporated as part of the remediation plan monitoring. |
| | | | Plant growth under-performed in soil tests, but the relative contribution of copper versus physical and structural limitations of the soil has not been confirmed. | Field monitoring of plant performance (see above).<br>Focused investigations to determine relative contribution of copper versus physical limitations may be added, but only if needed based on findings from field monitoring. |
| | Soil invertebrates | Low to moderate | The early successional nature of soil conditions means limited soil invertebrates were available for sampling. | Field monitoring of soil invertebrate community will be incorporated as part of the remediation plan monitoring;<br>Focused investigations to determine relative contribution of copper versus physical limitations may be added, but only if needed based on findings from field monitoring. |
| | Wildlife | Low | Existing mathematical relationships between soil and tissue concentrations are based on currently available data. This results in uncertainty in how risk estimates are being applied to smaller areas. | Field monitoring of plants and soil invertebrate (see above) will include sampling for tissue chemistry to supplement the currently available data. |
| | | | Understanding of copper bioavailability was informed by available PBET data and literature values, resulting in uncertainty in the HQ. | Field monitoring (see above) will include collection of soil samples for PBET analysis to increase spatial coverage and diversity of soil types covered by PBET.<br>Targeted study to expand PBET analysis to determine relative bioavailability (e.g., include additional types of items in the PBET analysis). |
| | | | Toxicity Reference Values (denominator in the HQ calculation) were based on screening level benchmarks. | No specific field activities. Desktop refinement to develop a site-specific toxicity reference value to replace the default TRVs. |
| Terrestrial – Riparian Habitats | Amphibians | Indeterminate | Amphibians have not been formally assessed beyond the qualitative observations described in the risk assessment. | Existing data (potentially with a targeted supplemental program) to be used to determine a screening-level estimate of hazards to amphibians exposed to soil, sediment and water. |
| Aquatic – Hazeltine Channel | Benthic invertebrates and fish | Indeterminate – effects-based lines of evidence were deferred while restoration was in progress | Concentrations of copper exceed water quality guidelines. | Monitoring (post-habitat rehabilitation) to evaluate benthic invertebrate re-colonization.<br>Ongoing monitoring of Hazeltine Creek water chemistry to evaluate trends. |
| Aquatic – Quesnel Lake | Benthic invertebrates | Low to moderate | Toxicity test performance was reduced but relative contribution of copper versus physical and structural limitations of the sediment has not been confirmed.<br>Diversity metrics show improvement, transplant studies show positive recolonization potential but abundance remains reduced. | Monitoring of benthic community recovery to confirm that recolonization is progressing and that copper concentrations are not a barrier. |
| Aquatic – Polley Lake | Fish | Low | Clarification of the cause of Trout age-class structure alteration in Polley Lake. | Evaluate age class frequency of fish species in Polley Lake.<br>Monitor copper concentrations in water samples from Polley Lake. |

PBET - physiologically based extraction test; TRV – toxicity reference value.

#### 3.2.4.1 Risks to the Terrestrial Environment

Overall, while certain metal concentrations are elevated over background risks to the terrestrial environment from tailings constituents were moderate; however, considerable physical impacts occurred. The physical nature of the tailings is expected to be an issue because tailings lack the heterogeneity and nutrient processing that is fundamental to a healthy soil ecosystem. This deficiency would be expected to decrease over time (Frouz et al. 2008), as organic carbon and biological function returns to the system, but currently, the magnitude of the effect is such that a conclusion of moderate risk is considered an appropriate characterization. Active intervention to enhance the return of such soil function is part of the ongoing remediation activities and is an identified residual effect for management under the RP.

There was no evidence that copper would act as an additional stressor over and above the influence of the physical and nutrient deficiency. Accumulation of copper in the food chain is considered to be low risk, based on the findings of the food chain model. The food chain model considered a wide variety of wildlife receptors with varying feeding strategies and dietary items and the general conclusion regarding low risks associated with copper bioaccumulation is therefore considered to be applicable to all wildlife species occupying the study area. Further information is contained in the ERA (Golder, 2017c).

Areas of uncertainty identified in the ERA have been carried through to the CEMP and additional assessment is underway as follows:

- Diversity of soil ecosystem: Field-based monitoring of the diversity or abundance of plants, soil invertebrates or other parts of the soil ecosystem is valuable in an ERA but was not practical to address at the time the ERA was prepared due to the variability associated with natural successional changes. Through the CEMP, a tiered program has been planned to further evaluate the potential for effects on the soil ecosystem (Golder 2018a).
- Copper bioaccumulation in plants and soil invertebrates: The ability to quantify the relative influence of copper versus the physical limitations of the soil is important from a theoretical perspective. This would typically be evaluated using controlled experiments. However, further experiment-based studies are not warranted unless there is evidence (from field monitoring) that natural succession is not progressing. It is reasonable to continue refining the site-specific understanding of copper bioaccumulation in plants and soil invertebrates in lieu of further experimental studies while the long-term field monitoring is conducted. Through the CEMP, a tiered program has been planned to further evaluate the relative influence of copper on soil invertebrates and plants (Golder 2018a).
- Wildlife: Risks to wildlife were assessed with a single technique (a food chain model). Conservative assumptions were used in the model, resulting in hazard quotients of less than one for 11 of the 15 receptor species evaluated in the model. Further refinement of the food chain model is being conducted for the four receptor species that had an HQ > 1 (Golder 2018a).
- Amphibians: Only a limited amount of direct measurement of exposure or effects relevant to amphibians was available at the time the ERA was undertaken. From a practical perspective, rehabilitation of the riparian areas, and restoration of Hazeltine Creek was ongoing throughout the risk assessment process and therefore the habitat suitability for amphibians was considered low. Moreover, completion of the ERA for other major groups of receptors (e.g., mammals, plants) was needed to determine if further remediation activities, which would further disrupt habitat suitability, was needed to address the residual concentrations of copper in the deposited material. Through the CEMP, a tiered program has been planned to further evaluate the potential for effects of metals on amphibians (Golder 2018a).

### 3.2.4.2 Risks to Polley Lake

In Polley Lake, no parameters were identified as stressors or COPCs in surface water based on comparisons of chemistry data collected between March and August 2015 with BC WQG. In terms of effects-based measures, there are multiple indications of recovery:

- Plankton - no adverse effects were observed in toxicity tests (acute or chronic tests with cladocerans) conducted in representative water samples, and no apparent change in biomass relative to background areas. The median concentration of copper in zooplankton collected from Polley Lake is lower than the upper limit of the normal range of samples collected from reference areas.
- Benthic Invertebrates - Polley Lake locations, in both deep and mid-depth locations, exhibited signs of biological recovery following the first year of sampling. Copper concentrations in benthic invertebrate tissue samples from Polley Lake, were significantly elevated relative to reference, but had lower concentrations than profundal Quesnel Lake benthic invertebrate tissues. The benthic organism species richness and abundance was not significantly different from Bootjack Lake, which has been used by MPMC as the reference location in their monitoring work (CEMP). A more detailed discussion of benthic invertebrate tissues is provided in Section 4.9.4 of the ERA.
- Fish - Median concentrations of copper in benthic invertebrate tissue were less than the dietary threshold for adverse effects to fish and water quality now meets guidelines. The fish population structure indicates a reduction in recruitment for Rainbow Trout (*Oncorhynchus mykiss*) (Minnow 2017a) which was inferred to be the result of precluded spawning access to upper Hazeltine Creek while it was being reconstructed. In 2018, following an evaluation of the suitability of the reconstructed habitat (water quality and temperature) for juvenile Trout (Golder 2018b), it was decided by the HRWG that fish would be re-introduced to upper Hazeltine Creek (discussed further in Section 4.5.1) and this resulted in successful spawning and recruitment of juveniles to Polley Lake (Connors et al. 2018). Additionally, MPMC established a temporary hatchery to supplement the population structure in Polley Lake as a contingency to the production from Hazeltine Creek.
- Physical effects to Polley Lake included deposition of settled outwash materials in the nearest approximately one third to one half of Polley Lake. Unlike Quesnel Lake, sediments in Polley Lake were mixed with existing Polley Lake sediments and organic material in the outwash area of Polley Flats. Lakeshore vegetation adjacent to Polley Flats was also damaged by the breach event and several logs/trees were washed into Polley Lake. Following observations that these logs and trees were providing cover for fish and fish were utilizing that area, a decision was made by the HRWG to leave those logs and trees in Polley Lake.
- The available data does not show a detectable impact on fish productivity of Polley Lake. However, the fish population structure does show signs of change as a result of the loss of their main outlet spawning area (upper Hazeltine Creek). Steps were taken in 2018 by MPMC to mitigate the population structure effects; however, monitoring is necessary to identify whether there may be productivity impairment using the metrics developed by the HRWG. While the benthos appears to have recovered quickly in Polley Lake, some impacts would have inevitably occurred, even if they could not be reflected in the monitoring data.

#### 3.2.4.3 Risks to Hazeltine Channel and Lower Edney Creek

The assessment of risks for Hazeltine Channel was impeded by the coincidence in timing of when data would need to be collected and the timing of active remediation works which are a source of physical disturbance that would affect the data obtained. Given that the extensive construction and remediation efforts (see for example Bronsro et al. 2016) have modified the site conditions, the ERA report identified the risks in Hazeltine Creek as "indeterminate" (i.e., risks uncertain). The RP focuses on the current, post-remediation (where remediation has occurred) conditions. The RP is predicated on the present understanding of those conditions but is subject to the implementation of an acceptable CEMP to quantitatively validate that understanding and expectations regarding risks in Hazeltine Creek. Some relevant qualitative observations provided within the above context are outlined below. It should be noted that Hazeltine and to a lesser extent Edney Creek have been subject to physical disturbances from ongoing habitat remedial works. Quantitative sampling using accepted methodologies are required to provide a reliable basis to form risk management conclusions as well as to verify the performance of constructed habitats; however, such methods do not apply well to systems under physical disturbance. Qualitative observations are provided for context and are intended to be indicative but not confirmatory.

- Algae – Periphyton can be seen growing on the substrate in Hazeltine and Edney Creek and quantitative assessments are expected to occur when creek remediation has concluded, as part of the CEMP. Periphyton sampling was carried out in Edney and Hazeltine Creeks in 2017 but the data were not available for inclusion in the ERA.
- Benthic Invertebrates - There were statistically significant reductions (greater than 20% reduction) in diversity at upstream and downstream locations relative to reference for samples collected with Surber sampler or a kicknet. Data were limited to 2015, and creek remediation was subsequently initiated. It is worth noting that Edney Creek already shows clear evidence of recolonization, and similar recovery for Hazeltine Channel is anticipated in response to the remediation based on proximity to upstream organisms that provide a continued source of colonization and based on visual examination of substrates for macroinvertebrates which have shown the presence of EPT taxa[4]. Additional sampling was conducted in 2017 but the data were not available for inclusion in the ERA. This is an area of uncertainty that can best be addressed following the conclusions of construction activities and the physical disturbance associated with those activities.
- Fish - Direct assessment of fish in Hazeltine Creek could not be undertaken as part of the ERA because fish had been excluded over the course of the creek remediation with a series of fish fences near the Polley Lake outlet and the Quesnel Lake inlet. A partial (upper Hazeltine Creek) re-introduction of fish took place during the 2018 spawning season and Rainbow Trout successfully spawning (4,890 adults) and producing juvenile trout (an estimated 18,084 juveniles) that have since moved into Polley Lake (Connors et al. 2018). Monitoring of that age class within Polley Lake is ongoing by MPMC. MPMC's sampling (Minnow 2018a) has found that all of the species of fish previously making use of Edney Creek are again present in Edney Creek, including the reconstructed portion. In addition, Kokanee (*Oncorhynchus nerka* freshwater variant) spawners were observed in the reconstructed portion of the channel. Detailed assessments of productivity will be required as part of the long-term commitments of MPMC with regards to verification of monitoring of habitat.

[4] EPT taxa are those organisms that are members of the orders Ephemeroptera, Plecoptera and Trichoptera (mayflies, stoneflies and caddisflies). EPT taxa are considered to be sensitive to aquatic pollution making their presence a positive indication of good water quality.

- Water quality in Hazeltine Creek shows an improving trend for dissolved copper concentrations (Golder 2018b) which are below the 30-day average BC WQG[5] (at higher values of water hardness) and have been below the biotic ligand model (BLM) site specific target values developed as part of the setting of treatment targets (Golder 2016b). The BLM used does not represent an accepted science-based environmental benchmark (SBEB; MOE 2016) or policy-based screening benchmark. Rather, it was used to provide context to the water quality data and an indication that development of an SBEB, should it be required in the future, may be feasible. Some of the earlier data was collected prior to the removal of tailings in the Polley Flats area and further monitoring of Hazeltine Creek water quality as well as seeps in Polley Flats remains a part of the CEMP. Dissolved copper has been used for planning purposes rather than total copper (for which the water quality guidelines apply) because it is more closely related to effects and because total copper would be affected by construction activities. Updated water quality data, including a broader suite of parameters (aluminum, copper, selenium, temperature, and dissolved oxygen), were also compiled as part of planning for re-introduction of fish into the upper portion of Hazeltine Creek (Golder 2018b). Those data were used to support the decision to re-introduce the fish. Water quality conditions in upper Hazeltine Creek do show an influence from construction activities related to remedial work (Golder 2018b).

The RP for Hazeltine Creek is focused on habitat reconstruction, subject to monitoring data confirming that copper and other parameters either meet the BC WQG or, alternatively, an SBEB derived following ENV policy (MOE 2016). An SBEB has not been developed for Hazeltine Creek at this time. If risks associated with changing water quality are identified through ongoing monitoring, additional remediation may be planned (vis-à-vis Section 4.1 and Figure 8).

#### *3.2.4.4 Risks to Quesnel Lake*

Risks are low for organisms associated with the water column (plankton, pelagic fish). Water chemistry shows that copper and turbidity are unlikely to present hazards to aquatic life especially after turbidity decreased over the first several months following the TSF breach (MPMC 2015b; Nikl et al. 2016). However, impairment to the benthic community remains in the profundal (deep lake bottom) environment where tailings deposited, and also in shallow portions of the lake close to Hazeltine Channel. These signs of impairment are associated with the physical burial of benthic communities and associated changes to substrates, in particular a low organic carbon content which is characteristic of the tailings material. The profundal areas are recovering, but the rate of recovery appears to be slower than in Polley Lake.

- Plankton - There were no significant reductions in chronic water algal growth tests or vascular plant growth toxicity tests on field collected water samples, or apparent change in primary productivity. There was no chronic toxicity to cladocerans in representative non-turbid waters, and no discernable difference in copper concentrations of zooplankton tissue samples between the exposed area and the reference areas of Quesnel Lake. There was also no discernable response in total zooplankton biomass or abundance, or in the relative biomass or abundance of dominant taxa, relative to reference.

[5] The 30-day average WQG is intended to be used in conjunction with the average of five samples collected weekly. In some cases, the monitoring data were not collected on this frequency; however, the values are conservative and where individual receiving environment concentrations are lower than the 30-day average guidelines, effects would not be expected.

- Benthic Invertebrates - The results of toxicity tests with two species indicate potential risk, based on the observation of greater than 20% responses in several samples; however, results were likely influenced by physical factors, particularly organic carbon. The responses were higher in sediments characteristic of tailings (elevated copper and low organic carbon). The addition of organic carbon or mixing samples (1:1 ratio) with reference sediment that contained higher organic carbon eliminated those observed growth effects in toxicity tests using the near field sediments. In terms of benthic community alterations, several Quesnel Lake assemblages remain impaired but data indicate that they are improving. Species richness in 2015 was not significantly different from reference areas but invertebrate abundance was lower in the impact area. A study in which breach-impacted sediments were transplanted to a reference area shows that recolonization of breach-impacted sediments is not impaired (these data are discussed further in Section 4.11.3). The main factors that are making recolonization slower is the need to accumulate organic carbon in the lake bed and the large (approximately 1.8 $km^2$) impact zone which makes in-migration of benthic invertebrates slower than when the transplanted sediments were surrounded by colonized sediments. Overall, recovery at these stations is slower than what has been observed in Polley Lake.
- Fish - No meaningful impairment from water quality was observed (i.e., performance is not inhibited by more than 25% relative to control samples) in fish toxicity tests that included the 7-d Rainbow Trout survival and growth test and the 7-d Fathead Minnow (*Pimephales promelas*) survival and growth toxicity tests in field collected water samples. The concentrations of copper in field-collected samples of representative fish diet (benthic invertebrates) are below the dietary threshold for adverse effects by consumption as derived in the ERA (Golder 2017c). Information available on the microscopic structure of fish tissues (histology) does not indicate ongoing water quality-induced stress associated with the presence of the tailings in the lake (unpublished DFO study). The condition factors of juvenile Sockeye Salmon (*Oncorhynchus nerka*) collected from different sampling zones in Quesnel Lake do not indicate a negative tailings influence – the fish were larger and more numerous in the West Basin of Quesnel Lake (DFO data, unpublished). Fish have also been observed using the profundal zone of the West Basin during an ROV inspection of the outfall (Figure 5); however, these are coincidental observations during an ROV survey of the outfall structure and not quantitative surveys.
- Physical effects to Quesnel Lake were summarized in the PEEIAR (MPMC 2015a). Material volumes estimated to have been transported to Quesnel Lake include 12.8 M $m^3$ of tailings and interstitial water, 1.2 M $m^3$ of native soils scoured along Hazeltine Creek and 4.6 M $m^3$ of overlying water in the TSF. The entry of this material resulted in water quality impacts, most notably/visibly on turbidity, particularly in the deeper parts of Quesnel Lake at first and throughout the water column following lake overturn in November 2014. The breach outwash materials settled onto the bottom of Quesnel Lake, covering an estimated 1.81 $km^2$ of lake bed. Although the depth of settling was variable, it was estimated to be up to 10 m deep in some locations (Figure 6). Physical changes to the lakeshore area, including scour and vegetation loss adjacent to Hazeltine and Edney Creeks also occurred.

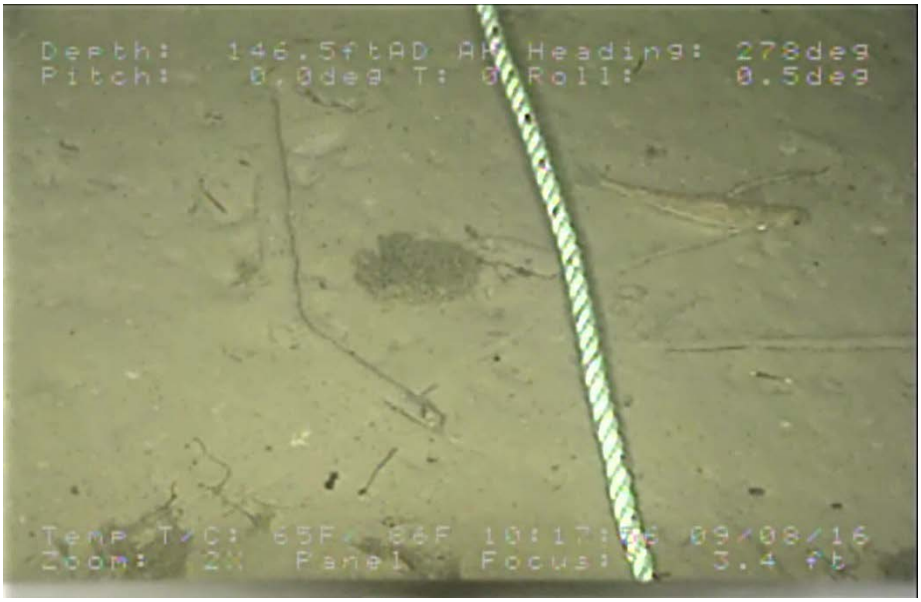

**Figure 5: Image extracted from an ROV video (coincident observations, not a quantitative fish survey) recorded during an outfall inspection, showing that the lakebed is being used by fish in Quesnel Lake, near the outlet of Hazeltine Creek (fish is in the upper right quadrant of the image, the rope was temporarily placed to set the course for the ROV).**

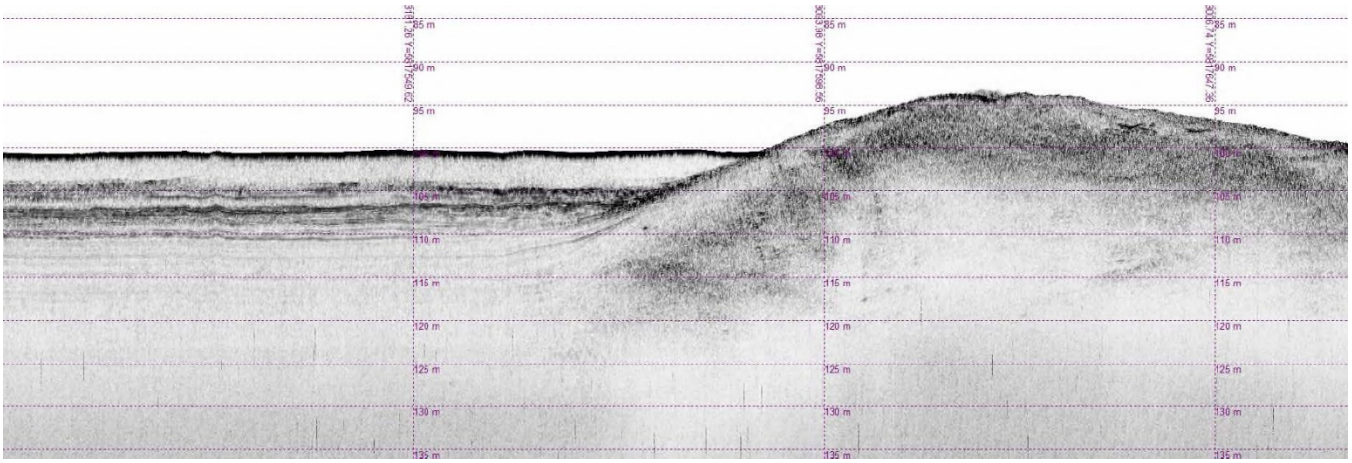

**Figure 6: A sub-bottom profile image of a section of Quesnel Lake showing fine-grained sediments settled along a flat section (left of image) and an underwater lake side slope along the rise on the right half of the image.**

#### 3.2.4.5 Risks to Quesnel River

The available evidence indicates a low magnitude of risk comparable to reference conditions:

- Plankton - No significant reductions in chronic water algal growth tests or vascular plant growth toxicity tests on field-collected water samples. No chronic toxicity to cladocerans in representative non-turbid waters.
- Benthic Invertebrates - Benthic invertebrate samples collected from Quesnel River and the corresponding reference area in Cariboo River had concentrations of COPCs similar to reference conditions.
- Fish – Significant effects were not observed for fish toxicity tests including 7-d Rainbow Trout survival and growth, 30-d Rainbow Trout survival and development, and 7-d Fathead Minnow survival and growth toxicity tests on field collected water samples.

## 3.3 Habitat Remediation Working Group

The HRWG (previously called the Habitat Objectives Working Group) was formed to provide a forum that would enable collaborative input from agencies and First Nations on the remediation of fish habitat based on objectives developed for each area or ecological unit of fish habitat affected by the TSF breach. These objectives are based on physical conditions (e.g., gradient), constructability, life history requirements of the fish species and a broader ecosystem context (e.g., amount of spawning or rearing habitat available). DFO (2014) determined that a S. 35 Authorization under the *Fisheries Act* was not required to carry out the remediation work and that the field design and build approach was a prudent means of advancing such remediation. DFO further recommended the development of a framework to guide the designs where restoration objectives were set for each of the ecological units. The HRWG is composed of DFO, ENV, FLNR, Soda Creek and Williams Lake Indian Bands and their representatives, and MPMC and their representatives. The group has provided input and independent external review of designs to MPMC and its river engineering and habitat ecology Qualified Professionals (QPs).

The HRWG has been the forum in which remedial options for breach-impacted sections of Hazeltine and Edney Creeks are considered and evaluated and become the aquatic remedial plan for that area. The detailed implementation of the remediation plan then becomes the responsibility of MPMC who coordinate equipment and construction materials and the QPs who engineer river work, design habitat elements and oversee their construction. Members of the HRWG carry out site visits either in a regulatory or contributory capacity.

Areas of Hazeltine Creek, Edney Creek, Quesnel Lake and Polley Lake were categorized into EU by the HRWG based on the nature of disturbance and the fish species known to use that area (Figure 4). These EUs are somewhat different from the Remediation Areas or Reaches described in Section 1.3, but are devised to help guide the development of habitat objectives, evaluation of the effects and compare pre-breach and post-remediation conditions. The Working Group developed a habitat remediation framework (separate from the broader remediation framework and specific to habitat) that identified the fish community within each EU, the ecological function of the EU, the pathway, magnitude, and duration of the breach effects, the life history component affected by the breach, available baseline data for pre-breach conditions, and potential indicators that may be used to quantify effects and evaluate the success of remediation.

## 3.4 Input to the RP Through Consultation

The PAO requires:

> *A description of consultation completed with local First Nations and with stakeholders on the remedial objectives and how remedial objectives have been refined taking into account the outcome of such consultation.*

Public and First Nations consultation has occurred prior to the Remediation Plan. In 2011 and 2012, MPMC executed Participation Agreements with the Williams Lake Indian Band (WLIB) and the Soda Creek Indian Band (SCIB), respectively. In August 2016 and April 2017, MPMC and WLIB and SCIB (respectively) renewed these agreements. Through these respective Participation Agreements, Implementation Committees (IC) were formed to facilitate open dialogue between each of the First Nations and MPMC, providing a formalized, regular venue to discuss environmental, social and economic matters related to mine development, operation, reclamation, and closure (e.g., mine updates, permitting, environmental protection, reclamation, employment opportunities, and potential joint ventures). In addition, First Nations have been providing extensive technical input into habitat remediation work through the HRWG and as reviewers of the various documents that form part of the remedial planning basis and habitat remedial designs.

Numerous and varied public and First Nations comments have been received by MPMC before and particularly following the breach. The input subject matter has varied widely. With specific regard to this RP, the following public meetings took place:

- Mount Polley Public Liaison Committee (PLC) on 16 November 2017.
- Williams Lake Public Meeting on 16 November 2017.
- Town of Likely Community Meeting on 17 November 2017 on the Human Health and Ecological Risk Assessments that form part of the remedial planning basis.
- Public Webinar using GoToMeeting™ to project slides via the web and voice via web or telephone on 10 January 2017.
- Public Meetings During December 2018 at: Quesnel, Williams Lake, and Likely.
- A web-based meeting for the Public Liaison Committee on 25 February 2019.

At the above meetings, a number of questions were asked and answers were provided. With regards to questions or concerns raised that may relate specifically to the remedial planning basis, the following items were identified:

- Concerns were expressed by a local resident about potential resuspension of the breach outwash materials that have settled on the bottom of the lake, particularly during lake overturn.
- Concerns have been expressed by some residents who have occasionally observed a green-coloured tinge to the water (this has at times been connected to the preceding bullet), plugging of water intake filters with organic material and local observations that algae growth on rocks appears to be greater than it was before the breach.
- A question was posed by another local resident (and Professional Biologist) about the potential for predation on Trout by birds upon trout re-introduction to upper Hazeltine Creek in 2018.

## Resuspension of Lake Bed Materials

This concern stems from the clear (low turbidity) water characteristics of Quesnel Lake, which local residents and vacationers value and the effect of lake overturn in November 2014 which resulted in the mixing of deeper, post-breach turbid waters with surface waters making the Quesnel Lake surface water cloudy in appearance (turbidity of ~ 15 NTU; MPMC 2014a) over a period of several months until turbidity measurements showed dissipation in the summer of 2015. These concerns have been previously raised as have those of an intermittent cloudiness and greenish hue to the lake. This occasional cloudiness has not been observed by all residents in the area.

The possibility of resuspension of breach outwash materials was identified as a strategic information need to inform remedial decisions and was part of early evaluations carried out as part of the Post-Event Environmental Impact Assessment (MPMC 2015a). Tetra Tech EBA (Tetra Tech 2015a) carried out a study of Quesnel Lake water column quality and evaluations based on a 3-dimensional hydrodynamic model that they constructed. The model predicted that mixing, flushing and settling of the fine-grained breach-related materials suspended in Quesnel Lake would occur but it predicted that resuspension would not occur once these materials had settled. In response to the public concerns noted above and as a cautionary step, MPMC retained Tetra Tech to carry out an updated evaluation using additional information not available in 2015 to re-examine whether re-suspension was likely. The new information available included water column profiling data, data on the rate of sediment deposition, contemporary grain size distribution data from the bed of Quesnel Lake and observations regarding the extent to which settled materials are consolidated, computational analysis of critical bed shear stress forces that would be needed to initiate erosion and the near bed hydraulic loading that could be expected, and remote operated vehicle (submersible) video analysis. Based on the abundant additional observational and computational lines of evidence, Tetra Tech concluded that the tailings would remain on the lake bed (Tetra Tech 2017).

The observations of some, though not all residents, of an occasional mildly cloudy-green hue to the lake that they feel was not there pre-breach cannot be reconciled against the extensive turbidity data set and the observational and computational analyses noted above. Public perception of water colour can, under circumstances be accurate but can also be prone to interference by a variety of factors (Smith et al. 1995). The remedial planning basis adopts the findings based on multiple lines of evidence regarding the physical stability (i.e., that they are not re-suspending) of the tailings (Tetra Tech 2017).

We are aware of subsequent work by university researchers that suggests some turbidity near the lake bed; however, this information is based on a hypothesis. Details of methods and findings have not been published or provided to Golder as of writing.

## Lake Colour, Water Filters and Algal Growth on Rocks

The potential influence of resuspension has formed part of studies as noted above. Regarding the potential for increased organic production in the water column and increased algal growth on the rocks, data are not available to directly address these observations. However, chlorophyll *a* data are available for a period of time before mining at Mount Polley Mine (Nidle et al. 1994) as well as for the years following the breach (Figure 7).
A comparison of whole lake averages over the period for which pre-impact data are available (1985 to 1990) with chlorophyll *a* concentrations in the years following the breach indicates that the algal biomass of Quesnel Lake may have been higher prior to mining at Mount Polley than has been the case following the breach. This suggests that the conditions favouring algal growth are not higher post-breach.

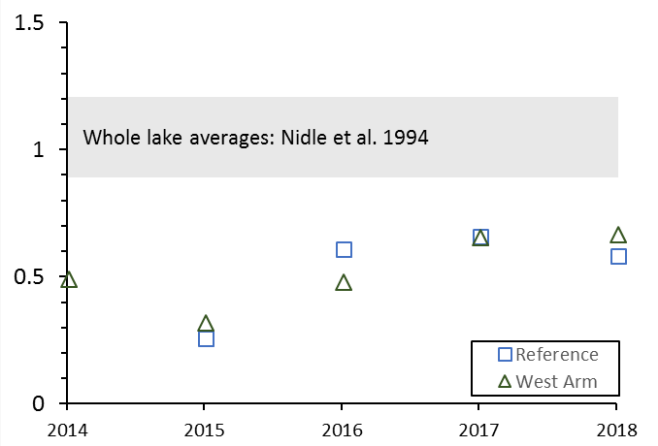

**Figure 7: A comparison of pre-mining (1985-1990) chlorophyll *a* whole lake averages (grey band) concentrations and post-breach chlorophyll *a* concentrations in the West Arm and reference area.**

## Predation by Birds on Fish Re-Introduced to Hazeltine Creek

A question was asked whether consideration had been given to use of anti-avian predator netting upon the re-introduction of fish to Hazeltine Creek. The revegetation along Hazeltine Creek, following habitat build-out will take several years to provide over-story vegetative cover of Hazeltine Creek which, in a natural system provides some cover from predation of fish by birds – though not against all species of piscivorous birds or other piscivorous wildlife. The potential effect of predation on fish re-introduced into Hazeltine Creek was identified in a Golder memorandum (Golder 2017d). The re-introduction took place and while some small numbers of fish were taken by predators, as is natural, there were nevertheless an estimated 18,084 juvenile trout that returned to Polley Lake (Connors et al. 2018). Instream cover installed as part of the second phase of creek remediation provided sufficient protection from predators based on numbers of fish enumerated. MPMC are monitoring the population structure of Polley Lake fish to quantify the adequacy of these steps vis-à-vis fish productivity of Polley Lake Trout.

### 3.4.1 Remediation Plan Implementation – Future Consultation

Implementation of the remedial plan will require consultation with regulators, First Nations and the local community. The purpose of this consultation is to inform, listen to concerns and provide answers, identify whether revisions to the CEMP are needed, take input to enhance the outcomes of remedial work and to comply with statutory/permit requirements. Some of the bodies with whom beneficial consultation would occur are:

- BC ENV, FLNR, DFO – regulatory oversight, technical expertise from the respective agency).
- MPMC Public Liaison Committee – community representatives who are expected to bring community concerns to the table from the community and to facilitate the dissemination of information provided by MPMC and a forum to discuss concerns, concepts, ideas and community aspirations.
- HRWG – technical input from local knowledge of First Nations and their staff, technical input and oversight by agency specialists.
- First Nations Implementation Committee – a forum that includes environmental remediation topics but also includes broader First Nations/MPMC relations, opportunities and concerns.
- Public meetings/field tours – direct engagement of the broader community (i.e., beyond the public liaison committee) to provide information updates and opportunities to directly observe remedial works.

# 4.0 REMEDIATION PLAN

This RP identifies the proposed actions to remediate residual effects from the TSF breach identified by the preceding assessments (Golder 2016a, 2017b,c). This report provides a consideration of options for remediation of those risks and an evaluation and recommendation of the selected remedial option. Where remediation has already started or is substantially advanced in certain areas, the RP describes the process under which the remedial options were developed and selected. An example of the latter situation was the initiation of Hazeltine and Edney Creek remediation, on an expedited basis, to control erosion and turbid water discharge and, in the case of Edney Creek to reconnect unaffected habitat in the upstream portions of Edney Creek with Quesnel Lake to allow access to the watershed by fish returning to spawn. In this case, various remedial options were identified and considered as the work progressed, with oversight and input provided by the HRWG.

The RP is presented by area with a presentation of the generalized approach applicable to the main habitat types (creek, terrestrial and lake). Quantification of habitat losses and identification of potential remedial/offset requirements in each EU is provided in Section 5.0.

## 4.1 Remediation Plan Components and Linkages

The remediation plan has been developed as information has been obtained from the numerous studies that have been carried out. The plan has connections to those studies, regulatory requirements, outcomes, and specific actions to be taken (e.g., habitat remediation and habitat offsets, monitoring). Figure 8 shows various components of the remediation plan and how those components are linked to information obtained as part of preceding studies, actions that have been taken, still need to be taken and how those actions lead to compliance with regulatory requirements. It should be noted that compliance is expected to be part of an ongoing compliance program by MPMC and that there are several long-term commitments for MPMC. Figure 8 is a process diagram that represents how remediation plan components turn into specific work, how that work is monitored and adjusted based on verification monitoring as part of MPMC's long-term commitments and how the remediation plan is linked to compliance when concluded.

The RP linkages start with the breach event. In addition to standing regulatory requirements under both federal and provincial law, formal and specific regulatory requirements were invoked by ENV and FLNR the following day (PAO, EO). DFO relied on the general provisions contained in the *Fisheries Act*. The remedial design basis, summarized in Section 3.0, results in five outcomes that have connection to remediation. These are:

- Human health risks are acceptable and remediation for that purpose is not required.
- Some ecological risks are acceptable and remediation for that purpose is not required.
- Some ecological risks are acceptable but there is scientific uncertainty in that determination. Remediation is not identified for such risks, but monitoring is a requirement to address that uncertainty. Verification and, if data show it is necessary, then remedial work plans to address those risks would be developed.
- Some ecological risks are uncertain – neither an absence nor clear conclusion regarding risk can be made with current data. In such cases, a specific focused study/monitoring program is carried out as an addendum to the CEMP process. The results of that study will either identify the need for more detailed assessment, identify that risks are absent (compliance) or identify that remediation is required. For the latter finding, a remedial work plan would be developed.

- Remediation is clearly required (e.g., where an environmental effect has been identified without need for clarifying study). Remediation approaches are recommended in later sections of this plan. Because the remediation work is focused on habitat remediation, this includes identifiable physical work that has been completed, in progress, or to be carried out on site and habitat offsets to address impacts and productivity losses (including time) resulting from the breach.

The areas where physical remediation work was required are those involving physical damage to aquatic and terrestrial habitats and those involving public safety risks. The focus of the RP is therefore on planning out the amounts of habitat that are needed to offset the losses from the TSF breach event. Some of those offset "credits" have been and will be constructed at the location where the damage took place. However, additional offset habitat will be needed, and the amounts are set out in subsequent section of the RP. Figure 8 outlines a high-level process flow for evaluating habitat losses, identifying habitat designs, quantifying habitat "debits" and "credits" and quantifying offset requirements. That process has been set out in general by the HRWG, is described quantitatively in the RP and remains part of MPMC's long-term commitments. These long-term commitments include monitoring of remediated habitats (including for contaminant endpoints), quantification of "credits" and "debits" and outstanding "balance" of offsets owing. The specific offsetting projects will be determined by the HRWG, as they have been since the early stages of breach response. Habitat verification will include maintaining a ledger of offsets completed, credits "made good" and habitat work still owed.

Habitat monitoring is a necessary component of the RP because uncertainty exists when habitat is constructed. When uncertainties are known and anticipated, they can form part of the design process and calculations, but verification monitoring of physical habitat stability and function remain necessary. Some of the common means of addressing uncertainty in habitat remediation is using arbitrary compensation ratios *a priori*. Such ratios are typically reduced or eliminated when habitat is constructed in advance of a loss because structure and function can be verified, thereby addressing the uncertainty of outcome. Given the scale of the TSF breach event, we have proposed the use of Habitat Equivalency Analysis (HEA; Section 4.2.4) and performance verification to address uncertainty. Offsets can therefore be scaled to provide a reasonable amount of offset habitat and can be scaled upwards should actual habitat function fall short of expectations. MPMC's long-term commitments are underlain by attainment of regulatory requirements.

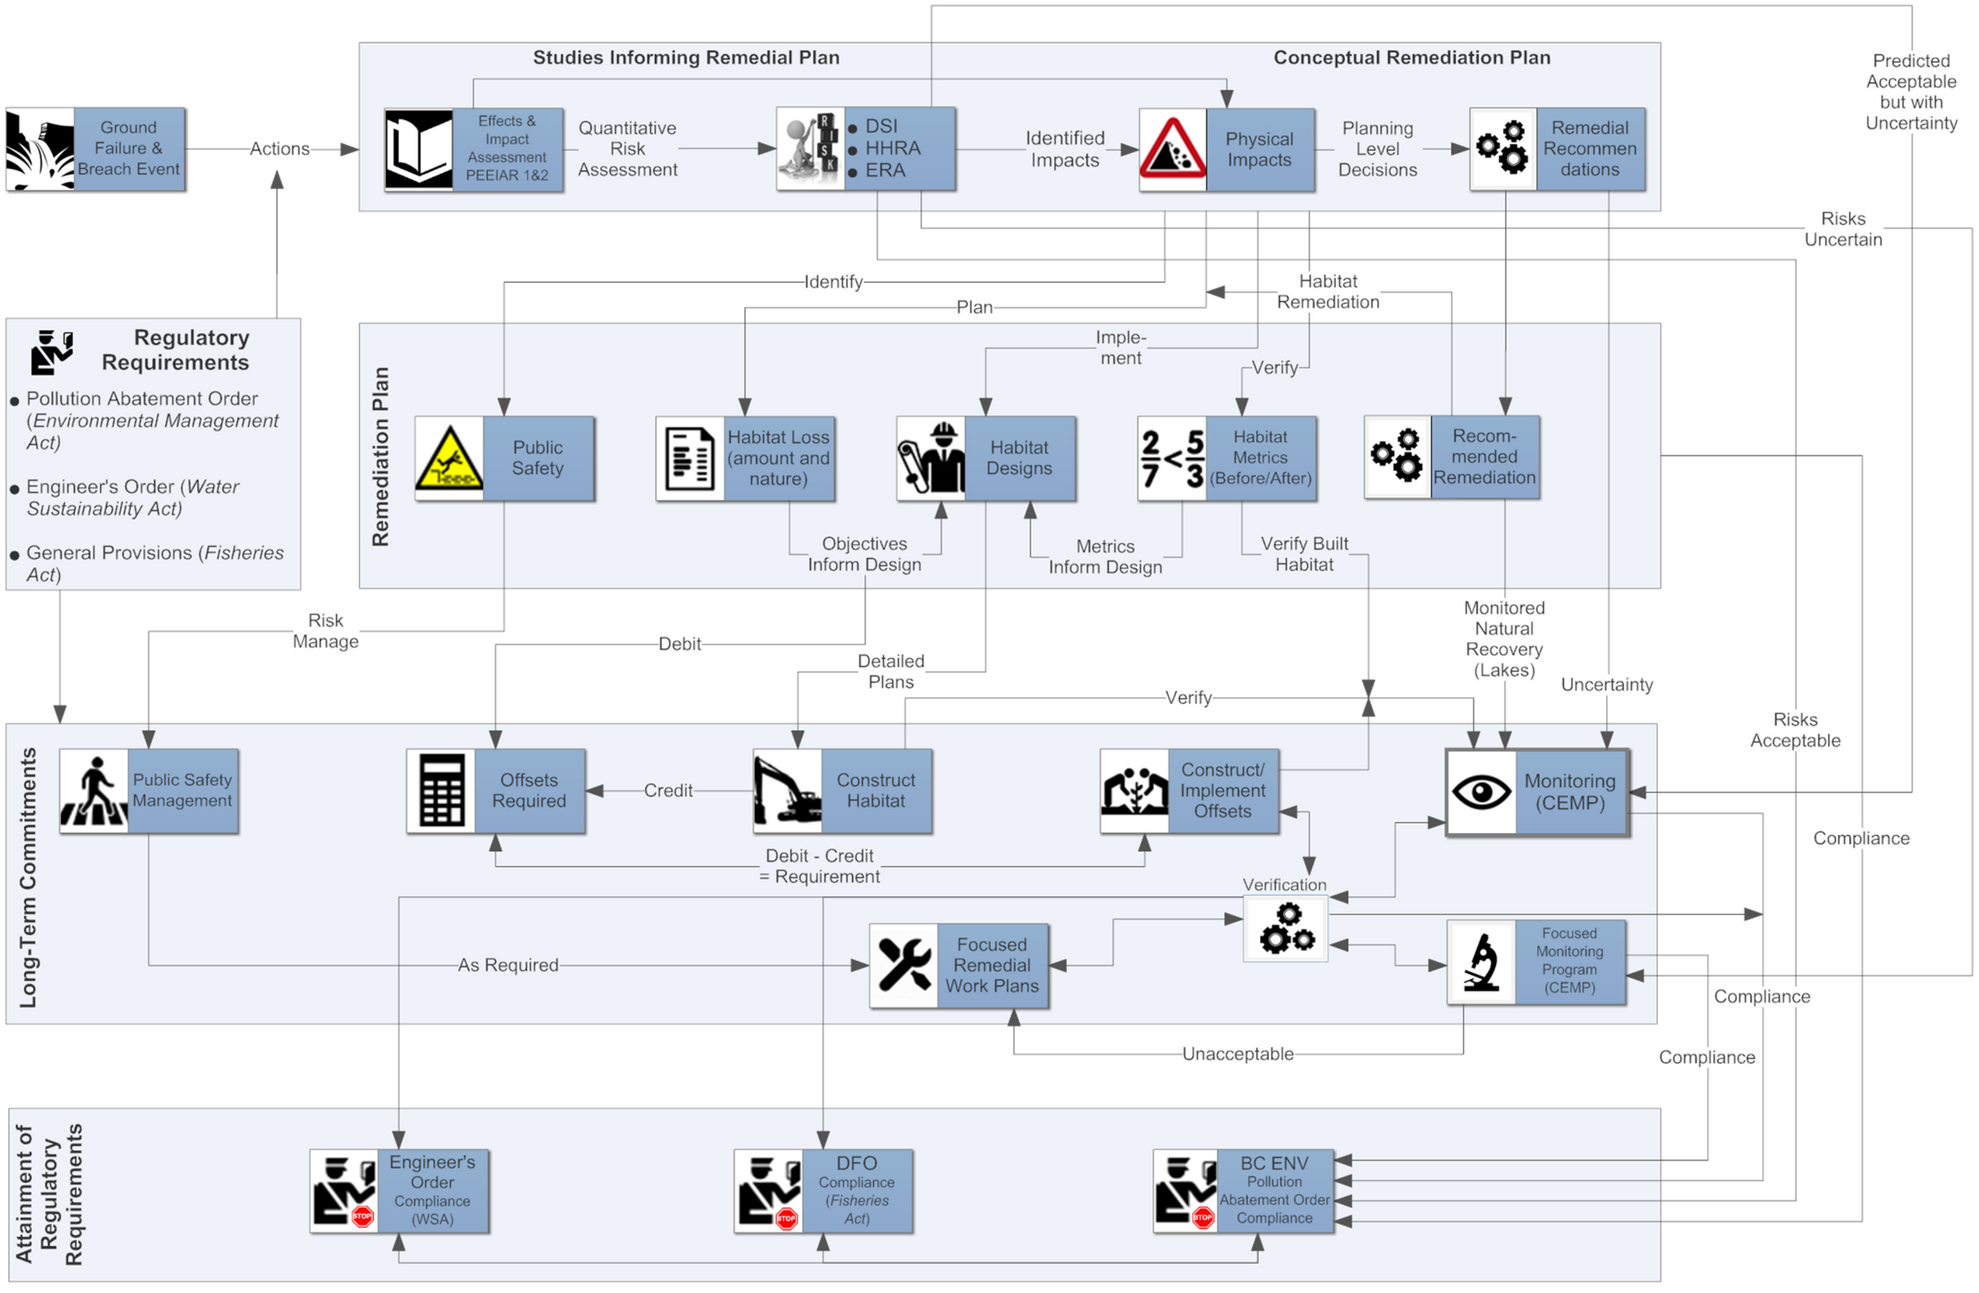

**Figure 8: Diagrammatic Representation of Remediation Plan Component Linkages**

## 4.2 Remediation and Offsetting Approach

### 4.2.1 Remediation of Creek Habitats

Based on the remedial planning basis for the creek habitat, remedial needs for creek habitat are associated with the physical impacts of the breach event. The overall remedial objective for impacted stream habitats is to restore the life history functions of fish, particularly salmonids, by constructing an engineered stream base in the otherwise erodible (fluvial and lacustrine) native sediments below Hazeltine Creek, with habitat features to support an aquatic ecosystem. Design features will also restore ecological functions for wildlife associated with small streams and their riparian environments. For the purposes of developing habitat objectives for creek remediation, the HRWG defined ecological units and potential pathways of effects in a manner guided by DFO (2012) (Table 2).

**Table 2: Potential Pathways of Effect Associated with Creek Ecological Functions and Indicator Fish Species (DFO 2012)**

| Remediation Area / Ecological Unit | Ecological Function | Potential Pathway of Effect | | | | Indicator Fish Species |
|---|---|---|---|---|---|---|
| | | Deposition of Material | Alteration or Removal of Structure | Alteration of Riparian Habitat | Exclusion from Habitat by Temporary Fences or Blockages | |
| Upper Hazeltine (H1) | Spawning | ● | ● | | ● | Rainbow Trout |
| | Rearing | ● | ● | ● | | |
| | Overwintering | ● | ● | | | |
| | Migration | ● | | | ● | |
| Lower Hazeltine Creek (H2) | Spawning | ● | ● | | | Rainbow Trout<br>Coho, Chinook and Sockeye Salmon<br>Kokanee<br>Mountain Whitefish<br>Burbot |
| | Rearing | ● | ● | ● | | |
| | Overwintering | ● | ● | | | |
| | Migration | ● | | | | |
| Upper Edney Creek (E1) | Spawning | | | | ● | Rainbow Trout |
| | Migration | | | | ● | |
| Lower Edney Creek (E2 and E3) | Spawning | ● | ● | | | Rainbow Trout<br>Coho, Chinook and Sockeye Salmon<br>Kokanee<br>Mountain Whitefish<br>Burbot |
| | Rearing | ● | ● | ● | | |
| | Overwintering | ● | ● | | | |
| | Migration | ● | | | | |

● - pathway of effect potentially operable.

Pre-disturbance morphology of Hazeltine Creek is relatively well known due to previous stream assessment work done in the area (Bruce and Slaney 1991, MPMC 2009). An important aspect of the remedial design of fish habitat is the integration of three specific channel meander patterns. Each pattern is associated with features of the overall channel of Hazeltine Creek, specifically the lower floodplain, the mean annual flood (MAF) channel, and the low flow channel. The primary meander pattern is exhibited by the lower floodplain; this part of the overall floodplain will be engaged by flows associated with freshet. The second meander pattern is displayed by the MAF channel. This channel can convey the average peak discharge of Hazeltine Creek throughout the year; flows overtop the channel during freshet and enter the lower floodplain. The MAF channel meanders off the centre line of the lower floodplain. The tertiary meander pattern is associated with the low flow channel. This channel meanders off the centre line of the MAF channel. It will concentrate low flows during late summer, fall and winter.

The process of creek habitat remediation that has been carried out is as follows:

- Habitat objectives for each reach of stream habitat were determined by the HRWG and in some cases (detailed in the sections below) habitat that fits those objectives has been constructed.
- Based on these objectives, channel morphology and habitat characteristics are designed and reviewed with the HRWG before being constructed.
- Following the construction of the habitat based on reach-specific objectives, the habitat is evaluated based on pre-determined criteria (set by HRWG; Table 3) and residual effects of the TSF breach on fish habitat and the functionality and value of the habitat is evaluated to determine whether habitat offsetting measures to address residual effects are warranted. In addition, the HRWG will follow DFO policy (DFO 2013) to developed criteria for evaluating, ranking and selecting appropriate offsetting measures.
- All construction and repair is documented, and record drawings are produced. Once the initial habitat meets the design specifications, monitoring based on the evaluation criteria (Table 3) continues annually until the habitat has reached project objectives. Post-construction evaluation may result in adjustments or repair to installed habitat features resulting in another round of implementation and evaluation.

A list of design and record drawings issued for Hazeltine Creek remediation is provided in Appendix A.

Creek habitat remediation by remediation area / reach is described in further detail in the following sections for each of the areas.

**Table 3: Metric Criteria for Defining Poor, Fair, and Good Quality Stream Habitat and Channel Structure and Form**

| Habitat Parameter | Quality Rating | | |
|---|---|---|---|
| | Poor | Fair | Good |
| Bankfull width-to-depth ratio | >25:1 | 16-25:1 | ≤15:1 |
| Entrenchment ratio | <1.4 | 1.4 to 2.2 | >2.2 |
| Channel complexity | <2 mesohabitat units/10xWbf | 2-3 mesohabitat units/10xWbf | 3 mesohabitat units/10xWbf |
| Percent pool (by area)* | <15 | 15 to 40 | 40 to 60 |
| Pool frequency (mean pool spacing)* | >10 channel widths/pool | >8-10 channel widths/pool | <8 channel widths/pool |
| Holding pools (adult migration) | <1 pool/km >1 m deep with good cover (30% of pool area) | 1 to 2 pools/km >1 m deep with good cover (30% of pool area) | >2 pools/km >1 m deep with good cover (30% of pool area) |
| LWD pieces per channel length, measured as bankfull width* | <1 | 1 to 2 | >2 |
| Percent wood cover in pools* (i.e., wood cover as a percent of pool area) | pools in reach average 0 to 5% LWD cover | pools in reach average 6 to 20% LWD cover | pools in reach average >20% LWD cover |
| Spawning substrate size, quality and area | size mostly <6 or >60 mm; >25% fines (<2 mm); <10% spawning gravel area within wetted area of all habitats surveyed | size 6-60 mm; 15 to 25% fines (<2 mm); ≤25% spawning gravel area within wetted area of all habitats surveyed | size 6-60 mm; ≤15% fines (<2 mm); >25% spawning gravel area within wetted area of all habitats surveyed |

Modified after Johnston and Slaney 1996, Slaney and Zaldokas 1997, Newbury and Gabourey 1993 and Hickman and Raleigh 1982.

Note: For riffle-pool streams with mean gradient <2%, bankfull widths <15 m, and for summer/winter rearing use.

LWD - Large woody debris; Wbf – bankfull width.

The quality ratings are specific to the habitat parameters identified by the HRWG and are not intended to imply quality of remediation.

### 4.2.2 Remediation of Lake Habitats

The residual effects that require remediation in Quesnel and Polley Lakes are risks that arise from the physical impacts of the breach outflow and associated materials and the low organic carbon content which is characteristic of the tailings material. The size and profile of a lake results in distinct ecological components that have implications for habitat types and fish usage, and ultimately the influence that the event had on Polley Lake and Quesnel Lake. These components are illustrated in Figure 9 and described below:

- Benthic – associated with the lake bottom.
- Emerging insects – insects that have a water-based larval stage and a flying adult stage.
- Epilimnion – the water column above the thermocline.

- Hypolimnion – the water column below the thermocline.
- Limnetic zone – the portion of the water column through which light penetrates.
- Littoral zone – the area of the lakeshore where aquatic plants grow. In Quesnel Lake, this area is variable but approximately 4 to 6 m deep.
- Phytoplankton – free-floating plants/algae and photosynthetic bacteria.
- Profundal zone – the portion of the water column that light does not reach and as a result does not support plant growth. Elsewhere in this report, this may also be referred to as the “benthic” zone.
- Thermocline – a sharp density gradient in the water column that limits mixing of the water column which is caused by differences in temperature between the upper and lower water column. In the summer, the surface of the water column is warmer and the water at depth is cooler.
- Zooplankton – free-floating invertebrates.

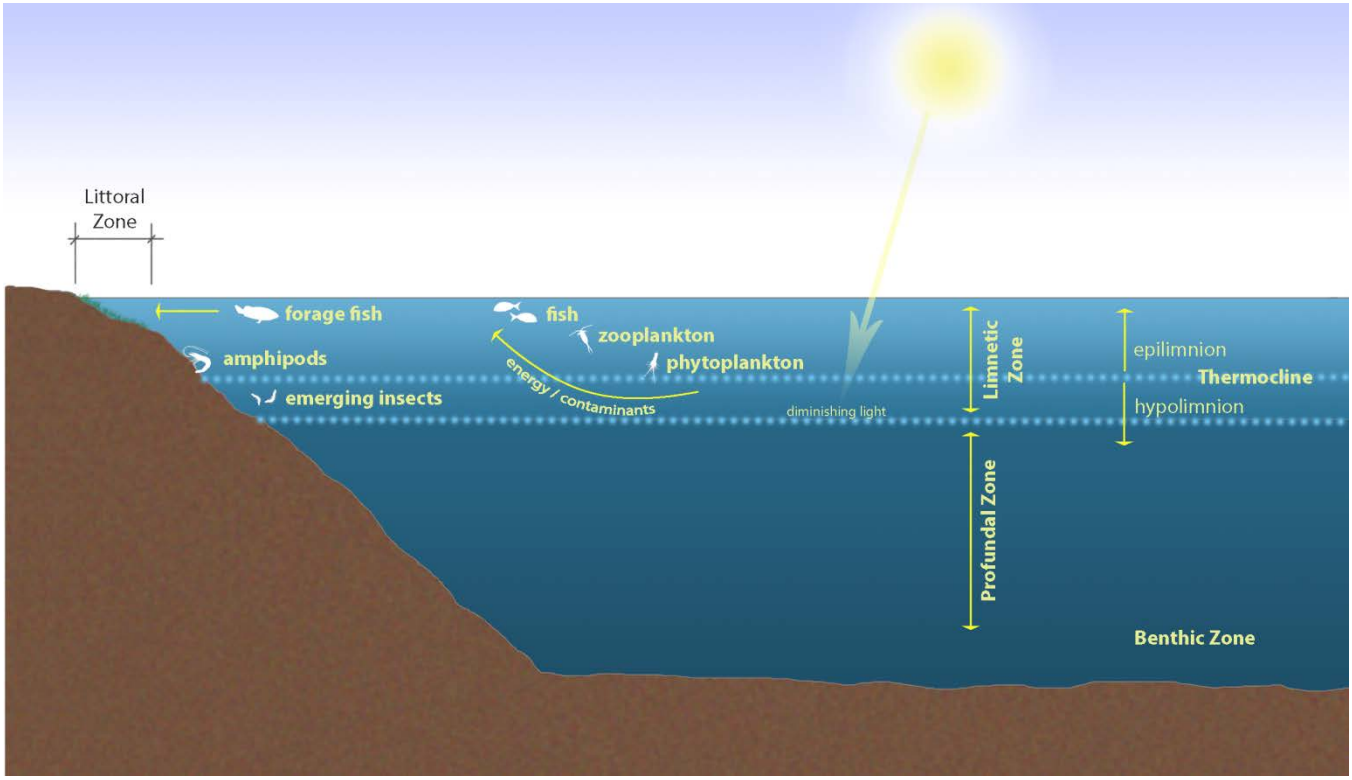

**Figure 9: Generalized Conceptual Ecological Model for a Lake**

Golder (2015c) reviewed life history and feeding requirements for the 20 fish species identified in Quesnel Lake and developed a conceptual ecological model for fish-habitat-food assemblages in Quesnel Lake, of which three general assemblages were identified:

- Littoral zone and benthic habitats – Fish associated with the littoral zone and benthic habitats are oriented to the near-shore environment and feed largely on benthic prey, periphyton, or in some cases crustacean zooplankton in the water column (McPhail 2007, Scott and Crossman 1973). Fish in this group include juvenile stages of salmon (*Oncorhynchus* spp.) and adult and juvenile Mountain Whitefish (*Prosopium williamsoni*) which eat plankton, Lake Whitefish (*Coregonus clupeaformis*) and Pygmy Whitefish (*Prosopium coulterii*), and juvenile Burbot (*Lota lota*), which are benthivores (i.e., their food comes from benthic substrates), and forage fish such as sucker, sculpin, chub, shiner and Northern Pikeminnow (*Ptychocheilus oregonensis*). The forage fish have a range of feeding habits and may consume primarily benthic invertebrates or periphyton, or in the case of Northern Pikeminnow, eat other fish (i.e., they are piscivorous). Other fish considered in this assemblage are adult Burbot, which are also piscivorous, and make vertical migrations in the summer to feed on Trout, minnow, sucker and sculpin.
- Open-water habitat and fish that feed on emerging insects – Fish that are associated with open-water habitat and feed on emerging insects include Mountain Whitefish, which typically inhabit the upper 20 m of the water column, and smaller Rainbow Trout, which undertake a diel (i.e., daily) vertical migration (McPhail 2007, Scott and Crossman 1973). Larger adult Rainbow Trout in Quesnel Lake may consume juvenile Sockeye Salmon and Kokanee (Parkinson et al. 1989).
- Open-water habitat and fish that feed on crustacean zooplankton - The assemblage of fish that is associated with open-water habitat and that feed on crustacean zooplankton consists of juvenile Sockeye Salmon which undertake a diel vertical migration, orienting to the lower boundary of the thermocline at night (Levy et al. 1991) and descending to 60 to 80 m depth at night (McPhail 2007; Morton and Williams 1990; Scott and Crossman 1973). Kokanee also undertake a vertical migration, generally feeding near surface at dawn and dusk, and staying below the thermocline during the day and at night. During the summer, this assemblage may also include Lake Trout (*Salvelinus namaycush*).

The conceptual ecological model for Polley Lake is a simplified version of that of Quesnel Lake. Rainbow Trout is the only CRA fish species present and other fish in the lake include Longnose Sucker and Redside Shiner. The conceptual model for open-water habitat and fish that feed on emerging insects is applicable to Rainbow Trout.

For the purposes of developing habitat objectives for lake remediation, the HRWG refined the conceptual ecological model for Quesnel Lake into three ecological units and selected ecological functions and indicator fish species for each unit (Table 4) in a manner guided by DFO (2012). Polley Lake is considered one ecological unit.

As described in previous sections, the breach event resulted in scouring and deposition of material in and along Polley Lake and Quesnel Lake and temporarily altered water quality. The ERA indicated that altered water quality is no longer an operable pathway of effect and thus the focus of the identification of potential lake remediation needs was on physical effects. Physical habitat remediation and offsets will be addressed by the HRWG. An analysis of the remedial options for Quesnel Lake is provided in Section 4.11. For Polley Lake, the options evaluation would be based on similar considerations although the circumstances of Polley Lake are different in terms of its stage of benthic community recovery and it has specific issues with regards to the age class structure of Rainbow Trout in Polley Lake.

**Table 4: Potential Pathways of Effect Associated with Lake Ecological Functions and Indicator Fish Species (DFO 2012)**

| Ecological Unit | Ecological Function | Potential Pathway of Effect | | | | Indicator Fish Species |
|---|---|---|---|---|---|---|
| | | Deposition of material | Alteration or Removal of structure | Alteration of Riparian Habitat | Exclusion from Habitat by Temporary Fences | |
| Polley Lake | Spawning | ● | ● | | ● | Rainbow Trout |
| | Rearing | ● | ● | ● | | |
| | Overwintering | ● | ● | | | |
| | Migration | ● | | | ● | |
| Quesnel Lake Limnetic Zone | Rearing | | | | | Rainbow Trout, Coho Salmon, Chinook Salmon, Sockeye Salmon, Mountain Whitefish, Bull Trout, Kokanee, Lake Trout, Lake Whitefish, Pygmy Whitefish, Burbot |
| | Migration | | | | | |
| Quesnel Lake Littoral Zone | Spawning | ● | ● | | | Rainbow Trout, Coho Salmon, Chinook Salmon, Sockeye Salmon, Mountain Whitefish, Bull Trout, Kokanee, Lake Trout, Lake Whitefish, Pygmy Whitefish, Burbot |
| | Rearing | ● | ● | ● | | |
| | Migration | | | | | |
| Quesnel Lake Benthic Zone | Rearing | ● | ● | | | Rainbow Trout, Bull Trout, Lake Trout, Mountain Whitefish, Pygmy Whitefish, Lake Whitefish, Burbot |

● - pathway of effect potentially operable.

### 4.2.3 Remediation of Terrestrial Habitats

Aquatic ecosystems are linked to adjacent terrestrial ecosystems by transitional riparian zones and wetland areas (Gregory et al. 1991). For the purposes of this report, terrestrial ecosystems include riparian areas, floodplains and upland areas that may escape even the highest water levels. The residual effects to terrestrial habitats that need to be remediated are from the physical impacts of the breach outflow and because the tailings lack the heterogeneity and nutrient processing that is part of a healthy soil or sediment ecosystem. The physical impacts (e.g., undercutting of banks, scour) have in part been addressed through the re-contouring of the slopes along Hazeltine Creek; however, the loss of forest soils is part of the needed remediation.

Terrestrial conditions after the TSF breach consisted of a general absence of original vegetation in the Hazeltine Creek corridor and floodplain. The force of the debris flow diminished at the edges of the floodplain, such that the trees in the “halo” zone were not uprooted, but the forest floor was covered by a variable thickness layer of mixed tailings, soil and debris. Where the tailings cover was thicker, it led to anoxic conditions in the location of the tree root causing root death and eventually the trees died (Golder 2015a). Further summary of the impacts to the forest community within the halo area is provided in Golder (2016a, 2017c).

The general forest successional process, as observed in natural disturbances, can be emulated, with enhancement, when re-establishing functional ecosystems on disturbed sites. Successful remediation will put reclaimed ecosystems onto a trajectory that will eventually lead to successional processes similar to natural systems. Deliberate actions such as mixing in natural soils which contain soil fauna and local seed banks, selecting and planting appropriate species that accelerate restored soil structure and making the soil more “rough and loose” to enable seed and oxygen penetration and root formation will accelerate the speed with which that trajectory can progress. The goal is to establish naturally diverse and functional communities on the ecosystem, landform, and landscape scales. These ecosystems will provide services similar to undisturbed ones. The establishment of this trajectory will develop conditions that allow a self-sustaining ecologically diverse community in the affected riparian and adjacent forest areas. Part of developing this trajectory is to establish key pioneering species which are typically tolerant of difficult growing conditions, contribute to the re-establishment of soil organic content and soil fauna, and establish suitable growing conditions for later-successional seedlings by creating shade and increasing relative humidity in the understory (Walker and del Moral 2003).

The terrestrial remediation strategy applied by MPMC takes a managed successional trajectory approach to remediation, based on the principles of ecological succession, and relies on the assisted auto-regeneration capacities of vegetation and natural processes of soil renewal. Site preparation methods can be used to A) mix forest floor, mineral soils and any residual tailings to increase soil porosity, B) create raised microsites that have aerated root zones, and C) create plantable microsites. These approaches have been applied in the breach-impacted terrestrial areas. If monitoring indicates it to be necessary, soil fertility can be further improved in areas with nutrient deficiencies by applying soil amendments such as imported soils, microbial inoculum and fertilizer in planting zones or in each planting hole. In the areas where site preparation has yet to be applied, it is important to preserve the organic matter in situ as much as possible and avoid soil compaction during site work.

Once soil conditions are amenable to seed germination and growth, early successional species will establish and late successional species will slowly colonize through dispersal from nearby seed sources. To assist this process, various planting efforts have been undertaken to establish early-mid successional native species in the TSF breach area.

The choice of the remediation target for terrestrial ecosystems is based on the types of habitats and ecological parameters of a given area, according to local ecosystem classification and end land use. The goal of remediation in this case is to assist the establishment of as many functional elements as possible relative to target ecosystems. MPMC is currently in the process of implementing terrestrial remediation and revegetation actions in the TSF breach area and these efforts are detailed for each Remedial Area in the report sections that follow.

Target ecosystems are based on the BC Biogeoclimatic Ecosystem Classification (BEC) system, which categorizes ecosystems using a hierarchical system. Landscapes are divided into zones, subzones, and variants based on climate (Pojar et al. 1987). BEC subzones are further divided into site series, which are ecosystems that are classified on the basis of site, soil, and vegetation characteristics, resulting in sites capable of producing the same basic mature or “near-climax” plant communities (Meidinger and Pojar 1991). The TSF breach area falls within the Interior Cedar Hemlock biogeoclimatic zone (ICH) and the Quesnel Wet Cool (ICHwk2) and Horsefly Moist Cool (ICHmk3) subzone variants.

Revegetation as part of the RP uses the BEC system to identify appropriate ecosystem targets (i.e., late succession ecosystems) by matching site conditions of areas to be rehabilitated to predicted site series in the ICH-wk2 and -mk3. Vegetation communities present in the TSF breach area were primarily riparian and wetland communities along Hazeltine Creek consisting of forested, shrub-dominated or meadow vegetation communities. The distribution of pre-breach mapped ecosystems is shown in the PEEIAR, (Appendix G: Terrestrial Wildlife and Vegetation; MPMC 2015a).

Considerable planting has occurred under the direction of MPMC, by experienced contractors, in the breach outwash area. Planting data provided by MPMC are broken down as follows:

- all of Hazeltine Creek
  - shrubs (355,112)
  - conifers (192,480)
  - wattles (10,498 meters)
  - ground cover by seeding (136 ha)
- lower floodplains and Quesnel Lake shoreline
  - willow and cottonwood wattles and stakes (1 stem per 0.5 to 1m spacing, planted along shorelines and creek edges)
  - plug stock comprised of Prickly Rose, Red Oiser Dogwood, and Black Twinberry planted (planting density of 15,000 to 20,000 stems/ha)
- Ground Cover Seed – Mixed species
  - 25% Mountain Brome
  - 25% Bluebunch Wheatgrass
  - 25% Blue Wildrye
  - 14.31% Rocky Mountain Fescue
  - 10% Native Red Fescue
  - 0.014% Fireweed
  - 0.68% Big Leaf Lupine

### 4.2.4 Offsetting Approach

As discussed in Section 4.1, it is expected that additional habitat will need to be provided to offset for the temporal loss of habitat use following the breach and before habitat remediation has been undertaken. This section presents the approach that is being taken to estimate the quantity of offsetting that will be needed, specifically, habitat equivalency analysis (HEA). Examples of these calculations are provided in Section 5.0. In some cases, the available data may not support an offsetting calculation, or it may not be feasible to construct in-kind habitat (e.g., deep lake benthic habitat) and therefore alternative approaches to deriving offsetting estimates are also provided in Section 5.0. Concepts for potential offsetting options are also discussed in Section 5.0.

HEA is a procedure initially developed by NOAA (1995) and provides a framework for determining the area required for compensatory restoration (i.e., offsetting) for temporary habitat disturbances (Kohler and Dodge 2006). The main assumption underlying HEA is that the losses of habitat resources can be compensated for (offset) by habitat replacement projects that provide additional resources of a similar type. The more commonly used methods apply subjective offsetting ratios. A key difference in this application of such ratios in land development scenarios is that the habitat loss is complete and permanent (e.g., where a shoreline area is filled in for construction of a land-backed wharf or a stream is covered by a structure), whereas the nature of habitat impact resulting from the breach event is a temporary disturbance and / or reduction in function (e.g., productivity, organism movement), provided that the loss has been rehabilitated. The HEA approach is thus a more appropriate means of estimating the amount of habitat that would offset such impacts because it recognizes the temporary nature of the “injury”. An illustration of the concepts behind HEA is provided in Figure 10.

1. **Productive capacity** - the maximum natural capability of a habitat to produce fish or to support aquatic organisms upon which fish depend, or in other words the physical area of substrate. Productive capacity remains even in the absence of an ecosystem function or productivity (see note 2), such as may result from contamination or temporary disruption to or alteration of physical habitat. For the purposes of this conceptual model, productive capacity is defined as the area of habitat available ($m^2$).
2. **Productivity** –the sum of production rates in a given area. Productivity integrates the contribution of primary production, food, cover and other habitat variables to producing fishery resources. For the purposes of this conceptual model, productivity is considered to be a nominal "output" per area (output/$m^2$). In the context of HEA, productivity may also be termed as "ecosystem services".
3. **Disturbance –** a disturbance to productivity, in the case of the Project involves changes to physical habitat or introduction of contaminants that affect productivity.
4. **Recovery –** recovery refers to a return of productivity and occurs where productive capacity (physical habitat) remains. The period of recovery is dependent on the ecosystem type. For example, lakebed sediments will recolonize with benthic organisms relatively rapidly, whereas replanted riparian vegetation make take multiple years to reach expected productivity.
5. **Lost productivity** – the production or ecosystem service lost following a temporary disturbance of the habitat. The productive capacity is assumed to remain.
6. **Habitat Equivalency Analysis** – HEA converts lost productivity (or ecosystem services) accumulated over time (if applicable) into an equivalent area (potential productive capacity)
7. **Equivalent compensatory habitat** – the area of habitat that can be constructed to offset lost productivity during a temporary disturbance.
8. **Compensatory habitat construction –** will increase productive capacity and in turn contribute productivity to offset losses experienced during a temporary disturbance.

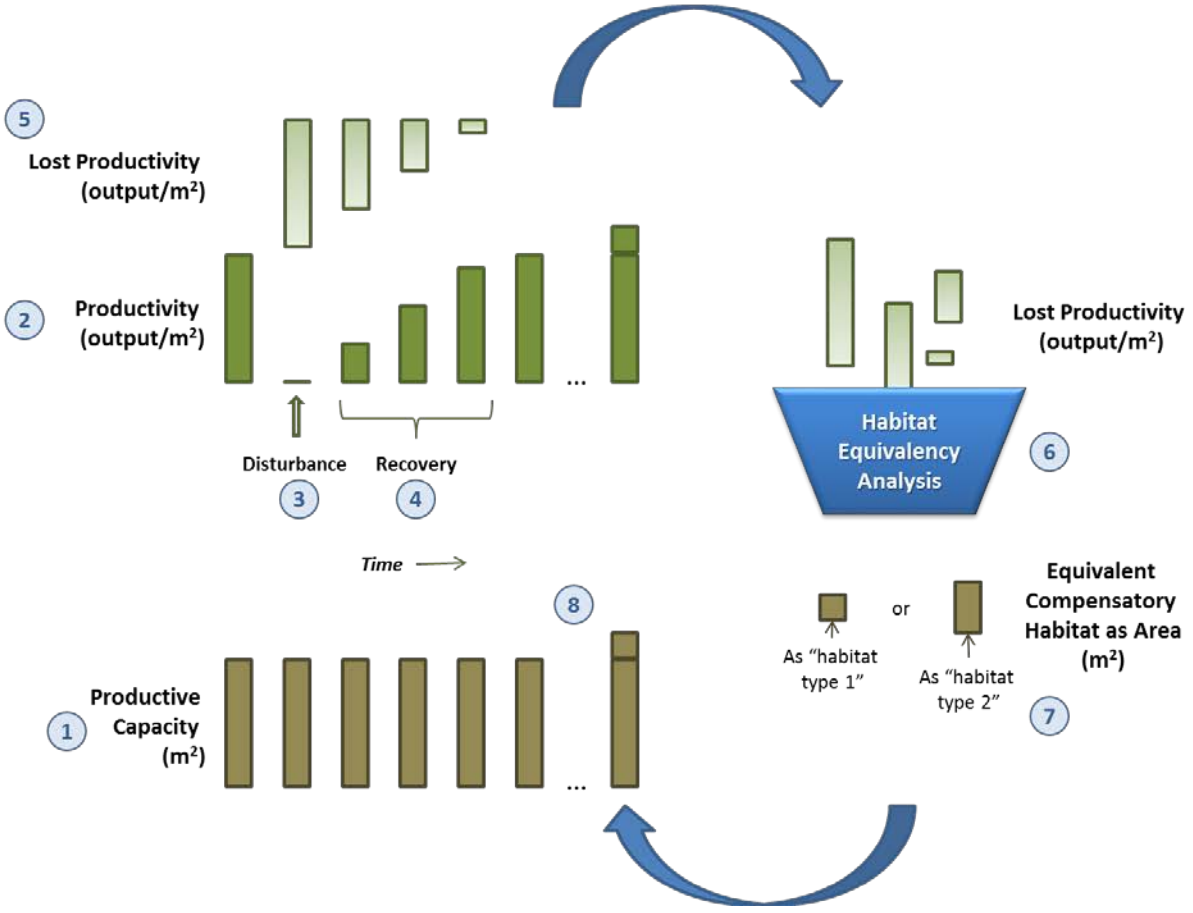

**Figure 10: Illustration of Habitat Equivalency Analysis Concept**

The HEA concept developed by NOAA (1995) is expressed as a complex equation:

$$J * V_j * \sum_{t=0}^{N+1}\left[(1+r)^{C-t} * \frac{b^j - 0.5\left(x_{t-1}^j + x_t^j\right)}{b^j}\right] + \left[\left(\frac{b^j - x_{t=N+1}^j}{b^j}\right) * \frac{1}{r} * (1+r)^{C-(N+1)}\right] =$$

$$P * V_p * \sum_{t=I}^{M+1}\left[(1+r)^{C-t} * \frac{0.5\left(x_{t-1}^p + x_t^p\right) - b^p}{b^j}\right] + \left[\left(\frac{x_{t=M+1}^p - b^p}{b^j}\right) * \frac{1}{r} * (1+r)^{C-(M+1)}\right]$$

Kohler and Dodge (2006) translated NOAA's equation into user-friendly software, Visual_HEA (with updates per Pioch et al. 2017), that requires the following input parameters:

- **Year of "claim".** This is the year in which the habitat damages/harmful disruption are made. The "claim" is an anchor point in time. The HEA calculations use the claim year as the reference point in calculating discounted service levels. The discount level at the time at which the damages were incurred is 1.0.
- **Service loss parameters from the habitat disruption.** This includes the size of the habitat damages/harmfully disrupted area and the time history of the loss of services at the disrupted site. In other words, it identifies the duration and level of service loss from time of disruption through habitat compensation.
- **Compensation ratio.** This parameter is the ratio of the area of disrupted habitat to the area of compensatory habitat. In this formulation of the Visual_HEA program, the compensation ratio is held constant throughout the analysis and was assumed to be 1:1 because of the system of monitoring and offset adjustment. The compensation ratio required by DFO for a given project is intended to qualitatively consider the length of time it takes for the habitat to become functional and/or for potential uncertainty in the habitat functioning as anticipated (DFO 2010). When there is uncertainty in the success of the new habitat, variance in the quality of habitat being replaced, and the lag time required for the new habitat to become functional DFO may request a higher ratio. HEA replaces arbitrary ratios with scientifically supportable estimates of recovery duration and in this RP, uncertainty in those estimates is accounted for through verification monitoring and adjustment of offsets owing.
- **Discount rate.** This default parameter incorporates the assumption that services provided sooner are more highly valued than those provided later. Because service losses and gains occur at different times, they should be adjusted to be compared. This adjustment is accomplished using a "discount factor" which decreases the value of future services and increases the value of past services to reflect the service benefits today. The incorporation of a discount factor therefore rewards the early construction of habitat and penalizes delays in constructing habitat. This discount rate is specified as a percentage rate per time unit; a default of 3% is commonly used as this is analogous to the common default inflation rate used for evaluating financial costs into the future. The discount rate does not consider potential short term economic fluctuations that may influence inflation.

- **Baseline levels of services.** These percentage values indicate the level of services being provided by the injury site prior to the habitat disruption and the level of services provided by the compensation site prior to any compensatory action. That is, in the case of the damaged or disrupted site, the baseline represents the level of services that would have been provided by the site had the disruption not occurred. For example, the baseline level of services of a habitat prior to disruption might be 100% (full services) or at some lower value depending upon the condition of the habitat. Conversely, the services level provided by the restoration site immediately upon restoration action might be 0% (no services such as would be the case upon immediate placement of a new substrate).
- **Pre-restoration service level**: This is the service level provided by the habitat during the period of disruption. In the case of Hazeltine Creek, this service level would be zero prior to build-out of a reach.
- **Service gain parameters from the compensatory action (restoration).** This includes the time history of service levels of the compensatory action.

## 4.3 Overview of Remedial Objectives by Area

Table 5 provides a summary of the remediation objectives by area and the work that has been carried out in those areas is summarized in Table 6. The focus of these objectives is to define the design basis for physical (structural) habitat that delivers the functions defined in those objectives. Protection of water and sediment quality is an overarching objective for the aquatic components of the project area and soil quality for the terrestrial components. As described in Section 4.1, water, sediment and soil quality are being risk managed and addressed through the CEMP as appropriate and, if monitoring demonstrates it to be needed, site-specific remediation work plans may be developed in the future to address potential risks to organisms from chemical stressors.

**Table 5: Habitat Remediation Objectives by Area**

| Area | Area Name | Reach | Fish Habitat EU | Aquatic Objectives | Terrestrial Objectives |
|---|---|---|---|---|---|
| 1 | Tailings Storage Facility | NA | NA | NA | NA |
| 2 | Polley Flats | 1 | H1 | ■ Create rearing habitat for juvenile Rainbow Trout (primary objective)<br>■ Create spawning habitat for Rainbow Trout<br>■ Create overwintering habitat for Rainbow Trout | ■ Establish self-sustaining riparian revegetation that provides cover, insect drop and eventually LWD to Hazeltine Creek<br>■ Establish riparian and adjacent forest vegetation that provides resistance of soils to erosion<br>■ Increase oxygen exchange with native soil<br>■ Create micro sites with suitable growing conditions for regenerating plants<br>■ Increase habitat complexity for riparian wildlife including amphibians |
| 3 | Polley Lake | NA | Polley Lake | ■ Restored benthic invertebrate community that contributes food organisms to fish that prey on emerging insects | ■ Establish riparian revegetation along impacted shoreline of Polley Lake<br>■ Increase oxygen exchange with native soil<br>■ Create micro sites with suitable growing conditions for regenerating plants<br>■ Increase habitat complexity for riparian wildlife including amphibians |
| 4 | Upper Hazeltine Creek | 2 | H1 | ■ Create spawning habitat for Rainbow Trout (primary objective)<br>■ Create rearing habitat for juvenile Rainbow Trout | ■ Establish self-sustaining riparian revegetation that provides cover, insect drop and eventually LWD to Hazeltine Creek<br>■ Establish riparian and adjacent forest vegetation that provides resistance of soils to erosion<br>■ Increase oxygen exchange with native soil<br>■ Create micro sites with suitable growing conditions for regenerating plants<br>■ Increase habitat complexity for riparian wildlife including amphibians |

✓Complete; ⭘ Partially Complete (see notes below); ⊙ To Be Completed; × Not Planned; NA Not Applicable.

Notes:

Reach 4 - Created access only.

Reach 3 - Some seeding and some planting has been done; however, more work will need to be done. Habitat work (placement of spawning gravels, woody debris, etc.) still to be completed and will disturb some of the planted areas.

- Regrading at cut banks complete except for the big blowout at 5,800 m.

Reach 5 - Some seeding and some planting has been done; however, more work will need to be done. Habitat work (placement of spawning gravels, woody debris, etc.) still to be completed and will disturb some of the planted areas.

[1]Riparian planting consisted of planting staked live wattles of willow and black cottonwood, prickly rose, black twinberry, red osier dogwood, Sitka alder and conifers as well as a custom locally collected multispecies seed blend.

[2] Parts of Polley Flats remediated in 2017

[3] Remediation work completed in Reach 1 in 2016 extended down into Reach 2 to chainage 1+265 m in progress October 2017.

## 4.4 Remedial Approach by Area

The following sections present background on the physical characteristics requiring remediation, the work that has already been carried out, the options considered, and the preferred conceptual remediation approach.
The options analysis for work that has already proceeded (e.g., in Hazeltine Creek) was undertaken at the time the work was being planned and implemented and those options included the input of external advice through the HRWG. The resulting work incorporated that advice.

The focus of the following section is on aquatic habitat remediation because the objectives differ by reach. Terrestrial remediation is also necessary but the objectives have some commonalities such as riparian function along all reaches (and lakeshores), provision of habitat complexity for riparian wildlife, including amphibians and regeneration of soil structure. These are outlined in Table 5.

### 4.4.1 Tailings Storage Facility / Area 1 (Dam Breach Re-engineering)

The TSF breach in the perimeter embankment has been repaired and considerably upgraded with buttressing as described below and MPMC has since received permits enabling the operation of the TSF within the parameters of those permits.

- The 4 August 2014 breach of the TSF Perimeter Embankment was about 100 m long, although damage occurred to an approximately 400 m length of the embankment. A temporary upstream rockfill berm was constructed between August and September 2014 to control the release of tailings.
- A Freshet Management Embankment was constructed at the breach zone between November 2014 and June 2015 to allow capture and temporary storage of the 2015 freshet flows and prevent release of tailings to the downstream environment. The Freshet Management Embankment was constructed with rock-fill, crushed rock aggregate and sandy tailings to an elevation of 950 m. A cut-off wall was then constructed through the Freshet Management Embankment by mixing the crushed rock aggregate with cement and bentonite slurry.
- The Freshet Management Embankment was raised in 2016 and 2017 to elevation 963 and 966 m, respectively. A compacted till core was used as the low permeability element to raise the cut-off wall of the Freshet Management Embankment. Rock-fill, crushed rock aggregate and sandy tailings were placed upstream and downstream to support the till core. A buttress was built downstream of the Freshet Management Embankment in 2016 and 2017. The Freshet Management Embankment, raises and buttress were constructed using non-potentially acid generating (NAG) materials.
- A Perimeter Embankment Buttress was constructed downstream of the Perimeter Embankment in 2015, and the Main Embankment Buttress was constructed downstream of the Main Embankment in 2016. The Buttresses were constructed using NAG rockfill. The buttresses were constructed with a downstream slope of 3H:1V. The Perimeter Embankment Buttress was extended in 2016.

### 4.4.2 Polley Flats / Area 2 (Reach 1)

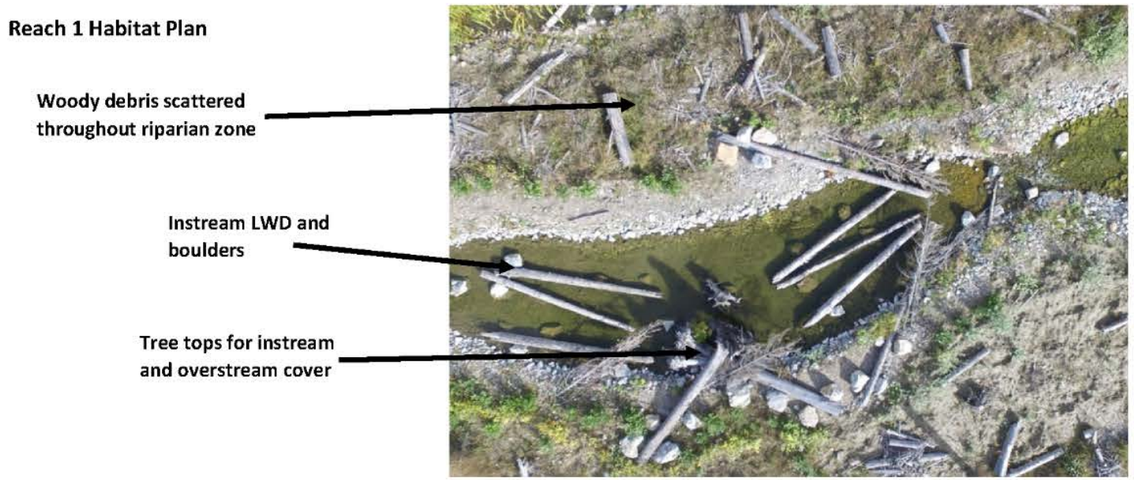
Using the classification system of the HRWG, this area corresponds to Ecological Unit H1. Polley Flats / Reach 1 represents the outlet channel of Polley Lake and encompasses approximately 70 ha of the TSF breach area. The natural stream alignment flowing out of Polley Lake had been historically (late 1800s to early 1900s) directed into a manmade, diversion channel for the first 775 m (Golder 2015b) as part of the water supply for hydraulic mining in the area (Figure 11). This channelized outlet ran along the east side of what was historically a vegetated, meandering flood plain. The pre-breach channel connected with a beaver pond which also received input from Bootjack Creek. Polley Flats and Area 2 extended a short distance (~300 m) past this stream convergence, part way into Reach 2 where the stream channel became better defined but still incorporated some beaver dam ponds and side channel meanders (Golder 2015b).

**Figure 11: Historic Photo of Polley Lake Cut for Hydraulic Mining (CCHMC, undated, ca. 1900)**

Channel, floodplain and vegetation characteristics in Area 2 were significantly altered by the TSF breach. However, with active channel and floodplain remediation integrated with a comprehensive revegetation strategy, there is a high potential for recovery. Limiting factors for Area 2 included large deposits of tailings and associated material, along with scouring and poor, post-breach soil substrate fertility. Overall ecological risk was considered low-moderate for Area 2 (Golder 2017b). As of the end of 2018, approximately 350,000 metric tonnes of tailings have been removed from Polley Flats and a small area in Reach 2. Area 2 aquatic remediation efforts have advanced considerably, with initial armoured channel and creation of complex aquatic habitat completed in 2017. Planting in the riparian zone has also occurred. Remediation activities in Reach 2 are further described in Section 4.6.

A summary of the current remediation actions conducted to date in Area 2 (Reach 1) is summarized in Figure 12 and Table 6.

Primary objectives for aquatic habitat in Area 2 (Reach 1 or Ecological Unit 1) are to provide rearing, spawning and overwintering habitat for rainbow trout. This includes establishing a moderate sinuosity, moderately entrenched, and confined stream type with coarse gravel and small cobble substrate. The channel bed morphology includes riffle-pool morphology with irregularly spaced scour pools. Pools are formed and maintained by large woody debris structures associated with outside meander bends, boulders and eventually, vegetation. Aquatic habitat objectives also include providing a heterogeneous mix of components such as depth, velocity substrate, cover, and pools that support populations of trout and other aquatic organisms. Aquatic habitat construction in Area 2 was carried out in 2017 with ongoing monitoring.



Objectives for terrestrial sites in Area 2 include rehabilitating the floodplain to target ecosystems representing a diverse mosaic of shrubs and trees of varying age classes. Hydrogeomorphic and other disturbance processes will affect the development of the riparian and floodplain ecosystem, ultimately determining the spatial pattern and successional development of riparian vegetation. A mosaic of riparian conifer forest, cottonwoods, aspen and riparian shrubs would be present within the future floodplain depending on topography, disturbance patterns, and morphology. Terrestrial habitat objectives also aim to provide shade, nutrients and small organic debris (SOD) to support riparian ecological functions (Koning and Wendell, 1999). This in turn would support wildlife use in Area 2 and maximise the wildlife habitat features present in the system.

Terrestrial remediation efforts are ongoing with a focus on site preparation and planting. Mounding and ripping as a site preparation method, has helped alleviate compaction and helped liberate the original topsoil over 14.5 ha (20%) of Area 2. This site preparation also creates atmospheric connectivity which increases oxygen exchange and promotes soil fauna and microbial communities. Additional site preparation methods include placing imported soil over 19 ha to bring in needed nutrients and improve growing medium structure. Woody debris has been placed over all the site preparation areas to promote structural heterogeneity and to provide microsites for establishing plants. Remediation efforts such as these, improve the physical and structural properties of the soil, and facilitate re-establishment of vegetation. Upland and riparian plantings have been initiated over 35.6 ha (50%) of the disturbance zone in Area 2.

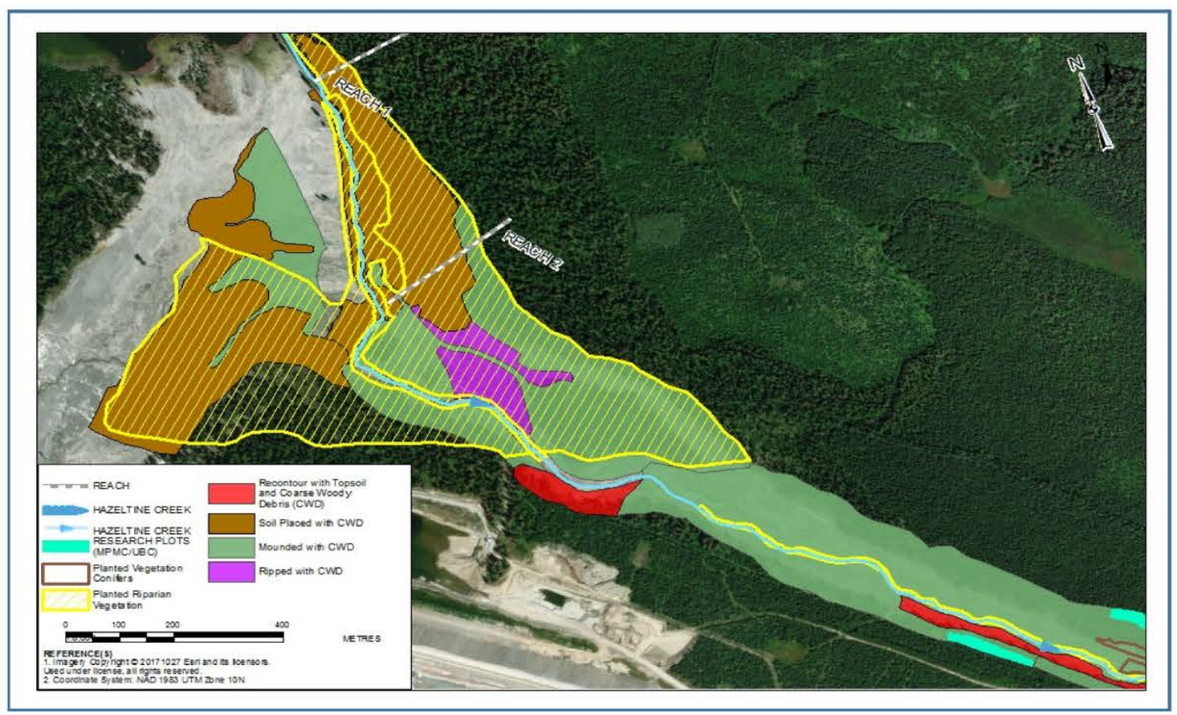


**Figure 12: Polley Flats / Area 2 (Reach 1) Description and Current Remediation and Rehabilitation Status**

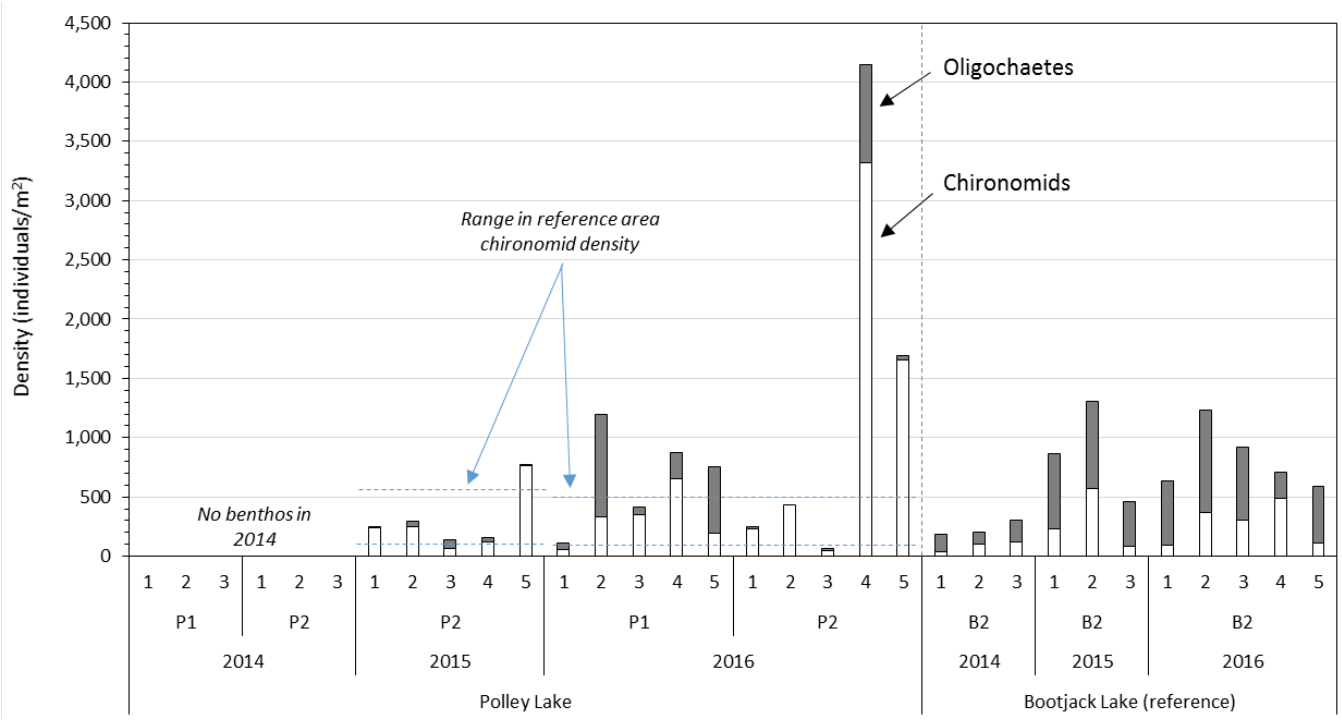
## 4.5 Polley Lake / Area 3



Using the classification system of the HRWG, this area is one EU – Polley Lake. Polley Lake is situated adjacent to the Mount Polley Mine and has a long (6.17 km), narrow (0.65 km) configuration. The lake has a pre-breach mean depth of 18 m and maximum depths of 35 m in the south basin and 33 m in the north basin. The main inflow to the lake is from the Frypan Lake sub-watershed to the northwest and the estimated hydraulic residence time of the lake is approximately 16.2 years (MPMC 2015a). The lake was previously used to supply water for hydraulic placer operations (see for example Figure 11). Polley Lake is dimictic and mixes from the surface to the lake bottom twice each year. Thermal stratification occurs in summer with the thermocline typically forming at a depth between 5 and 15 m (Minnow 2014). Hypoxic (low oxygen) conditions generally occur at depths greater than 20 m, with dissolved oxygen (DO) concentrations less than 5 mg/L, including before the breach (Minnow 2014). The trophic status of the lake reportedly changed from oligotrophic/mesotrophic prior to mine development (1995/1996) to mesotrophic/ eutrophic in 2012 (Minnow 2014).

Water and tailings released during the spill were deposited directly into Polley Lake. Tailings inundated a wetland at the outlet of Polley Lake and deposited heterogeneously throughout the lake itself (MPMC 2015a). As well, a thick deposit of tailings and other debris (known as the “Plug”), blocked water from flowing out of Polley Lake and into Hazeltine Creek. Immediately following the event, the water level in Polley Lake increased by approximately 1.7 m and turbidity increased in the deeper waters of the lake below the thermocline. In mid-October 2014, turnover occurred causing mixing of shallow and deep water in the lake; during that period, turbidity and DO were uniform throughout the water column. In mid-November 2014, turbidity and DO concentrations in the lake returned to pre-event conditions and have remained consistent since (Golder 2016a).

The deposit of material at the outlet of Polley Lake affected spawning and rearing areas for Rainbow Trout and Longnose Sucker both in the lake as well as downstream of the outlet in Upper Hazeltine Channel. In addition, shortly after the TSF breach a fish fence and flow control structure was installed at the outlet of Polley Lake to Hazeltine Channel. This fish fence had (until April 2018) prevented Rainbow Trout in Polley Lake from accessing historical spawning habitat in Upper Hazeltine Creek during ongoing reconstruction and remediation of Hazeltine Creek. As demonstrated in the age frequency distribution for Rainbow Trout, in 2016 there were a greater number of older fish and an apparent absence of year-1 and -2 individuals compared to the distribution for 2014 (Minnow 2017a).

The deposit of tailings and outwash material in Polley Lake temporarily reduced the density (number of individuals per a given area) of benthic invertebrates. Benthic invertebrates, such as chironomids (the aquatic larvae of midges) and oligochaetes (freshwater worms), are eaten by fish and their abundance provides an indication of habitat quality for rearing and overwintering fish. Chironomid density is particularly relevant to the fish population of Polley Lake as both Rainbow Trout and Longnose Sucker feed on the aquatic stage of this insect group, although they can also be opportunistic and feed on other taxa (MPMC 2015a).

Figure 13 shows the density of chironomids and oligochaetes in deep areas of the lake and Figure 14 shows the density in mid-depth areas of the lake in Polley Lake and in the reference area, Bootjack Lake, for 2014, 2015, and 2016. No benthic invertebrates were found in the deep area of Polley Lake in 2014 and in the mid-depth zone, the numbers were lower than found in Bootjack Lake. In the year after the breach, the deep benthic community was recolonizing the substrate and chironomid density in all but two replicates was within the range observed in reference Bootjack Lake. By 2016, the mid-depth benthic community had a higher density than that of Bootjack Lake (Figure 14). Subsequent sampling of Polley Lake has not been undertaken.

Note: Bars show individual replicates. Source of data: Golder (2017c).

**Figure 13: Spatial and Temporal Variability in Benthic Invertebrate Density in Polley Lake Deep Areas, 2014, 2015, and 2016**

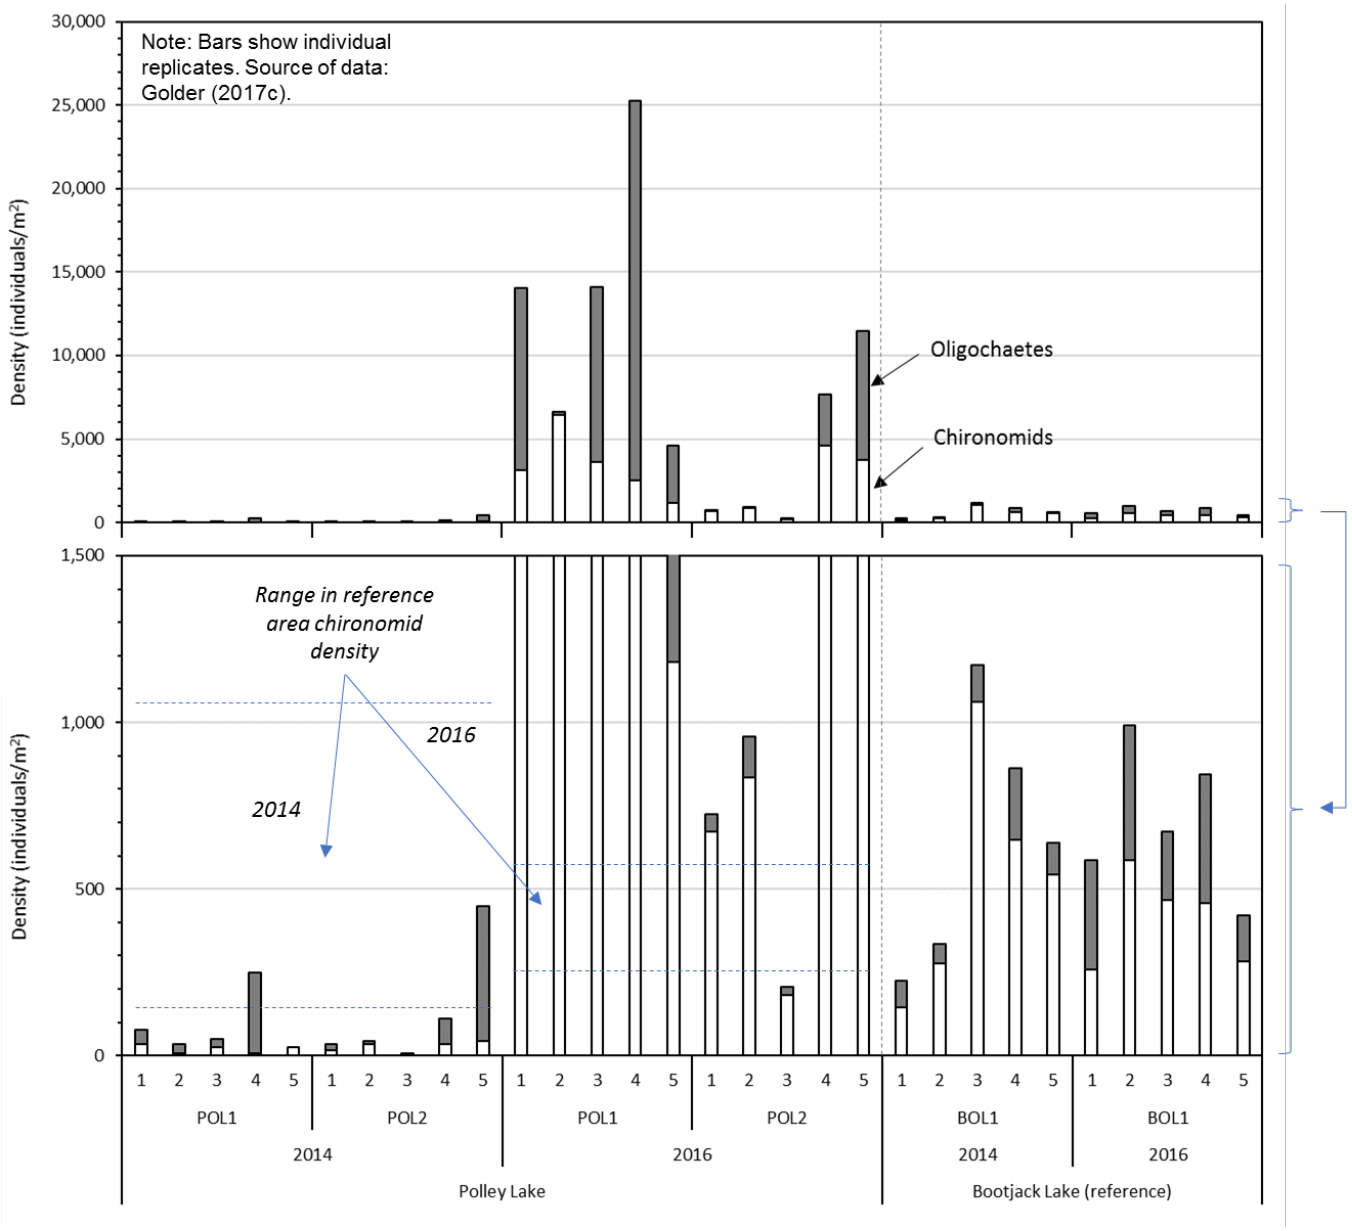


**Figure 14: Spatial and Temporal Variability in Benthic Invertebrate Density in Polley Lake Mid-depth Areas, 2014 and 2016**

There is some uncertainty regarding the suitability of Bootjack Lake as a reference over the longer term given a recent amendment to the waste discharge authorization which now allows the discharge of seep water to Bootjack on a contingency basis. As of writing, there has not been a discharge. Nonetheless the Polley Lake monitoring data show a trend in increasing abundance of benthic invertebrates and the temporary disruption to this food source for these species did not appear to have affected either Rainbow Trout or Longnose Sucker, as measured by condition factor (calculated from fish length and weight) which was similar for both species between 2014 and 2016. Should the permitted Springer Pit seep discharge be utilized, the study design will need to be re-evaluated as part of the CEMP update process.

### 4.5.1 Remediation Activities to Date

Reconstruction of the Hazeltine Creek channel has largely restored the connection between Polley Lake and upper Hazeltine Creek, except for a flow control structure which was constructed at the mouth of Polley Lake to control flows during reconstruction of the Hazeltine Creek channel. The outflow control structure (or weir) can impound water in the lake, for example during freshet or at times when water flows would impede habitat construction works. The weir also allows for the discharge of water at a controlled rate to control erosion as reconstructed areas of Hazeltine Creek stabilize as planted vegetation grows. An additional benefit of the weir is that it can allow for a more moderate hydrograph, providing extended flow durations in Hazeltine Creek which have historically (pre-breach) been low in the summer months. While it has yet to be decided by the HRWG, the weir may form part of habitat offsets. The weir was recently (2018) also equipped with a fish ladder allowing fish to successfully move between Polley Lake and upper Hazeltine Creek.

From the time the weir was constructed until April 2018, Polley Lake Rainbow Trout, which use upper Hazeltine Creek for spawning and rearing, were excluded by a fish fence from using that habitat while the channel reconstruction was underway. Based on the findings of an evaluation of flows, habitat availability, and water quality (Golder 2018b), a fish bypass structure was installed beside the flow control structure which will remain in place, and Rainbow Trout now have access to Upper Hazeltine Creek. Monitoring of the re-introduction effort demonstrated high utilization by Polley Lake Rainbow Trout adults, estimated to number 4,890 and an estimated recruitment of 18,064 juvenile Trout were produced in this lake outlet. The adults returned to Polley Lake following spawning and most of the juveniles also returned to Polley Lake as new recruitment to that population (Connors et al., 2018).

Planting of the riparian area adjacent to Hazeltine Creek was also carried out by MPMC (see details in Table 6).

### 4.5.2 Remediation Plan

The potential pathways of effect for the identified ecological functions for Polley Lake (rearing, overwintering, spawning, migration) were deposition of material, alteration of habitat structure, loss of riparian vegetation and exclusion from habitat by temporary fencing (Table 3). The remediation objectives for this area are summarized in Table 5.

As illustrated above (Figure 13 and Figure 14), the deposition of material initially caused a reduction in the benthic invertebrate community (e.g., a reduction in food organisms for fish) which, based on more current data appears to be approaching recovery. In Polley Lake, unlike Quesnel Lake, the TSF Breach outwash materials mixed with soils and sediments of Polley Lake which retained organic carbon in the settled material. As discussed in Section 4.11.3.3, potential remediation options identified for deposited material in Quesnel Lake were: dredging, addition of organic carbon (unlikely to provide benefit for Polley Lake), thin-layer capping, and monitored natural recovery (MNR). The evaluation of those options is considered in detail in the remedial options evaluation for Quesnel Lake. Some of the principles of that evaluation for Quesnel Lake have similarities to the situation of Polley Lake. While dredging in Polley Lake would have less logistical implications than Quesnel Lake (see below), dredging would be similarly disruptive and would not provide a clear benefit given the signs of recovery observed in Polley Lake, which has similar abundance and diversity of benthic organisms when compared with the reference lake (Figure 14). For the bottom of Polley Lake, the selected remedial option is therefore MNR, which is described in further detail in Section 4.11.3.4, in the context of Quesnel Lake.

Polley Lake benthic invertebrate monitoring study design will be addressed in the CEMP so that consistent and appropriate techniques are used to support MNR.

## 4.6 Upper Hazeltine Creek / Area 4 (Reach 2 & 3)

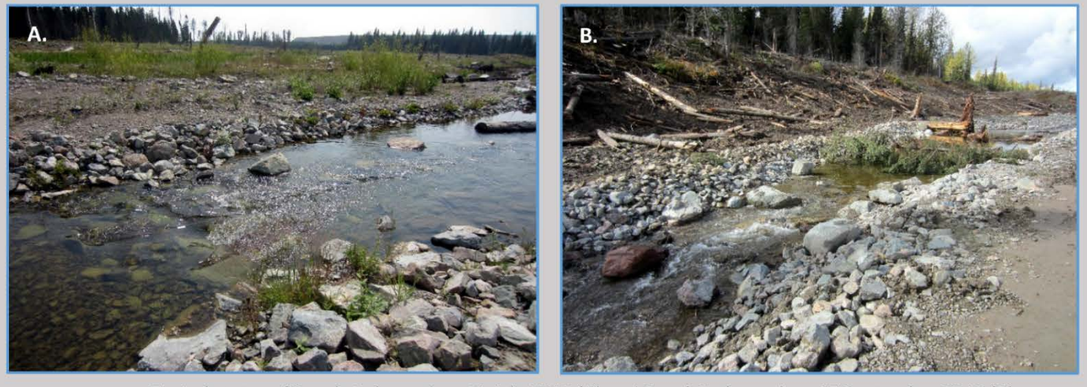
The EU for aquatic habitat in the area are provided in Table 2, remediation objectives for Upper Hazeltine Creek are in Table 5, and the current remediation actions conducted to date in Area 4 (Reaches 2 and 3) are summarized in Figure 15 and Table 6. Using the classification system of the HRWG, this area corresponds to EU H1. Section 4.5 describes how the breach event affected the area.

Reach 2 extends downstream from Polley Flats to the Gavin Lake road crossing. This reach is a relatively low gradient with a wide floodplain between Hazeltine Creek flows from Polley Lake to the start of Hazeltine Canyon. The habitat objectives for Reach 2 are to provide both rearing and spawning habitat for Rainbow Trout (Table 4). The hydraulic grade of Reach 2 is modest, with an average grade of approximately 0.9%. Typical flow velocities at this grade are conducive to spawning by Trout. Primary, secondary and tertiary meanders occur throughout Reach 2. The channel was designed to facilitate spawning by Trout at points of downwelling and upwelling along the meanders of both the low flow and MAF channels. Spawning habitat was also provided within gravel platforms associated with the upstream end of v-notch weirs constructed to create pools within the design alignment of the MAF channel. These weirs are fish passable. The upstream ends of the pools are fitted with boulder weirs to facilitate scour of the pools (to minimize the accumulation of sediments) and to mitigate head-cutting. The channel (apart from the weirs) and the pools have been complexed with boulders, logs and tree tops to provide instream and overstream cover for fish. The interaction of flows with these features will sustain and/or create runs, small riffles and small pools along the design alignment of the low flow channel and will facilitate mixing throughout the water column of the pools. It is this complexity that will sustain rearing habitat for juvenile Trout.

Provision of spawning habitat for Rainbow Trout and rearing habitat for juvenile Rainbow Trout are the primary objectives for Reach 3 (Table 4). The hydraulic grade of Reach 3 is relatively steep, with an average grade of approximately 2.3%. Flow velocities are at about the upper limit of those associated with spawning by Trout. The secondary meander represented by the MAF channel is absent. It is expected that spawning by Trout will occur at points of downwelling and upwelling along the meanders of the low flow channel. Boulders weirs are a common feature of the MAF channel due to the steepness of the channel; they will mitigate head-cutting. They are also instrumental in maintaining the meander of the low flow channel; without the weirs, the low flow channel would eventually straighten due to the relatively high flow velocities, facilitating laminar flow and hindering downwelling and upwelling, and decreasing habitat values for Trout. Large v-notch weirs occur within the design alignment of the MAF channel to create ponds. These weirs are at about the steepest grade associated with passage by Trout; passage is facilitated (through turbulent flow) by a meander in the v-notch and a dense aggregation of boulders orientated in a haphazard pattern. The upstream ends of the pools are fitted with boulder weirs to facilitate scour of the pools (to minimize the accumulation of sediments) and to mitigate head-cutting.

The remainder of Reach 3 and the pools have been complexed with boulders, logs and tree tops to provide instream and overstream cover for fish. It is expected that the pools will provide rearing habitat for juvenile Trout. The interaction of flows with complexing features will enhance turbulence, important in creating hydraulic refugia for both adult and juvenile Trout. This will mitigate the ‘flushing’ and downstream ‘losses’ of Polley Lake fish through the canyon and into Quesnel Lake.

Trout access into upper Hazeltine Creek was facilitated by removing the fish fencing between Polley Lake and Hazeltine Creek. At the same time, new fish fences were installed at the lower range of constructed habitat in Hazeltine Creek. The recent use of the area by Rainbow Trout is described in Section 4.5.1. Monitoring carried out (Connors et al. 2018) identified that the desired habitat functions appear to have been achieved. Habitat monitoring will continue as the remainder of Hazeltine Creek habitat is built-out.



Monitoring data collected in 2015 and 2017 indicated that the reconstructed streambed has been colonizing with benthic invertebrates and periphyton (Minnow 2018c). In 2017, the abundance of invertebrates (collected by kicknetting for a specified time) was in the range of 10,000 organisms per sample, comprised of mayflies (Ephemeroptera), caddisflies (Trichoptera), chironomids (Chironomidae), and oligochaetes (Oligochaeta). Periphyton biomass (as chlorophyll *a*) ranged from 5 to 21 mg/m$^2$.

Overall, remedial activities to date appear to be successful. Monitoring for attainment of intended ecological functions and water quality monitoring will need to continue as part of MPMC's long term commitments (Figure 8).

Reach 2 and 3, Upper Hazeltine Creek (Area 4) receives input from Polley Lake via Polly Flats and flows into the start of Hazeltine Canyon. It consists of a 60 to 200 m disturbance zone surrounded by second growth hybrid white spruce forest stands. The rehabilitation strategy involves creating a stable channel morphology with an armored base lined with a 75mm minus spawning gravel. Mean Annual Flow (MAF) channel width varies between 4.5 m and 7.7 m and the lower floodplain averages 20 m wide.

Primary aquatic habitat objectives for this area are to provide rearing and spawning habitat for Rainbow Trout by creating step pool channels with interspersed riffles and rapids. Large woody debris and boulders have been added to meander points and channel margins to introduce aquatic habitat and cover for trout and other aquatic organisms. These weirs are fish passable and while they are not intended for spawning they help maintain spawning substrate in other areas. The upstream ends of the ponds are fitted with boulder weirs to facilitate scour of the ponds (to minimize the accumulation of sediments) and to mitigate head-cutting. In 2018, upper Hazeltine Creek supported spawning by and estimated 4,890 adult trout.

Terrestrial objectives in Reach 2 and 3 include improving soil conditions and reducing long term sediment load into Hazeltine Creek, as well as improving structure and function of habitat by introducing coarse woody debris and surface roughness via mounding and ripping. Revegetation efforts to date consist of grass seeding with an erosion mix and allowing natural ingress from nearby seed sources. The establishment of shrubs and deciduous trees mature is expected to be gradual and be replaced by dense stands of conifers. Channel conditions should continue to evolve into productive trout habitat with nutrient inputs from the surrounding vegetation.

Typical status of Reach 2 channel on 31 July 2018 (A) and Reach 3 channel on 17 September 2018 (B)

**Upper Hazeltine Creek Plan**

Aerial View of Reach 2 (17 October 2018)

**Figure 15: Reach 2 and 3, Upper Hazeltine Creek (Area 4) Description and Current Remediation and Rehabilitation Status**

## 4.7 Hazeltine Canyon / Area 5 (Reach 4)

Hazeltine Canyon has not been assigned an EU and remediation work for the canyon is not prescribed. The remediation objectives for the area are summarized in Table 5 and the current remediation actions conducted to date in Area 5 are summarized in Table 6.

Reach 4, Hazeltine Canyon (Area 5) is approximately 1.3 km in length and extends from the lower end of Upper Hazeltine Creek, at chainage 6+600 m, to the upper end of Lower Hazeltine Creek, at chainage 7+900 m. The canyon averages 50 m wide, with incised channel walls, and is the steepest reach with an average slope of 5%. The steep banks and the high longitudinal gradient create a narrow, structurally controlled valley or canyon that prevents upstream passage of fish. The upper edge of the canyon is lined with coniferous forest and there is limited floodplain development within this section. Some rearing (minor) of Trout is expected to occur in the Hazeltine Canyon area.

The high flows associated with the canyon provides little potential for fish habitat, therefore, remediation of fish habitat was not planned for Reach 4. Site preparation in the area has consisted of creating access and limiting erosion potential only. The fish habitat objective for this reach is controlling erosion and maintaining water quality for downstream habitats.

Terrestrial objectives in Reach 4 were limited to promoting natural successional processes. Remediation to date in Hazeltine Canyon has consisted of grass seeding to provide short term erosion protection and assist natural ingress of local vegetation.

## 4.8 Lower Hazeltine Creek / Area 6A (Reach 5)

Using the classification system of the HRWG, this area corresponds to EU H2. The EU and potential pathway of effects for aquatic habitat in Lower Hazeltine Creek are provided in Table 2 and the remediation objectives for the area are summarized in Table 5. The current remediation actions conducted to date in Area 6A (Reach 5) are provided in Figure 17 and Table 6.

Lower Hazeltine Creek / Reach 5 extends from the downstream end of Hazeltine Canyon to the Edney Creek confluence. The reach crosses over an alluvial fan that has formed at the outlet of the canyon (including pre-breach). The streambed in this reach has a low gradient of approximately 1.8%.

The lower Hazeltine Creek Area, extending to the shore of Quesnel Lake has been the location of considerable site preparation, addition of organic carbon (wood mulch) and multispecies planting as part of both habitat remediation work and erosion control. The physical habitat construction of Hazeltine Creek in Reach 5 has not yet concluded and additional planting is expected after the physical remediation and erosion control works are finished. Stream remediation designs for lower Hazeltine Creek have not yet been developed. However, a number of design concepts were discussed at November 2018 HRWG meeting. The consensus view was that the preferred option was that Hazeltine Creek and Edney Creek would be joined into a single creek, as it was pre-breach (Figure 16). The ponds will be decommissioned though specific details of that decommissioning have not yet been decided. However, their connection to the creek was not viewed as a desired design element.

Monitoring data collected in 2015 and 2017 indicated that the reconstructed foundational stream channel has been colonizing with benthic invertebrates and periphyton (Minnow 2018c). In 2017, the abundance of invertebrates (collected by surber sampling) was on the order of 5,000 organisms per $m^2$. This density is lower than observed in 2007; however, the community in 2017 was comprised of similar taxa as observed previously (i.e., mayflies, stoneflies (Plecoptera), caddisflies, non- chironomids (Chironomidae), true files (Diptera)). Periphyton biomass (as chlorophyll *a*) was on average 5 $mg/m^2$. Creek habitat substrates and habitat complexity features have not yet been constructed in lower Hazeltine Creek and the final creek alignment will differ from that assessed.

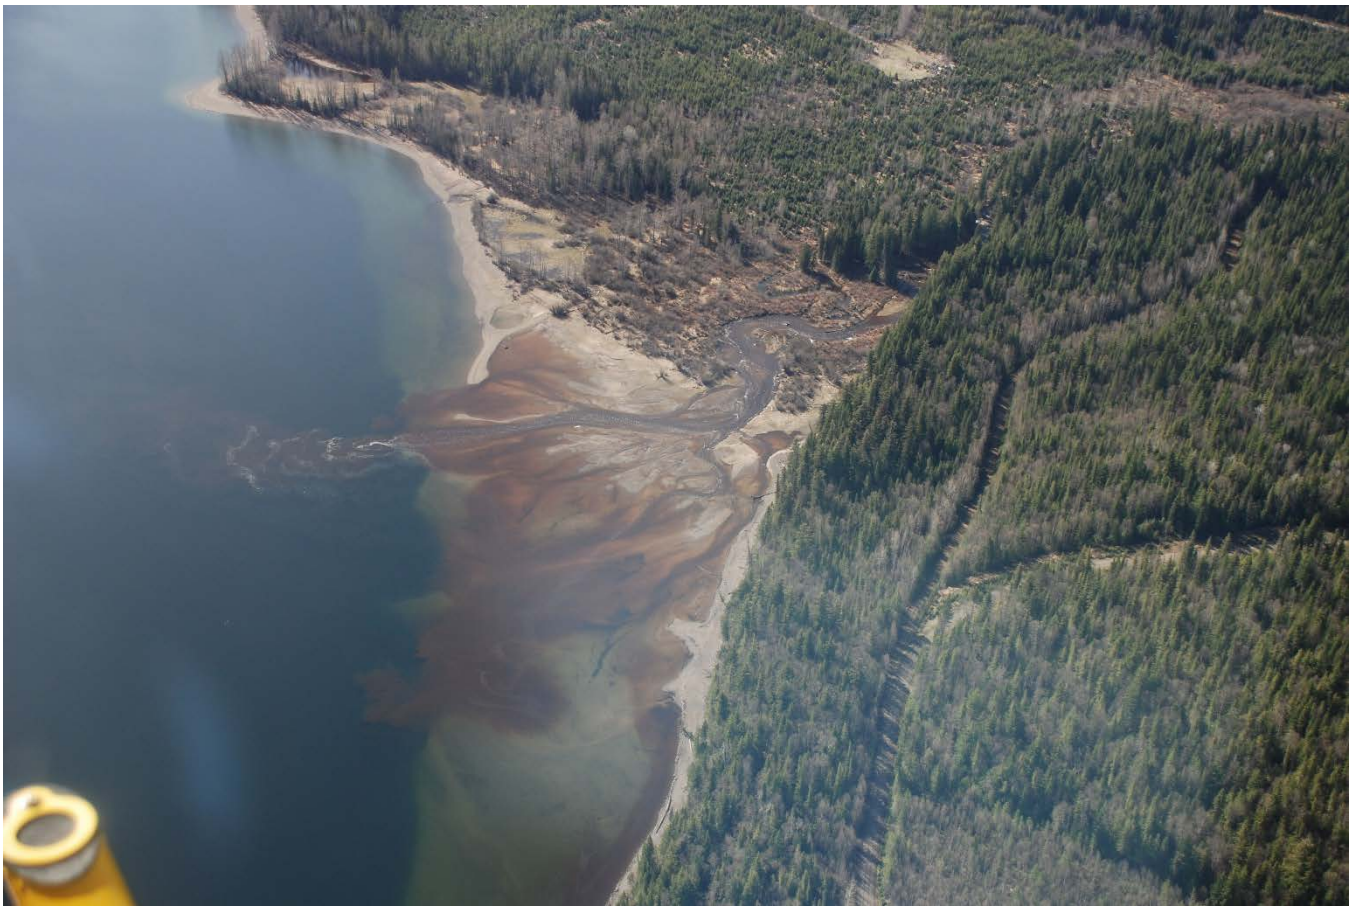


**Figure 16: A 2008 Photo of the mouth of Hazeltine and Edney Creeks. Prior to the breach, these streams were combined in a single channel. (Photo Courtesy MPMC).**

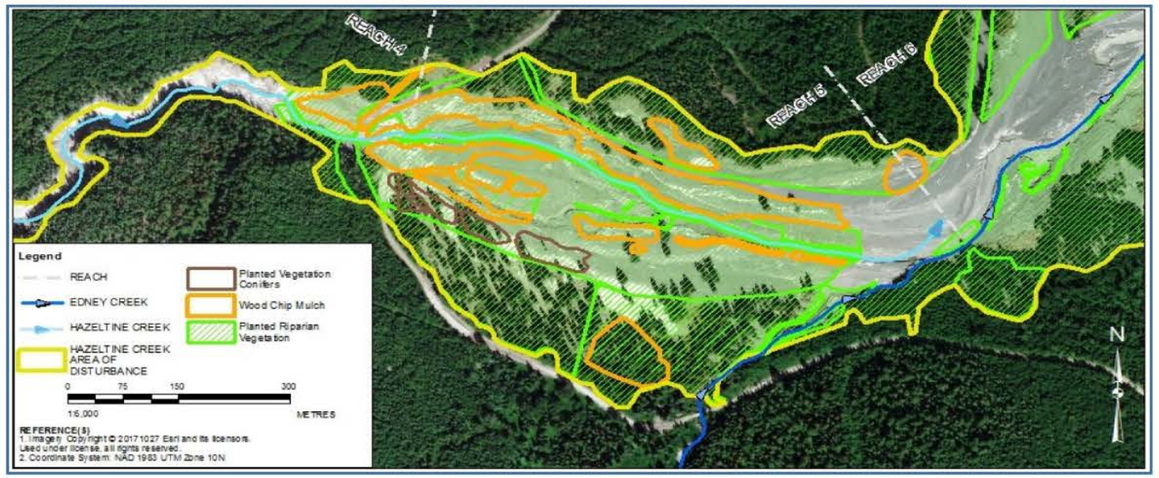

The primary aquatic objective for Reach 5 (Area 6a) is to provide both rearing and spawning habitat for Sockeye salmon Rainbow Trout and Coho salmon. The overall channel remediation of Hazeltine Creek includes the lower floodplain, the Mean Annual Flow (MAF) channel, and the low flow channel. The primary meander pattern is exhibited by the lower floodplain; this part of the overall floodplain is engaged by flows associated with freshet. Armouring was undertaken to minimize erosion of the materials underlying the channel. Pockets of tailings and breach outwash materials were removed from the footprint of the constructed channel and from the footprint of any fill materials placed in the floodplain. Flow velocities in Reach 5 are conducive to spawning by both rainbow trout and Coho salmon. Grades were deeply incised by the release event and cuts into adjacent slopes to achieve relatively elaborate meanders were minimized as this would exacerbate existing cuts, resulting in further impacts to treed woodlands.

Instream habitat features resemble those defined for Reach 2. The v-notch weirs constructed to create ponds within the design alignment of the MAF channel are slightly steeper than those of Reach 2, at about 3.0 percent compared to 2.5% for Reach 2. These weirs are fish passable. The upstream ends of the ponds are fitted with boulder weirs to facilitate scour of the ponds (to minimize the accumulation of sediments) and to mitigate head-cutting.

The remainder of Reach 5 will be complexed with boulders, logs and tree tops to provide instream and overstream cover for fish. The interaction of flows with these features will sustain and/or create runs, small riffles and small ponds along the design alignment of the low flow channel and will facilitate mixing throughout the water column of the ponds. The features will enhance turbulence, important in creating hydraulic refugia for both adult and juvenile fish. It is this complexity that will sustain rearing habitat for juvenile trout. To date, soil rehabilitation efforts have reduced long-term sediment load flow into Hazeltine Creek by removing tailings and increased oxygen exchange with native soil. Ripping and mounding, along with Coarse Woody Debris (CWD) placement, have created micro sites that foster regenerating plants increase habitat complexity in this reach. Of the 29 ha in this area, 22 ha have been roughened and planted with riparian species while over 6 ha have been recontoured with imported soil and complexed with CWD. In addition, wood chip mulch has been spread over 5 ha to control erosion and reduce soil moisture loss.

Reach 5 on 17 September 2018 (A) and 31 July 2018 (B)

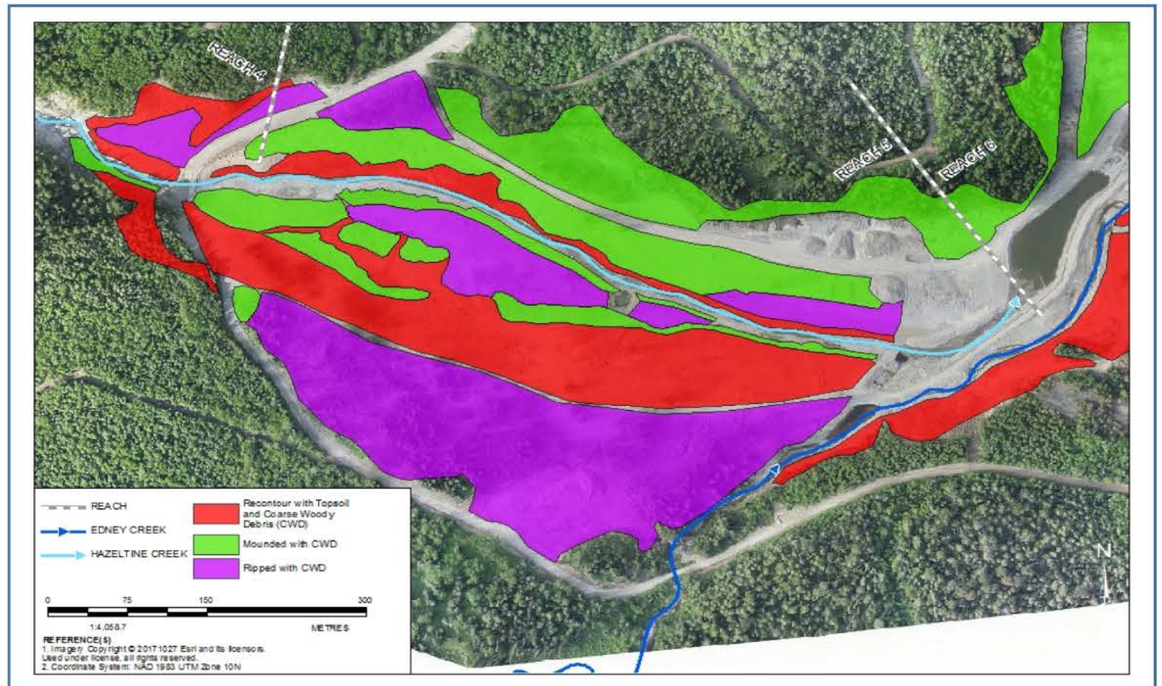

**Figure 17: Reach 5, Lower Hazeltine Creek (Area 6a) Description and Current Remediation and Rehabilitation Status**

## 4.9 Lower Edney Creek / Area 6b (Reach 6)

Using the classification system of the HRWG, this area corresponds to EU E3. The ecological units and potential pathway of effects for aquatic habitat in Lower Edney Creek are provided in Table 2 and the remediation objectives for the area are provided in Table 5. The current remediation actions conducted to date in Area 6b (Reach 6) are summarized in Figure 18 and Table 6.

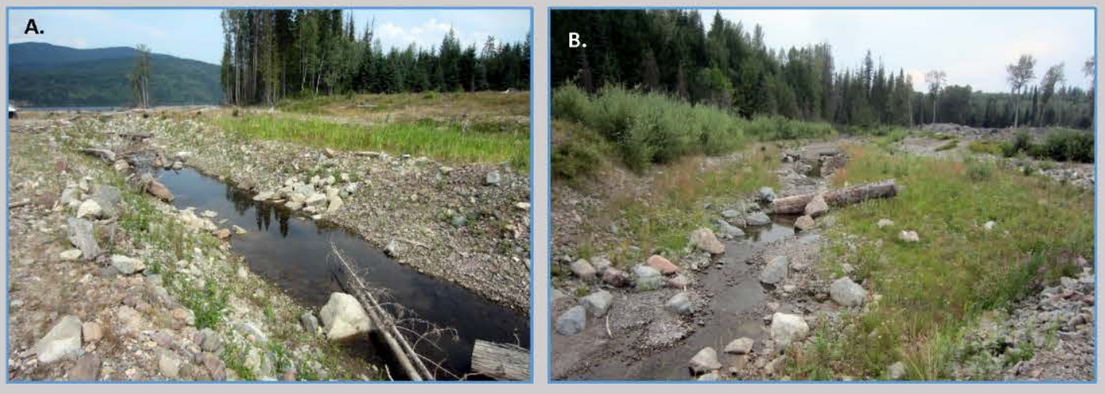
This section is the furthest downstream reach and extends from the confluence of Hazeltine Creek and Edney Creek to the outlet into Quesnel Lake. Currently (as of fall 2017), the two creeks were separated in order to control outflow from Hazeltine Creek and facilitate fish passage and habitat remediation in Edney Creek. Hazeltine Creek now flows into two temporary settling ponds before discharging into the lake through a temporary diversion. Edney Creek follows its natural route with a secondary overflow channel that splits from the main channel less than 100 m from Quesnel Lake. Typical MAF channel width is approx. 7.1 m with a minimum lower floodplain width of 35 m. The hydraulic grade of Reach 6 is approximately 1.0%.

Sampling carried out (Minnow 2018a) has found that the habitat constructed is being used by the same species as were documented in the creek before the breach. Twelve fish species were captured from Edney Creek in 2016, including juvenile Rainbow Trout, and Coho and Chinook Salmon, confirming that the connection between Edney Creek and Quesnel Lake is functioning. Other species observed were: Kokanee, Mountain Whitefish, Northern Pikeminnow, Burbot, Largescale Sucker, Longnose Sucker, Bridgelip Sucker, Longnose Dace, Peamouth Chub, and Redside Shiner. Rainbow Trout and Longnose Dace were the most abundant fish.

Monitoring data collected in 2015 and 2017 indicated that the reconstructed streambed has been colonizing with benthic invertebrates and periphyton (Minnow 2018c). In 2017, the abundance of invertebrates (collected by surber sampling) was on the order of 5,000 organisms per $m^2$, comprised of mayflies, stoneflies (Plecoptera), caddisflies, non- chironomids (Chironomidae), true files (Diptera), and oligochaetes (Oligochaeta). Periphyton biomass (as chlorophyll *a*) was on average 5 $mg/m^2$.

## 4.10 Edney Creek Mouth / Area 7

Using the classification system of the HRWG, this area corresponds to EU E3. At the pre-breach confluence of Edney Creek and Hazeltine Creek, Edney Creek channel was scoured resulting in a drop of approximately 2 m in elevation, resulting in a barrier to the free movement of fish from Quesnel Lake to Edney Creek. The upper reaches of Edney Creek provided good fish habitat that was not impacted by the breach event and restoration of its connectivity to Quesnel Lake was identified as a priority action and was the first section of habitat to be constructed as part of the breach response program (Bronsro et al. 2016). The connection of Edney Creek to Quesnel Lake was constructed by February 14, 2015.



The mouth of Edney Creek was designed to distribute flow from the mouth of Edney Creek and create two channels. The low flow channel connects to Quesnel Lake under all flow conditions while the higher flow channel distributes the flow during moderate and higher flows. The shoreline design at the mouth of Edney Creek incorporates a large area of shallow gravel shoal habitat that is accessible to fish under a wide range of lake levels. The installation of the habitat features for the lower section of Edney Creek were constructed September 2015. Modification of portions of lower Edney Creek are expected as the flows of Hazeltine Creek and Edney Creek will be combined per consensus reached at the November 2018 HRWG meeting.

Primary aquatic habitat objectives for Area 6b (Reach 6) are to provide spawning habitat for Sockeye Salmon, Kokanee Salmon, Coho Salmon and Rainbow Trout, and rearing habitat for Coho salmon and rainbow trout. This will be achieved by re-establishing a non-erodible engineered channel, and re-establishing fish and riparian habitat.

In 2015, boulder weirs were placed throughout the MAF channel. Strategically placed boulders were placed to work with the weirs to 'train' the low flow channel such that it did not straighten during high flows. Off channel ponds were constructed to associate with the secondary channel. Channels and ponds were complexed with boulders, logs and tree tops to provide instream and overstream cover for fish. These features were placed such that the interaction of flows with these features will sustain and/or create runs, small riffles and small ponds along the design alignment of the low flow channel, and will facilitate mixing throughout the water column of the ponds. The features will enhance turbulence, important in creating hydraulic refugia for both adult and juvenile fish. It is this complexity that will sustain important rearing habitat for juvenile trout.

In 2017, over 31 ha of the Lower Edney Creek area has been planted and plots indicate >10,000 stems/ha of *Populous trichocarpa* in some areas. MPMC have also collected a custom seed mix from the site that includes Sitka Alder, Red Elderberry, Willow Spp., Pink Spirea, Yarrow and Cow Parsnip. . Terrestrial objectives in Reach 6 include improving soil conditions, creating micro sites with suitable growing conditions for regenerating plants, providing habitat structure and increased habitat complexity by incorporating Coarse Woody Debris (CWD), and assisting recovery of plant communities appropriate for the local conditions. Sections of Reach 6 were re-contoured with topsoil and CWD (3.7 ha) and mounded with CWD (9.9 ha).

In 2018, a tree planting program for ongoing revegetation include live staking with willow and poplar in riparian areas to assist ingress of conifer seedlings and establish an erosion control grass cover in the upper floodplain was put down.

Reach 6 on 31 July 2018 (A and B)

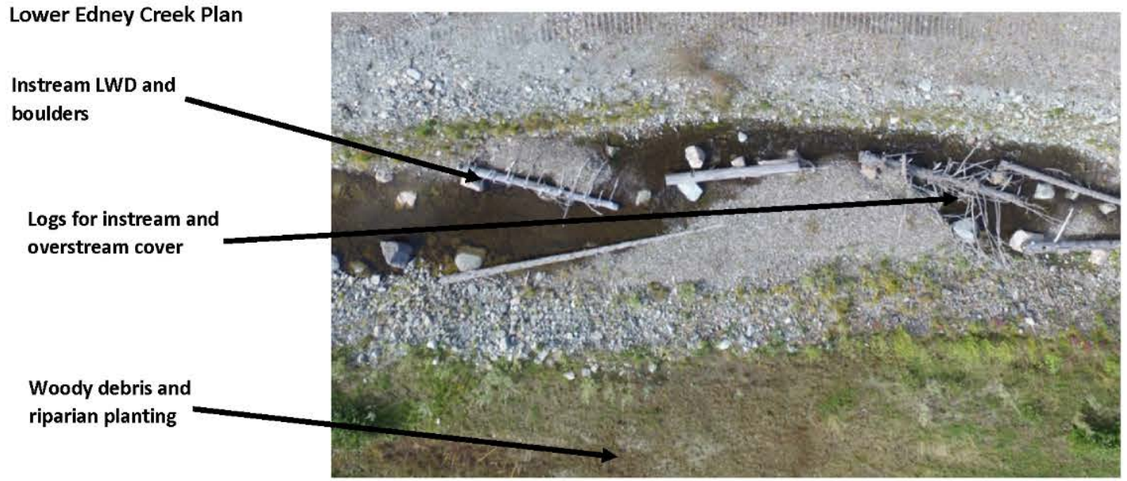


**Figure 18: Lower Edney Creek /Area 6b (Reach 6) Description and Current Remediation and Rehabilitation Status**

## 4.11 Quesnel Lake / Area 8

### 4.11.1 Lake Characteristics

Quesnel Lake is a large, deep fjord lake reaching from the Cariboo Mountains into the Interior Plateau of BC. The lake has a surface area of 266 $km^2$ and is comprised of West, East, and North Arms. The average and maximum depths of the lake are 157 and 511 m, making Quesnel Lake one of the deepest fjord-type lakes in the world (Laval et al. 2008). The Quesnel Lake remediation area consists of the West Basin area between Cariboo Island and the Quesnel River, a relatively shallow (pre-breach, 113 m maximum depth) portion of the lake that is separated from the rest of the lake by an approximately 35 m deep sill near Cariboo Island (Laval et al. 2008).

The West Basin has vertical mixing that is typical of temperate lakes, with thermal stratification for most of the year interrupted by brief turnover periods in the spring and the fall when vertical density gradients are weakest. In the deeper portions of the lake, seasonal overturn events only occur in the upper 100 to 200 m of the water column due to changes in temperature-density relationships with increased pressure at greater depths (Laval et al. 2008). Water chemistry data indicate that the lake is slightly alkaline, has low sensitivity to acid inputs, and is oligotrophic, with phosphorus being the limiting nutrient (Nidle et al. 1994; Shortreed et al. 2001).

As summarized in Section 3.2.4, the ecological risk assessment found that residual effects due to alteration of water quality for organisms associated with the water column (plankton, pelagic fish) were low. In comparison, physical habitat and benthic invertebrate communities were altered from the effect of scouring along the lake side wall adjacent to the outlet of Hazeltine Creek and deposition of that scoured material as well as material from the Hazeltine corridor and the TSF on to the lake bed below the 100-m contour. The remainder of this section focusses on physical/benthic habitat in the littoral and benthic zones of the lake.

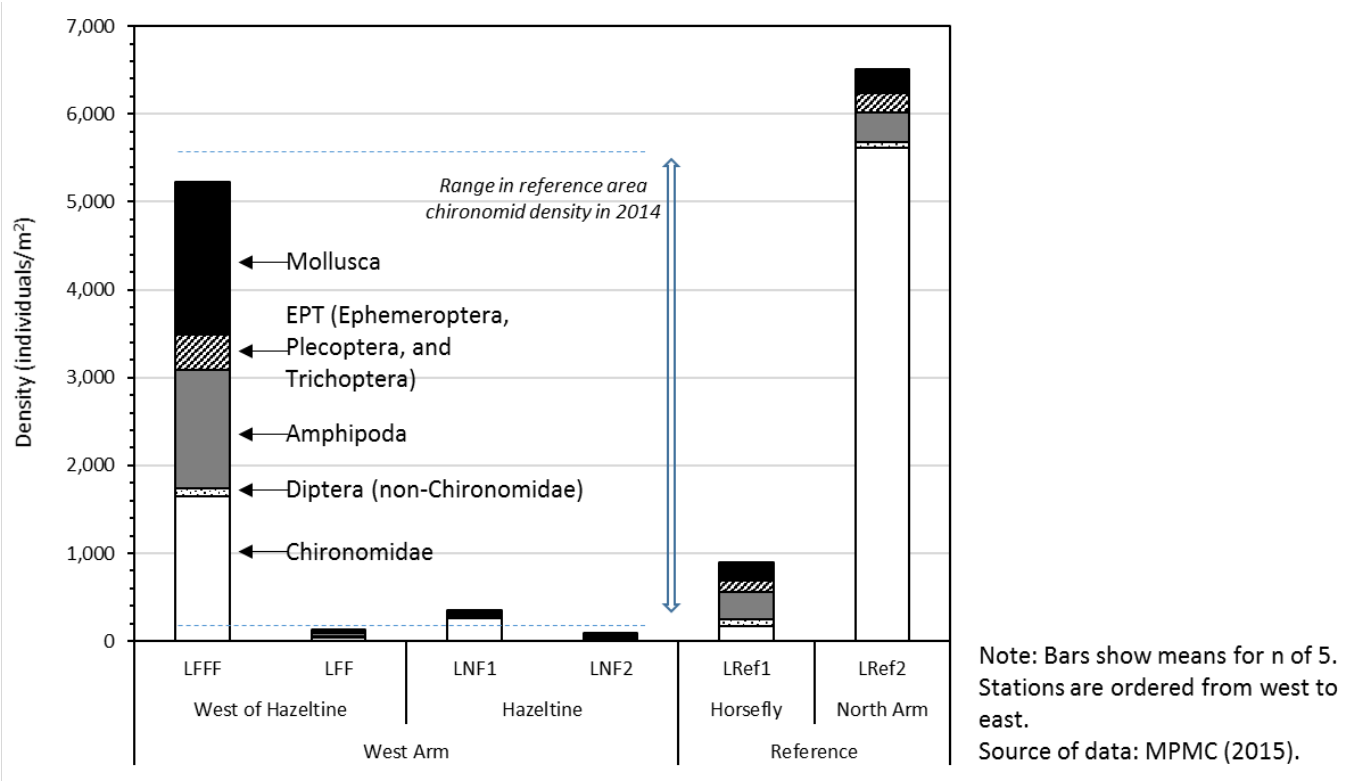
### 4.11.2 Littoral Zone

#### *4.11.2.1 Overview of Effects*

Using the classification system of the HRWG, this area corresponds to Ecological Unit QL-Littoral. The littoral zone in the Hazeltine Creek delta was scoured by the debris flow, affecting approximately 2.1 km and 94 ha of shoreline (approximately 5.8% of the shoreline length and 6.5% of the littoral area in the West Arm). The effect of the event was a reduction in the benthic invertebrate community and the alteration of shoreline rearing and spawning habitat. The event also blocked access to unimpacted upper reaches of Edney Creek, which is discussed above in Section 4.10.

The scouring of the Quesnel Lake shoreline also temporarily reduced the density (number of individuals per a given area) of benthic invertebrates. Benthic invertebrates such as chironomids (the aquatic larvae of midges), non-chironomid Diptera (e.g., the aquatic larvae of black flies), oligochaetes (freshwater worms), amphipods, EPT taxa (the aquatic larvae of mayflies, stoneflies, and caddisflies), and molluscs (snails and clams) are found in the littoral zone and can be eaten by fish. The abundance of these types of benthic invertebrates provides an indication of habitat quality for rearing and overwintering fish. Chironomid, amphipod, and EPT taxa density is particularly relevant to the fish population of Quesnel Lake as the fish that occupy the littoral zone feed on these groups.

Benthic invertebrate community sampling in September 2014 showed that the density of organisms in the West Arm of the lake adjacent to the mouth of Hazeltine Creek was significantly lower than observed at a reference area in the North Arm of the lake and at a far-field station in the West Arm near the outlet to Quesnel River (Figure 18). Reference areas of the lake were dominated by chironomids, amphipods, molluscs, and EPT taxa and these taxonomic groups were affected primarily in the immediate vicinity of the Hazeltine Creek mouth. The data also show that the density of benthic invertebrates is variable in Quesnel Lake and the degree of effect was variable through the West Arm. For example, chironomid, amphipod and EPT density was lowest at the stations immediately adjacent to Hazeltine Creek whereas the station closest to the Quesnel River had a greater density of chironomids than at Horsefly, suggesting lesser effect there.



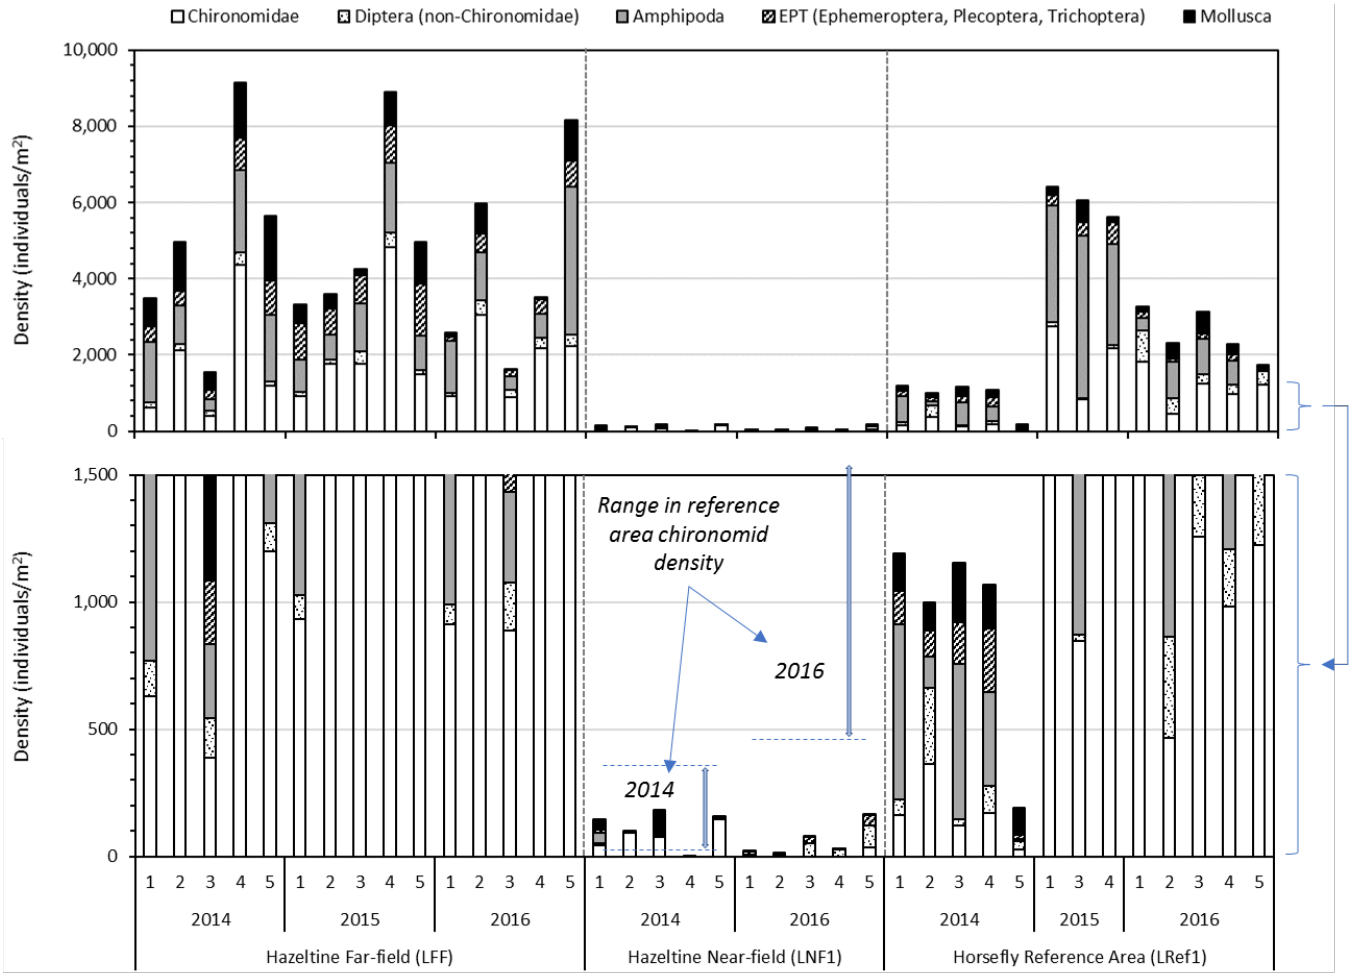


**Figure 19: Spatial Variability in Benthic Invertebrate Abundance in the Quesnel Lake Littoral Zone in September 2014**

Data from subsequent sampling indicate that benthic invertebrate density of the Hazeltine shoreline was still lower in 2016 than observed at the far-field station in the West Arm and in the reference area at Horsefly (Figure 20). A follow-up sampling event was undertaken in 2017, but the sampling methods were changed between 2016 and 2017 and it is therefore not possible to undertake a quantitative comparison of the data (Minnow 2018c). As well, additional habitat reconstruction activities are planned, which may disrupt the recovery of the benthic community.

Note: Bars show results for individual replicates (numbered from 1 to 5 except where noted). LNF1 not sampled in 2015.
Source of data: Golder (2017c).

**Figure 20: Spatial and Temporal Variability in Benthic Invertebrate Density in the Quesnel Lake Littoral Zone, 2014 and 2015**

The actual contribution of the affected area of littoral zone to fish productivity is not known; however, the available data suggest that the decrease in benthic invertebrate prey items have not resulted in a decrease in condition factor of forage fish, Lake Trout, or Burbot captured in the littoral zone (Figure 21).

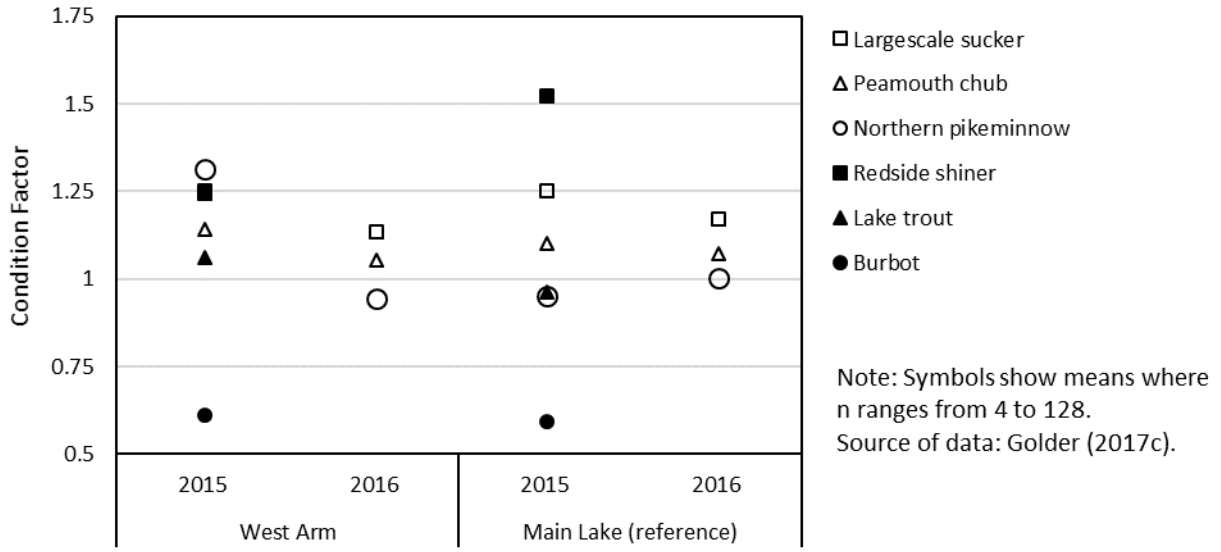

**Figure 21: Spatial and Temporal Variability in Condition Factor for Fish Species Potentially Using Littoral Zone Habitat, 2015 and 2016**

### *4.11.2.2 Remediation Activities to Date*

MPMC has been implementing a remediation strategy over the last two years that resulted in the removal of tailings from the Hazeltine Channel bed and surrounding areas, reconstruction of the Hazeltine and Edney Creek channels, and restoration of the connection of Edney Creek with Quesnel Lake through the littoral zone (Section 4.10). The lower area of Edney Creek was reconstructed on a prioritized basis to stop erosion and restore fish access (completed February 2015), with instream habitat features subsequently added (initial work August 2015). In the littoral areas adjacent to the Edney Creek channel, material has also been placed to help manage erosion.

Fish access to Hazeltine Creek from Quesnel Lake is still restricted at this time due to ongoing remediation activities but Quesnel Lake is connected to Edney Creek.

### *4.11.2.3 Remediation Plan*

The HRWG has not finalized the remediation objectives for the littoral zone of Quesnel Lake; however, based on the pathways of effect (Table 4) that are still considered operable, it is expected that the objectives will focus on habitat suitability for spawning and rearing, in particular around structure and riparian vegetation. This remediation work will tie into work that is underway in Lower Hazeltine Creek or has already been completed in Edney Creek.

The Quesnel Lake littoral zone benthic invertebrate monitoring study design will need to reflect the requirements to monitor recovery using consistent (over time) techniques to support the evaluation of the efficacy of the remediation to address uncertainties in the risks associated with residual sediment contamination. The monitoring study design will be included in an updated CEMP.

It is anticipated that productivity losses during the period of loss will be addressed through the development of habitat offsets as noted in Section 5.3.1.8.

## 4.11.3 Benthic Zone

### *4.11.3.1 Overview of Effects*

Using the classification system of the HRWG, this area corresponds to Ecological Unit QL-benthic. The benthic zone[6] below the 100 m contour was impacted by outwash materials across an area of 1.81 km$^2$. This material covered benthic substrate and invertebrate organisms, and as demonstrated by benthic invertebrate community sampling in September 2014, the density of benthic invertebrates in the West Arm of the lake adjacent to the mouth of Hazeltine Creek was significantly lower than observed at a reference area near Horsefly River as well as other reference areas of the lake (Figure 22). Reference areas of the lake were dominated by chironomids and oligochaetes and both of these taxonomic groups were affected in the West Arm, primarily in the vicinity of Hazeltine. The data also show that the density of benthic invertebrates is variable in Quesnel Lake and the degree of effect was variable through the West Arm. For example, chironomid density was lowest at the stations immediately adjacent to Hazeltine Creek whereas the station closest to the Quesnel River had a similar density of chironomids as observed at the North Arm reference station, suggesting lesser effect there. The density of chironomids is particularly relevant to fish such as Mountain Whitefish and Lake Trout as these fish tend to eat these insects as they hatch and rise up through the water column to the surface of the lake.

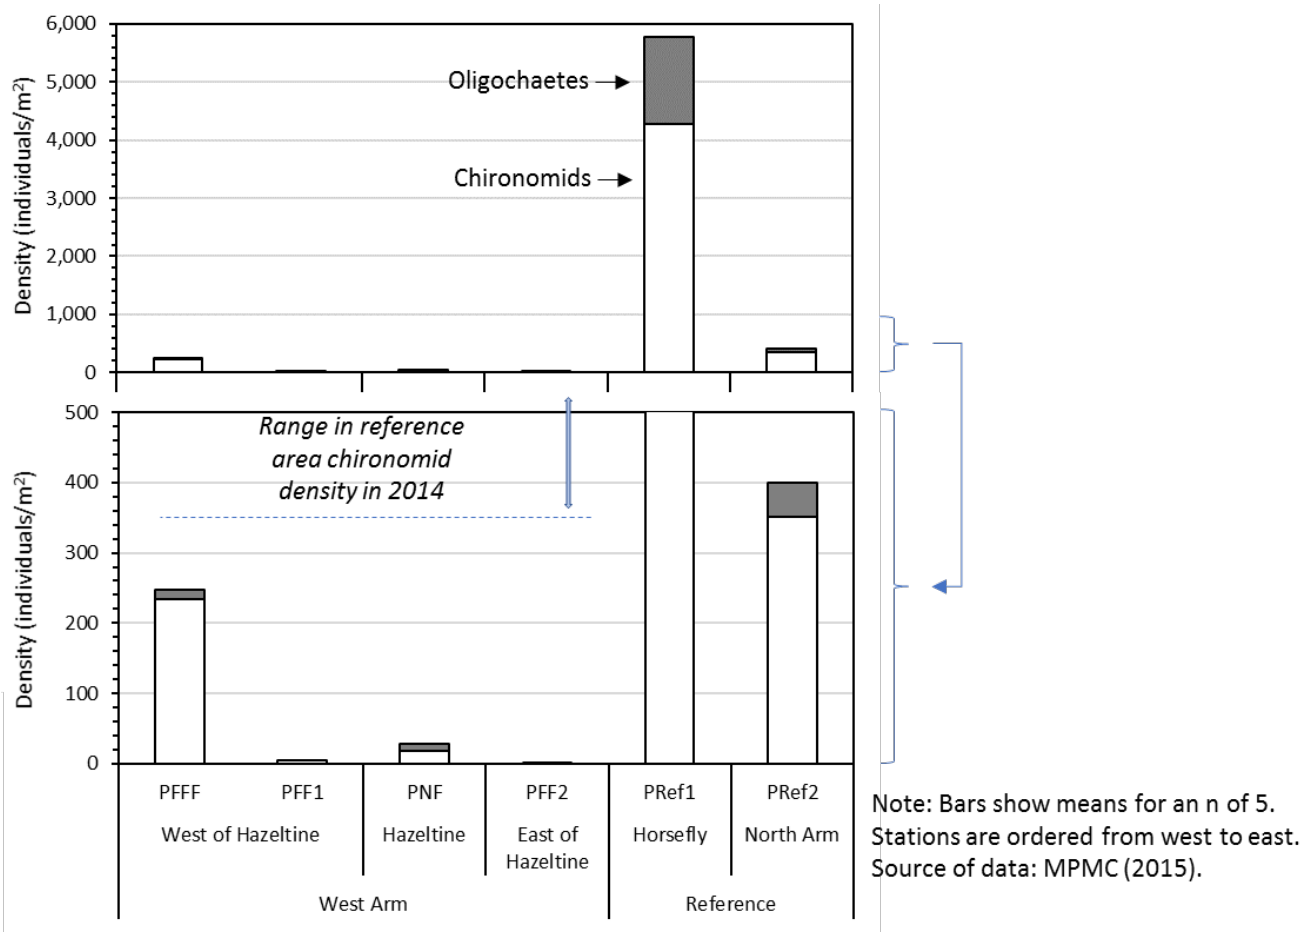

**Figure 22: Spatial Variability in Benthic Invertebrate Abundance in Quesnel Lake Benthic Zone in September 2014**

[6] also called the “profundal” zone in some of the Quesnel Lake studies

Benthic invertebrate data collected in 2015 and 2016 show that the benthic invertebrate community has started to recover in the vicinity of Hazeltine Creek (Section 3.2.4). Samples were also collected in 2017 but as of the time of writing, results are not yet available. Figure 23 shows the density of chironomids and oligochaetes in individual replicates for the Horsefly reference station and the Hazeltine affected station for 2014, 2015, and 2016.
The communities were dominated by oligochaetes and chironomids, and spatially variable at both stations.
The significantly higher number of oligochaetes at the reference station in 2015 appears to be related to an influx of tubificids (one of the types of oligochaete worms in that area), potentially from the Horsefly River itself or the shorelines of the lake. Although a positive (increasing) trajectory of recolonization is apparent in the data (Figure 23), those data are based on only three seasons of sampling events and verification of such a trajectory is required. As only three annual sampling events (2014 to 2016) have been conducted to date and in limited areas of the lake bottom, the trajectory of recolonization requires confirmation.

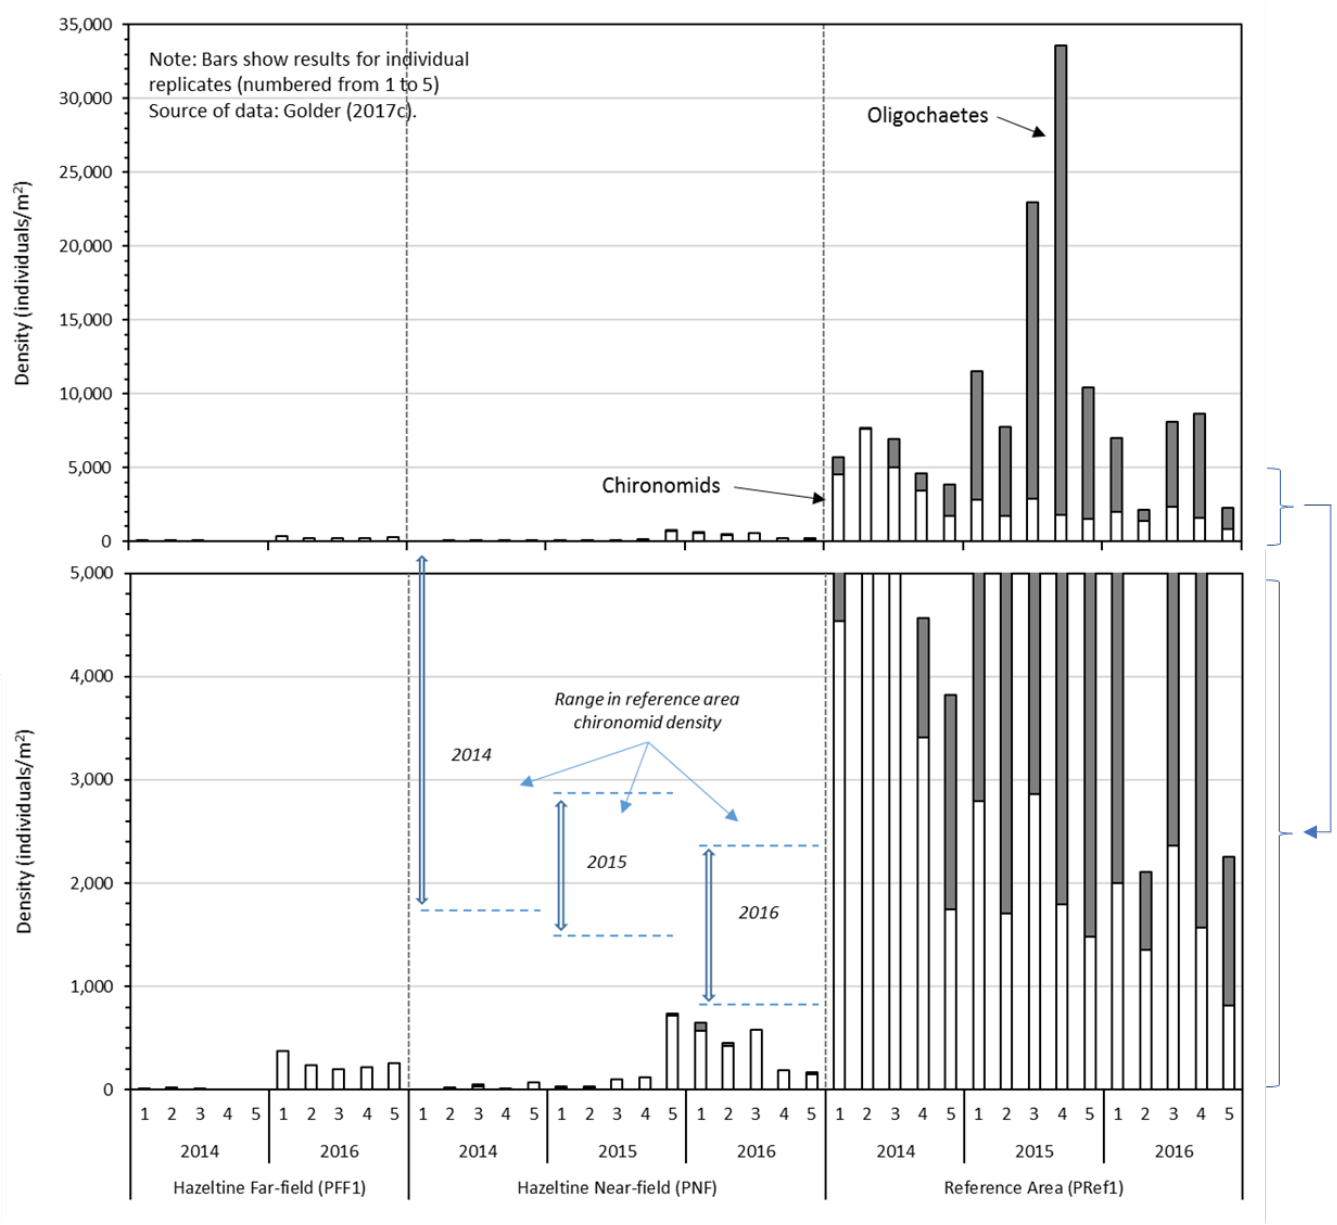

**Figure 23: Spatial and Temporal Variability in Benthic Invertebrate Abundance in Quesnel Lake Benthic Zone in 2014, 2015, and 2016**

The ERA suggested that the physical structure, more specifically the low organic carbon content of the sediments, is affecting the recolonization of those sediments. In laboratory-based sediment tests, it was found that in low organic carbon sediments dominated by outwash materials that are low in organic carbon, growth was reduced. However, adding organic carbon to those sediments resulted in normal organism growth. Figure 24 illustrates the spatial and temporal variability of total organic carbon (TOC) in the sediments of the West Arm and in references areas at Horsefly and in the North Arm. In 2014, sediments collected adjacent to Hazeltine had relatively low TOC (<0.5%). Subsequent sampling indicated that TOC was higher in 2015 and 2016, and while not at the average TOC content observed in the reference areas, TOC was within the range of reference samples. Thus, it appears that natural processes are contributing organic carbon to the sediments. This is a reasonable inference based on the TOC content of sediments collected in sediment traps at the West Arm far field station (towards Quesnel River; 2.3 to 4.3%) and the Horsefly reference station (2 to 3.5%) between 2014 and 2015. The increasing TOC in the sediments at Hazeltine could in turn be related to the increasing density of benthic invertebrates observed in the West Arm.

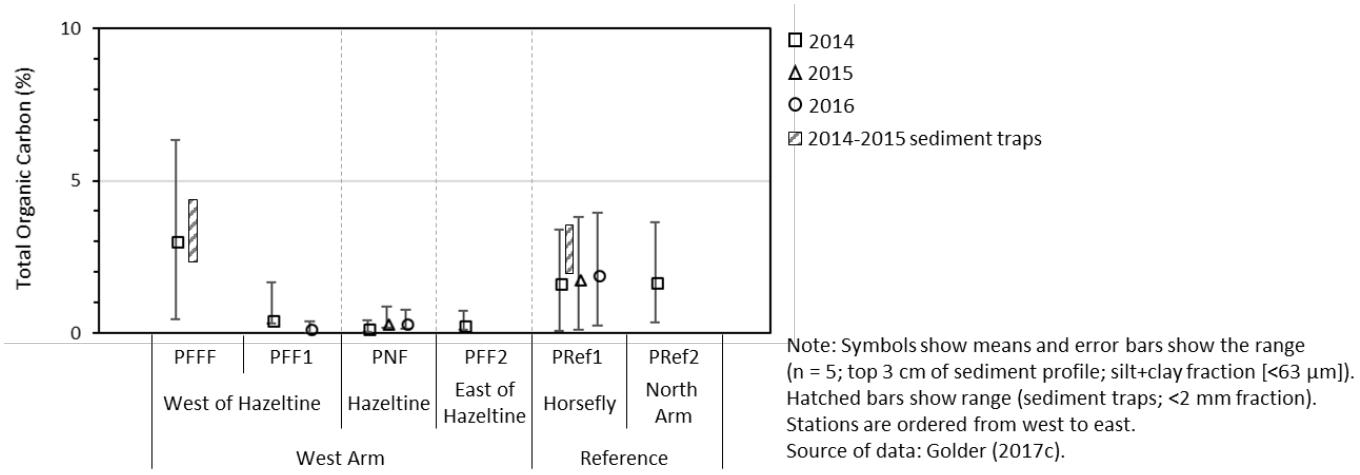

**Figure 24: Spatial Variability in Total Organic Carbon in Quesnel Lake Benthic Sediments in 2014, 2015, and 2016**

A literature review was undertaken to identify factors that influence succession and recolonization of disturbed sediments in lake environments. Little useful information was found as studies regarding succession and recolonization of disturbed benthic substrates have focussed on marine areas which are:

- dredged or received disposal of dredged material (e.g., Oliver et al. 1977, Van Dolah et al. 1984, Bolam and Rees 2003, Cruz-Motta and Collins 2004)
- have become organically enriched (e.g., Holte and Oug 1996; Norkko and Bonsdorff 1996; Nilsson and Rosenberg 2000)
- have received tailings (e.g., Kathman et al. 1984; Ellis and Hoover 1990; Olsgard and Hasle 1993; Burd 2002; Hughes et al. 2015)

The literature review also sought studies of British Columbia lakes that are known to have received operational (i.e., deliberate and permitted) deposits of tailings (Table 7). For these locations, studies were either only done prior to the commencement of tailings deposits, or, where post-discharge studies were available, they were conducted decades after the fact and therefore did not provide an indication of either recovery rates or recovery of benthic invertebrate communities in the near-term (e.g., MEMPR 1991; Mudroch et al. 1993). The potential use of data from the available studies is also confounded by the fact that the tailings from the mines studied were acid generating, unlike Mount Polley tailings (Kennedy et al. 2016), and the contaminants of primary concern were different (e.g., mercury, arsenic, zinc). Nonetheless, although the profundal (deep) zone of Benson Lake was devoid of benthic invertebrates when the Benson Lake Coast Copper Mine stopped discharging tailings in 1973, the follow-up study, which wasn't undertaken until some 17 years later "found that Benson Lake showed little evidence of the fact that it was the recipient of mine waste" (MEMPR 1991). The authors of that study suggested that the organic layer that had accumulated on the lake bed may have prevented the further flux of metals (e.g., zinc) from the underlying tailings.

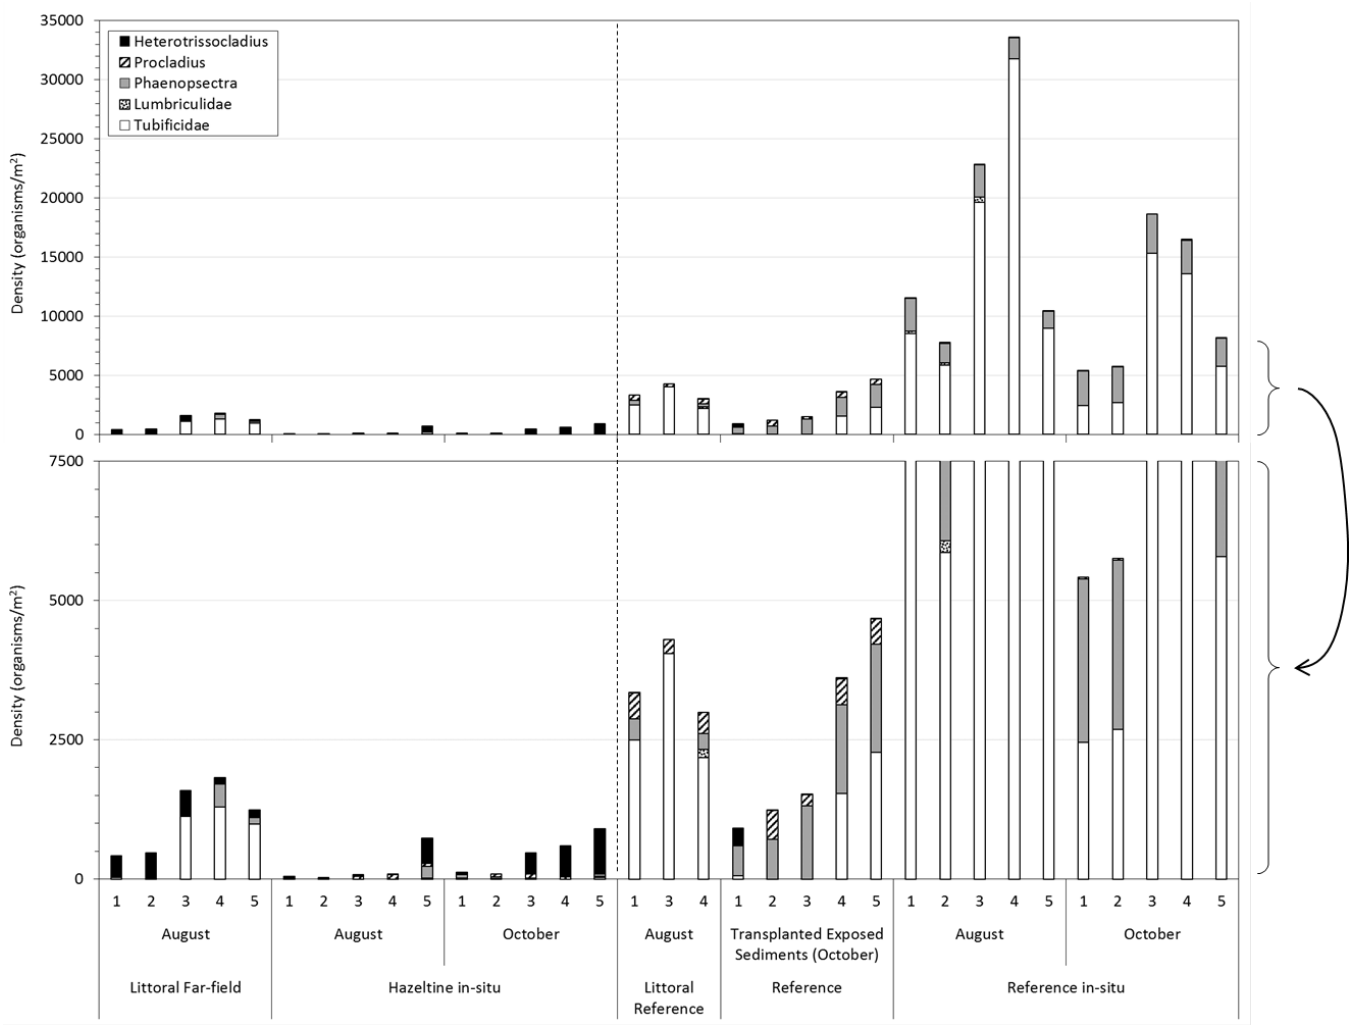
**Table 7: Mines in British Columbia That Deposited Tailings to Lakes**

| Area | Waterbody | Mine | Type | Active Period |
|---|---|---|---|---|
| Central BC | Jack of Clubs Lake | Cariboo Gold Quartz Mine | gold | 1933 to 1964 |
| Vancouver Island | Benson Lake | Benson Lake Coast Copper Mine | copper | 1962 to 1973 |
| | Buttle Lake | Myra Falls/Lynx Mine | zinc, copper, gold | 1966 to 1984 |
| Northwest BC | Tom MacKay Lake Albino Lake | Eskay Creek Mine | gold | 2002 to 2008 |
| | Brucejack Lake | Brucejack Mine | gold | Commenced in 2017 |

Although studies from the marine environment provide a positive indication that disturbed sediments can and will start to recolonize relatively quickly after the initial disturbance, they are not direct analogues for deep lakes. This is because dispersal of organisms is influenced by movement of the water column, which is typically greater in the tidal marine environment than in lakes where water movement at the bed of deep lakes tends to be relatively low by comparison. However, the principle that colonization sequence and speed are dependent on dispersal mode/abilities (i.e., how they move) of a given taxonomic group and size of area disturbed are also true for freshwater environments (e.g., Cañedo-Argüelles and Rieradevall 2011).

The primary taxonomic groups found in the profundal area of Quesnel Lake are chironomids and oligochaetes. The predominant chironomid species found in Quesnel Lake tend to be clingers or burrowers/tube dwellers that feed on detritus (e.g., *Phaenopsectra* sp., *Heterotrissocladius* sp.; Merritt and Cummins 1978). *Procladius* sp. is another chironomid species present that "sprawls" or stays on the surface of the sediment. Regardless of the mode of existence (burrower versus sprawler), because benthic in-faunal chironomids are the aquatic larval stage of flying insects, they reach the lake bed as eggs deposited on the surface of the lake or eggs/larvae flushed from the littoral zone or tributary streams rather than via lateral "migration" at the lake bed. Once in deep lakes, chironomid development can take a longer period of time than for the same species in shallower areas (Wallace and Anderson 1995). This suggests the possibility (but not certainty) that in the initial year after disturbance of a deep lake bed, a majority of the organisms in the sediments may be small enough that they are not retained in a sediment sieve. In subsequent years, the retained organisms may be the more developed larvae that were deposited in prior years.

In comparison, the oligochaete species present in Quesnel Lake (Lumbriculidae and Tubificidae) spend their entire life cycle in the aquatic environment. They therefore colonize lake bed sediments either by *in situ* reproduction or via discharge from tributary streams (Pennak 1978). Aquatic oligochaetes tend to burrow into the sediments and lateral movement would be slow relative to the dispersion of a species that does not burrow.



That the dispersal processes described above are naturally successful is supported by the fact that sediment in other areas of Quesnel Lake are colonized by chironomids and oligochaetes. The hypothesis that the sediments in the West Arm will recolonize naturally is also supported by data from a sediment transplant study conducted in 2015 with the objective of identifying potential constraints to recolonization of the West Arm sediments (Minnow 2016a). The study involved collection and taxonomic analysis (identification and enumeration) of sediment from:

- The lakebed near Hazeltine and transplant of that material to the reference area in buckets that were retrieved after seven weeks ("transplanted exposed sediment").[7]
- The profundal zone in the West Arm and reference areas in August and October ("*in-situ* sediment"). These data illustrate the change in the benthic community during the transplant period.
- The littoral zone in the West Arm and reference areas in August ("littoral sediment"). These data provide an indication of the benthic invertebrate community in adjacent shallow areas which may be a source of colonizing organisms.

Figure 25 shows the density (number of organisms per $m^2$) for the dominant taxonomic groups that occur in the deep lake sediments: three chironomid taxa (*Phaenopsectra* sp., *Procladius* sp., and *Heterotrissocladius* sp.) and two oligochaete taxa (Tubificidae and Lumbriculidae). The upper graphs show the full range of density (up to 35,000 organisms/$m^2$) and the lower graph shows density up to 7,500 organisms/$m^2$ to highlight the dominant taxa in the Hazeltine sediments. The stations are organized to show the littoral zone results next to the *in situ* benthic zone results for the West Arm location, and the littoral zone, *in situ* benthic zone, and transplanted West Arm sediments at the reference location.

As shown in Figure 25, sediment from the benthic zone of Quesnel Lake adjacent to the mouth of Hazeltine Creek transplanted to the reference area had a greater density of benthic invertebrates than did the sediments *in situ* at Quesnel Lake near Hazeltine. The benthic invertebrate density and composition in two of the transplanted sediment replicates was also similar to that observed in two of the in situ reference sediments as of October when the sediment buckets were retrieved. The benthic community in the transplanted sediments after the seven-week deployment was dominated by the oligochaete Tubificidae and the chironomids *Phaenopsectra* sp. and *Procladius* sp., which were also observed in the littoral zone at Horsefly. In comparison, the *in situ* sediments at Hazeltine were dominated by the chironomid *Heterotrissocladius* sp., which was the dominant chironomid in the littoral zone. These data suggest that the recolonization of the sediments in the West Arm may be more dependent on proximity to a source of colonizing organisms than on the quality of the sediment itself.

[7] The sediments were transplanted with and without a carbon amendment. The results for the amended sediments were not significantly different from the un-amended sediments therefore the data for the amended sediments are not shown here.

Note: Bars show results for individual replicates (numbered from 1 to 5 except where noted).
The upper graph shows the full range of density and the lower graph shows density up to 7,500 organisms/m².
The month indicates when the samples were collected for taxonomic analysis. The transplanted sediments were deployed for seven weeks.
Source of data: Golder (2017c).

### *4.11.3.2 Remediation Activities to Date*

To date, the focus on the Quesnel Lake benthic zone has been testing, monitoring and evaluation of data through the aquatic ecological risk assessment to identify appropriate remedial decisions. Remedial actions with regards to the Quesnel Lake benthic zone have consisted of actions to stop the further release of particulate materials into the lake from erosion of Hazeltine Creek (Bronsro et al. 2016).

#### 4.11.3.3 Remediation Plan

Based on the identified ecological function of rearing (Table 4) and the effect of the event on the benthic invertebrate community as illustrated above, the remediation objective for the Quesnel Lake benthic zone is a benthic invertebrate community that is similar to that occurring in other, unaffected areas of the lake, and which contributes food organisms to fish. The benthic community would be used as an indicator for fish productivity because there is a poor understanding of the contribution from profundal benthic communities to fish productivity (for example Figure 23) whereas the density of benthic organisms can be directly measured.

### Overview of Net Environmental Benefit Analysis

Net environmental benefit analysis (NEBA) is a method developed to identify and compare alternative site management options, often for contaminated sites or for oil spill clean-up (Efroymson et al. 2003). The focus of this methodology is net environmental benefit, which is the balance of the environmental benefit achieved from a management option with the environmental costs associated with the option (e.g., habitat disruption). "Environmental benefit" addresses a range of natural resource "services" from habitat that supports ecological function (water quality, fish habitat, bird nesting), direct human uses (e.g., recreation, fisheries), and passive values (e.g., existence value, aesthetic value). Environmental costs and benefits are therefore considered in a broad context. NEBA was undertaken for the Quesnel Lake portion of the RP because (unlike Hazeltine Creek) the remedial options have not been evaluated by the HRWG. NEBA provides context for the evaluation of those options.

As a result of physical smothering from the settled breach outwash materials, the environmental services of the lakebed have been disrupted and low organic carbon content has been identified as a potentially limiting factor for benthic invertebrate community recovery. NEBA is therefore, conceptually, a useful tool for identifying and comparing potential management options for addressing the Quesnel Lake remediation area. A framework for undertaking NEBA is illustrated in Figure 26.

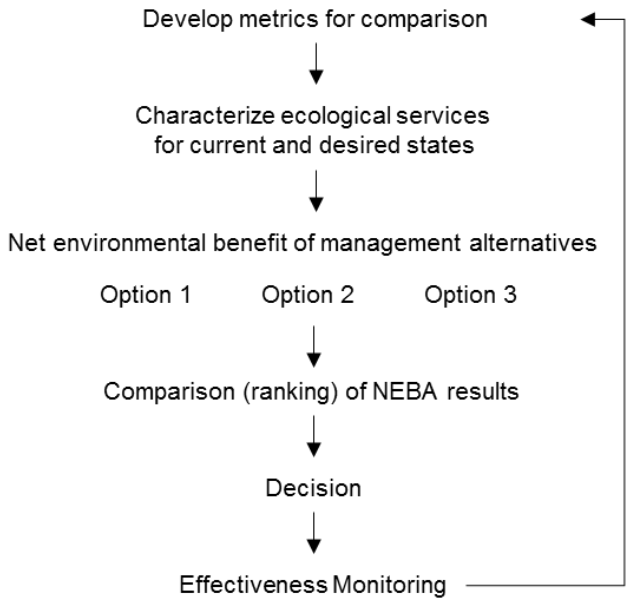

**Figure 26: Framework for Net Environmental Benefit Analysis (adapted from Efroymson et al. 2003)**

The focus of the remainder of this section is to identify alternative remediation (action) options, selection of metrics for comparing those options, and the ranking of the options based on their respective net environmental benefit in the context of the remedial objectives of (re) establishing a benthic invertebrate community that is similar to that occurring in other, unaffected areas of the lake, and which contributes food organisms to fish.

## Identification of Conceptual Remedial Options for Quesnel Lake

The three general remedial options typically considered in a NEBA are (Efroymson et al. 2003):

- Monitored Natural Recovery
- physically, chemically, or biologically remediate the site – this may mean, in the context of sediments, physical dredging of the material or the addition of materials to amend the sediment (e.g., organic carbon)
- improve the ecological value of the site through remediation and restoration

A combination of the above may also be appropriate depending on site specific considerations. For the Quesnel Lake remediation area, the more specific remedial options that could be applied are as follows:

- monitored natural recovery (MNR), together with productivity offsets for interim losses
- physical remediation in the form of dredging
- chemical/biological remediation in the form of sediment amendment with organic carbon
- chemical/biological remediation in the form of thin-layer capping

The options evaluation starts by considering each of these four options and considering, at a conceptual level (i.e., not including engineering design, costing), how each of these options might be implemented under the a priori assumption that the options are technically and financially feasible. Given these implementation scenarios, factors that would influence environmental costs and benefits, in the broad sense described above, are considered so that there is a basis for evaluating the remedial options on that basis. Simple categorical ranks were applied to those variables to evaluate the net environmental benefits.

Table 8 provides an overview of each of these remediation options as well as variables that need to be taken into consideration in the planning and implementation of the options. Habitat offsets are not included in Table 8, however, they are recognized in environmental policy as a remedial method and offsets are the proposed means of addressing service losses over the period of recovery and are discussed further in Section 5.4.2.

**Table 8: Overview of Considerations for Remediation Options for Quesnel Lake Profundal Benthic Zone**

| Variable | Dredging | Amendment or Chemical Stabilization | Thin-layer Capping | Monitored Natural Recovery |
|---|---|---|---|---|
| **Description** | | | | |
| Overview | Physical removal of lakebed substrates that were contributed by the deposit of outwash material, debris and tailings during the event. Estimated volumes to be removed are 1.81 $km^2$ x 10 m in depth (some consolidation of those materials will have occurred making the consolidated thickness of deposits less). Although depth would be variable and this may overestimate deposit, it is a plausible planning basis to account for over-dredging and bulking of dredged materials.<br><br>Deposited material is at water depths greater than conventional dredging equipment, which is designed for enabling vessel navigation. Clam shell dredging would be feasible but turbidity would be very difficult to control and material handling would involve heavy truck traffic throughout the area. Depths exceed conventional suction dredging depths though unconventional equipment may be modifiable.<br><br>Dredged material would need to be dewatered at a rate proportional to production and with suction dredging, large water volumes would be involved. | Involves (in this case) the addition of organic matter into lakebed substrates to provide an initial food source to enhance recovery of benthic invertebrate community. This approach has been proposed, though not operationalized, for submarine tailings placement areas in Norway (Kvassnes et al. 2009). Possible sources of organic carbon include:<br><br>■ bio char (e.g., burned wood) – may not have organic carbon in a form that is metabolically accessible by benthic organisms<br>■ unburned coal – may not have organic carbon in a form that is metabolically accessible by benthic organisms<br>■ compost or biosolids – likely to have organic carbon in a bioaccessible form<br><br>This option is considered experimental at the scale necessary. Research has been conducted at other locations on the delivery mechanism, different types of organic carbon, and thickness of the layer of amendment material needed to be successful. These studies have been conducted in relatively shallow water and most commonly for remediation of organic contaminants such as petroleum hydrocarbons and PCBs over limited spatial scales. Reports on studies regarding a lack of organic carbon at water depths similar to that of Quesnel Lake were not found; therefore, the success of organic carbon amendment as a remediation tool is uncertain, and a site-specific trial study would be needed to develop an appropriate design. Quesnel Lake is used as a drinking water source, thereby limiting the forms of organic carbon that would be acceptable and this may include most commercially sourceable forms that are also bioaccessible for benthic organisms. | Involves the addition of a thin layer (e.g., 1 to 10 cm depth) of material to the surface of the lakebed substrates to separate the colonizing biota from the deposited tailings. The material may be inert geological material (e.g., sand, clay) or may be composed of a mixture of geological material and components intended to bind with contaminants, such as activated carbon, as described for the amendment/chemical stabilization option.<br><br>Where capping material consists of an inert geological material and is not amended with a carbon source such as activated carbon, capping may not address the lack of carbon that has been identified in toxicity testing as a potential limitation to re-colonization. Conversely, when a carbon source is included, a greater impact on the existing benthic community may occur that if an inert geologic material is used (e.g., Samuelsson et al. 2017).<br><br>Depending on the area to be capped and the desired depth of the capping layer, the volume of material that would need to be imported and placed on the lake bottom could range from 150,000 to 1,500,000 $m^3$. | Involves allowing natural processes (e.g., sinking of diatoms and plankton, particulate organic matter from tributary streams) to contribute organic carbon to sediments.<br><br>There is no specific provincial guidance but parallels can be drawn to Monitored Natural Attenuation (MNA) of groundwater contaminants which is addressed by Technical Guidance 22 (MOE 2014), which identifies specific factors that must be in place for MNA to be considered feasible. |
| **Constructability** | | | | |
| Equipment availability | Deep-sea mining has been done at 200 m depth by purpose-built vessels with cutter suction dredge (CSD) heads that cannot be transported intact to Quesnel Lake. A shipyard would be needed on the shore of Quesnel Lake to assemble and/or construct vessels and dredge units.<br>Suction dredging units with proven capability at -70 m are available; it is possible that they could be custom-modified to work at the ~110-m depth that would required<br>Clam-shell dredging through 110 m of water column could be conducted but would require the construction of a work platform on site.<br>A fleet of dredge scows would need to be constructed on site. The required equipment is not readily available and would need to be procured, fabricated, and assembled. | Different methods for amending sediments have been used:<br>■ surface dumping from a split-hull barge<br>■ pumping a mixture of sand and carbon through a down pipe to a few meters above the substrate – usually in waters shallower than 100 m<br>■ “Injection” and rotor-tilling directly into the bedded sediment usually in waters shallower than 100 m<br><br>The selection of the equipment would dictate the precision of the placement of the organic carbon material.<br>For any of the scenarios listed above, the required equipment is not readily available or not easily transportable to the site; it could take years to procure/fabricate/assemble. | Different methods for amending sediments have been used:<br>■ surface dumping from a split-hull barge<br>■ pumping a mixture of sand and carbon through a down pipe to a few meters above the substrate – usually in waters shallower than 100 m<br><br>The selection of the equipment would dictate the precision of the placement of the capping material.<br>For any of the scenarios listed above, the required equipment is not readily available or not easily transportable to the site; it could take years to procure/fabricate/assemble. | N/A |

| Variable | Dredging | Amendment or Chemical Stabilization | Thin-layer Capping | Monitored Natural Recovery |
|---|---|---|---|---|
| Staging/work areas | A work area would be needed to:<br>■ Construct dredge platforms and scows.<br>■ Launch equipment into the lake and for offloading of dredged material from the dredger to a pump station or trucks, which would then transfer the material to the disposal site (notionally a disused pit or enlarged TSF.<br>■ If suction dredged, a floating umbilical with booster stations at 700 to 1,000,m intervals would extend from dredging unit to a single shore point (several km depending on the location of the dredge assembly).<br>■ If materials to be pumped, a pipeline would need to be constructed.<br><br>An additional pipeline would need to be constructed for dewatering in the case of suction dredging. | A work area would be needed to launch equipment into the lake and for loading of the vessel that would place the amendment material on the lake bed. This may require the construction of a ramp and/or jetty along the lake shore as well as removal of trees. | A work area would be needed to launch equipment into the lake and for loading of the vessel that would place the amendment material on the lake bed. This may require the construction of a ramp and/or jetty along the lake shore as well as removal of trees. | N/A |
| Water management (treatment and disposal) | Hydraulic dredging produces volumes of water at a 1:6 to 1:10 ratio of solids to water that would require management. For a dredged material volume of 32.4 M $m^3$, 194 approximately to 324 M $m^3$ of dredged slurry would be generated. This water would need to be conveyed from the lake bottom, across the lake and up to the disposal location where solids would be removed. The clarified water would then need to be returned to the lake.<br>Clam-shell dredging re-suspends sediments into the water column. For typical, nearshore construction dredging projects, this type of work is conducted with in a turbidity curtain. A turbidity curtain would be operationally infeasible deeper than about 10 m. Therefore, if this type of equipment were used, active turbidity control would not be possible. Clam shell dredged material would need to be loaded to a barge and dewatered at that location, in Quesnel Lake. | N/A – Water requiring treatment would not be handled. | N/A – Water requiring treatment would not be handled. | N/A |
| Safety Considerations | Health and safety planning to address operation of:<br>■ water-based equipment<br>■ transport of equipment<br>■ potential interaction with recreational users of Forest Service Roads<br><br>Navigational risks to recreational boaters from a 24/7 operation and potentially several km long “umbilical” slurry line on the water surface – even with navigational lights, this would pose a risk, particularly to non-local boaters | Health and safety planning to address operation of:<br>■ water-based equipment<br>■ transport of equipment<br>■ potential interaction with recreational users of Forest Service Roads and Quesnel Lake boaters | Health and safety planning to address operation of:<br>■ water-based equipment<br>■ transport of equipment<br>■ potential interaction with recreational users of Forest Service Roads and Quesnel Lake boaters | Health and safety planning to address operation of a sampling vessel similar to a typical recreational vessel as operated on Quesnel Lake |
| Access to Site | Potential need to upgrade access roads to accommodate size of equipment that would need to be brought to the lakeshore<br>Clearing of staging area(s) along Quesnel Lake shoreline | Potential need to upgrade access roads to accommodate size of equipment that would need to be brought to the lakeshore | Potential need to upgrade access roads to accommodate size of equipment that would need to be brought to the lakeshore | N/A. Existing infrastructure can be used. |
| In-water footprint | Estimated at a minimum of 1.81 $km^2$ with additional allowance for over-dredging (controllability of suction dredging unit at 110m depth may be a challenge). | Up to 1.81 $km^2$ | Up to 1.81 $km^2$ | No incremental amounts beyond the initial impact |

| Variable | Dredging | Amendment or Chemical Stabilization | Thin-layer Capping | Monitored Natural Recovery |
|---|---|---|---|---|
| **Conceptual Schedule** | | | | |
| Planning, Engineering and Permitting | 2 to 4 years | 2 to 4 years + study durations for small scale trials | 2 to 4 years + study durations for small scale trials | N/A. Available data indicates that the process of natural recovery is already occurring (Section 4.11.3) |
| Procurement and/or construction of equipment | 5+ years | 5 years | 5 years | N/A |
| Implementation | At 4,000 $m^3$/day (convention clam-shell dredging using four spreads) to 6,000 $m^3$/day (deep-sea cutter suction dredging, assuming that it were feasible) and assuming 6-months of production during ice-free season and suitable weather conditions, dredging of 32.4 million $m^3$ would take 30+ years. | One to two open water seasons (depending on method of placement) with potential need to repeat application of amendments | One to two open water seasons (depending on method of placement) with potential need to repeat application of amendments | N/A |
| Certainty in Outcome | Dredging would remove the deposited material, but there is uncertainty as to whether the material at the dredge cut depth would have sufficient organic carbon to support benthic invertebrate recolonization. It would not be possible to have a dredge cut that is at the former mud line and therefore, it is unlikely that the newly exposed material would have organic carbon levels similar to reference conditions. There is not a clear risk reduction benefit that would occur by removing the deposited materials. | Option is experimental, based on benchtop laboratory testing; there is low certainty that application to a large area on the lake bed would improve recolonization over and above MNR, given that mechanisms of colonization (Section 4.11.3) would be the same as for MNR. | Option is experimental, based on laboratory and field-scale testing to determine the applicable material type and layer thickness.<br><br>There is low certainty that application to a large area on the lake bed would improve recolonization over and above MNR, given that mechanisms of colonization (Section 4.11.3) would be the same as for MNR. | Recolonization by benthic invertebrates has already been observed *in situ* in the West Arm and in transplanted sediment to other parts of Quesnel Lake. Natural processes are expected to be successful. Monitoring is required to verify this expectation and attainment of diversity and abundance similar to other areas in Quesnel Lake. |
| **Considerations** | | | | |
| ***Geotechnical*** | | | | |
| Slumping of lake walls | ■ Removal of material at toe of lake wall could destabilize the submerged slope and cause further scouring and deposition of material, and subsequent effects to water quality. | ■ The mass of material anticipated for placement is unlikely to affect slopes. | ■ The mass of material anticipated for placement is unlikely to affect slopes. | N/A |
| Compaction of lake bed | ■ Depending on the removal method, the remaining sediment at the dredge cut depth could be compacted, thus creating additional conditions that affect benthic invertebrate recolonization or would require more “aggressive” dredging equipment. | ■ Placement of a layer of material could potentially result in compaction of underlying materials, thus creating additional conditions that affect benthic invertebrate recolonization. However, it is expected that organic carbon amendment would be a thin layer. | ■ Placement of a layer of material could potentially result in compaction of underlying materials, thus creating additional conditions that affect benthic invertebrate recolonization. However, it is expected that the cap would be a thin layer. | N/A |
| ***Aquatic Habitat*** | | | | |
| Fish | ■ Dredging for a long time frame would continually displace fish from the area of work and disrupt food sources for benthic-feeding fish as they are disturbed while the work progresses. | ■ Application of amendment may temporarily displace fish in the immediate work area.<br>■ Food sources during implementation would be disrupted, to the extent that those sources come from the benthos. | ■ Application of capping material may temporarily displace fish in the immediate work area.<br>■ Food sources during implementation would be disrupted, to the extent that those sources come from the benthos. | N/A |

| Variable | Dredging | Amendment or Chemical Stabilization | Thin-layer Capping | Monitored Natural Recovery |
|---|---|---|---|---|
| Offsetting/rehabilitation costs | ■ Additional offsetting might be needed to address time lag in benthic habitat recovery as a result of the ongoing disturbance. | ■ Additional offsetting might be needed to address time lag in benthic habitat recovery; however, both the extent of loss and the time lag would be expected to be smaller than the initial impacts of the event. | ■ Additional offsetting might be needed to address time lag in benthic habitat recovery; however, both the extent of loss and the time lag would be expected to be smaller than the initial impacts of the event. | N/A |
| ***Terrestrial Habitat*** | | | | |
| Riparian vegetation | ■ Creation of sufficiently large staging area(s) might require removal of shoreline vegetation. | ■ Creation of sufficiently large staging area might require removal of riparian vegetation. | ■ Creation of sufficiently large staging area might require removal of riparian vegetation. | N/A |
| Birds | ■ Creation of staging area could disrupt bird habitat, although site selection and timing would likely be able to address such disruption. | ■ Creation of staging area could disrupt bird habitat, although site selection and timing would likely be able to address such disruption. | ■ Creation of staging area could disrupt bird habitat, although site selection and timing would likely be able to address such disruption. | N/A |
| Wildlife | ■ Creation of staging area could disrupt wildlife habitat. | ■ Creation of staging area could disrupt wildlife habitat. | ■ Creation of staging area could disrupt wildlife habitat. | N/A |
| ***Water Quality*** | | | | |
| Induced turbidity | ■ Clam shell dredging would induce turbidity. Given the clear water characteristics of Quesnel Lake, it is likely that this would result in visible turbidity in the lake. A clamshell would move turbid waters across the thermocline.<br>■ Hydraulic dredging would have much reduced turbidity generation compared to mechanical (clamshell) dredging, but some induced turbidity would occur.<br>■ With depths involved it would not be possible to have a barrier/turbidity curtain in place to contain induced turbidity using either method. | ■ Where application of amendment is via surface or near surface dumping, amendment material would cause turbidity.<br>■ Bottom substrates may be disturbed as amendment material reaches lake bed; computational or empirical approaches could assist in quantifying whether that would be significant.<br>■ With depths involved it would not be possible to have a barrier/turbidity curtain in place to contain induced turbidity. | ■ Where application of capping material is via surface or near surface dumping, the material would cause turbidity.<br>■ Bottom substrates may be disturbed as capping material reaches lake bed; computational or empirical approaches could assist in quantifying whether that would be significant.<br>■ With depths involved it would not be possible to have a barrier/turbidity curtain in place to contain induced turbidity. | N/A |
| Contaminant dispersion | N/A | ■ N/A, although the organic carbon may disperse into the water column during application. | ■ N/A, although the capping material may disperse into the water column during application. | N/A |
| Introduction of foreign substances and potential breakdown products | ■ N/A. Dredging does not involve introduction of foreign materials.<br>■ As with the use of machinery around water generally, there is always some risk of loss of fuel and lubricants to the water, despite exercise of precaution. | ■ The addition of an organic carbon amendment would be experimental and the optimal application rate is unknown at this time. If too much organic carbon was added to the lake bed, breakdown products such as sulphides and ammonia could be released, and dissolved oxygen could be consumed, creating anaerobic conditions in the sediment, which would retard colonization by communities compared to reference locations. | ■ Depends on the material selected for the cap. A geologically inert material would not be expected to contain foreign substances. | N/A. |
| ***Navigation / Recreation*** | | | | |
| Boat passage | ■ Large work platform (50 x 100 m) and safety zone (100-m radius) around work area would restrict usage of portions of lake.<br>■ With suction dredging, a floating slurry pipeline would have an uninterrupted span of potentially up to 10 km or more depending on dredged material disposal location and dredging rigs. Diesel booster pumps would operate every 0.5 to 1 km. | ■ Potentially large work platform and safety zone (100 m radius) around work area would restrict usage of portions of lake although that would likely be minor. | ■ Potentially large work platform and safety zone (100 m radius) around work area would restrict usage of portions of lake although that would likely be minor. | N/A. Typical recreational boat operation. |

| Variable | Dredging | Amendment or Chemical Stabilization | Thin-layer Capping | Monitored Natural Recovery |
|---|---|---|---|---|
| Fisheries | ■ Large work platform (50 x 100 m) and safety zone (100 m radius) around work area would restrict usage of portions of lake for fishing. | ■ Potentially large work platform and safety zone (100 m radius) around work area would restrict usage of portions of lake by fishermen although that would likely be minor. | ■ Potentially large work platform and safety zone (100 m radius) around work area would restrict usage of portions of lake by fishermen although that would likely be minor. | N/A. Typical recreational boat operation. |
| ***Noise and Air Quality / Nuisance*** | | | | |
| Construction noise and lighting | ■ Some noise generated through operation of equipment (motors, metal upon metal, vessels, verbal communication).<br>■ During seasonally allowable periods, the operation would likely operate 24/7, necessitating lights in the work zones, booster stations would have lights and diesel-powered pumps. | ■ Some noise generated through operation of equipment (motors, metal upon metal). | ■ Some noise generated through operation of equipment (motors, metal upon metal). | N/A. |
| Air quality | ■ Typical emissions from construction equipment and from trucks transporting dredged material to the mine site.<br>■ If the material is dewatered near the lake and transported by truck, local dust could be an issue. | ■ Typical emissions from construction equipment.<br>■ Potential dust generation from stockpiles.<br>■ Nuisance odors may be associated with the organic carbon amendment. | ■ Typical emissions from construction equipment.<br>■ Potential dust generation from stockpiles. | N/A. |
| ***Traffic*** | | | | |
| Import of equipment and materials | ■ Additional traffic through adjacent communities to bring equipment and construction materials to site.<br>■ Municipal and regional by-laws may have restrictions on truck routes and schedules, which may have an influence on the overall schedule. | ■ Additional traffic through adjacent communities to bring equipment and construction materials to site.<br>■ Municipal and regional by-laws may have restrictions on truck routes and schedules, which may have an influence on the overall schedule. | ■ Additional traffic through adjacent communities to bring equipment and construction materials to site.<br>■ Municipal and regional by-laws may have restrictions on truck routes and schedules, which may have an influence on the overall schedule. | N/A. Typical recreational boat operation. |
| Export of dredged material | ■ Not expected with suction dredging and hydraulic transport of slurry.<br>■ If clamshell dredging is used, material would need to be brought to shore, dewatered sufficiently for safe truck transport.<br>■ Municipal and regional by-laws may have restrictions on truck routes and schedules, which may have an influence on the overall schedule. | N/A | N/A | N/A. |

## Studies Needed to Support Remediation Planning

Depending on the remediation option selected, additional studies may be required to support the planning and assessment of the remediation, for example, if the option of dredging were selected:

- Geotechnical evaluation (e.g., to support design of shoreline infrastructure such as ramps and docks; to understand the potential for dredging to destabilize the lakeshore) for the dredging option.
- Evaluation of mine roads to determine if upgrades would be necessary to support additional truck traffic that may be required to transfer dredged material to the mine site for disposal, if trucks are selected for this purpose.
- Evaluation of a new pipeline route and detailed pipeline engineering to support engineering of a new pipeline to transfer dredged material if direct pumping is selected for this purpose.
- Dredged material dewatering and dewatering effluent treatment and disposal; location selection for dredged material and volumes of water that can be practicably treated, which would govern dredging production rates.
- Optimal dredging methods, equipment availability, vessel sizing requirements.
- Bench-scale and in situ pilot testing to evaluate the potential efficacy of a remediation option (e.g., tests to determine the preferred material for carbon amendment and dosing rates, or material for thin-layer capping).

## NEBA Metrics

Table 8 identified a number of considerations regarding potential options that could be implemented to meet the remediation goals for the benthic zone of Quesnel Lake. The primary indicator metrics selected from those considerations for inclusion in comparing the net environmental benefit of the potential remediation options (i.e., gains versus losses) are as follows and discussed further below. “Environmental Benefit” is considered broadly. While the main biological measure of gains and losses is invertebrate production, environmental benefits in this case also include use of the environment of Quesnel Lake and effects on the human environment (aesthetics).

- net benthic invertebrate productivity – gains from the action less the losses from those actions
- effects on water quality – including all uses of Quesnel Lake water (e.g., aquatic life, drinking water, etc.)
- effects on adjacent terrestrial areas
- effects on air quality
- effects on recreational activities (e.g., boating, swimming)
- effects on aesthetics (noise, traffic)

### *Net Benthic Invertebrate Productivity*

The ultimate remediation goal is that the benthic invertebrate community recover to a level that is similar to adjacent areas. As the data show, this recovery has started (Section 4.11.3) and therefore this variable is intended to capture how physical or other perturbations associated with a remediation option may affect productivity over time due to that additional disturbance. This means that if an additional perturbation is to be beneficial, the productivity gain needs to be greater than the loss from the perturbation for there to be a net benefit. Net benthic invertebrate productivity is thus defined as follows: Productivity of desired stated minus the initial loss from TSF breach and the incremental additional loss or gain from implementation of a remediation activity.

Although the data are not sufficient at this time to quantify the overall recovery trajectory and when the density of chironomids, in particular, will be consistently within the range of natural variability of reference areas, a qualitative comparison of potential additional productivity loss can be identified. For example, Figure 27 illustrates the conceptual time scale at which recovery reaches the range of natural variability. The amendment and dredging options are expected to result in a second disruption to the benthic community and therefore additional lost productivity, following a period of detailed planning, site preparation, and procurement of equipment. The dredging option is expected to take the longest time to implement with continual disruption to the lake bed where dredging is occurring at a given time. The amendment option is expected to take less time than dredging and cause a lesser effect on productivity initially than dredging because the sediments are not being “excavated”. In comparison, monitored natural recovery allows for the recolonization of the sediments to continue its current trajectory without a second disruption to productivity. Based on the timeline illustrated in Figure 27, the net benthic productivity of the three remediation options is therefore ranked from highest to lowest as:
MNR > amendment > dredging.

It should be noted that Figure 27 is a conceptual figure and the dotted lines are notional projections. It is possible that the impacts of dredging, in particular, could be reduced somewhat through project planning with recovery starting as the dredge works its way across Quesnel Lake. However, given the depth of the design dredge cut being upwards of 10 m, it is possible that such a depth would need to be achieved through multiple passes. A 10 m deep cut would be filled by inwards collapse of the uncut sidewalls and such events would generate turbidity at depth which may be available for surface water turbidity at lake overturn. Therefore, while the absolute losses notionally depicted in Figure 27 may be greater than achievable in a well-designed dredging program, in relative terms, the figure nevertheless depicts the concept of extended duration perturbations to the benthic community should the dredging option be pursued. There is no evidence available to suggest that following dredging, benthic productivity would be higher than it would otherwise be with MNR. Accordingly, dredging scores poorly on net environmental benefits, whether considered in the broad context as described above or in the narrower context of non-human biological metrics.

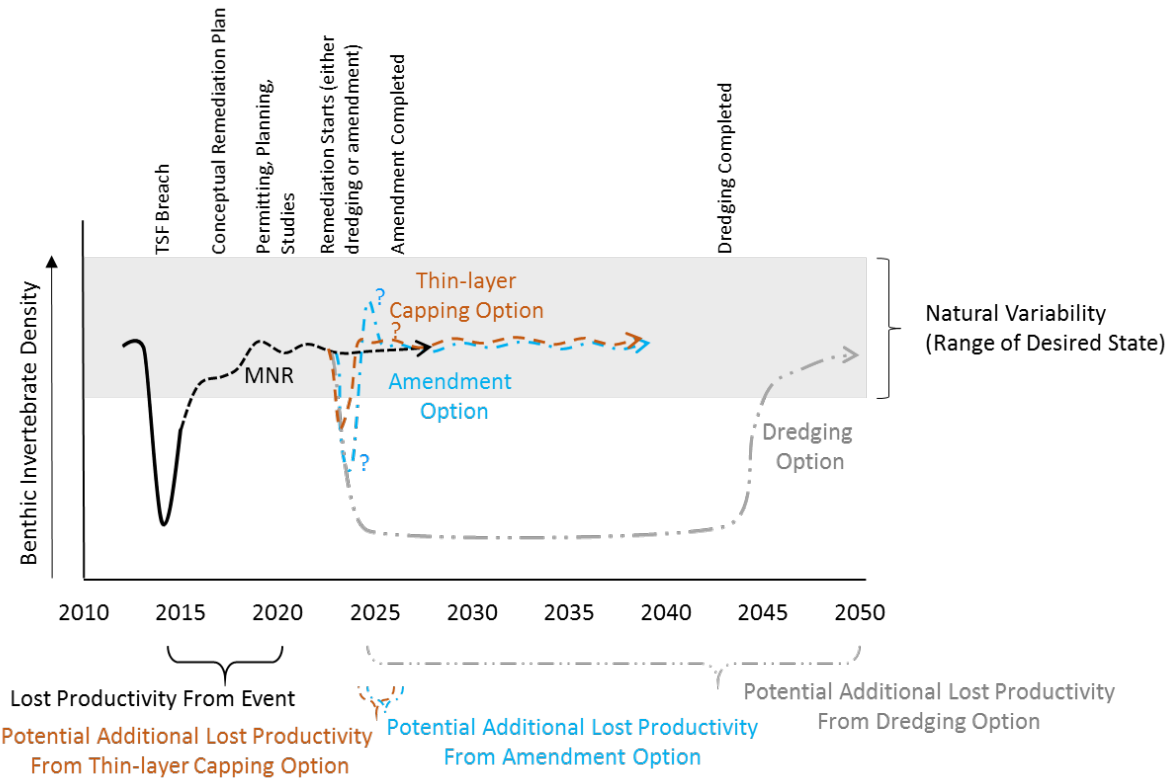

**Figure 27: Conceptual Comparison of Influence of Remediation Option on Net Benthic Invertebrate Productivity (Not Based on Actual Data from Quesnel Lake)**

### *Effects on Water Quality*

Two of the remediation options (dredging and carbon addition) may have an effect on water quality, which may in turn affect productivity of the water column or the safety of the water for human consumption, specifically:

- Dredging has the potential to introduce suspended sediments into the water column. This re-suspension of sediments would occur throughout the duration of dredging, which is estimated to be six months per year for > 30 years. The degree to which sediment may be re-suspended during dredging is dependent on the equipment used. Mechanical dredging (i.e., with a clam shell bucket) introduces a considerably greater amount of solids into the water column than hydraulic dredging. As well, a temporary water treatment system with effluent discharge back to the lake may be needed, depending on the dredging method selected. For example, hydraulic dredging generates six parts of water to each part of solids. At a dredging rate of 6,000 $m^3$ solids per day and assuming an 8:1 water:solids ratio (the middle of the notionally expected range), 48,000 $m^3$ of dewatering effluent would need to be treated to remove solids and this treated effluent would then be discharged back into the lake. Additional turbidity may be generated using either method depending on the depth of the dredge cut at a given location. A dredge cut with a 10 m mud wall adjacent to that cut would be infilled by slumping and the force of that slumping would generate considerable turbidity at depth. To prevent this, dredging would need to be carried out as “shaved” layers, which would then result in further delays to recovery over a wider area.

- Capping the sediments would necessarily involve introducing a substance to the lake (inorganic sediment), which may become entrained in the water column depending on the placement method. This water quality effect is expected to be relatively short-term compared to dredging. None of the data so far suggest a benefit or need for thin-layer capping.
- Amending the sediments would necessarily involve introducing a substance to the lake (organic carbon), which may become entrained in the water column depending on the placement method, or may result in degradation products being released as the carbon breaks down on the lake bed. These water quality effects are expected to be relatively short-term compared to dredging.

In comparison, monitored natural recovery is not expected to have any water quality effects because the sediments are both physically (Tetra Tech 2017) and chemically (Kennedy at al. 2016) stable at the bottom of the lake. Physical stability will be re-evaluated if and when university data and methods become available for review.

In summary, from least to greatest negative impact on water quality, the remediation options are ranked as follows: MNR < capping < amendment < dredging.

### *Effects on Terrestrial Areas*

Given the magnitude of the lakebed area that would need to be actively remediated, considerable infrastructure and staging areas may be needed for the following logistic needs for the dredging and, to a lesser extent, capping and carbon addition methods:

- Constructing and storing equipment – the type and size of equipment (e.g., barges) that would be needed are not readily available in the Cariboo Region and/or may not be transportable to the site due to physical size and weight. Therefore, it may be necessary to transport raw materials (e.g., sheet metal) or sections to the site and construct the needed equipment along the Quesnel Lake shore.
- Operation of booster pumps if the transfer of dredged sediment from the lake to the pit is done via direct pumping. The booster pumps would be needed approximately every 0.5 to 1 km and would need to be placed in a relatively flat area that is easily accessible for maintenance. Several booster pumps would be needed for the section of slurry pipeline that would be floating on Quesnel Lake.
- Construction of ramps and wharves for launching equipment and facilitating trans-loading of materials. For example, material to be applied to the lake bed would need to be transferred from trucks to the floating platform from which it will be placed on the lake bed. In the event that dredged sediment is transferred to the disposal area via truck, the material would need to be transferred from a dredge scow to a processing area for dewatering and then to trucks.

The area required for staging is not yet defined, but it would likely involve the removal of vegetation and reconfiguration of land forms along the shoreline and adjacent upland areas. Following completion of the remediation, these areas would then also need to be remediated.

In comparison, monitoring of natural recovery can be done using a vessel that can be trailered and launched at an existing ramp.

In summary, from least to greatest effect on terrestrial areas, the remediation options are ranked as follows: MNR < capping < amendment < dredging.

### *Effects on Air Quality, Light, and Noise*

Air quality and light and noise levels may be affected by the operation of equipment (e.g., engines on excavators, generators, metal on metal contact):

- The duration of dredging is conceptually estimated to be, in aggregate, six months per year for approximately 30 years, with operations occurring 24 hours per day. The dredging could potentially occur at a faster rate by having more dredge rigs deployed to the lake; however, production rates may be limited based on the ability to dewater the slurry and treat the return water to acceptable levels. Further engineering design would be required, should this option be selected. The dredging season would coincide with the greatest period of recreational use of Quesnel Lake because weather windows suitable for dredging would occur over the spring to fall timeframe. Noise and light effects would occur during this time on a 24/7 basis. Additional booster pumps (lights and noise) would be needed at the shoreline and potentially every 0.5 to 1 km to direct pump dredged material to the mine if that is the transfer option selected. The other potential transfer method would be the use of heavy haul trucks, which could be loaded by excavator and introduces the possibility of metal-on-metal contact which induces noise.
- The application of capping or amendment material to the lake bed would also involve heavy machinery, although it is expected that less equipment would be operating at a given time and the duration is expected to be considerably shorter.
- Monitored natural recovery would involve the intermittent operation of a recreational-type boat, during daylight hours only

In summary, from least to greatest effect, the remediation options are ranked as follows: MNR < capping < amendment < dredging.

### *Effects to Recreational Activities*

Recreational use on Quesnel Lake could include boating (power boats, canoes), fishing, and swimming. These activities could be affected as follows:

- During dredging, the work would be done from one or more mobile “spreads” consisting of a dredge barge and potentially hopper barges which could impede lake and shoreline-based activities. As noted previously, this equipment could be on the lake 6 months per year for >30 years. For mechanical dredging, the hopper barges would transit between the dredge barge and the shore-based trans-loading area. For hydraulic dredging, the most efficient delivery method is via direct piping from the dredging location to the shore. This is done via a floating pipe with booster pump stations potentially every 1 km. For health and safety purposes, exclusion zones would be established around the equipment. Shoreline work areas would also have exclusion zones set around them.

- The carbon addition option would also involve the use of relatively large work platforms with exclusion zones, but for a lesser amount of time, potentially within a single season depending on the specific requirements of such application.

In summary, from least to greatest effect, the remediation options are ranked as follows:
MNR < capping < amendment < dredging.

#### *Effects to Aesthetics (Visual)*

As described above, dredging and carbon amendment involve large work platforms that would be on the lake and visible from the shoreline. This would be ongoing potentially for 6 months per year for >30 years if the dredging option were selected, and a lesser period of time if the carbon amendment option is selected. Both options may also involve construction of shoreline staging areas and thus temporary loss of treed areas.

Quesnel Lake is a clear water system and in numerous public and other meetings, the local community has been clear about how much they value this (and other) aspects of Quesnel Lake. If turbidity induced by dredging were to come to the surface either through seasonal overturn or through clamshell dredging, even a minor increase in turbidity of a few NTUs would likely be noticeable by local community members.

In comparison, monitored natural recovery would involve sampling from a vessel similar to those used by recreational boaters and would not involve the installation of shoreline facilities or the generation of turbidity. Carbon addition could potentially result in some minor turbidity but with further design efforts may not result in significant (visible) turbidity.

In summary, from least to greatest effect, the remediation options are ranked as follows:
MNR < capping < amendment < dredging.

### *4.11.3.4 Recommended Remediation Option*

The options were categorically ranked relative to one another without weighting one variable more strongly than the other (Figure 28). Based on the metrics for comparison of the net environmental benefits associated with each conceptual remediation option, dredging has the greatest potential to have higher environmental costs and would result in the lowest net environmental benefits (benthic invertebrate productivity) because dredging would result in extended perturbations at the bed of Quesnel Lake. Given the observations of a recovering lake bed – species richness is similar to the unimpacted lake bed station and abundance is increasing though not yet within the range of natural variability – the time benefit of recovery between the initial impact of the event and the initiation of dredging would be reversed. There is also no basis from which to expect that the post-dredged lake bed would be more highly productive. The addition of carbon is a concept that comes from laboratory tests where carbon was added and restored growth to pre-impact conditions. This does not mean that it would result in certainty of benefit if scaled up from lab to field, especially given that organic carbon in the sediments is increasing as a result of natural processes (Figure 24) and there would be a time delay to develop this remedial option from concept to final design.

Monitored natural recovery is expected to result in the greatest net benthic invertebrate productivity and is not expected to cause further environmental effects (beyond those caused by the event itself). As with all three options, performance verification of MNR would be a necessary component of the CEMP.

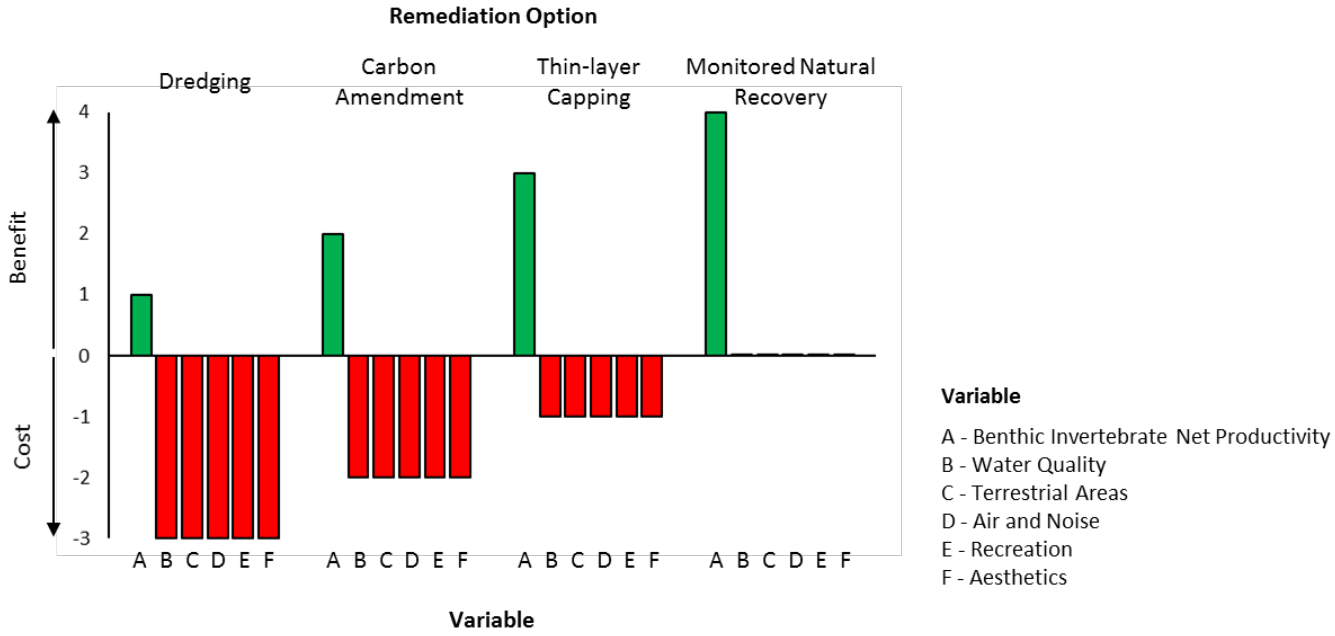

**Figure 28: Net Environmental Benefit Analysis of Dredging Versus Carbon Amendment versus Thin-layer Capping versus Monitored Natural Recovery**

The recommended remedial option is MNR. As noted in Table 6, there is no specific provincial guidance but parallels can be drawn to guidance respecting Monitored Natural Attenuation of groundwater contaminants (Technical Guidance 22; TG-22; MOE 2014). Table 9 provides an adaption of factors from TG-22 that are applicable to the Quesnel Lake benthic zone and how the conditions are met. Based on this guidance, MNR is feasible as a remediation option.

**Table 9: Overview of Factors for Monitored Natural Recovery to be Feasible (Adapted from TG-22 [MOE 2014])**

| Factor | How this Condition is Met |
|---|---|
| 1) MNR is to be performed in the context of a risk assessment that indicates an absence of significant risks to human health or the environment. | The human health risk assessment did not identify risks.<br>The aquatic ecological risk assessment showed that although abundance of benthic invertebrates was lower in the West Arm, species richness was similar between the West Arm and reference areas and that recolonization in sediment from a reference area transplanted to the West Arm was not impaired. The main risks are associated with the nutrient (organic carbon) poor nature of the sediment and organism growth was restored with its addition. Sediment organic carbon has increased (Figure 24) and while it is within the range of reference stations, the average concentration is still reduced. |

| Factor | How this Condition is Met |
|---|---|
| 2) A long term performance monitoring and validation program can be and will be put in place | MPMC conducts regular monitoring in accordance with their CEMP. Monitoring components to validate that the benthic invertebrate community is continuing to recover are part of the CEMP. The CEMP is part of MPMC's permit and the execution of the CEMP is therefore compelled by regulatory instrument. |
| 3) The use of MNR will result in the remediation goals being met within a reasonable time. | Based on the currently available data (i.e., from 2014 through 2016), the benthic invertebrate community is continuing to recover. Species richness and diversity is already similar between the West Arm and reference areas. In 2016, the density of benthic invertebrates was still lower in the West Arm than in the reference area; however, the trajectory is one of continuous improvement. Based on the current trajectory, it is expected that the benthic community in the West Arm will be similar to that in reference areas within a reasonable time frame. An additional round of sampling was conducted in 2017 and once the data are available, this trajectory can be verified. Monitoring in future years (frequency to be determined based on data) is an expected part of MNR. |
| 4) A contingency plan that includes defined implementation triggers for identifying when the remedial goals are not being met. | The CEMP will include a response framework that identifies triggers for potential additional remediation activities. |

#### *4.11.3.5 Addressing Residual Impacts Post-remediation*

Even with the selected remediation option for Quesnel Lake benthic zone remediation (MNR), as a result of the event there was a loss of benthic invertebrate productivity and quantifying that lost productivity is part of the objective of identifying and quantifying productivity offsets. Figure 29 illustrates the conceptual offsetting requirements for the initial impact with MNR (and other options). Estimated remediation duration for MNR is approximately 5 years based on estimates from literature plus a reduced rate of colonization in year one as turbid materials were settling out. There is uncertainty in this estimate. Residual impacts and offsets for Quesnel Lake are discussed in Section 5.4.2.

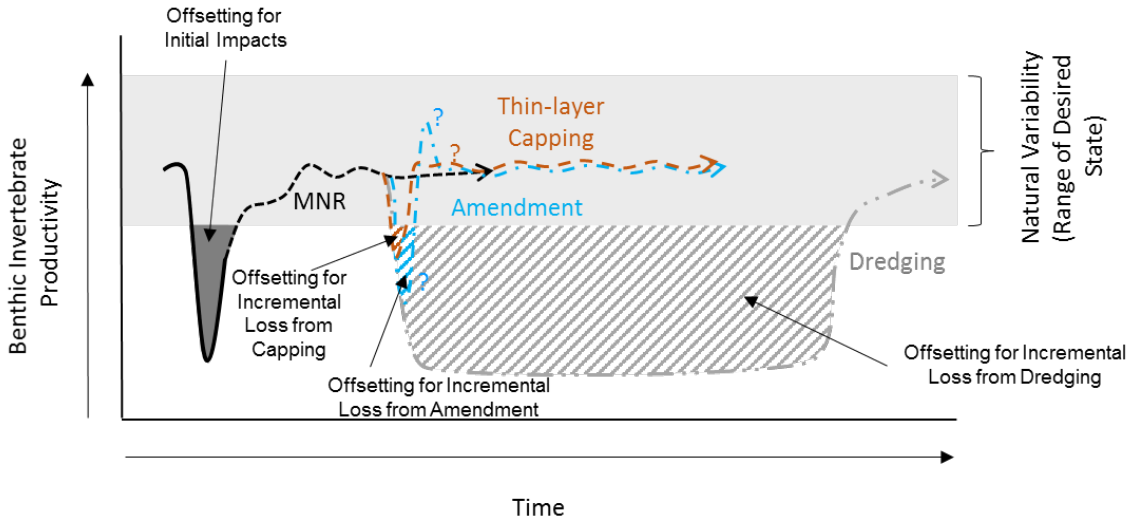

**Figure 29: Conceptual Illustration of Offsetting Needs Post-Remediation**

## 4.12 Quesnel River / Area #9

Using the classification system of the HRWG, this area corresponds to EU-Quesnel River. Quesnel River is the major drainage from Quesnel Lake and is located at the north end of the lake's West Basin. The river is located approximately 13 km north of where Hazeltine Creek discharges into Quesnel Lake. Following the TSF breach, turbidity concentrations in Quesnel River were generally below the long-term BC WQG, with the exception of measurements from late November 2014 to late January 2015 following the fall turnover of Quesnel Lake and mixing of the deep turbid water. Modelling predicted that by summer 2015, between 15 and 20% of the original amount of suspended material in Quesnel Lake from the tailings spill would have been discharged into Quesnel River (MPMC 2015a). That amount of material represents 12% or less of the river's annual sediment load. Daily average and *in situ* turbidity concentrations in Quesnel River have shown an overall progressive decrease over time throughout 2015 (Golder 2017c). Turbidity measurements continue to be low.

Objectives for Quesnel River are directly related to stability of benthic sediments in the West Basin of Quesnel Lake and maintenance of downstream water quality (related to the breach).

## 4.13 Public Safety Risks

### 4.13.1 "Edney Flats"

Potential public safety risks were identified in the flat sediment area near the mouth of Edney Creek as well as general risks along the Hazeltine Creek corridor.

The WSA Engineer requested that a safety evaluation be carried out of the deposited materials with regard to persons or human occupied vehicles becoming stuck. A geotechnical evaluation was carried out (Golder 2019) using hand augers and Dynamic Cone Penetrometer (DCP) testing at 5 stations across the area of concern. Hand augers were advanced to depth ranging from 0.4 to 2.9 m below ground surface and DCP tests were advanced between 1.3 and 2.9 m below ground surface. Soil cuttings collected from the hand auger were visually logged and classified in the field and representative samples were collected for further visual classification and geotechnical index testing in Golder's laboratory, including moisture content determinations, gradation analyses and Atterberg limits. Field observations indicated that groundwater level is hydraulically connected to and controlled by the water level of Quesnel Lake and seasonal fluctuation, including inundation can therefore be expected.

Based on findings of the study and the strength gain since deposition, the loose/soft ground hazard at Edney Flats was concluded to not present a life safety concern. Observations of vehicle tracks were also noted. However, given the variable nature of the material and inferred fluctuations in groundwater level, especially at times of flooding, the area may become untrafficable. For this reason, Golder recommended that signage be erected around the perimeter of the site, cautioning users of the potential soft ground conditions and MPMC will be erecting that signage in 2019 once weather and ground conditions allow. No additional remediation for safety purposes was recommended.

### 4.13.2 Sediment Ponds, Lower Hazeltine Creek

The sediment ponds at lower Hazeltine Creek were built as temporary structures with relatively steep side walls and, if retained in their present form, would present a public safety hazard. Life rings are placed near the ponds and signage is in place indicating the steep slope and open water at present. However, remediation of Hazeltine Creek habitat will involve the decommissioning of those ponds based on the consensus decision reached at the HRWG meeting in November 2018. While current habitat design concepts do not include the ponds in whole or in part, should they be retained, public safety considerations will need to form part of engineering design.

### 4.13.3 Public Safety Issues Along Hazeltine Creek

Some of the changes that occurred because of the TSF breach included a steepening of the banks of Hazeltine Creek and deposition of tailings material among the trees along the Hazeltine Creek corridor. The deposited tailings resulted in conditions that caused a die-back of some of the affected trees (Golder 2015a). A danger tree assessment was carried out by MPMC in 2018 and most danger trees in any area where the public would access were removed. MPMC crews also re-sloped most of the steep banks so that they were not a drop off. There remains an area above Hazeltine Canyon that has not been re-sloped as this slope provides habitat for bank swallows in its current form. MPMC will need to consider whether bank swallow habitat is to remain (in consultation with wildlife specialists) and means of restricting access to the tops of those slopes.

# 5.0 RESIDUAL EFFECTS, OFFSETS AND COMPENSATION

This section describes the residual effects (current to March 2019) to fish populations, instream fish habitat, riparian habitat, and upland terrestrial habitat from the event (Section 5.3), as well as the current determination of compensation and offsets required to counterbalance these residual effects (Section 5.4). Proposed and potential on-site and off-site offset and compensation options are also described in Section 5.4. Some local opportunities are tabulated in Appendices B and C; however, projects will be evaluated and prioritized by the HRWG.

## 5.1 Ecological Units, Ecological Functions, and Indicators

DFO guidance on offsetting (DFO 2013) articulates the view that effective offsets are those that prioritize benefit for the specific fish populations and areas that were affected. In that context, the HRWG divided the affected areas from the event into ten EUs, identified the CRA fish species present pre-event, and described the ecological functions for each of these fish species (Table 10). The HRWG then developed indicators and metrics (vis-à-vis Loughlin and Clark 2014) for each EU to compare the difference between pre- and post-event effects to fish and fish habitat and to use these comparisons to estimate the residual effects and determine whether offsets are required.

Increasing fisheries productivity is the key objective of offsetting activities under the *Fisheries Act* (Bradford et al. 2016). Fisheries productivity can be measured directly through measurement of production rates of fish species of interest, or indirectly through measurement such as catch per unit effort, biomass, or fishing yield (Minns 1997). Fish population indicators (i.e., fish abundance, fish age class structure, fish condition factor) are the HRWG's preferred indicators for estimating residual effect. Fish habitat suitability and availability indicators (e.g., habitat function metrics, mesohabitat type, microhabitat features) are a less direct surrogate for assessing fisheries productivity - they measure productive capacity – which does not directly translate to fish abundance, community structure or health (Bradford et al. 2016). As such, the HRWG put greater weight on fish population indicators compared to fish habitat suitability and availability indicators. Indicators are listed in priority order against each EU in Table 10.

**Table 10: Ecological Units, Ecological Functions, and Indicators Selected to Determine Residual Effect**

| Ecological Unit (EU) | CRA Species | Ecological Functions | Indicator (in Priority Order) * |
|---|---|---|---|
| Upper Edney Creek (E1) | Rainbow Trout | S; M | ■ Rainbow Trout Abundance<br>■ Rainbow Trout Age Class Structure |

*FHWRG Habitat Objectives Tables 2015 ** Metric criteria for diagnostics of habitat function are outlined in reference Table 1, adapted from Johnston and Slaney 1996 Technical Circular.

## 5.2 Pathway of Effect

Pathways of Effects are used in DFO's Fisheries Protection Policy Statement (DFO 2013) to describe the types of cause-effect relationships that are known to exist for specific activities or events and the mechanisms by which these actions ultimately lead to effects in the aquatic environment. Each cause-and-effect relationship is represented as a pathway, connecting the activity to a potential stressor, and the stressor to an effect on fish or fish habitat. Each pathway represents connections where mitigation measures could be applied to break the connection and reduce or eliminate the effect. When mitigation measures are not or can not be applied or are not fully effective, the remaining effect is referred to as a residual effect that will require offsetting to balance the impact on fisheries productivity.

Because the event affected fish populations and fish habitat differently among the EUs, the HWRG developed Habitat Objectives Tables that included the main "pathways of effect" associated with the event for each EU and these are presented against each EU by ecological function in Table 11. For example, the HWRG identified one "pathway of effect" to Upper Edney Creek (E1) – the potential effect to spawning and migration functions from the "potential downstream disruption of access for returning adult spawners". While, the HWRG recognized a greater number and different types of "pathways of effect" of the event on Middle Edney Creek (E2) – for example, the potential effect to spawning, rearing, overwintering and migration functions from the "deposition of material", and "instream streambed scour and removal of structure".

**Table 11: Pathway of Effect of the Event on each Ecological Unit by Ecological Function**

| Pathway of Effect | Ecological Unit (EU) | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | E1 | E2 | E3 | H1 | H2 | Polley Lake | QL - Benthic | QL - Limnetic | QL - Littoral | Quesnel River |
| Potential downstream disruption of access for returning adult spawners | S; M | | | | | | | | | |
| Deposition of material | | S; R; O; M | S; R; O; M | S; R; O; M | S; R; O; M | S; R; O; M | R | | S; R | |
| Instream streambed scour and removal of structure | | S; R; O; M | S; R; O; M | S; R; O; M | S; R; O; M | | | | | |
| Riparian habitat alteration associated with deposition of material | | S; R | S; R | S; R | S; R | R | | | R | |
| Riparian clearing associated with channel remediation work | | S; R | S; R | | S: R | | | | | |
| Removal of natural channel morphology, mesohabitat proportions | | S; O; M | S; O; M | S; O; M | S; O; M | | | | | |
| Removal of critical and important fish habitat | | S; O | S; O | R | S; R; O | | | | | |

## 5.3 Residual Effects, Compensation and Offset Determination

Effects to each EU have been quantified both spatially (i.e., geographical area) and temporally (i.e., the time lag between the event occurrence [August 2014] and remediation). This is because the event has caused different effects to each area, and for different periods of time. For example, Lower Edney Creek remediation work was conducted within nine months of the event, whereas Lower Hazeltine Creek remains in the design stage, with no habitat remediation (beyond the foundational channel for erosion control) undertaken since the event (i.e., as of writing, approximately 4.5 years).

Residual effects have been determined for each indicator, for each EU, using pre- and post-event monitoring data (Sections 5.3.1.1 to 5.3.1.10 and Table 12 to Table 21). Residual effects from the event have also been quantified for riparian habitat (Section 5.3.1.11;Table 22) and upland terrestrial habitat (Section 5.3.2).

Residual effect values have been used to calculate the requirement for offsets for each EU (Sections 5.3.1.1 to 5.3.1.10). The residual affected area (i.e., the “spatial balance”), and the time lag to remediation (i.e., the “temporal balance”), for each EU represents a specified loss of habitat productivity. The spatial and temporal balances for each indicator have been incorporated into offset calculations for each EU and the riparian habitat, and compensation for upland terrestrial habitat (Sections 5.3.1.1 to 5.3.2).

### 5.3.1 Aquatic Habitat

#### *5.3.1.1 Upper Edney Creek (E1)*

In Upper Edney Creek (E1), no habitat was directly altered, and therefore there was no spatial loss of Rainbow Trout productivity. There was potential for the event to cause a blockage in the lower sections of Edney Creek that could have obstructed access for spawning Rainbow Trout migrating from Quesnel Lake to Upper Edney Creek. The event occurred in August of 2014 after the spawning migration of Rainbow Trout. Remediation work in the lower sections of Edney Creek restored access to Upper Edney Creek (E1) from Quesnel Lake prior to the 2015 spawning migration of Rainbow Trout and therefore it is not expected that there was a temporal loss of Rainbow Trout productivity in Upper Edney Creek (E1; Table 12).

Abundance of Rainbow Trout in Upper Edney Creek was higher post-event compared to pre-event conditions and the age class structure of Rainbow Trout in Upper Edney Creek (E1) was similar pre-and post-event (Table 12). Based on these indicators, negative effects on the functionality of habitat in Upper Edney Creek (E1) were not likely.

As the event caused no direct physical effects to Upper Edney Creek (E1), and there were no measured negative effects to the indicators, no offsetting is required for Upper Edney Creek (E1).

Determination**: No Offsetting**

**Table 12: Upper Edney Creek (E1)**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Rainbow Trout Abundance<br><br>(Catch Per Unit Effort [CPUE]) | Spawning; Migration | Rainbow Trout CPUE (# fish per minute by electrofishing) in 2007 (August) was **0.67** in Upper Edney Creek (UEC-1) (Minnow 2016b). | Average CPUE (# fish per minnow trap day) for Rainbow Trout in 2016 (April to October) was **0.429** (Minnow 2016b) and in 2017 (May to November) was **1.09** (Minnow 2018a). | Rainbow Trout CPUE was higher in 2017 than 2016 indicating they successfully migrated upstream to E1 (Minnow 2016b, 2018).<br><br>Overall spatial balance **= Positive** | (-) 9 months<br>Fish passage from Quesnel Lake to Edney Creek watershed was restored 9 months post-event (i.e., prior to Rainbow Trout migration)<br><br>Overall temporal balance **= Neutral** |
| Rainbow Trout Age Class Structure | Spawning; Migration | Rainbow Trout age class structure data for 2007 (August) show **79%** of Rainbow Trout were **Young of Year** (YOY [age "0"]; Minnow 2007; SNC 2015a).<br>There is limited pre-event juvenile salmon abundance data. There is no pre-event salmon spawner escapement data (except some limited observations). | Rainbow Trout age class structure data for 2016 (April; August/September; October) and 2017 (April; October; November) show most Rainbow Trout were **YOY** (i.e., <3.5 to 12 cm), with some **Age 1 or 2** fish, in both years (Minnow 2018a). No Rainbow Trout spawners were observed in spring 2016 or 2017 (Minnow 2018a). | Rainbow Trout age class structure post-event (2016/2017) and pre-event (2007) were comparable (Minnow 2007, 2018a; SNC 2015a).<br><br>Overall spatial balance **= Neutral** | (-) 9 months<br>Fish passage from Quesnel Lake to Edney Creek watershed was restored 9 months post-event (i.e., prior to Rainbow Trout migration)<br><br>Overall temporal balance **= Neutral** |

Sources: Minnow 2007, 2016b, 2018a; SNC 2015a.

#### 5.3.1.2 Middle Edney Creek (E2)

In Middle Edney Creek (E2), approximately 1,350 $m^2$ of high-quality spawning, rearing, overwintering, and migratory habitat was altered for one year, resulting in a temporal loss of fish productivity. Approximately 1,553 $m^2$ of instream habitat was remediated, resulting in a spatial net gain of high-quality habitat (Table 13).

The reconstructed habitat features were assessed and rated good (Table 3) for the following metrics: bankfull-width-to-depth ratio, entrenchment ratio, channel complexity, percent pool (by area), pool frequency, and holding pools (Table 13). A higher abundance of Rainbow Trout was observed in 2017 compared to 2016, as was a similar age class structure pre- and post-event. Based on these indicators, negative effects on the functionality of habitat in Middle Edney Creek (E2) were not likely.

HEA calculations were undertaken for Middle Edney Creek (E2; Appendix D). The HEA calculation resulted in a required offset of units (Table 23). Because a greater amount of habitat has been remediated (1,553 $m^2$) than needed for offsetting (1,499 $m^2$), no further offsetting is required.

Determination: **No Offsetting**

**Table 13: Middle Edney Creek (E2)**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Area | Spawning; Rearing; Overwintering; Migration | 1,350 $m^2$ of total instream habitat was altered. | 1,553 $m^2$ of total instream habitat was remediated. | Balance of +203 $m^2$ total instream habitat.<br><br>Overall spatial balance<br>**= Positive** | 1 to 2 years<br><br>Overall temporal balance<br>**= Negative** |
| Rainbow Trout Abundance<br><br>(Catch Per Unit Effort [CPUE]) | Spawning; Migration | There is no pre-event Rainbow Trout CPUE data for Middle Edney Creek. | Average CPUE for Rainbow Trout in Lower and Middle Edney in 2016 (21 April to 22 October) was **0.119** CPUE (# fish per trap day) with minnow traps and **0.054** CPUE (# fish per minute) with electrofishing (Minnow 2016b; Minnow 2018a).<br><br>Average CPUE (# fish per trap day) for Rainbow Trout in Lower and Middle Edney in 2017 (28 May to 4 November) was **0.419** (Minnow 2018a). Survey method was minnow trapping (Minnow 2018a).<br><br>Rainbow Trout CPUE in Lower and Middle Edney increased between 2016 and 2017 (Minnow 2016b, 2018). | The different in Rainbow Trout abundance in Middle Edney Creek pre-event and post-event cannot be determined.<br><br>Overall spatial balance<br>**= Unable to determine due to the absence of pre-event data; this indicator has not been used in determination of residual effects.** | 1 to 2 years (spawning)<br><9 months (migration)<br><br>Overall temporal balance<br>**= Negative** |
| Rainbow Trout Age Class Structure | Spawning; Migration | The size and age of Rainbow Trout in Middle and Lower Edney Creek have been related historically, with reported mean/median fork lengths during August sampling events of 5.4 to 5.8 cm for **YOY**, 9.1 to 11.3 cm for **Age 1** fish and 12.1 to 13.6 cm for **Age 2** fish (HKP 1997; Minnow 2009).<br><br>Rainbow Trout age class structure in Middle and Lower Edney in 2007 (21 to 28 August) ranged from **YOY to Age 3** fish (Minnow 2007; SNC 2015a).<br><br>There is limited juvenile salmon abundance data. There is no salmon spawner escapement data (except some limited observations). | Most Rainbow Trout individuals measured in Middle and Lower Edney in 2016 were **YOY** (i.e., between 5 and 8 cm; Minnow 2018a). No Rainbow Trout spawners were observed in spring (21 April to 24 April), summer (28 August to 1 September), and fall (19 to 22 October) of 2016 (Minnow 2018a); however, the 2016 data indicates successful spawning in spring 2016.<br><br>Rainbow Trout individuals measured in Middle and Lower Edney Creek in 2017 ranged from **YOY to Age 2** fish (i.e., between 7 and 13 cm; Minnow 2018a). No Rainbow Trout spawners were observed in spring (5 April) and fall (24 to 29 October and 4 November) 2017 (Minnow 2018a); however, the 2017 data indicates successful overwintering of the 2016 juveniles and successful spawning in spring 2017. | Rainbow Trout age class structure in Middle Edney Creek post-event (i.e., 2017) and pre-event (i.e., 2007) were comparable (Minnow 2007, 2018a; SNC 2015a).<br><br>Overall spatial balance<br>= **Neutral** | 1 to 2 years (spawning)<br><9 months (migration)<br><br>Overall temporal balance<br>**= Negative** |
| Habitat Function Metrics* | Spawning; Rearing (Mesohabitat Type by Area)<br><br>Overwintering (Mesohabitat Type by Area and Quality)<br><br>(Microhabitat Features) | Pederson (1998) classified Middle and Lower Edney Creek as having a cascade-pool morphology dominated by cobble substrates, with functioning LWD as the most prevalent aquatic cover type. Fish habitat value was rated as high (SNC 2015a). Middle Edney Creek was observed to be ponded just upstream from its confluence with Hazeltine Creek due to the presence of a beaver dam (SNC 2015a). | Habitat functionality of Middle and Lower Edney Creek were assessed together. The habitat objectives for E2 was to create access and rearing habitat for juvenile salmonids including rainbow trout. Habitat parameters achieving quality ratings of good were: bankfull width-to-depth ratio, entrenchment ratio, channel complexity, percent pool (by area), pool frequency (mean pool spacing), and holding pools (adult migration). Habitat parameters achieving quality ratings of fair were: LWD pieces per channel length and percent wood cover in pools (Golder 2017e). The habitat was not designed to prioritize spawning habitat and as such the substrate was more suitable for rearing but less so for spawning. Evaluation of habitat preferences and suitability criteria for the spawning / incubation life stage indicated the presence of some functional spawning habitat.<br><br>Evaluation of habitat preferences and suitability criteria for the juvenile/rearing life stage indicated that habitat is suitable (relative to the reference site). However, dissolved oxygen was identified as being less suitable to Rainbow Trout. Additional cover (additional of large woody debris) could help moderate temperatures in the area (Golder 2017e).<br><br>Current length of channel and channel configuration are different from prior to the event. Beaver activity near confluence had increased pool habitat (dynamic system; Golder 2017e). | Habitat function metrics in Middle Edney Creek was rated as high quality both pre-event and post-event<br><br>Overall temporal balance<br>= **Neutral** | 1 to 2 years<br>(spawning, rearing and overwintering)<br><br>Overall temporal balance<br>**= Negative** |

Sources: HKP 1997; Golder 2017e; Minnow 2007, 2009, 2016b, 2018a; Pederson 1998; SNC 2015a.

* Metric criteria for diagnostics of habitat function are outlined in reference Table 1, adapted from Johnston and Slaney 1996 Technical Circular.

#### 5.3.1.3 Lower Edney Creek (E3)

In Lower Edney Creek (E3), approximately 1,158 $m^2$ of high-quality spawning, rearing, overwintering, and migratory habitat was destroyed, with remediation occurring over the span of one year, resulting in a temporal loss of fish productivity. Approximately 3,795 $m^2$ of instream habitat was remediated, resulting in a spatial gain of high-quality habitat (Table 14).

Other indicators to suggest a recovering functional creek habitat for Rainbow Trout include an increase in abundance of Rainbow Trout between 2016 and 2017, and a similar age class structure pre- and post-event. The reconstructed habitat features were assessed and rated good for the following metrics: bankful-width-to-depth ratio, entrenchment ratio, channel complexity, percent pool (by area), pool frequency, and holding pools (Table 14).

An HEA was not undertaken for Lower Edney Creek (E3) because this section of stream did not exist prior to the event. The construction of this section of creek contributes 2,643 $m^2$ of habitat credit.

Determination**: No Offsetting**

#### 5.3.1.4 Upper Hazeltine Creek (H1)

Rainbow Trout in Upper Hazeltine Creek (H1) is an important contributing population/stock to overall Rainbow Trout recreational fishery in Polley Lake (Lirette 2015).

In Upper Hazeltine Creek (H1), 44,650 $m^2$ of fair quality fish habitat was destroyed. The pre-event habitat was rated as fair due to well documented anthropogenic alteration of Reach 1, ponding associated with beaver dams in Reaches 1 and 2, reasonable rearing habitat, and poor spawning substrate (comprising mostly fines) in Reaches 1 and 2. Overall, Reach 3 was rated as high-quality habitat pre-event.

In the fall of 2015 and 2017, remediation work within Reaches 1, 2, and 3 resulted in the creation of 15,266 $m^2$ of high-quality habitat. In Reaches 1 and 2, habitat was improved from its pre-event state by the addition of spawning gravels, course woody debris, and enhancing the channel complexity. Remediation work on Reach 3, is not complete. The reconstructed habitat features in Reaches 1 and 2 were assessed and rated good for the following metrics: bankful-width-to-depth ratio, entrenchment ratio, channel complexity, percent pool (by area), pool frequency, LWD pieces per channel length, percent wood cover, and spawning substrate. Reaches 3, 4 and 5 of upper Hazeltine Creek have not been remediated and are thus lacking many habitat features (e.g., spawning gravels, course woody debris; Table 15). The continued remediation of Upper Hazeltine Creek (H1) is expected to be completed during 2019.

Other indicators to suggest a recovering functional creek habitat for Rainbow Trout include preliminary spawner survey data showing 4,890 adult spawners using Reaches 1 and 2 in May 2018, and 40,250 YOY were estimated to be recruited to Polley Lake from Upper Hazeltine Creek (H1) in August 2018 (Minnow unpublished). Abundance (CPUA) for juvenile Rainbow Trout is similar pre-event (i.e., 258 to 612 CPUA in August 2007) and post-event (i.e., 310 to 640 CPUA in August 2018; Table 15). This data appears to indicate a level of recruitment that should support a stable Rainbow Trout population in Polley Lake.

A HEA was undertaken for Upper Hazeltine Creek (H1; Appendix D). The HEA calculation results in a negative balance of 53,314 $m^2$ units that require offsetting (Table 23). The current offsetting deficit will be adjusted as continued remediation in Upper Hazeltine Creek (H1) occurs and the remediated habitat is monitored and determined to be functioning. If there are residual productivity losses following remediation (i.e., due to time lags or changes in habitat area), additional offsetting options for Upper Hazeltine Creek (H1) are discussed in Section 5.4.1.

Determination**: Offsetting Required**

**Table 15: Upper Hazeltine Creek (H1)**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Area | Spawning; Rearing; Overwintering; Migration | 44,650 $m^2$ of total instream habitat was lost through scour and deposition of material (Reaches 1 to 5). | 15,266 $m^2$ of total instream habitat was remediated. Reaches 1 to 3 have been remediated (approximately 3 km) - designed, constructed and monitored. The design has been approved for the remainder of Upper Hazeltine Creek (approximately 3 km). | Balance of -29,384 $m^2$ total instream habitat. Fish access to the remediated sections was restored in spring 2018.<br><br>Overall spatial balance<br>**= Negative** | (-) >4.5 years<br><br>Overall temporal balance<br>**= Negative** |
| Rainbow Trout Abundance<br><br>(Catch Per Unit Effort [CPUE]) | Spawning; Migration | Rainbow Trout CPUE (# fish per minute) in Upper Hazeltine Creek in 2007 (21 to 28 August) in UHC-1 was **3.90**; in UHC-2 was **7.04**; and in UHC-3 was **3.64** (Minnow 2007). | There is no officially published post-event CPUE monitoring data available for Rainbow Trout in Upper Hazeltine Creek.<br><br>Initial surveys of Upper Hazeltine Creek recorded 4,890 adult spawners using Reaches 1 and 2 of Upper Hazeltine Creek between 10 and 25 May 2018. Electrofishing stations in August 2018 suggest recruitment of 40,250 YOY to Polley Lake from Upper Hazeltine Reaches 1 and 2 combined (Minnow unpublished). | The different in Rainbow Trout CPUE in Upper Hazeltine Creek post-event and post-event cannot be determined.<br><br>Overall spatial balance<br>**= Unable to determine due to the absence of post-event data; this indicator has not been used in determination of residual effects.** | (-) >4.5 years (spawning and migration)<br><br>Overall temporal balance<br>**= Negative** |
| Rainbow Trout Abundance<br><br>(Catch Per Unit Area [CPUA]) | Spawning; Migration | Rainbow Trout CPUA (# fish per 100 $m^2$) in Upper Hazeltine Creek in 1991 ranged from **188** to **554** (Bruce and Slaney 1991).<br><br>Rainbow Trout CPUA (# fish per 100 $m^2$) in 2007 (21 to 28 August) in UHC-1 was **258**; in UHC-2 was **612**; and in UHC-3 was **467** (Minnow 2007). | Rainbow Trout CPUA (# fish per 100 $m^2$) in Upper Hazeltine Creek in August 2018 ranged from **310** to **640** (Minnow unpublished). | Rainbow Trout CPUA in Upper Hazeltine Creek is lower post-event (2018) compared to pre-event (1991 and 2007).<br><br>Overall spatial balance<br>**= Neutral** | (-) >4.5 years (spawning and migration)<br><br>Overall temporal balance = **Negative** |
| Rainbow Trout Age Class Structure | Spawning; Migration | Rainbow Trout age class structure in Upper Hazeltine Creek in 1990 ranged from **YOY to Age 2** fish and in 2007 ranged from **YOY to Age 1** fish (Minnow 2007; SNC 2015a). In 1990, 99.4% of Rainbow Trout caught were YOY (Bruce and Slaney 1991). In 2007, 97% of Rainbow Trout caught were YOY (Minnow 2007; SNC 2015a). | There is no officially published post-event age class structure monitoring data available for Rainbow Trout in Upper Hazeltine Creek. | The different in Rainbow Trout age class structure in Upper Hazeltine Creek pre-event and post-event cannot be determined.<br><br>Overall spatial balance<br>**= Unable to determine due to the absence of post-event data; this indicator has not been used in determination of residual effects.** | (-) >4.5 years (spawning and migration)<br><br>Overall temporal balance<br>**= Negative** |

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Habitat Function Metric* | Spawning; Rearing (Mesohabitat Type by Area)<br><br>Overwintering (Mesohabitat Type by Area and Quality)<br><br>(Microhabitat Features) | The habitat for Upper Hazeltine Creek was described in 1991 by Bruce and Slaney (Reaches 3-5) and in 2006 by Minnow (Reaches 1-5). Habitat Parameters for Reach 1 of Upper Hazeltine Creek was described as a low gradient run habitat with gravel-sand substrate. Percent wood cover achieved a quality rating of good. Reach 1 habitat parameters with ratings of fair were: bankfull width-to-depth ratio, channel complexity, percent pool, and spawning substrate (Minnow 2007).<br><br>Reach 2 of Upper Hazeltine Creek was described as a large ponded area associated with beaver activity. The area was roughly 210 m by 45 m and greater than 100 cm deep (Minnow 2007). Reach 2 habitat parameters that achieved quality ratings of good were: percent pool, holding pools, percent wood cover in pools. Reach 2 habitat parameters with ratings of fair were: channel complexity and spawning substrate.<br><br>A comparison of composite probability-of-use values suggests that Hazeltine Creek contained a fair quantity of suitable rearing habitat for Rainbow Trout fry, but very little for yearling or older fish. Stream depth appears to be the main factor limiting habitat capability for older fish and may in part explain the exodus of yearling and older fish from the system (Bruce and Slaney 1991).<br><br>Upper Hazeltine Creek provided important spawning habitat for Rainbow Trout from Polley Lake with adults migrating to spawn in the creek between early May and early June (SNC 2015a).<br><br>Overall, Hazeltine Creek was dominated by shallow riffle/run mesohabitat with some limited pool habitat. Functional aquatic cover was provided mainly by LWD, overhanging vegetation, and pool depth. The proportion of functional aquatic cover, particularly deep pool habitat, was relatively low in Hazeltine Creek. As such, suitable overwintering habitat for sub-adult/adult salmonids was limited (SNC 2015a). | Habitat functionality of Reaches 1 and 2 of Upper Hazeltine Creek were assessed in 2016 (Golder 2017c). Habitat parameters that achieved quality ratings of good were: bankfull width-to-depth ratio, entrenchment ratio, channel complexity, percent pool (by area), pool frequency (mean pool spacing), LWD pieces per channel length, percent wood cover in pools, and spawning substrate size, quality and area (in Reach 2). Holding pools (adult migration) achieved a fair quality rating. Reach I was designed to emphasize juvenile rearing habitat and as such spawning substrate size, quality and area had a lower rating (Golder 2017c). However initial surveys indicate that spawning habitat structures are being used as designed<br>(e.g., redds were observed in 2018; Connors 2018). | Habitat function metrics in Upper Hazeltine Creek pre-event in reaches 1, 2 and 3 were rated as poor, fair, and good respectively. Habitat function metrics in Upper Hazeltine Creek post-event in reaches 1, 2, and 3 were rated as good, good, and not remediated respectively.<br><br>Overall temporal balance **Reach 1 = Positive**<br>**Reach 2 = Positive**<br>**Reach 3 = Negative** | (-) >4.5 years (spawning, rearing and overwintering)<br><br>Overall temporal balance **= Negative** |

Source: Bruce and Slaney 1991; Golder 2017c; Minnow 2007; Minnow unpublished; SNC 2015a.

* Metric criteria for diagnostics of habitat function are outlined in reference Table 1, adapted from Johnston and Slaney 1996 Technical Circular.

#### 5.3.1.5 Lower Hazeltine Creek (H2)

In Lower Hazeltine Creek (H2), approximately 17,966 $m^2$ of high-quality spawning, rearing, overwintering, and migratory habitat was destroyed. Lower Hazeltine Creek is currently inaccessible to fish and has been temporarily converted into settling ponds, resulting in an ongoing spatial and temporal loss to fish productivity. Instream habitat remediation has not yet occurred (Table 16).

A HEA was undertaken for Lower Hazeltine Creek (H2; Appendix D). The HEA calculation results in a negative balance of 26,046 $m^2$ that require remediation and offsetting (Table 23). Once habitat remediation in Lower Hazeltine Creek (H2) is completed and the habitat has been monitored and determined to be functional the residual habitat offset deficit will be recalculated. Offsetting options for Lower Hazeltine Creek (H2) are discussed in Section 5.4.1.

Determination: **Offsetting Required**

**Table 16: Lower Hazeltine Creek (H2)**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Area | S; R; O; M | 17,966 $m^2$ of total instream habitat was destroyed. | 0 $m^2$ of total instream habitat was remediated. Remediation of H2 is currently in the design process. H2 is currently two settling ponds. | Balance of -17,966 $m^2$ total instream habitat.<br><br>Overall spatial balance<br>**= Negative** | (-) >4.5 years<br><br>Overall spatial balance<br>**= Negative** |
| Rainbow Trout Abundance<br><br>(Catch Per Unit Effort [CPUE]) | S | Rainbow Trout CPUE (# fish per minute) in Lower Hazeltine Creek in 2007 (21 to 28 August) in LHC-1 was **0.83**; in LHC-2 was **0.55**; and in LHC-3 was **0.56** (Minnow 2007; SNC 2015a). | No remediation has occurred post-event.<br><br>There is no post-event CPUE monitoring data available for Rainbow Trout in Lower Hazeltine Creek. | The different in Rainbow Trout CPUE in Lower Hazeltine Creek pre-event and post-event cannot be determined.<br><br>Overall spatial balance<br>**= Unable to determine due to the absence of post-event data; this indicator has not been used in determination of residual effects.** | (-) >4.5 years<br><br>Overall temporal balance<br>**= Negative** |

#### 5.3.1.6 Polley Lake

Other than lakeshore habitat (Riparian) alteration, no permanent physical habitat loss occurred in Polley Lake during the event. A habitat disruption occurred; however, the overall area of Polley Lake remained the same during the event. Habitat alterations to Polley Lake caused by the event included depth changes where shallower shoals were created and the deposition of woody debris occurred. These alterations may serve to increase spring and fall fish habitat (i.e., by providing cover and other beneficial attributes for fish), while reducing available summer habitat (i.e., deeper water). The benthic invertebrate community was smothered in part of the lake through smothering with sediment; however, the benthic invertebrate community is naturally regenerating (Golder 2017c). Elevated copper levels in Polley Lake water were recorded post-event; however, the levels were chemically similar to natural conditions (Minnow 2015). The event caused a spatial and temporal loss to Rainbow Trout productivity due to the blockage of adults from Polley Lake unable to spawn in Upper Hazeltine Creek (H1; Table 17). This resulted in the disruption of the age class structure of Rainbow Trout as juveniles from Hazeltine Creek did not enter Polley Lake for over 4 years (Table 17). Polley Lake was stocked in the fall of 2018 to help address the age class structure of Rainbow Trout and to account for potential mortality of adults entering the Upper Hazeltine Creek (H1). Considering the high abundance, re-stabilizing age class structure and good condition factor of Rainbow Trout and the recovering benthic invertebrate community the productivity of Polley Lake may not require additional offsetting.

Additional monitoring will be necessary to verify that effects on productivity of Rainbow Trout have been addressed, in particular age class structure is identified as productivity indicator by the HRWG (Table 10). Data on measures to address age class structure will be collected and these data will inform the need for offsets. Offsets are therefore to be determined for Polley Lake.

Determination**: To be determined (TBD)**

**Table 17: Polley Lake**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Rainbow Trout Abundance<br><br>(Catch Per Unit Effort [CPUE]) | S; R; O; M | Rainbow Trout CPUE (# fish per square foot per hour) in 1973 was **0.0008**, in 1995 was **0.0006**, and in 2012 was **0.0006** (Lirette 2017; Minnow 2018b; SNC 2015a). Survey method was seine netting for the 1973, 1995 and 2012 surveys. | Rainbow Trout CPUE (# fish per square foot per hour) was very similar in September 2014 (**0.0028**) and September 2016 (**0.0036**), and higher than previously documented in 1973, 1995, and 2012 (Lirette 2017; Minnow 2018b). Survey method was overnight gillnet sets. | Rainbow Trout CPUE was higher post-event (**0.0028** and **0.0036** in September 2014 and 2016 respectively), compared to pre-event data (1973, 1995, and 2012; Lirette 2017; Minnow 2018b; SNC 2015a). However, the survey methods used were different pre- and post-event, so it cannot be conclusively determined that the increase in CPUE is related to an actual increase in Rainbow Trout abundance.<br><br>Overall spatial balance **= Neutral** | (-) >4.5 years (spawning and migration)<br>(-) <1 year (rearing and overwintering)<br><br>Overall temporal balance **= Negative** |
| Rainbow Trout Abundance<br><br>(Population Estimate) | S; R; O; M | Bruce and Slaney (1991) estimated in August 1991 that approximately **54,500** Rainbow Trout fry and parr migrate to Polley Lake from Hazeltine Creek after hatching (SNC 2015a). | In 2016, the Rainbow Trout population was estimated as **42,388** in the **spring** and **21,635** in the **fall**. It is likely that the fall estimate is lower than the actual Rainbow Trout population size (Minnow 2017a). | There is a decrease in Rainbow Trout population in Polley Lake post-event.<br><br>Overall spatial balance **= Negative** | (-) >4.5 years (spawning and migration)<br>(-) <1 year (rearing and overwintering)<br><br>Overall temporal balance **= Negative** |
| Rainbow Trout Age Class Structure | S | Rainbow Trout age class structure have been collected before and after the event (1990 to 2014). Age range of Rainbow Trout in 1990 was **Ages 2 to 6** fish; in 1995 was **Ages 3 to 4** fish; in 2009 was **Ages 3 to 6** fish; and in 2014 was **Ages 1 to 6** fish (SNC 2015a). | There was 3 years of blockage of the Upper Hazeltine Creek for adult passage to spawn; therefore, it was 3 years when no new juveniles were entering Polley Lake. Overall juvenile numbers in the lake declined in this timeframe. This affected age class structure in the lake.<br>Fewer **Ages 1 and 2** fish were captured in 2016 than in 2014 (Minnow 2017a). In 2017, **Ages 1 to 3+** fish were absent from Polley Lake, confirming the limited recruitment associated with no access to Hazeltine Creek for spawning and rearing (Minnow 2018b). | A brood stock of Rainbow Trout was collected and put into a hatchery established on the Mount Polley site in 2014. Approximately 15,000 juveniles from the hatchery were released into Polley Lake in fall 2018 to help readdress the age class structure.<br><br>Age class structure of the Rainbow Trout population in Polley Lake was less diverse post-event (i.e., 2016 and 2017).<br><br>Overall spatial balance **= Negative** | (-) >4.5 years (spawning and migration)<br>(-) <1 year (rearing and overwintering)<br><br>Overall temporal balance **= Negative** |
| Rainbow Trout Condition Factor | R | Rainbow Trout condition factor (weight/length) was collected between 1973 and 2014. Mean condition of Rainbow Trout in 1973 was **1.341**; in 1995 was **1.253**; in 2012 was **0.993**; in 2007 was **1.06**; and in 2014 was **1.103** (Minnow 2007; SNC 2015a). | Examination of 2016 data relative to 2014 indicated that females were lighter at length, males were not significantly different, and immatures were heavier and longer than those measured in 2014 (Minnow 2017a).<br><br>In 2017, there appeared to be a general shift towards longer and heavier fish, particularly for female Rainbow Trout, indicative of a demographic shift to older, larger fish (Minnow 2018b). | The condition factor of Rainbow Trout population in Polley Lake is increasing. This is most likely reflective of a shift in the age-class structure instead of being reflective of a positive change in the health of the population. Because of this uncertainty, the positive change in condition factor indicator is not applicable.<br><br>Overall spatial balance **= Neutral** | (-) <1 year<br><br>Overall temporal balance **= N/A** |

Sources: Lirette 2017; Minnow 2007, 2016b, 2017a, 2017b, 2018b; SNC 2015a.

#### 5.3.1.7 Quesnel Lake – Limnetic Zone

No permanent physical alteration occurred in the limnetic zone of Quesnel Lake during the event. The event likely caused an unquantifiable temporary disturbance to fish communities during the event, resulting in a temporal loss of fish productivity (Table 18).

Other indicators on habitat function include limnetic fish relative abundance and condition factor (Table 18). The event introduced a large volume of fines into the water column. Monitoring data suggests a benefit to fish in the limnetic zone as measured both by abundance and condition factor. The fines released into Quesnel Lake contained nutrients and may have acted as fertilizer in the West Arm. With the addition of these nutrients, zooplankton bloomed, providing more forage for fish communities. Abundance (CPUE) was higher in exposed areas (the West Arm) of Quesnel Lake compared to reference areas. Juvenile Sockeye collected in the West Arm were larger than those caught in reference areas of the lake (DFO, unpublished data).

Laboratory testing of water suggested that the changes in water quality from the event is unlikely to present hazards to aquatic life.

There are no quantifiable negative effects to Quesnel Lake - Limnetic Zone, and there appears to have been a temporary increase in fish abundance and condition. No further offsetting is proposed.

Determination**: No Offsetting**

**Table 18: Quesnel Lake - Limnetic Zone**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Limnetic Zone Fish Relative Abundance (CPUE) | R | There is no pre-event data available on relative abundance of limnetic zone fish. | Hoop-net monitoring was conducted in 2015 to 2017. Similar fish communities were observed at the West Arm and in other parts of the lake east of Cariboo Island. Eight fish species were captured from both exposed and reference areas in Quesnel Lake (Minnow 2016b). CPUE (# fish per hour) was higher at exposed areas (calculated by Golder based on Minnow 2016b data). | The difference in limnetic zone Rainbow Trout abundance pre-event and post-event cannot be determined.<br><br>Comparing post-event relative abundance of limnetic zone Rainbow Trout from reference areas to the West Arm shows CPUE was higher in the West Arm in 2016 (calculated by Golder based on Minnow 2016b data).<br><br>Overall spatial balance = **Neutral** | (-) < 1 year<br><br>Overall temporal balance **= Neutral** |
| Limnetic Zone Fish Condition Factor | R | There is no pre-event data available on condition factor of limnetic zone fish. | Juvenile Sockeye collected from the West Arm west of Cariboo Island in 2014 were notably larger than those collected from reference areas in other parts of the lake east of Cariboo Island (Golder 2015c).<br><br>Acute lethality (96 h) and 7-d survival and growth testing indicated that water collected from Quesnel Lake, during September and November 2014, was not acutely lethal for Rainbow Trout and survival and growth of Fathead Minnow was not affected (Golder 2017c) | The difference in limnetic zone fish condition factor pre-event and post-event cannot be determined.<br><br>Comparing post-event condition factors of limnetic zone fish from reference areas to the West Arm shows condition factor for juvenile Sockeye Salmon was higher in the West Arm in 2014. In 2015, condition factor was similar across all regions of the lake (Golder 2017c).<br><br>Overall spatial balance **= Neutral** | (-) <1 year<br><br>Overall temporal balance **= Negative** |
| Turbidity | R | Between May 1995 and July 2014, the mean, minimal, and maximum turbidity (NTU) were 1.3, 0.35 and 4.8 respectively (MPMC 2014b). | By mid-November 2014, measurements of temperature, turbidity and specific conductivity were uniform throughout most of the water column. Turbidity at depth decreased to less than 10 NTU, which corresponded with an increase in turbidity in surface waters. This relatively small change in turbidity at the surface compared to deeper waters resulted in a cloudy appearance within the West Basin of the lake throughout the late fall and winter. By early spring (March and April 2015), turbidity at surface and depth decreased and was below 24-h (9 NTU) and 30-d (3 NTU) BC aquatic life WQGs. (Golder 2015a).<br><br>In 2014, Juvenile Sockeye did not appear to move out of the West Arm to avoid turbidity. Effects to limnetic fish foraging efficiency did not appear to have occurred (Golder 2015c). | Water chemistry shows that turbidity and total metals concentrations in the limnetic zone of the West Arm are unlikely to present hazards to aquatic life (Golder 2017c).<br><br>Overall spatial balance = **Neutral** | (-) <1 year<br><br>Overall temporal balance **= Negative** |
| Phytoplankton and Zooplankton Biomass | R | There is pre-event zooplankton abundance and biomass data presented in Hume et al. (2005) and MacLellan et al. (1993); however, due differences in resolution of taxonomic identification and units, these data cannot be compared to post-event data (Golder 2015c). | Chlorophyll *a* assessments were undertaken annually between 2014 and 2017, and results indicate that there is no discernable difference in biomass (chlorophyll *a*) in the West Arm relative to the east of Cariboo Island (i.e., the reference site; Golder 2017c), and chlorophyll *a* concentrations were within the range of historical values (Golder 2017c). There is no discernable difference in total zooplankton biomass or abundance, or in the relative biomass or abundance of dominant taxa, relative to the reference (Golder 2017c). Water from Quesnel Lake was not acutely lethal for *Daphnia* and survival of *Ceriodaphnia* was not impaired lab tests from post-event water samples (Golder 2017c). | The differences in phytoplankton and zooplankton biomass in the limnetic zone pre-event and post-event cannot be determined.<br><br>Comparing post-event data from the West Arm to reference areas shows that no changes in phytoplankton and zooplankton biomass were observed in the limnetic zone (Golder 2017c).<br><br>Overall spatial balance = **Neutral** | (-) <1 year<br><br>Overall temporal balance **= Neutral** |

#### 5.3.1.8 Quesnel Lake – Littoral Zone

In the littoral zone of Quesnel Lake, approximately 94,394 $m^2$ of rearing, spawning, and migratory habitat was permanently altered through the smothering of sediment from the event. Approximately 6,350 $m^2$ has been remediated, so there is currently a spatial loss of shoreline habitat. The event also caused a temporal loss to fish productivity as previous habitat was altered for approximately 4.5 years (Table-19). Additional monitoring information is required to evaluate the functionality of the remediated littoral habitat.

Determination**: TBD**

**Table-19: Quesnel Lake - Littoral Zone**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Area | R; S; M | 94,394 $m^2$ of littoral area was affected (SNC 2015a). | 6,350 $m^2$ of total shoreline habitat was remediated. This includes the areas of remediated habitat at the mouth of Edney Creek and the gravel shoals created along the shoreline. | Balance of -88,044 $m^2$ total instream habitat.<br>Overall spatial balance **= Negative** | (-) >4.5 years<br>Overall temporal balance **= Negative** |
| Littoral Zone Fish Relative Abundance | R | There is no pre-event data available on littoral fish abundance. | The actual contribution of the affected area of littoral zone to fish productivity is not known; however, the available data suggest that the decrease in benthic invertebrate prey items have not resulted in a decrease in condition factor of forage fish, Lake Trout, or Burbot captured in the littoral zone (Golder 2018c).<br><br>Similar fish communities observed at effluent-exposed and reference areas. Eight different fish species were captured from both exposed and reference areas in Quesnel Lake (Minnow 2016b). CPUE was higher in exposed areas (calculated by Golder based on Minnow 2016b data). | The different in littoral zone fish abundance pre-event and post-event cannot be determined.<br><br>Comparing post-event fish abundance of littoral zone fish from reference areas to the West Arm shows similar fish communities with higher CPUE were observed<br><br>Overall spatial balance **= Neutral** | (-) >4.5 years<br><br>Overall temporal balance **= Negative** |
| Littoral Zone Fish Condition Factor | R | There is no pre-event data available on littoral zone fish condition factor. | Mean condition factors were similar both across years and regions for sentinel fish and the data do not suggest a difference in body condition for sentinel fish residing in the West Basin compared to those in the reference areas (Golder 2017c). | The different in littoral zone fish condition factor pre-event and post-event cannot be determined.<br><br>Comparing post-event fish condition factors of littoral zone fish from reference areas to the West Arm shows similar fish conditions were observed<br><br>Overall spatial balance **= Neutral** | (-) >4.5 years<br><br>Overall temporal balance **= Negative** |
| Littoral Habitat Quality | R | In 2012, 51% of littoral habitat of Quesnel Lake was ranked as “Very High” and “High”; 48% was ranked “moderate; and 2% was ranked “Low” and “Very Low” (SNC 2015a). The shoreline next to Hazeltine Creek Mouth was ranked “Very High” (SNC 2015a). 15% of “Very High” ranked juvenile fish habitat at the mouth of Hazeltine Creek was permanently altered (SNC 2015a). | Natural recovery is in progress. | The different in littoral habitat area pre-event and post-event cannot be determined.<br><br>Overall spatial balance **= Unable to determine due to the absence of post-event data; this indicator has not been used in determination of residual effects.** | (-) >4.5 years<br><br>Overall temporal balance **= Negative** |
| Potential Shoreline Spawning Habitat Area | S | 2 km of shoreline was affected by the event. Approximately 1.2 km of shoreline near the mouth of Hazeltine Creek was rated “Very High”, and the remainder was rated “High” (SNC 2015a). | The shoreline design at the mouth of Edney Creek incorporates shallow gravel shoal habitat that is accessible to fish under a wide range of lake levels (Golder 2018c). | Most of the potential shoreline spawning habitat area has not been remediated.<br><br>Overall spatial balance **= Negative** | (-) >4.5 years<br><br>Overall temporal balance **= Negative** |
| Habitat Features by Area | R | In 2012, the littoral habitat of Quesnel Lake comprised: gravel beach (49%); rocky shore (35%), and 36% had aquatic vegetation (SNC 2015a). | There is no post-event habitat features data available for the littoral zone of Quesnel Lake. | The different in habitat features pre-event and post-event cannot be determined.<br><br>Overall spatial balance **= Unable to determine due to the absence of post-event data; this indicator has not been used in determination of residual effects.** | (-) >4.5 years<br><br>Overall temporal balance **= Negative** |
| Submergent and Emergent Vegetation by Area | R | In 2012, 36% of the shoreline area of Quesnel Lake had aquatic vegetation, predominantly emergent vegetation (SNC 2015a). | There is no official monitoring data available. | The different in submerged and emergent vegetation pre-event and post-event cannot be determined.<br><br>Overall spatial balance = **Unable to determine due to the absence of post-event data; this indicator has not been used in determination of residual effects.** | (-) >4.5 years<br><br>Overall temporal balance **= Negative** |
| Benthic Invertebrate Relative Abundance and Diversity | R | In 2007, the depositional benthic invertebrate community at the mouth of Hazeltine Creek at Quesnel Lake had a density of 21,000 organisms per $m^2$ and a richness of 30 taxa, comprised of chironomids (midges; 26.5%), ostracods (seed shrimp; 14.5%), and oligochaetes (aquatic worms; 10.4% (Minnow 2007). | The 2014, 2015, and 2016 data indicated that far-field littoral areas did not show reductions in density or diversity. However, the near-field littoral areas exhibited statistically significant reductions in mean density and diversity, and recovery was not yet evident in 2016 (Minnow 2015, 2016a, 2018b). The 2017 data are not directly comparable to the data collected earlier because the methods used were changed (Minnow 2018c). | Benthic invertebrate abundance and diversity is still recovering to pre-event levels.<br><br>Overall spatial balance **= Negative** | (-) >4.5 years<br><br>Overall temporal balance **= Negative** |

Sources: Golder 2017c, 2018c; Minnow 2015, 2016b, 2018c; SNC 2015a.

#### 5.3.1.9 Quesnel Lake – Benthic Zone

In the benthic zone of Quesnel Lake, about 1.8 $km^2$ of benthic habitat was altered with the smothering of tailings. No anthropogenic remediation work has been conducted in the Quesnel Lake benthic zone, resulting in a spatial and temporal loss (Table 20). Natural recolonization has been occurring over the last 4.5 years.

There is limited data to compare benthic fish abundance or condition factor pre and post-event. Preliminary benthic invertebrate monitoring suggests the recovery process is starting, but density and diversity are still significantly lower post-event compared to pre-event (Table 20).

A HEA has not been undertaken for Quesnel Lake – Benthic Zone. However, impacts did occur, and the approach will be to provide out-of-kind offsets. Offsetting options for Quesnel Lake - Benthic Zone are discussed in Section 5.4.2.

Determination**: Offsetting Required**

**Table 20: Quesnel Lake - Benthic Zone**

| Indicator | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Area | R | The area of breach-related infill within the estimated depositional zone is approximately 1.8 $km^2$ (Tetra Tech 2015b). | 0 $m^2$ of total benthic habitat was remediated. Potential remediation options are discussed in Section 4.11.3; MNR was selected as the preferred option. | Overall spatial balance **= TBD** | (-) >1 year<br><br>Overall temporal balance **= TBD** |
| Total Benthic Area Smothered | R | The deposition of material initially caused a reduction in the benthic invertebrate community (e.g., a reduction in food organisms for fish) which, based on more current data appears to be recovering (Figure 22; Minnow 2015, 2016b, 2017c). | Preliminary data suggests natural recovery of the benthic community is in progress (Figure 22; Minnow 2015, 2016b, 2017c). | The density of benthic invertebrates in the Quesnel Lake – Benthic Zone is lower than pre-event.<br><br>Overall spatial balance **= Negative** | (-) >1 year<br><br>Overall temporal balance **= Negative** |
| Benthic Zone Fish Relative Abundance | R | Based on the available information, relatively little is known about the specific distribution of fish species within Quesnel Lake, particularly benthic and pelagic, non-salmonid species (SNC 2015a). | Fish have been observed in the profundal zone of the West Basin during a remote operated vehicle (ROV) inspection of the outfall in 2018. | The different in benthic fish relative abundance pre-event and post-event cannot be determined.<br><br>Overall spatial balance **= Unable to determine due to the absence of both pre-event and post-event data; this indicator has not been used in determination of residual effects.** | (-) >1 year<br><br>Overall temporal balance **= Negative** |
| Benthic Zone Fish Condition Factor | R | There is no pre-event benthic zone fish condition factor data available. | There is no post-event benthic zone fish condition factor data available. | The different in benthic fish condition factor pre-event and post-event cannot be determined.<br><br>Overall spatial balance **= Unable to determine due to the absence of pre-event data; this indicator has not been used in determination of residual effects.** | (-) >1 year<br><br>Overall temporal balance **= Negative** |
| Benthic Invertebrate Relative Abundance and Diversity | R | There is limited data on the abundance and diversity of the benthic invertebrate community pre-event. In 2007, the mean density (organisms per $m^2$) was approximately 31,000, the number of taxa was approximately 30 (Minnow 2007). | Early sampling indicates some recovery, but additional benthic sampling will be necessary to determine the current status of the benthic community and its current trajectory to recover. | Benthic invertebrate relative abundance and diversity post-event is lower compared to pre-event conditions.<br><br>Overall spatial balance **= Negative** | TBD<br><br>Overall temporal balance **= Negative** |

Sources: Golder 2017c; Minnow 2015, 2016a, 2016b, 2017b; Tetra Tech 2015b.

#### 5.3.1.10 Quesnel River

No permanent physical alteration of habitat occurred in Quesnel River and benthic invertebrate abundance and diversity were similar in Quesnel River and reference stations. As there was no significant physical alteration of habitat in Quesnel River and no measurable residual effects, no offsetting is proposed.

Determination: **No Offsetting**

**Table 21: Quesnel River**

| Metric | Habitat Function | Pre-Event Data | Post Event Data | Spatial Balance | Temporal Balance |
|---|---|---|---|---|---|
| Turbidity | S; R; O; M | No permanent physical alteration of habitat has occurred in the Quesnel River (SNC 2015a).<br><br>The available evidence indicates a low magnitude of risk comparable to reference conditions:<br>■ Plankton - No significant reductions in chronic water algal growth tests or vascular plant growth toxicity tests on field-collected water samples. No chronic toxicity to cladocerans in representative non-turbid waters.<br>■ Benthic Invertebrates - Benthic invertebrate samples collected from Quesnel River and the corresponding reference area in Cariboo River had concentrations of COPCs similar to reference conditions.<br>■ Fish – Significant effects were not observed for fish toxicity tests including 7-d Rainbow Trout survival and growth, 30-d Rainbow Trout survival and development, and 7-d Fathead Minnow survival and growth toxicity tests on field collected water samples. | Monitoring results of Quesnel River conducted in 2014, 2015, 2016, and 2017 show no indications of further effects post-event (Golder 2017c). | Turbidity of Quesnel River pre-event and post-event are comparable (Golder 2017c).<br><br>Overall spatial balance **= Neutral** | (-) <1 year<br><br>Overall temporal balance **= Negative** |

Sources: Golder 2015d, 2017c; SNC 2015a.

### 5.3.1.11 Riparian Habitat

Riparian areas are important fish habitat because they link terrestrial and aquatic ecosystems and provide ecological functions such as improving water quality, providing bank stability, contributing organic matter (e.g., leaf litter and large woody debris) to waterbodies, and providing habitat complexity.

For the purposes of quantifying riparian area losses, we have defined the riparian zone as the Riparian Management Zone as described in Part 4 of the Forest Planning and Practices Regulation under the *Forest and Range Practices Act*.

SNC (2015a) estimated that the event altered 737,464 $m^2$ of riparian habitat along Hazeltine and Edney Creek. Altered riparian habitat for Polley Lake and Quesnel Lake - Riparian Zone were estimated using the application of a 10 m Riparian Reserve Zone to the affected area. In total, 765,574 $m^2$ of riparian habitat are estimated to be altered by the event. A breakdown of the riparian habitat altered by EU, and riparian habitat replanted to-date by EU, is provided in Table 23. The estimated area of replanted riparian habitat (i.e., 285,689 $m^2$) was calculated based on the assumptions in Section 5.3.12.1. An estimated 479,885 $m^2$ of riparian habitat still requires replanting.

To-date, riparian planting consists of staking live wattles of willow and planting black cottonwood, prickly rose, black twinberry, red osier dogwood, sitka alder, and coniferous trees species. In addition, riparian areas have been seeded using a locally sources multispecies seed blend.

**Table 22: Riparian Habitat**

| Ecological Unit | Altered Riparian Habitat ($m^2$) | Remediated Riparian Habitat ($m^2$) | Spatial Balance ($m^2$) |
|---|---|---|---|
| Edney Creek | 20,215 | 26,771 | +6,556<br>Overall spatial balance **= Gain** |
| Upper Hazeltine Creek (H1) | 530,094[2] | 265,047 | -265,047<br>Overall spatial balance **= Negative** |
| Lower Hazeltine Creek (H2) | 187,155[2] | 0 | -187,155<br>Overall spatial balance **= Negative** |
| Polley Lake | 7,300[3] | 7,300 | 0<br>Overall spatial balance **= Neutral** |
| Quesnel Lake - Littoral Zone | 20,810[4] | 0 | -20,810<br>Overall spatial balance **= Negative** |
| **Total** | **765,574** | **285,689** | **-479,885** |

[1]Based on Edney Creek being in Riparian Class S3, with a Riparian Management Area width of 40 m (Section 47 (1) of the Forest Planning and Practices Regulation, SNC 2015a). Altered riparian habitat estimate based on SNC (2015a).

[2]Based on Hazeltine Creek being in Riparian Classes S2, S3 and L1-B (reach-dependent), with a Riparian Management Area width of 40 m (S2), 50 m (S3), and 70 m (L1-B) (Section 47 (1) of the Forest Planning and Practices Regulation; SNC 2015a). Altered riparian habitat estimate based on SNC (2015a).

[3]Based on Polley Lake being in Riparian Class L1-B, with a Riparian Reserve Zone width of 10 m (Section 49 (1) of the Forest Planning and Practices Regulation).

[4]Quesnel Lake is in Riparian Class L1-A (i.e., lakes greater than 1,000 ha). Lakes of Riparian Class L1-A have a Riparian Reserve Zone of 0 m; however, to be conservative, a 10 m width was applied to Quesnel Lake (Section 49 (1) of the Forest Planning and Practices Regulation).

A HEA was undertaken for riparian habitat and results in a current negative balance of 774,069 $m^2$ that require offsetting Table 23. The current riparian habitat offset balance will need to be adjusted as ongoing habitat remediation continues to restore areas of riparian habitat. Riparian remediation will be ongoing through remediation of the remaining sections of the aquatic EUs.

Offsetting is required to compensate for the temporal loss of functional riparian fish habitat between the date of the event, and the time it will take for riparian habitat to reach a state similar to pre-event conditions, which Mallik et al. (2011) estimates to be approximately 18 years. Offsetting options for riparian habitat are discussed in Section 5.4.3.

Determination**: Offsetting Required**

#### *5.3.1.12 Offsetting for Aquatic and Riparian Habitat - Habitat Equivalency Analysis*

HEA is a means to determine the amount of compensatory restoration required to provide services that are equivalent to the interim loss of natural resource services following an “injury” (Kohler and Dodge 2006). Further background on HEA is provided in Section 4.2.4 and for convenience a brief summary is provided here.

HEA is used to determine the nature and degree to which a restoration project might provide adequate replacement for an injured resource. HEA uses a discounting algorithm to value a natural resource asset which is equal to all future services of that asset after degradation due to injury. The formula to calculate the level of ecological services gained and lost is a percent increase from a baseline level for each year of assessed losses and potential gains are added for the duration of years loss over the compensatory action period. A discount rate is applied each year to actualize the losses or gains as a percentage rate and per time services provided sooner are more highly valued that those provided later. These calculations were made using the software Visual_HEA (Kohler and Dodge 2006, Pioch et al. 2017).

A formal HEA assessment was conducted on EUs: Middle Edney Creek, Upper Hazeltine Creek, Lower Hazeltine Creek. HEA was conducted on these EUs due to insufficient data for pre- and / or post-event fish abundance (CPUE) and / or fish age class structure data for the injured sites. HEA was not conducted on Polley Lake, Quesnel Lake - Benthic Zone, and Quesnel Lake - Littoral Zone yet, due to the nature of the EUs as described in Sections 5.3.1.6, 5.3.1.8 and 5.3.1.9, respectively. The results of the HEA for each EU are presented in Table 23. EU-specific assumptions used to determine the input parameters are described in Table 24.

**Table 23: Summary of Habitat Equivalency Analysis Results**

| Ecological Unit (EU) | Area ($m^2$) | | | |
|---|---|---|---|---|
| | Impacted | Calculated HEA Units Required for Offsetting | Remediated (to date) | Remaining for Remediation or Offsetting (to date) |
| Polley Lake | TBD | TBD | TBD | TBD<br>See Section 5.3.1.6 |
| Upper Hazeltine Creek | 44,650 | 53,314 | 15,266 | 38,048 |
| Lower Hazeltine Creek | 17,966 | 26,046 | 0 | 26,046 |
| Middle Edney Creek | 1,350 | 1,499 | 1,553 | 0 |
| Quesnel Lake – Littoral Zone | 94,394 | TBD | 6,350 | TBD<br>See Section 5.3.1.8 |
| Quesnel Lake – Benthic Zone | 1,800,000 | TBD | TBD | TBD<br>See Section 5.3.1.9 |
| Riparian Areas | 765,372 | 1,059,767 | 285,698 | 774,069 |

Note: Habitat remediation remains underway in a number of EU. Additional habitat credits are expected to result when that habitat has been constructed (e.g., Reach 3 of Hazeltine Creek).

#### *5.3.1.13 HEA Calculation (Long Term Commitments)*

This Remediation Plan sets out the proposed components to be used in the calculation of habitat offsets. The time loss functions are based on estimates obtained from the literature which will have uncertainty associated with those estimates. Attainment of the offsets “owing” will be verified as part of habitat verification monitoring (see Figure 8) and it is expected that parameters used in the HEA calculations may be adjusted based on the findings of that monitoring. This could also result in adjustments to the amount of offsets. The HRWG provides a suitable forum for oversight of the delivery of sufficient habitat offset amounts and while the group is intended as a collaborative group, representatives of the HRWG include those with regulatory authority for such oversight. The RP sets out the initial amounts of habitat owing and provides a mechanism whereby accounting for offsets remains part of MPMC’s long term commitments.

The continuum of monitoring, assessment and recalculation of offsets “owing” provides a direct measurement and accounting for uncertainty in the success of habitat offset projects.

**Table 24: Habitat Equivalency Assessment (HEA) Per Site Using Assumptions for Natural Recovery Detailing the Parameters Used and Assumptions**

| Site | Injured Area ($m^2$) | Pre-Injury (Base-line) Service Level (%) | Pre-Restoration Service Level (%) | Time for 100% Natural Baseline Recovery | Natural Recovery Level (%) | Time for Baseline to Return from Restorations (years) | Size of Compensatory Replacement Habitat ($m^2$) | Area Remediated ($m^2$) | Remaining Area for Remediation or Offsetting ($m^2$) | Assumptions |
|---|---|---|---|---|---|---|---|---|---|---|
| Polley Lake | TBD | 100 | TBD | TBD | TBD | TBD | TBD | TBD | TBD | TBD See Section 5.3.1.6 |
| Upper Hazeltine Creek | 44,650 | 100 | 0 | Infinite (will never reach natural baseline services without restoration Service) | 0 | 7 | 53,314 | 15,266 | 38,048 | Restoration of physical construction was completed in 2017. For Reaches 1 and 2, remediation construction restored access and in-stream habitat function in 2017. Fish utilization occurred starting in 2018: four years post-event. For Reaches 1 and 2, after remediation activities, in-channel habitat features achieved a quality rating of "good" based on Table 1 habitat function metrics. This is as good, if not better, than the habitat was pre-event. Full recovery of Reaches 1 and 2 is anticipated six years post-event due to benthic invertebrate community recovery and unknown variables. This accounts for four years of blocked access and two years for recovery. Density of juvenile Rainbow Trout and YOY production is roughly equal pre- and post-event suggesting food supply is available and the benthic invertebrate community is recovering. For Reach 3, it is anticipated that remediation construction will restore access and in-stream habitat function in 2019. Fish utilization is expected to occur starting in 2020: six years post-event. For Reach 3, after remediation activities, it is anticipated that in-channel habitat features will achieve a quality rating of "good" based on Table 1 habitat function metrics. Full recovery of Reach 3 is anticipated eight years post-event due to benthic invertebrate community recovery and unknown variables. This comes from six years of blocked access and two years for recovery. Times for recovery for Reaches 1 and 2 and Reach 3 are averaged together. This results in a value of seven years used. |
| Lower Hazeltine Creek | 17,966 | 100 | 0 | Infinite | 0 | 10 | 26,046 | 0 | 26,046 | Post-event service levels provided by the habitat were rated at 0%. For Lower Hazeltine Creek, it is anticipated that remediation construction will restore access and in-stream habitat function in 2020. Fish utilization is anticipated to occur in 2021: seven years post-event. Full recovery of Lower Hazeltine Creek is anticipated 10 years post-event due to benthic invertebrate community recovery and unknown variables. This account for six years of blocked access and 4 years for recovery. |
| Middle Edney Creek | 1,350 | 100 | 50 | Infinite | 0 | 3 | 1,499 | 1,5532 | 0 | Productivity of Middle Edney Creek post-event is assumed to be 50%, as the channel was altered (i.e., not destroyed). The physical construction was completed in less than one year. Access to Middle Edney Creek was restored in less than one year, assuming no spawning productivity was lost. After two years of remediation activities, in-channel habitat features achieved a quality rating of "good" based on Table 1 habitat function metrics. A full recovery of in-stream habitat function will take three years. Abundance (CPUE) numbers pre-event and post-event is roughly equal, suggesting food supply is available for Rainbow Trout and the benthic invertebrate community is recovering. and some habitat features remained. |
| Quesnel Lake – Littoral Zone | 94,394 | 100 | 0 | Infinite | NA | 5 | TBD | 6,350 | TBD | TBD See Section 5.3.1.8 |

| Site | Injured Area ($m^2$) | Pre-Injury (Base-line) Service Level (%) | Pre-Restoration Service Level (%) | Time for 100% Natural Baseline Recovery | Natural Recovery Level (%) | Time for Baseline to Return from Restorations (years) | Size of Compensatory Replacement Habitat ($m^2$) | Area Remediated ($m^2$) | Remaining Area for Remediation or Offsetting ($m^2$) | Assumptions |
|---|---|---|---|---|---|---|---|---|---|---|
| Quesnel Lake – Benthic Zone | 1,800,000 | 100 | 0 | Infinite | 0 | 5 | TBD | 1,800,000 | TBD | TBD See Section 5.3.1.9 |
| Riparian | 765,372 | 100 | 0 | Infinite | 0 | 18 | 1,059,767 | 285,698 | 774,069 | For riparian areas, some remediation activities began in 2015 with planting and some are ongoing. An assumed average value of remediation occurring three years post-event is used for the HEA calculation. For riparian areas, it is anticipated that natural recovery would restore habitat function in 20 years. The riparian area for Hazeltine and Edney Creeks estimated by SNC (2015a) and the riparian area estimated by the HHWG for Polley Lake and Quesnel Lake littoral zone do not overlap. Riparian habitat in Upper Edney Creek (E1) and Quesnel River were not affected by the event (HRWG 2015). Riparian habitat was altered in the following EUs: Middle Edney Creek (E2); Lower Edney Creek (E3); Upper Hazeltine Creek (H1); Lower Hazeltine Creek (H2); Polley Lake; and Quesnel Lake - Littoral Zone (SNC 2015a; HRWG 2015). There is no riparian habitat in the following EUs: Quesnel Lake – Benthic Zone; and Quesnel Lake – Limnetic Zone. Riparian habitat in Middle Edney Creek (E2) and Quesnel Lake - Littoral Zone has not been replanted (Table 6). Riparian habitat in Lower Edney Creek (E3) has been replanted (Table 6). 50% of Upper Hazeltine Creek (H1) riparian habitat has been replanted (approximately 3 km); leaving 50% (approximately 3 km) yet to be replanted. Riparian habitat in Reach 5 of Lower Hazeltine Creek (H2) has been partially planted and seeded (Table 6); however, the majority of H2 has not been replanted; therefore, this area is considered 0% revegetated. The revegetated riparian habitat completed at Polly Flats includes all the affected riparian at Polly Lake (Table 6). |

Note: Reach 4 (Hazeltine Canyon) was not included in the HEA calculations because that section is not accessible to fish, and was not accessible pre-breach.

### 5.3.2 Upland Terrestrial Habitat

Areas of upland terrestrial habitat affected by the event occur in the Interior Cedar Hemlock (ICH) BEC zone. Site series within affected areas include the Quesnel Wet Cool (ICH wk2) and Horsefly Moist Cool (ICH mk3).

SNC estimated the event altered 2,374,700 $m^2$ of total terrestrial habitat, which includes 737,464 $m^2$ riparian habitat (Section 5.3.1.11; SNC 2015a, b). An additional 28,110 $m^2$ of riparian habitat was estimated by the HRWG for Polley Lake and Quesnel Lake - Littoral Zone leaving an estimated 1,609,328 $m^2$ of affected upland terrestrial habitat.

The remediation plan for the altered upland terrestrial habitat includes:

- **Site preparation and soil amendments**. Site preparation methods are described in Section 4.2.3 and include mixing natural soil with the tailings soil and creating microsites across the upland terrestrial area. Soil inoculation and using topsoil borrowed from donor natural sites may be added to some areas with large volumes of deposited material to bolster soil microbial communities, soil nutrient levels, soil structural properties, and to provide a local seed bank (Ohsowski et al. 2012).
- **Revegetation program**. The revegetation program aims to re-establish a natural trajectory of succession within the upland terrestrial area, using natural pioneer species that are tolerant of difficult growing conditions and early-mid successional species (Section 4.2.3). To-date, 90% (approximately 1,448,395 $m^2$) of upland terrestrial habitat has been replanted based on advice from University of British Columbia (UBC) Forest Ecology, First Nations wishes, and generally based on standard BC silviculture stocking standards (Province of British Columbia 2019), leaving approximately 10% (approximately 160,933 $m^2$) of upland terrestrial habitat to be replanted. Based on the *Reference Guide for Forest Development Stocking Standards* (Province of British Columbia 2019), the delay to establish regeneration ranges from four- to seven- years dependent on the site series for the ICH wk2 and mk3. Where short regeneration delay periods are indicated (i.e., four years), planting is the preferred reforestation method (MOF 2002). The regeneration date is defined as the date at which the minimum number of healthy well-spaced trees of the preferred and acceptable species are established and the minimum number of preferred trees are established, which must be maintained until the sites is determined to be free growing (MOF 2002).

Possible offsetting options for upland terrestrial habitat are described in Section 5.4.4.

Determination**: TBD monitoring required**

#### *5.3.2.1 Assumptions*

- The total upland terrestrial habitat affected is equivalent to the estimated affected terrestrial habitat reported by SNC (2015b) minus the riparian habitat area estimated by SNC (2015a) and the riparian habitat area estimated by the HRWG.
- Planting of the upland terrestrial area completed to-date follows the BC silviculture stocking standards for the appropriate BEC subzone and site series (Province of British Columbia 2019).
- Soil amendments completed to-date will be conducive to the growth of vegetation that has been planted in the upland terrestrial area.

### 5.3.3 Uncertainties in Residual Effects, Offset, and Compensation Determination

There are uncertainties associated with the determination of residual effects, offsets and compensation for the EUs, riparian habitat and upland terrestrial habitat. This section describes the key uncertainties accounted for in the determination of residual effects and offset / compensation determination for each area. Accounting for uncertainties allows for adaptive management of habitat offsets and better satisfies the “no-net-loss” outcome of fish productivity.

**Upper Edney Creek (E1)**

- Uncertainties from the limited pre-event data, including the lack of salmon spawner escapement data, and limited juvenile salmon abundance data.
- Uncertainties from inconsistencies between pre- and post-event survey methodologies. In 2007, the survey methodology used for calculating abundance (CPUE) of Rainbow Trout was electrofishing, while in 2016 and 2017 it was minnow trapping.
- Timing of surveys was also inconsistent in Upper Edney Creek (E1). Pre-event surveys were conducted in late August of 2007, while 2016 and 2017 surveys were conducted from April to October and May to November respectively.

**Middle Edney Creek (E3)**

- Uncertainties from the limited pre-event data, including the lack of pre-event Rainbow Trout abundance (CPUE) and salmon spawner escapement data, and limited juvenile salmon abundance data.
- Uncertainties from possible inconsistencies in the collection of fish for determining Rainbow Trout age class structure pre- and post-event, and possible different month of fish collection.

**Lower Edney Creek (E2)**

- Uncertainties from the limited pre-event data, including the lack of pre-event Rainbow Trout abundance (CPUE) and salmon spawner escapement data, and limited juvenile salmon abundance data.
- Uncertainties from possible inconsistencies in the collection of fish for determining Rainbow Trout age class structure pre- and post-event, and possible different month of fish collection.

**Upper Hazeltine Creek**

- Uncertainties due to the lack of post-event Rainbow Trout abundance (CPUE) and age class structure data.

**Lower Hazeltine Creek**

- Uncertainties due to the lack of post-event Rainbow Trout abundance age class structure data.

**Polley Lake**

- Uncertainties from inconsistencies between pre- and post-event survey methodologies. In 1973, 1995, and 2012, the survey methodology used for calculating abundance (CPUE) of Rainbow Trout was seine netting, while in 2014 and 2016 it was gillnet sets.
- Uncertainties from possible inconsistencies in the collection of fish for determining Rainbow Trout age class structure and condition factor pre- and post-event, and possible different month of fish collection.

**Quesnel Lake – Benthic Zone**

- Uncertainties from the lack of pre-event data, including the lack of pre-event benthic zone fish relative abundance (CPUE), pre-event benthic zone fish condition factor and consistent pre- and post-event benthic invertebrate community data.

**Quesnel Lake – Limnetic Zone**

- Uncertainties from the lack of pre- and post- event data, including the lack of pre-event limnetic zone fish relative abundance (CPUE), pre-event limnetic zone fish condition factor and official submergent and emergent vegetation monitoring data.

**Quesnel Lake – Littoral Zone**

- Uncertainties from the lack of pre-event data, including the lack of pre-event littoral zone fish relative abundance (CPUE), littoral zone fish condition factor and zooplankton abundance and biomass data.

**Riparian Habitat**

- Uncertainties associated with natural vegetation species growing and establishing on affected sites (so far monitoring has shown that replanted areas are growing).
- Uncertainties associated with natural infilling by propagules from the surrounding area leading to a natural trajectory for succession.
- Uncertainty in the loss of wetland areas adjacent with Edney and Hazeltine Creeks.

**Upland Terrestrial Habitat**

- Uncertainties associated with site preparation techniques making soils conducive to native plant establishment and growth.
- Uncertainties associated with the success of planting of pioneering species and natural infilled by propagules from the surrounding area leading to a natural trajectory for succession.

- Loss of wetlands in the upland terrestrial habitat will have effects on availability of amphibian breeding habitat. The compensation is not encompassed by only following the silviculture stocking guidelines as this does not replace loss wetland habitat.
- Uncertainties associated with the effect the event had, and continues to have, on amphibians. Further monitoring in the CEMP or a focused amphibian study may be required.

## 5.4 Proposed Offsets and Compensation

There are no proposed offsets for six EUs: Upper Edney Creek (E1), Middle Edney Creek (E2), Lower Edney Creek (E3), Polley Lake, Quesnel Lake – Limnetic Zone, and Quesnel River. The rationale for no proposed offset for these EUs is provided in Sections 5.3.1.1, 5.3.1.2, 5.3.1.3, 5.3.1.6, 5.3.1.7 and 5.3.1.9 respectively.

Offsets are proposed for riparian habitat and four EUs: Upper Hazeltine Creek (H1), Lower Hazeltine Creek (H2), Quesnel Lake – Benthic Zone, and Quesnel Lake – Littoral Zone. The rationale for proposing offsets for riparian habitat and these EUs is provided in Sections 5.3.1.11, 5.3.1.4, 5.3.1.5, 5.3.1.9 and 5.3.1.8 respectively. Proposed offset options for H1, H2 and Quesnel Lake – Littoral Zone are described in Section 5.4.1, for Quesnel Lake – Benthic Zone is described in Section 5.4.2, and for riparian habitat is described in Section 5.4.3. Proposed offsets are common approaches known to have the potential to increase fish productivity (Loughlin and Clarke 2014).

Compensation is proposed for upland terrestrial habitat. The rationale for proposing compensation for upland terrestrial habitat is provided in Section 5.3.2, and proposed compensation is described in Section 5.4.4.

The HRWG will provide input into a decision for the most appropriate offset to meet productivity effects/shortfalls for each EU, the riparian habitat and the upland terrestrial habitat.

### 5.4.1 Potential Offset Options for Hazeltine Creek (H1 and H2) and Quesnel Lake – Littoral Zone

#### *5.4.1.1 On-Site Off-Channel Habitat Creation*

Habitat creation is considered offset to serious harm to fish under the federal *Fisheries Act* (Loughlin and Clarke 2014) and has been common practice since the 1980s. Hazeltine Creek (H1 and H2) was destroyed and Quesnel Lake – Littoral Zone was altered as a result of the event. Pre-event, Upper Hazeltine Creek (H1) provided spawning and rearing habitat for a single species (i.e., Rainbow Trout), while Lower Hazeltine Creek (H2) provided spawning and rearing habitat for multiple species (e.g., Rainbow Trout and other salmonid species such as sockeye salmon). A potential offset option for H1, H2 and Quesnel Lake – Littoral Zone is the construction of small off-channel streams to provide additional spawning and rearing habitat, or to improve access to H1 from Polley Lake, and from Quesnel Lake to H2.

Habitat creation should be undertaken using a watershed approach to identify and remove potential stressors that will affect the created habitat prior to undertaking habitat enhancement and creation (Loughlin and Clarke 2014). Off-channel habitat can be created using different techniques such as groundwater fed off-channels, overflow channels that become wetted during flood events, and surface-fed channels (Lister and Finnigan 1997). Selection of the type of off-channel habitat created will depend on the characteristics of the site and the spawning and rearing requirements of the species the off-channel habitat is designed for (Lister and Finnigan 1997). Design of off-channel habitat for spawning and rearing must consider riparian vegetation, substrate type suitable for spawning for target species, the macroinvertebrate community, physical design of the habitat (e.g., channel width, channel depth, riffle / pool structure), and cover features available such as large woody debris (Loughlin and Clarke 2014). Monitoring and follow-up programs are necessary to determine the productivity provided by created off-channel habitat (Loughlin and Clarke 2014). For offsetting programs this will require data on the productivity prior to the disturbance event, productivity after the disturbance event, and productivity after habitat creation and enhancement projects are constructed.

#### *5.4.1.2 Off-Site Off-Channel Habitat Creation*

DFO (2013) prefer offsets that occur within the vicinity of the Project, or within the same watershed; therefore, a potential offset option for H1, H2 and / or Quesnel Lake – Littoral Zone is the construction of off-site off-channel habitat within the Quesnel Lake watershed. Off-channel habitat creation can provide spawning, rearing, and overwintering habitat for target fish species to increase fish productivity. Off-channel habitat can be created using different techniques such as groundwater fed off-channel habitat, overflow channels that become wetted during flood events, and surface-fed channels (Lister and Finnigan 1997). Selection of the type of off-channel habitat created will depend on the characteristics of the site and the spawning and rearing requirements of the fish species for which off-channel creation is being designed (Lister and Finnigan 1997). The design of off-channel habitat for spawning and rearing needs to consider riparian vegetation, substrate type suitable for spawning for target species, the macroinvertebrate community, physical design of the habitat (e.g., channel width, channel depth, riffle / pool structure), and cover features available such as large woody debris (Loughlin and Clarke 2014). The input of First Nations, local biologists and streamkeeper volunteers can provide considerable benefit to accelerating such concepts with locally informed ideas.

#### *5.4.1.3 Removal of Barriers and Reconnection of Fish Habitat*

Damaged and incorrectly installed culverts, fords and bridges can prevent the passage of fish. Perched culverts can reduce the chance a fish can access the culvert. Culverts can affect the flow of water which can affect fish passage. If there is not enough flow, the water can be too shallow for fish to pass. Alternatively, too much flow can make it too difficult for a fish to swim up the culvert. The chances of debris getting trapped and blocking the culvert is increased when the upstream opening is too narrow. The lack of proper habitat features, such as resting pools below the outfall of a culvert, can also create a barrier to fish passage (MOTI 2013; Votapka 1991).

There are 1,123 culverts (i.e., round culverts, oval culvert, wood box culverts, or pipe arch), fords, and bridges in the Quesnel River watershed identified as barriers to fish passage (Government of BC 2019; Pedersen 1998 Appendix C). The location of each fish barrier and the associated stream / tributary is provided in Appendix C. Where the length and channel width of the fish barrier is known, the potential offset area ($m^2$) is provided in Appendix C. A potential offset option for H1, H2 and / or Quesnel Lake – Littoral Zone is to maintain, remove or replace fish barriers to regain passage for fish to access spawning and rearing areas.

Numerous examples exist of the success of removing fish barriers and promoting habitat connectivity (DFO 2016). Culvert restoration and upgrades have shown, when completed properly, to increase passage success, fish biomass and species richness (Favaro et al. 2014; Goerig et al. 2015).

#### 5.4.1.4 Streambank Stabilization and Riparian Planting

A potential offset option for H1, H2 and / or Quesnel Lake – Littoral Zone is to stabilize banks and revegetated riparian areas within the Quesnel Lake to Edney Creek watershed. Anthropogenic activities such as forest harvesting and infrastructure construction has increased exposure to streams, resulting in increased water temperature, sediment, and channelization (Pedersen 1998). Restoration activities such as bank stabilization and revegetation of riparian areas, both of which are needed on a variety of watercourses throughout the watershed (Pedersen 1998), can contribute to the overall health of a stream, increasing the quality of salmonid habitat.

#### 5.4.1.5 Invasive Fish Eradication

DFO (2013) consider offsets that are undertaken outside of the Project site, or for fish species other than those affected, provided the offsets are supported by clear fisheries management objectives or regional restoration priorities. Therefore, a potential offset option for H1, H2 and / or Quesnel Lake – Littoral Zone is to provide funds to support the eradication of invasive smallmouth bass (*Micropterus dolomieu*) in the Beaver Creek watershed.

Smallmouth bass is an invasive fish species, occurring in reservoirs, ponds, rivers, and streams. It is an efficient predator, feeding on invertebrates as juveniles and then fish after the age of two (Bobrowski 2017). This has a negative effect on native fish species by reducing prey availability and through direct predation. Predation may have an impact on salmonid species in particular; juvenile salmonids can make up over 50% of smallmouth bass diet where they overlap (Tabor et al. 1993; 2007). Smallmouth bass is also able to reproduce faster and more often than most native fish, adding additional competition onto native fish populations (Bobrowski 2017). This species occurs in watersheds throughout southern BC as well as Vancouver Island (Government of BC 2019). A population was also illegally introduced into Beaver Creek, which drains into the Quesnel River, in 2003 (Bobrowski 2017). By 2007, smallmouth bass had moved downstream as far as the confluence of Beaver Creek and Quesnel River and upstream of Beaver Lake. It is expected to continue to spread throughout central BC (Bobrowski 2017).

Population control efforts can be focused through eradication and containment. Eradication focuses on removing populations of smallmouth bass through a variety of methods. Containment seeks to stop the spread of smallmouth bass through the installation of artificial barriers.

Eradication and control programs for smallmouth bass has shown some success in both reducing smallmouth bass population numbers and increasing native fish abundance; however, a multi-year approach is needed to avoid bass populations rebounding (Biron et al. 2014; Weidel et al. 2007).

### 5.4.2 Proposed Offset Option for Quesnel Lake - Benthic Zone

#### *5.4.2.1 Lake Fertilization*

The offset of Quesnel Lake benthic habitat with new deep lake habitat (like for like offset) is not a practical offsetting option because an ecologically viable lake with a depth of approximately 100 m would require construction of a water dam and would alienate considerable land. Given that desired outcomes for offsetting are to increase productivity, we have considered lake fertilization to be an appropriate means of directly increasing productivity of Quesnel Lake.

Nutrient addition can be used to enhance fish food production in lakes where food may be a limiting factor (Gerwing and Plate 2018; Basset et al. 2016; Envirowest 1990). It is well established that nutrient addition can compensate for the loss in productivity resulting from dam construction and operation (Ashley and Slaney 1997; Stockner and Shortreed 1985) by increasing productivity of edible phytoplankton and, in turn, increasing zooplankton biomass, such as *Daphnia spp*. which is a key forage item for planktivorous fish (Perrin and Stables 2001; Perrin and Stables 2000; Thompson 1999). The stimulation of the lower trophic levels, when done right can play a key role in increasing the productivity of fish populations (Hebert et al. 2013). Inorganic nutrients are added to the lake to enhance primary trophic levels (e.g., plants and phytoplankton), which in turn increases secondary trophic levels (e.g., zooplankton and benthic invertebrates) that are important food sources for juvenile Salmon (Envirowest 1990). Nutrient additions are particularly viable for oligotrophic lakes (Loughlin and Clarke 2014).

During habitat assessment in the late 1980s and early 1990s, Quesnel Lake was assessed to have excellent physical characteristics (e.g., temperature, thermocline and euphotic zone depth) for rearing habitat for juvenile Sockeye Salmon. However, nutrient concentrations and phytoplankton productivity was low relative to other interior Fraser lakes (Shortreed et al. 2001). *Daphnia* was abundant during years of lower fry density but during years of high fry density its abundance declined to levels where sockeye diet shifted to less efficient prey items (Shortreed et al. 2001). Quesnel Lake is a potentially suitable candidate for fertilization during dominant and subdominant brood years. Fertilization of Quesnel Lake was estimated to have the potential to produce several million additional adult Sockeye returns in each dominant and subdominant brood year (Stockner and Shortreed 1994).

Nutrient enrichment programs have been undertaken with measurable success. In 1999 The BC Ministry of Environment undertook a 5-year program, and nutrient addition to a limnetic area of 1,400 $ha^2$ in the Alouette Reservoir starting (Harris et al. 2010). Monitoring from the initial research phase from 1999 to 2002 indicated lake fertilization was meeting the established goals (Harris et al. 2010). Monitoring results from this program indicate increase in the density of phytoplankton, increase in zooplankton biomass and density, and increase in fish abundance during the nutrient addition program in comparison to pre-fertilization baseline conditions (Harris et al. 2010). Recently, BC Hydro undertook a 10-year program nutrient enrichment program to a 4.1 $km^2$ reservoir area in Wahleach Reservoir, BC (Hebert et al. 2013; BC Hydro 2005). Results from the monitoring program report increased phytoplankton and zooplankton abundance and biomass as a result of nutrient addition (Hebert et al. 2013). Increased phytoplankton and zooplankton productivity have translated into increased fish abundance and biomass since the program's inception. Assessments of Wahleach Reservoirs' fish populations indicate a significant increase in abundance and overall biomass since the start of nutrient enhancement (Hebert et. al. 2013).

Gerwing and Plate (2018) provide a contemporary review of the effectiveness of nutrient enhancement as a remediation or compensation strategy for salmonid fisheries from several such efforts. Their review provides important considerations in use of this offsetting method so that increased primary producer and invertebrate populations will transfer into increases in fishery productivity. A fertilization program needs to be coupled with appropriate monitoring. Anecdotally, following the year of the breach, DFO observed that sockeye salmon juveniles in the West Arm were more abundant and larger in size than sockeye juveniles in other parts of Quesnel Lake and water quality measurements in Quesnel Lake found that nutrient levels were increased as a result of forest nutrients being washed into the lake from the debris flow. This and experience elsewhere (Gerwing and Plate 2018) suggests that there is merit in considering this as a practical offset measure.

When done correctly, increased fishery productivity of Quesnel Lake does appear to be a likely outcome to such an offsetting measure. The estimate of 5 years of productivity impacts from the breach to Quesnel Lake benthos provides a suitable period over which the offset would involve MPMC funding a lake fertilization program for the Quesnel Lake west arm as an offset to the impacts of the breach on the West Arm of Quesnel Lake. Consultation with DFO would also be needed for conclusion of lake fertilization as the productivity increase from fertilization is largely transient, occurring for the duration of fertilization (Gerwing and Plate 2018; Envirowest 1990).

Through consultation for this RP (and more broadly), MPMC are aware that lake fertilization may be a controversial proposal for certain area residents and lake users. Consultation would be a required part of implementing lake fertilization. Based on expectations from what was heard through consultation to date and some of the concerns identified, it was felt that a contingent offset option was appropriate.

#### *5.4.2.2 Contingency Option for Quesnel Lake - Benthic Zone Offset*

A suitable contingency option was tabled by FLNR at a November 2018 HRWG meeting. A known negative impact on local fish productivity from invasive species has been identified as a conservation priority for action and it was suggested that contributions towards an invasive species eradication program could be a suitable form of productivity offsets.

The quantification of an appropriate dollar amount for that offset could be based on a costing exercise for 5 years of a lake fertilization program with that amount paid into invasive species control programs over that period of 5 years. The technical and managerial leadership of the invasive species program are already in place so MPMC would be a funding contributor towards a program seen by fishery managers as an important regional program. Additional information on such a program is provided in Section 5.4.1.5 above.

### 5.4.3 Proposed Offset Options for Riparian Habitat

Riparian habitat offsetting will be used to account for the time lag required for riparian plantings to become ecologically functional. To achieve riparian habitat offsetting a combination of options can be employed and are discussed below. Riparian enhancement and restoration within the watershed.

- **Riparian habitat creation:** through the creation of off-channel fish habitat (Sections 5.4.1.1 and 5.4.1.2) additional riparian areas will also be created.
- **Removal of barriers to fish passage:** removing fish barriers will enable fish to access areas that may contain suitable habitat for spawning and rearing including areas with intact functional riparian areas (Section 5.4.1.3).

- **Riparian enhancement or restoration:** identifying important areas for fish spawning, rearing, or overwintering in the Quesnel Lake and Edney Creek Watershed and the surrounding area may identify locations that would benefit from riparian enhancement or restoration due to degradation from natural (e.g., wildfire) or anthropogenic (e.g., road creation) events.

### 5.4.4 Proposed Offsets for Upland Terrestrial Habitat

For the purposes of this RP upland terrestrial habitat means those areas damaged that are not within the streamside riparian zone as defined by the province of BC. Those riparian zone areas are being handled as they would with other aquatic habitat disturbances in the riparian zone.

The remedial objectives for terrestrial habitat are to reforest those areas such that the terrestrial area provides forest on a successional trajectory and associated wildlife habitat. Offsets for the interim losses are based BC forestry model wherein reforestation of clear-cut areas is required. Additionally, for the “use” of the timber values, stumpage fees would be paid to BC. It is proposed that offsets therefore be based on the stumpage fee formula used by BC.

# 6.0 IMPLEMENTATION AND SCHEDULE

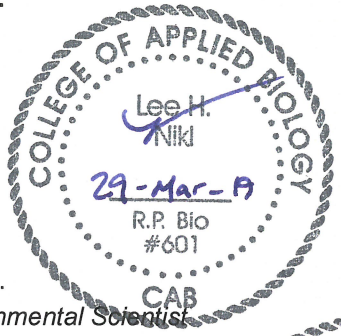
The RP is an integrated plan (Figure 8) that is developed to address both physical damages through direct remediation work and through risk management measures for the introduction of tailings constituents. The implementation of risk management requires ongoing monitoring (e.g., in the case of MNR) to confirm risk expectations and to verify identified areas of scientific uncertainty. In those instances where risks are uncertain (e.g., where conditions at the time of the ERA did not allow such a determination to be reached), MPMC are carrying out specific studies that are adjunct studies to the CEMP. The regulatory oversight for these studies is carried out through the CEMP process. The implementation of habitat remediation work will continue through the HRWG. This group is the logical group for confirmation of habitat credits as verified through monitoring, re-evaluation of offsets owing as monitoring data confirm habitats are functioning as intended. The HRWG will also have the role of evaluating and prioritizing offsetting options to be constructed. MPMC recognize that while the HRWG provides these inputs, the presentation of information and data to that working group remains part of MPMC's long term commitments. It is anticipated that the HRWG may wish to review their TOR for the implementation of the RP.

The implementation of the RP and the scheduling of resources is carried out by MPMC who direct either their own crews or the crews of locally contracted construction firms. Schedules and other matters are determined with greater clarity as the work plans become finalized with the HRWG. A conceptual schedule is provided below in Table 25. It will be subject to change as finalized work plans are concluded, monitoring is carried out and habitat offset balances are recalculated based on survey findings.

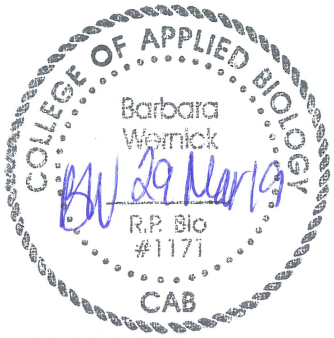
The schedule below was developed by MPMC.

**Table 25: Conceptual Schedule for Implementation of Remediation**

| Item | Anticipated Schedule |
|---|---|
| Remediation Plan | 29 March submission |
| Hazeltine Creek Reach 3 | Plans submitted agreed 2018, construction to +3100, remainder summer 2019 |
| Hazeltine Creek Reach 5 | 2020 |
| Hazeltine Creek/Edney Mouth Re-alignment | 2020-2021 |
| Sediment Control Ponds decommissioning designs | 2021 |
| Polley Lake Shoreline | 2020 |
| Comprehensive Environmental Monitoring Plan (CEMP) | Conditionally Approved 2018, and as updated every 3 years |
| HRWG Terms of Reference Review (to identify if changes needed for implementation of RP) | 2019 |



We note that the implementation of a remediation plan will normally require monitoring of the outcome of remedial works and adjustments to provide attainment of remedial objectives. A monitoring plan has not been included in this RP because monitoring will be carried out in accordance with the CEMP. The CEMP is currently designed as a tool for permit monitoring and risk management components of the RP. It is proposed that the HRWG develop a habitat-specific monitoring plan because risk management monitoring and habitat function monitoring are typically different technical areas that persons with appropriate technical backgrounds would provide feedback on. This will also fit with the main regulatory oversight for habitat remediation being within the *Fisheries Act* and the *Water Sustainability Act* and regulatory oversight over permit and risk management monitoring being overseen under the *Environmental Management Act*. There are logical linkages that exist within these two technical areas such as construction of habitat and water quality in that habitat. However, those linkages functioned well in making habitat decisions as water quality considerations were a substantial part of decisions on, for example, fish re-introduction into upper Hazeltine Creek (see for instance scope of information provided in Golder 2018b).



# 7.0 CLOSURE

We trust that this report provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at 604-296-4200.

**APPENDIX B**

# Offsetting Ideas Discussion

**Appendix C: Offsetting Ideas Tabulated by Rank, Source, Location and Project Description (assembled by MPMC)**

| Rank | Source | Location | Project Description |
|---|---|---|---|
| 1 | Richard Holmes | Horsefly River | Various creeks through out the Horsefly watershed can be addressed. Detailed info is available in the FRBC data bank (this is paper copy only).<br>See Appendix D. |
| 2 | Richard Holmes | Quesnel River | DFO rearing channels downstream of the Likely Bridge in Likely, BC. |
| 3 | Judy Hillaby | Horsefly River | Erosion near Mitchell Bay has high potential to under cut the access road. Would also effect fish passage. |
| 4 | Steve Hoxquard | Moffat Creek | Improve bank and channel stability. Preliminary Assessments have been done. |
| 5 | Colleen Hughes | Horsefly Spawning Channel | https://www.wltribune.com/community/horsefly-salmon-festival-creates-hopeful-future-for-run/<br><br>https://www.wltribune.com/community/horsefly-river-celebrates-sockeye-salmon-run-with-festival-sept-15-to-16/ |
| 6 | Colleen Hughes | Future | River watcher Camera system (Lee Williston agreed this has potential offset value). |

**APPENDIX C**

# Offsetting Activities - Barrier Removal

**Table 1: Potential Habitat Offsetting Activities**

| UTM V10 Easting | UTM V10 Northing | Stream Name | Potential OffsetArea m² | Habitat Value | Barrier Type | Potential Actions |
|---|---|---|---|---|---|---|
| 629036 | 5790127 | Tributary to Tisdal Creek | 0.4 | Low habitat value | Round Culvert | Remove / Deactivate Crossing |
| 608521 | 5789299 | Tributary to Deerhorn Creek | 0.7072 | Low habitat value | Round Culvert | Replace structure with streambed simulation CBS |
| 667223 | 5788229 | Tributary to McKusky | 1.8 | Low habitat value | Round Culvert | Replace structure with streambed simulation CBS |
| 644448 | 5782473 | Tributary to Gifford Creek | 1.845 | Low habitat value | Round Culvert | Remove / Deactivate Crossing |
| 619736 | 5804825 | Tributary to Horsefly Lake | 2.32 | Low habitat value | Round Culvert | Replace structure with streambed simulation CBS |
| 644343 | 5782524 | Gifford Creek | 2.337 | Low habitat value | Round Culvert | Install downstream weir(s) to backwater CBS |
| 647524 | 5802450 | Tributary to Horsefly River | 2.44 | Low habitat value | Round Culvert | Replace structure with streambed simulation CBS |
| 667778 | 5812480 | Tributary to Horsefly River | 2.45 | Low habitat value | Round Culvert | Replace structure with streambed simulation CBS |

# Executive Summary

Mount Polley Mining Corporation is submitting a Technical Assessment Report as part of a permit amendment application to discharge water from the site which includes modelling of water quality at the site and in the receiving environment. Inputs to this model are geochemical source terms which are predictions of the chemistry of water in contact with materials and surfaces exposed by mining activity. Source terms mainly consider the potential for metal leaching and acid rock drainage (ML/ARD). This report describes the derivation and use of the source terms.

The Mount Polley deposit is classified as an alkalic porphyry copper gold deposit. With the exception of the distinctive small Pond Zone skarn deposit, it has been mined from several mineralized zones (Springer, Cariboo, Bell, Southeast, Northeast, Boundary) with common geological features including mainly a monzonitic plutonic host rock, association with breccia bodies in the intrusion, dominantly potassic hydrothermal alteration, lack of pronounced pyrite haloes, enrichment in copper and selenium relative to global norms, pervasive calcite, and natural oxide alteration. As a result, geochemical characteristics are consistent between zones, allowing a site-wide approach to geochemical characterization.

Potentially ARD generating (PAG) and non-PAG waste rock materials occur locally as pyrite zones but non-PAG dominates. ARD potential was used to segregate waste rock, with non-PAG waste rock being placed in several waste rock dumps and PAG waste rock either deposited in completed pits that are projected to flood at the closure of the mine (in accordance with the management practice of subaqueous disposal) or placed in a temporary stockpile for final disposal in the Springer Pit. Based on review of operational processes and data, non-PAG waste rock is expected to be non-acidic in perpetuity because the classification approach tended to result in non-PAG waste rock reporting to PAG waste rock disposal locations rather than the reverse.

Tailings are classified as non-PAG based on operational monitoring and testing of tailings spilled into Hazeltine Creek in August 2014.

Major geochemical sources were identified as waste rock stockpiles and the tailings. Other sources include backfilled waste rock, ore processing, pit walls, ore stockpiles, the sulphur stockpile and magnetite stockpiles. Source terms were mainly developed from conceptual geochemical models then interpretation of rock geochemical characteristics and seepage data rather than scale-up of laboratory kinetic test data. Pit wall source terms (including PAG walls) were obtained by scaling of kinetic test data. Source terms were not specifically developed for the magnetite and sulphur stockpiles because they are small sources and assumed to influence seep data used as a basis for waste rock source terms.

# Table of Contents

**1 Introduction ..... 1**
1.1 Background ..... 1
1.1.1 General1
1.1.2 Geological Setting ..... 1
1.1.3 Mining History and Closure ..... 4
1.1.4 Waste Rock Management ..... 5
1.1.5 Rock Geochemical Characteristics ..... 8
1.1.5.1 Introduction ..... 8
1.1.5.2 ARD Potential ..... 9
1.1.5.3 Trace Element Content ..... 12
1.1.5.4 Extraction Tests ..... 13
1.1.5.5 Kinetic Testing ..... 13
1.1.6 Tailings Geochemical Characteristics ..... 16
1.1.6.1 Static Characteristics ..... 16
1.1.6.2 Kinetic Characteristics ..... 16
1.1.7 Other Sources ..... 20
1.2 Scope ..... 20
1.3 Acknowledgements ..... 20
**2 Conceptual Geochemical Models ..... 20**
2.1 Purpose ..... 20
2.2 Sources ..... 20
2.3 Ex-Pit NAG Waste Rock and Construction Fills ..... 21
2.4 Ex-Pit PAG Waste Rock ..... 22
2.5 Ore Stockpiles ..... 22
2.6 Pit Backfill ..... 22
2.7 Pit Walls ..... 23
2.8 Ore Processing ..... 23
2.9 Tailings Solids ..... 23
2.10 Sulphur Stockpile ..... 24
2.11 Magnetite Stockpiles ..... 25
2.12 Nitrogen Leaching ..... 25
**3 Source Terms ..... 25**
3.1 General Approach ..... 25
3.2 Incorporating Uncertainty ..... 26
3.3 NAG Waste Rock ..... 26

3.3.1 Method ..... 26
3.3.2 Inputs ..... 28
3.3.2.1 Mineral Partitioning During Blasting ..... 28
3.3.2.2 Potential for Acidification ..... 30
3.3.2.3 Waste Rock Seepage Database ..... 32
3.3.3 Results ..... 39
3.4 Ex-Pit PAG Waste Rock ..... 39
3.5 Ore Stockpiles ..... 39
3.6 Pit Backfill ..... 39
3.7 Pit Walls ..... 39
3.7.1 Method ..... 39
3.7.2 Inputs ..... 40
3.7.3 Results ..... 43
3.8 Ore Processing ..... 43
3.8.1 Method ..... 43
3.8.2 Inputs ..... 43
3.8.3 Results ..... 43
3.9 Tailings ..... 43
3.9.1 Method ..... 43
3.9.2 Inputs ..... 44
3.9.3 Results ..... 46
3.10 Sulphur Stockpile ..... 46
3.11 Magnetite Stockpiles ..... 46
3.12 Nitrogen Leaching ..... 46
**4 Conclusions ..... 47**

# 1 Introduction

## 1.1 Background

### 1.1.1 General

Mount Polley Mining Corporation (MPMC), a wholly owned subsidiary of Imperial Metals Corporation, has been operating the Mount Polley Mine (MPM), located approximately 56 km northeast of Williams Lake and approximately 15 km southwest of the community of Likely in British Columbia, Canada, since 1996. MPMC recovers copper and gold from porphyry-style mineralization by open pit and underground mining. The plant is capable of processing 22,000 t/d of ore using standard mineral flotation technology.

As a condition of *Environmental Management Act* Permit 11678, MPMC is submitting a Technical Assessment Report (TAR) for a long-term water management plan, which includes modelling of water quality at the site and in the receiving environment. Inputs to this model are geochemical source terms which are predictions of the chemistry of water in contact with materials and surfaces exposed by mining activity. Source terms mainly consider the potential for metal leaching and acid rock drainage (ML/ARD). The purpose of this report is to describe the derivation and use of the source terms.

### 1.1.2 Geological Setting

Understanding of the geological setting is provided below for context in the consideration of ML/ARD potential.

The Mount Polley deposit is classified as an alkalic porphyry copper gold deposit (BC MINFILE No. 093A 008). With the exception of the distinctive small Pond Zone, it has been mined from several mineralized zones which have the following common features:

- The host rock for porphyry mineralization is the Mount Polley Intrusive Complex (MPIC) which intruded into Nicola Group Volcanics (Figure 1). The intrusion is primarily monzonite to monzo-diorite in composition. Smaller phases vary in composition from diorite to syenite.
- Mineralization is associated with magmatic-hydrothermal breccias. Alteration and mineralization occurs in the matrix of the breccias, and in veins and swarms distributed around the breccias. BX1 is the main host for the bulk of the mineralization at MPM which is mined in the Cariboo and Springer Pits (Figure 1). BX1 is characterized by alteration which resulted in the strongest destruction of both primary and breccia textures. Breccia bodies BX2 host satellite mineralization in the Southeast Zone, Wight Pit and Boundary Zone. BX2 is less intensively altered and original textures are more apparent. BX3 is unmineralized and has not been mined.
- Alteration at MPM is classified as potassic (sodic and calcic) with salmon pink potassium feldspar as the main alteration mineral. Biotite is less common. Sodic alteration is defined by albite and calcic alteration (actinolite, diopside, epidote, clinozoisite, and sporadic andraditic garnet). Calcite is pervasive. Alteration is zoned with the strongest calcic-potassic alteration

in the core associated with BX1. Nicola Group rocks and fringing MPIC rocks are propylitically-altered and characterized by stronger epidote and pyrite.

- Like other alkalic porphyry deposits (e.g. Copper Mountain, Brenda), MPM lacks the strong hydrothermal alteration zoning that is commonly observed in calc-alkalic porphyry deposits (e.g. Highland Valley Copper, Island Copper, Gibraltar). In particular, phyllic alteration is absent at MPM. A common feature of calc-alkalic porphyry deposits is often a pronounced pyritic halo that surrounds the copper mineralization and is associated with phyllic and propylitic alteration. At MPM, discontinuous pyritic zones are present but do not appear to be mineralization halos. MPM geological staff identified a pyritic zone in the south wall of the Springer Pit which extends into the adjacent Cariboo Pit (Figure 2). Samples from Bell Pit blast holes collected in the early years of operations were identified as being from a Pyrite Zone but the location of this feature is not known.

- Sulphide mineralization consists mainly of chalcopyrite ($CuFeS_2$) and pyrite ($FeS_2$), with lesser bornite ($Cu_5FeS_4$), covellite (CuS), and digenite ($Cu_9S_5$). Bornite is relatively more abundant in the Northeast and Boundary Zones.

- Carbonate mineralization is principally calcite, with occurrences of malachite ($Cu_2CO_3(OH)_2$) formed as a natural weathering product; iron carbonates have not been reported.

- A significant portion of the copper at the MPM is not associated with sulphides (upwards of 50% in the upper portions of each pit). This fraction has been termed ‘copper oxide’ by MPM personnel and is associated primarily with chrysocolla ($(Cu,Al)_2H_2Si_2O_5(OH)_4 \cdot nH_2O$) and malachite ($Cu_2CO_3(OH)_2$) in equal proportions (Henry 2009). Recent investigations (SRK 2015a) have shown that chlorite is a significant host for copper. It is assumed that chlorite formed hydrothermally and incorporated copper as part of the mineralizing event rather than due to weathering. Suarez et al. (2009) found that the form of copper in chlorite at the Aguablanca Ni-Cu-PGE Sulfide Deposit was native copper between silicate layers rather than as a substitution in the crystal lattice. The mineral is suspected to have formed during hydrothermal alteration rather than by natural weathering processes. It is not known whether this same form of copper is also present at MPM.

The small Pond Zone is andradite-clinopyroxene-magnetite skarn mineralization occurring at the contact between a diorite to monzodiorite intrusion and Nicola Group volcanic rocks of andesite to basalt composition. It appears to be linked to the presence of a limestone unit in the Nicola Group.

From an ML/ARD perspective, a significant feature of the Mount Polley mineralization is the lack of reported arsenic, lead and zinc minerals which are commonly associated with porphyry deposits elsewhere in British Columbia and globally. Since arsenic, zinc, and associated cadmium are relatively mobile under non-acidic conditions, the lack of the minerals hosting these elements indicates that potential for leaching concerns is lower than other porphyries. Based on the copper sulphide and copper oxide dominated mineralogy, the primary metal leaching concern is expected to be for copper.

In addition, the lack of a distinctive pyrite halo means that pyrite abundance is lower than other porphyry deposits and ARD potential is expected to be lower.

### 1.1.3 Mining History and Closure

Full scale mining began in the Cariboo Pit by mining high oxide and high gold parts of the ore body then transitioning to the Bell Pit in 1999. Mining was suspended in 2001 due to unfavorable market conditions. The mine re-opened in 2005 after a 3½ year care-and-maintenance period. The following zones have been mined since 2005:

- Completed mining and backfilling of the Bell Pit.
- Completed mining and backfilling of the small Southeast Zone and Pond Zone Pits.
- Completed mining of the Wight Pit (Northeast Zone).

Active mining is focussed on the Cariboo and Springer Pits (which will merge to a single pit), Northeast Zone underground (access from the Wight Pit) and Boundary Pit.

Upon completion of mining, the Springer-Cariboo Pit will be backfilled by rock from the Temporary Northwest (NW) PAG Stockpile (the NAG/PAG Pad) and allowed to flood. The Wight Pit and underground workings will also flood. The Tailings Storage Facility (TSF) will be decommissioned with a minimal water cover.

### 1.1.4 Waste Rock Management

Mining at MPM is primarily by open pit. As of the end of 2015, about 95 million tonnes of ore had been processed.

*Mines Act* Permit M-200 issued on July 11, 1997 specified that waste rock is to be segregated according to ARD potential using a neutralization potential ratio (NPR) of 2. Rock with NPR greater than 2 is to be considered non-ARD generating (NAG). Rock with NPR less than 2 was to be considered potentially ARD generating (PAG). The definition of NPR is assumed to be neutralization potential (NP)/acid potential (AP) where NP is determined by a neutralization potential method and AP is acid potential determined from sulphide sulphur.

The procedure used by MPMC to identify and segregate PAG waste rock is attached in Appendix A.

To support the TAR, MPMC personnel developed a thorough inventory of the quantities of waste rock in each category and determined that about 167 million tonnes of waste rock were classified as NAG, and 19 million tonnes were classified as PAG. Development of the inventory showed the source of NAG and PAG materials and their disposal locations. Appendix B provides the inventory and Table 1 summarizes major disposal locations (Figure 3).

The primary NAG rock disposal locations are the North Bell Dump (which includes backfill in the Bell Pit), the South East Rock Dump Site (which also includes the backfilled Southeast Zone and Pond Zone Pits), and the Northeast Zone Dump[1]. NAG rock has been used for construction purposes (Waste Haul Road and the TSF). The inventory indicates that NAG rock from the open pits has been disposed at a variety of different locations resulting in waste rock dumps containing non-unique source materials. The exception is that the Northeast Zone and East Rock Dumps received waste primarily from the Wight Pit.

Prior to 2005 (i.e. before operations were re-started), limited PAG waste rock was mined and was dumped into the bottom of the Bell Pit (C. Hughes, MPMC, pers. comm.). A small amount was

[1] Also referred to as Wight Pit waste rock dumps.

dumped over the north end of the Cariboo Pit, but it was re-handled to the bottom of the Cariboo Pit. Acid-base accounting (ABA) analyses were performed by an external lab.

Since 2005, PAG waste rock has primarily been disposed in the Temporary NW PAG Stockpile (the NAG/PAG Pad; Ex-pit PAG in Figure 3) which is planned to be backhauled to the Springer Pit at closure for subaqueous disposal. PAG rock has also been disposed subaqueously in the Cariboo Pit backfill and Southeast Zone Pit. PAG rock mainly originates from the Cariboo Pit and Springer Pit. The PAG waste rock in the North Bell Dump originated from the Southeast Zone Pit which was dominated by PAG waste rock.

An amendment to *Mines Act* Permit M-200 in July 8, 2009 allowed the placement of low sulphur (less than 0.3%) waste (LSW) as 2 m layers with Springer Zone NAG waste rock to create a NAG waste rock blend. The quantity of PAG rock mined from the Pond Zone was 6,615 t, which was disposed in a portion of the Northeast Zone Dump referred to as the Sandwich Dump.

**Table 1. Major Waste Rock Disposal Locations**

| Placement Location | NAG | | PAG | |
|---|---|---|---|---|
| | Mass (tonnes) | Percent of NAG | Mass (tonnes) | Percent of PAG |
| Bell Pit Rock Dump | 80,878,729 | 48.6% | 187,573 | 1% |
| Cariboo PAG Dump | 999,750 | 0% | 1,573,456 | 8% |
| Dam | 9,871,313 | 5.9% | 0 | 0% |
| NAG/PAG Pad | 3,991,967 | 2.4% | 16,091,498 | 86% |
| South East NAG Dump | 32,271,810 | 19.4% | 3,105 | 0% |
| South East PAG Dump | 5,971 | 0% | 886,665 | 5% |
| Waste Haul Road | 6,915,893 | 4.2% | 1,290 | 0% |
| Northeast Zone Dump | 14,770,426 | 8.9% | 9,855 | 0% |

Source: P:\01_SITES\Mt_Polley\1CI008.007_Se_Source_Evaluation\Task 100_Evaluate Significance of Sources\2.Interpretation\[SourcesReview_1CI008007_SJD_REV04.xlsx]

8 Mt of ore was stockpiled to the north of the ore processing plant and has served as a source of ore during limited operations following the tailings dam failure in August 2014. The current remaining quantity of rock in the stockpiles is 2 Mt. The waste rock inventory also indicated that about 110,000 tonnes of ore has been placed at twelve other locations around the site. The largest disposal location is the South East Rock Dump (34,000 tonnes). Stockpiled ore is not classified by ARD potential but the quantities are insignificant relative to waste rock.

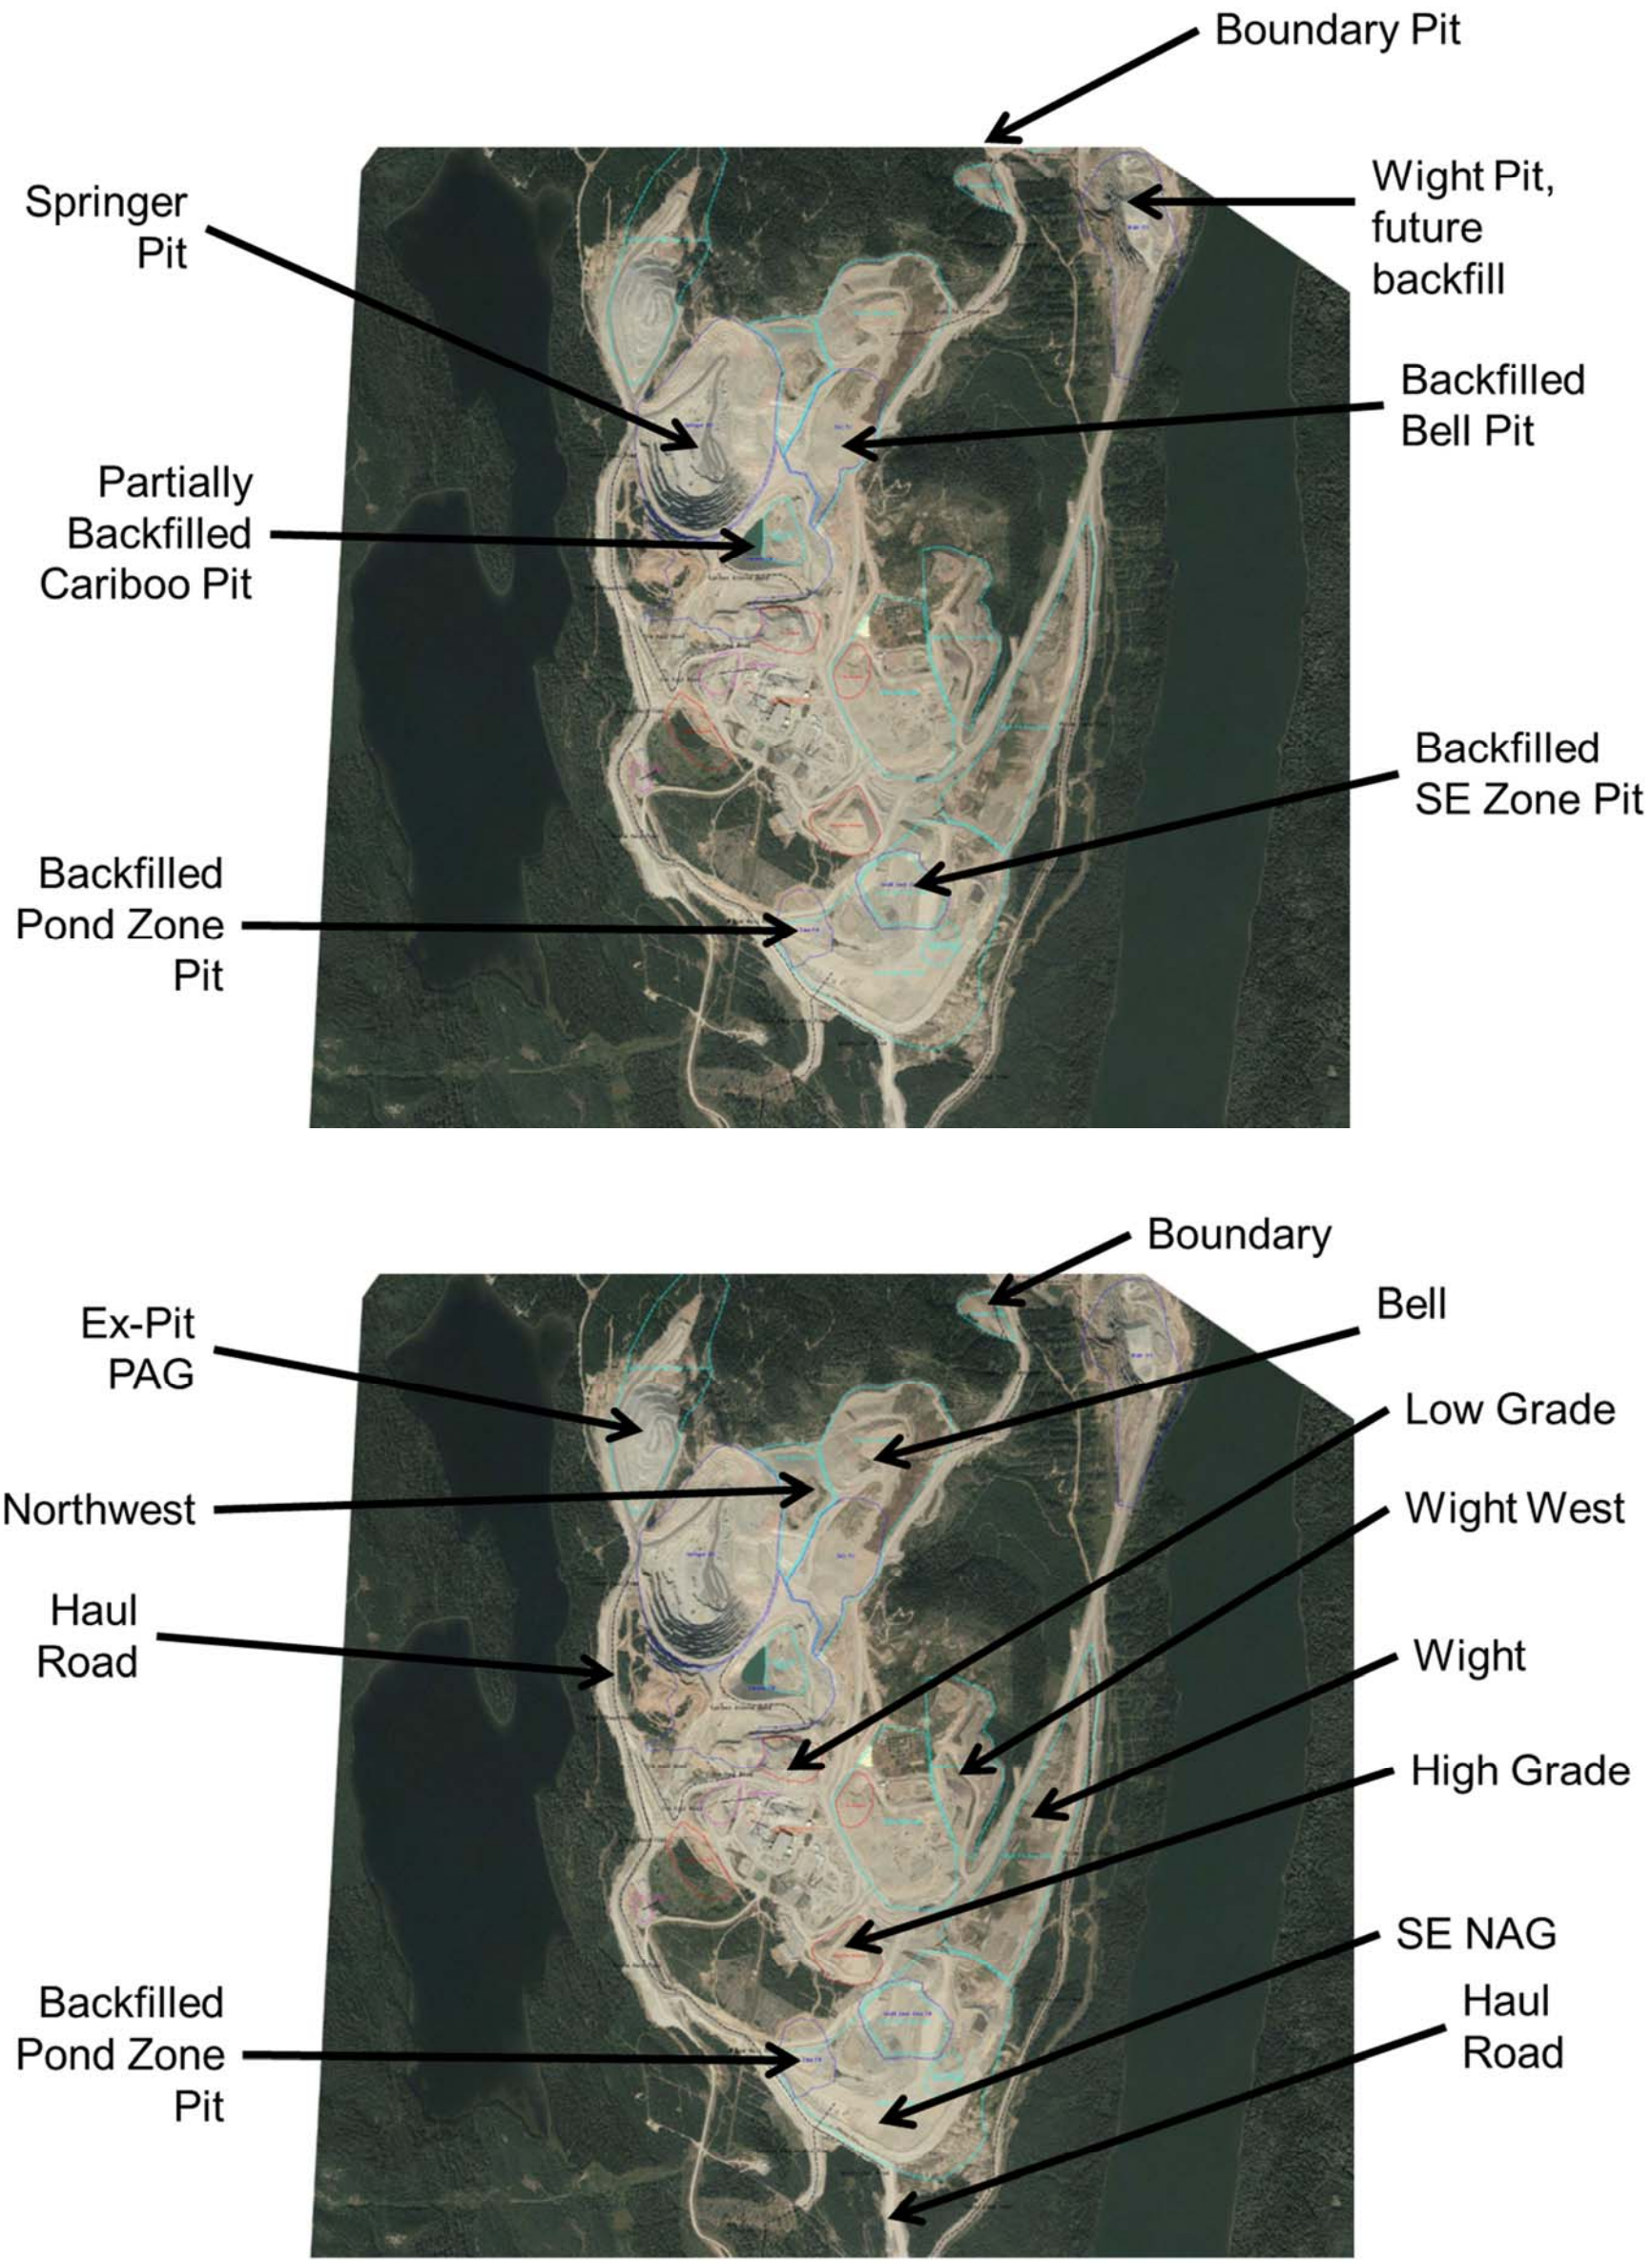

**Figure 3. Pits and Waste Rock Dump Features**

### 1.1.5 Rock Geochemical Characteristics

#### 1.1.5.1 Introduction

Understanding of waste rock geochemical characteristics has been accumulated from a variety of sources including diamond drill core tested prior to mining, blast hole cuttings to inform waste rock management operations in the pit during operations and post-depositional monitoring (Table 2). The database is dominated by the data gathered to operationally characterize waste rock in the Springer Pit which is the main source of PAG rock at the MPM. However, the database is incomplete because some of the earlier data were lost and blast hole data are lacking for Cariboo Pit and Wight Pit. For Cariboo Pit and Wight Pit, confirmatory post-depositional data partly address this gap.

The inventory primarily contains static ARD potential data though trace element scans are also available for all zones except the Boundary Pit.

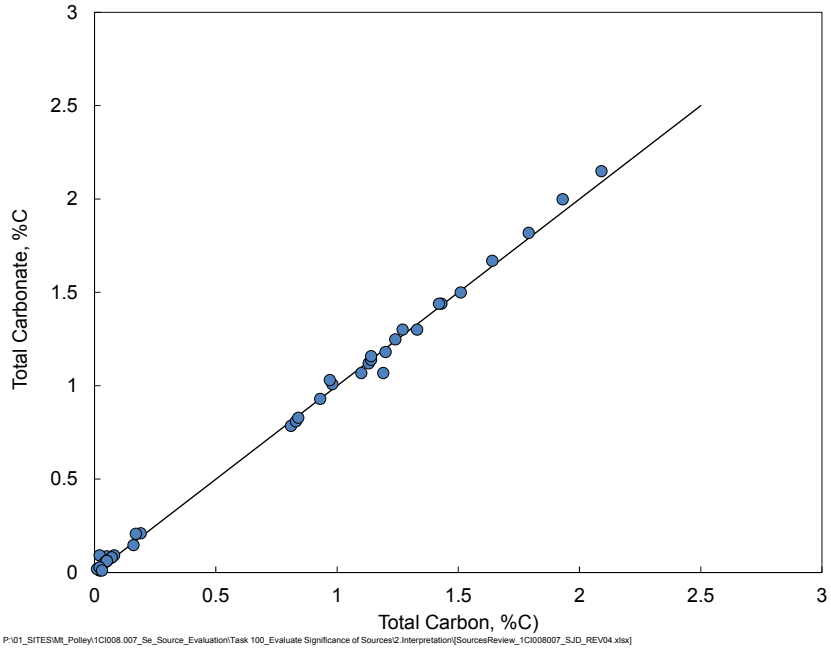
**Table 2. Static Test Inventory**

| Source | Drill Core | Blast Hole | Confirmatory | Total |
|---|---|---|---|---|
| Bell Pit and North Bell Dump | 0 | 78 | 52 | 130 |
| Cariboo Pit | 0 | 0 | 43 | 43 |
| Pond and Sandwich Dump | 27 | 174 | 5 | 206 |
| SE Zone Pit and Dump | 37 | 0 | 101 | 138 |
| Springer Pit and PAG Dump | 101 | 3789 | 20 | 3910 |
| Wight Pit | 102 | 0 | 0 | 102 |
| Boundary Pit and Dump | 16 | 123 | 5 | 144 |
| Other PAG | 0 | 0 | 29 | 29 |
| Roads | 0 | 0 | 37 | 37 |
| Dam | 0 | 0 | 31 | 31 |
| Total | 283 | 4164 | 323 | 4770 |

Source: P:\01_SITES\Mt_Polley\1CI008.007_Se_Source_Evaluation\Task 100_Evaluate Significance of Sources\2.Interpretation\[Confirmatry_Grabs_1CI008007_SJD_REV01.xlsx]

Drill core analyses were primarily performed by off-site laboratories and included total sulphur, sulphate, sulphide by difference, total carbonate, neutralization potential, and paste pH. For some samples, a trace element scan was performed. On-site tests were total sulphur and total carbon (see Appendix A). The former is assumed to be a proxy for sulphide sulphur because other forms of sulphur (including sulphate) are not common at MPM. The latter is assumed to be a proxy for reactive carbonate minerals. The assumption is supported by the observed dominance of calcite, the lack of reported iron carbonate and the strong correlation and equivalence of total carbon and total carbonate (Figure 4). The dominant plutonic geological setting supports the lack of non-carbonate carbon.

The following sections compare ARD and trace element characteristics of the various mineralized zones at MPM.



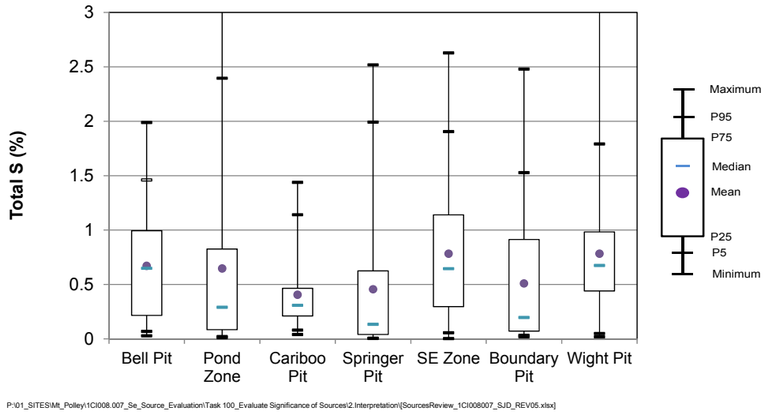


**Figure 4. Comparison of Total Carbon and Total Carbonate. The Diagonal Line Shows Equivalence.**

### 1.1.5.2 ARD Potential

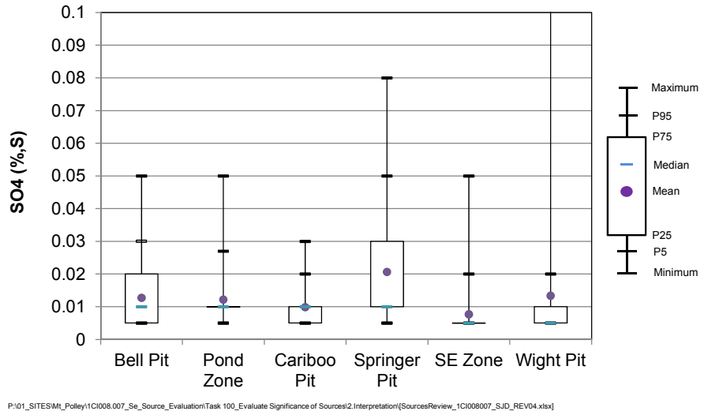

Figure 5 (top) shows the distribution of total sulphur and sulphate by zone. Sulphate concentrations are uniformly low (averages near the detection limit of 0.01%) with no apparent differences between zones. Total sulphur, which therefore provides an approximation of sulphide content, shows some differences by zone though there is also considerable overlap and higher end concentrations vary over a narrow range (95$^{th}$ percentiles 1.1% to 2.0%). The Southeast Zone and the Wight Pit have the highest mean sulphur concentrations at 0.78% whereas Cariboo Pit has the lowest at 0.47%.

Comparison of carbonate content with NP shows that, except for a few samples, NP exceeds carbonate. This reflects the digestion of silicates for the NP determination. The difference between NP and total inorganic carbon (TIC) varies by zone. The skarn mineralization of the Pond Zone shows the greatest NP relative to carbonate reflecting the presence of epidote that digests more readily in acid than feldspars which dominate in the other rock types. The Springer Pit, the Cariboo Pit and the Southeast Zone show the next greatest difference followed by the Wight Pit and the Bell Pit. The difference between NP and TIC at MPM led to the adoption of total carbon as a proxy for carbonate content rather than relying on NP. Comparison of AP and TIC shows that the Southeast Zone is dominantly PAG whereas the Wight Pit and the Cariboo Pit are dominantly NAG. Oher zones show characteristics overlapping the NAG and PAG.

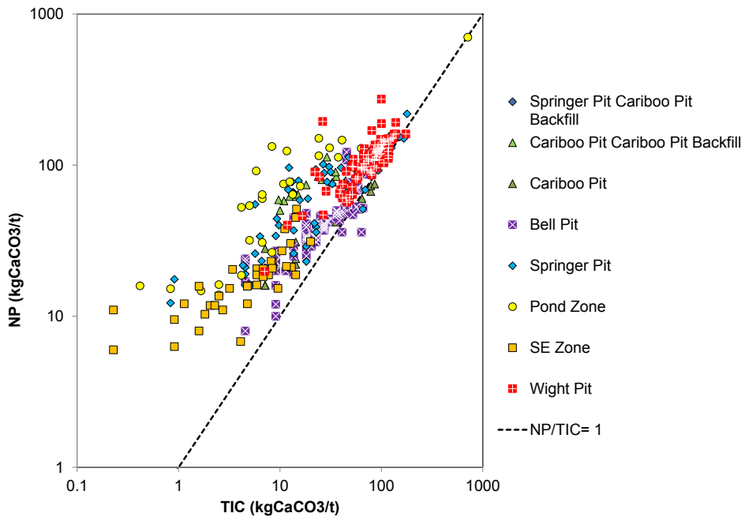

Figure 6 shows results of blast hole sampling for comparison. The complete dataset is provided in Appendix C. Bell Pit blast hole data are presented as part of the above descriptions because pre-mining ABA data were not available. The presence of PAG rock in all zones is apparent and resulted in segregation. This figure illustrates that for the most part PAG rock has higher sulphide content than NAG rock because NP is relatively consistent regardless of sulphide content.

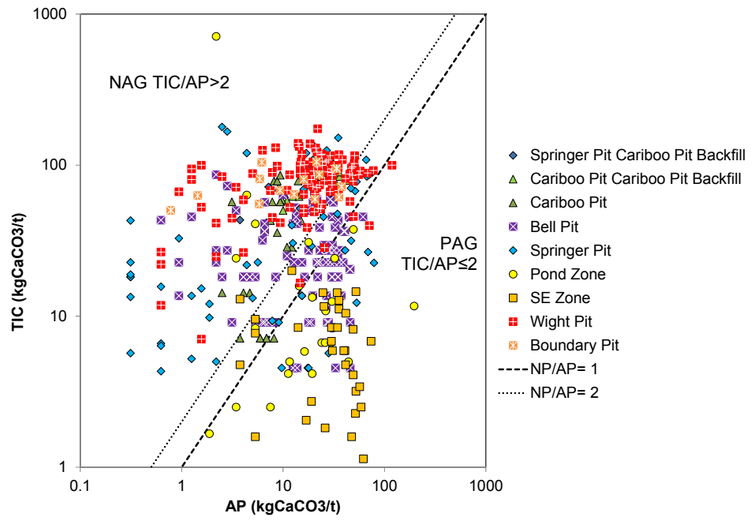

P:\01_SITES\Mt_Polley\1CI008.007_Se_Source_Evaluation\Task 100_Evaluate Significance of Sources\2.Interpretation\[SourcesReview_1CI008007_SJD_REV05.xlsx]

### 1.1.5.3 Trace Element Content

When compared to global average for igneous rocks (Price 1997), some of the rocks at MPM have concentrations an order of magnitude higher for arsenic, copper, selenium, and mercury (Southeast Zone and Wight Pit) though median concentrations only slightly pass this threshold. Arsenic concentrations weakly correlate with sulphur, and copper correlates with selenium.

Within the site, selenium concentrations were elevated in the Cariboo Pit rocks and lowest at the Wight Pit (Figure 7). Selenium-to-sulphur ratios were examined because selenium is typically released by oxidation of sulphide and the ratios can be indicative of differences in selenium release. The ratio is notably higher for the Cariboo and Springer Pits, intermediate for the Bell Pit and lowest for the Southeast Zone and Wight Pits. The distributions imply spatial zoning of selenium relative to sulphide possibly with selenium enrichment associated with the more intensive alteration of BX1.

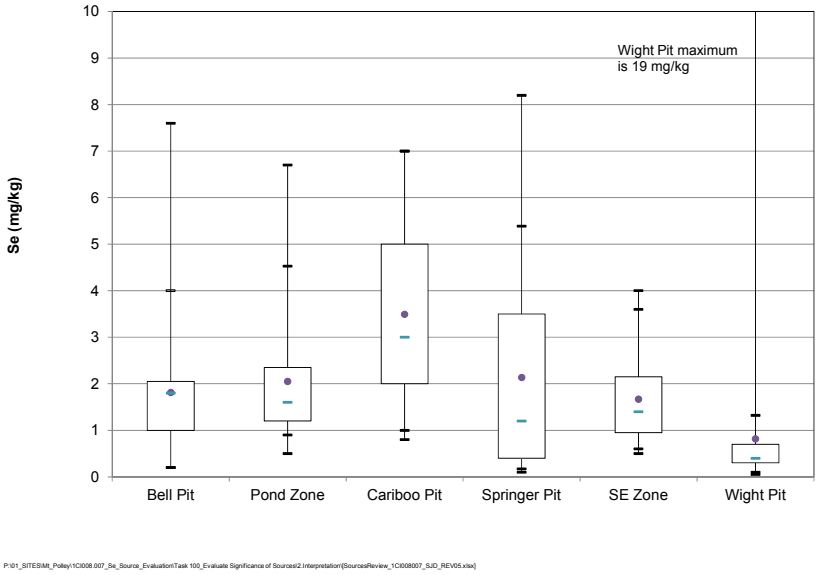

**Figure 7. Box-and-Whisker Plots for Selenium and Selenium-to-Sulphur Ratios**

#### 1.1.5.4 Extraction Tests

*Mines Act* Permit M-200 required that “oxidized” samples be tested for solubility using the Shake Flask Extraction (SFE) method of Price (1998). The definition of oxidized was not provided in the verbiage of the permit. Nine samples of the -2 mm fraction of blasted rock were submitted for the procedure in 2001. Eight samples of ore stockpile rock were tested in 2015 as part of a *Mines Act* Permit M-200 requirement to evaluate closure requirements for the stockpiles (SRK 2015b).

Leachates from all extraction tests were non-acidic with leachate chemistry dominated by sulphate, alkalinity and calcium. The 2015 tests were more useful than the 2001 tests for understanding trace element leachability due to the use of lower detection limits and testing of stockpiled waste rock. A number of trace elements were not detected or yielded concentrations close to detection limits including cadmium (0.05 µg/L), chromium (0.5 µg/L), cobalt (0.1 µg/L), lead (0.1 µg/L), mercury (0.05 µg/L), nickel (0.5 µg/L) and zinc (10 µg/L). Average arsenic, copper, molybdenum and selenium concentrations were 4, 5, 29 and 15 µg/L, respectively.

#### 1.1.5.5 Kinetic Testing

Laboratory kinetic (humidity cell) tests were performed on fifteen samples in support of geochemical characterization for permitting of mining of the Wight Pit (Northeast Zone), Southeast Zone, Boundary Zone, Pond Zone and expansion of the Springer Pit . Results have been reported annually as part of *Mines Act* Permit M-200 requirements. The samples were generally selected to evaluate oxidation rates for typical and elevated sulphide concentrations.

Samples from the Pond Zone were submitted for an acid-leaching procedure to remove carbonate and evaluate the reactivity of silicate minerals.

**Table 3. Characteristics of Samples in Waste Rock Humidity Cells**

| HCT | Sample ID | Zone | Rock Type | Date Started | Date Stopped | Paste pH | TIC %C | Total S % | $SO_4$-S %S | AP kg $CaCO_3$/t | NP kg $CaCO_3$/t | NP/AP | TIC/AP | Ag ppm | As ppm | Ca % | Cd ppm | Co ppm | Cu ppm | Hg ppm | Mg % | Mn ppm | Mo ppm | Ni ppm | Pb ppm | Sb ppm | Se ppm | Zn ppm |

Source: P:\01_SITES\Mt_Polley\1CI008.007_Se_Source_Evaluation\I080_Deliverables\2.SourceTermReport\Tables

One Pond Zone test is continuing. The other tests ran for 1 to 9 years. General findings were as follows:

- Except for the Pond Zone tests which were artificially depleted of carbonate, no other tests generated acid. Six samples were classified as PAG from ABA but carbonate content prevented acid generation for the duration of the test.
- Sulphate release was strongly correlated with sulphur content regardless of zone (Figure 8).
- There was a lack of correlation between trace element content and trace element release rates, and sulphide content and trace element content.
- Comparison of relative utilization of carbonate minerals to oxidation rates indicated that an NPR of 2 or lower is appropriate for classification of ARD potential.

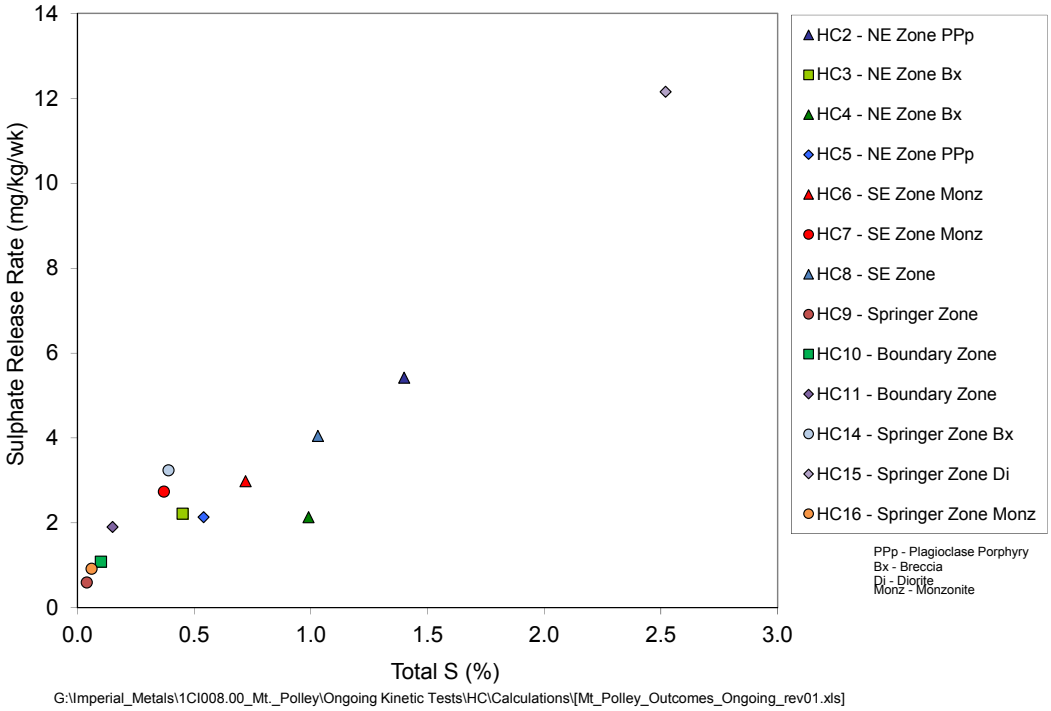

**Figure 8. Correlation of Sulphur Content with Oxidation Rate**

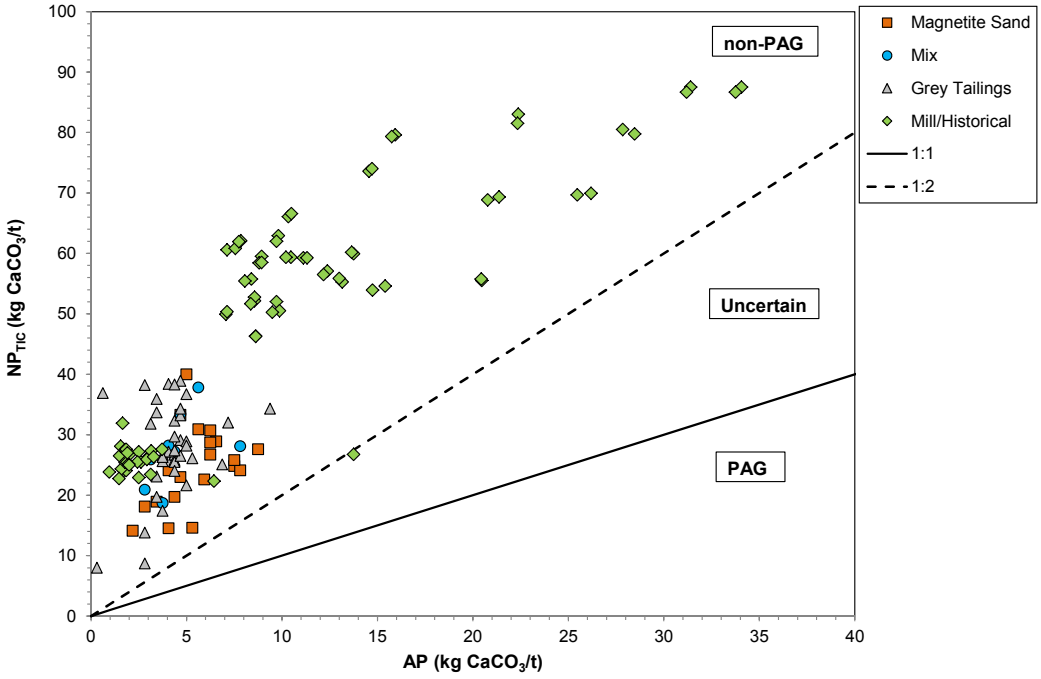
The strong relationship between sulphur content and oxidation rate yields the following predictive relationship for the onset of acidification ($t_{onset}$) in years at room temperature for waste rock with an initial (i.e., at time = 0) NP/AP of $\left(\frac{NP}{AP}\right)_0$:

$$t_{onset} = 70 \times \left(\frac{NP}{AP}\right)_0$$



A previous assessment using earlier humidity cell data (Appendix D) yielded a coefficient for this equation of 60 years and a confidence range of 42 to 100 years.

The equation indicates that waste rock with an initial NP/AP of 1 would become acidic in 70 years at room temperature. The general finding from the kinetic testing is that acidification of PAG materials at MPM will take decades to develop. This is consistent with the widespread pH neutral weathering conditions at MPM in both natural and mined materials.

### 1.1.6 Tailings Geochemical Characteristics

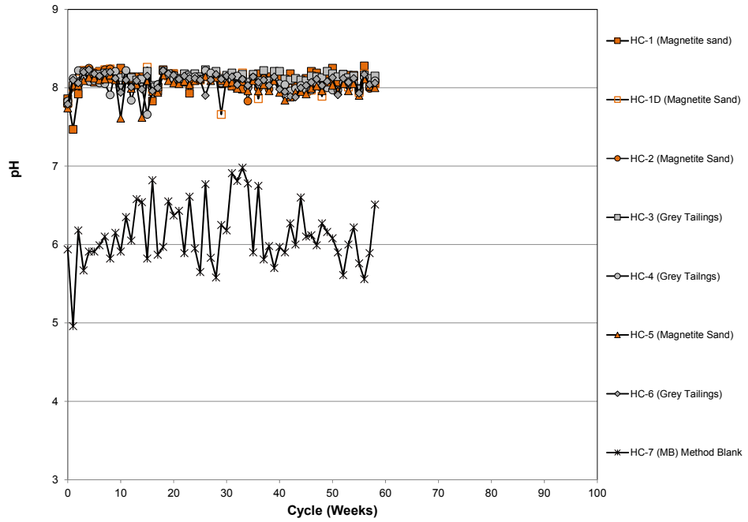
#### 1.1.6.1 Static Characteristics

SRK (2015) reviewed tailings geochemical characteristics as part of submissions following up on the tailings dam failure in August 2014 (Figure 9). The principal finding from this review was that the tailings are not PAG. Compared to crustal normal concentrations, copper and selenium were present in the tailings at order of magnitude higher concentrations. Copper is partially deported as silicate minerals. Selenium is associated with the sulphide component of the tailings and is also correlated with copper content. Kinetic testing on tailings samples has to-date confirmed they are non-acid generating. The tests are continuing.

Z:\01_SITES\Mt_Polley\1CI008.003_Privileged_and_Confidential\500_Reporting\Interpretations\Geochemistry\HzltnCrk_2014\[MtPolley_HzltnCrk_2014_1CI008.003_REV01_CBK sin.xlsx]

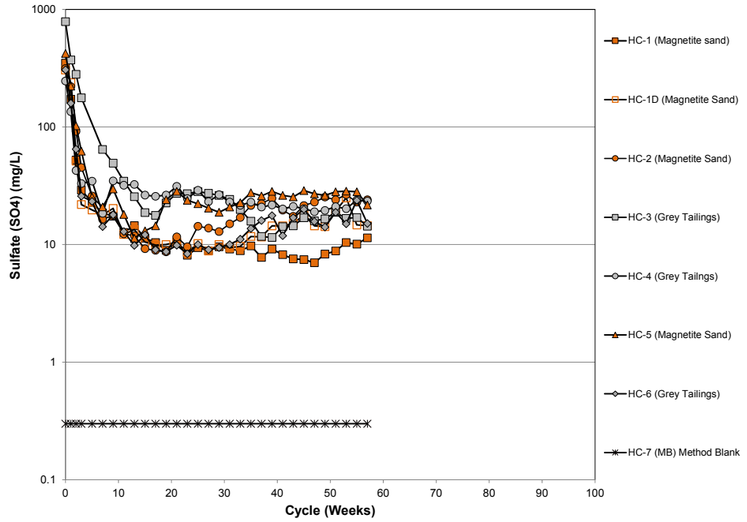
**Figure 9. Static Geochemical Characteristics of Tailings (SRK 2015)**

#### 1.1.6.2 Kinetic Characteristics



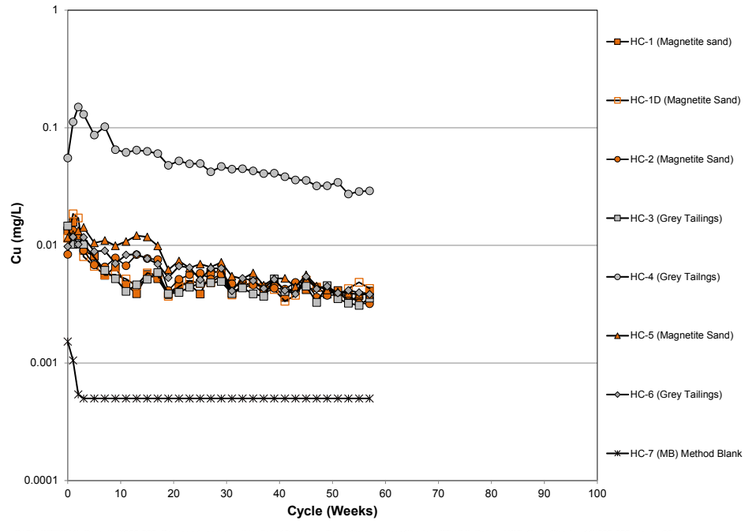
Six samples of tailings collected from Hazeltine Creek following the dam failure are being tested in humidity cells. Three of the samples are also being tested in columns using a trickle leach applied at less than 0.1 L/kg/week (compared to flood leach of 0.5 L/kg/week for humidity cells).

The samples were selected to represent visually distinctive tailings materials (magnetite sand and grey tailings). The samples are dominated by tailings solids but also contained native materials (mineral and organic soils, and glacial sediments entrained in the debris flow). The samples characterize weathering behaviour for a range of sulphur concentrations which align with typical characteristics of tailings in the impoundment.



The humidity cell tests (HCTs) have been running for about one year while the columns have operated for about 35 weeks. All tests have yielded leachate pHs typically between 8.0 and 8.2. Sulphate concentrations were initially near 1000 mg/L for humidity cells and above 1000 mg/L for columns. Both types of tests showed decreasing sulphate concentrations which have stabilized at lower concentrations. Humidity cells have generally reached stable concentrations for humidity cells while column test leachates continue to stabilize for some parameters. For parameters considered enriched in the tailings solids (copper and selenium):

- Highest copper concentration in one HCT was 0.15 mg/L but typical maximum copper concentrations were 0.02 mg/L in HCT leachates and 0.05 mg/L in column test leachates.
- Highest selenium concentrations were 0.01 mg/L in HCT leachates and 0.06 mg/L in column test leachates.



For other parameters, notable results were initial molybdenum concentrations between 2 and 3 mg/L in column leachates.

**Figure 11. Selected Leachate Chemistry for Tailings Columns**

### 1.1.7 Other Sources

Two other sources were identified as potentially requiring geochemical source terms.

Sulphur was imported in 2004 as part of evaluations of recovery of copper present as oxide. The stockpiles are located between the East Rock Dump and Ore Stockpile (Figure 3). Composition data for these stockpiles are not available but the stockpiles are expected to be composed of approaching 100% sulphur in elemental form. Neutralization potential is expected to be negligible and elemental sulphur generates acid through oxidation to sulphate.

Magnetite was recovered from MPM tailings to generate a concentrate for use as a dense medium in coal processing. The magnetite stockpiles are located adjacent to the ore processing plant. No geochemical data are available for the magnetite.

## 1.2 Scope

The scope of this work is to generate geochemical source terms that can be used as an input to operational and closure water quality models for MPM produced by Golder Associates Ltd. (Golder).

## 1.3 Acknowledgements

This work was performed by SRK using data collected and collated by MPM site personnel (primarily Katie McMahen, Colleen Hughes, Luke Moger, Ryan Brown and Art Frye).

# 2 Conceptual Geochemical Models

## 2.1 Purpose

The purpose of conceptual geochemical models (CGMs) is to describe the anticipated geochemical performance of each source at MPM which is then implemented as a numerical model to generate source terms. CGMs consider the current understanding of geochemical characteristics (as described in Sections 1.1.5 and 1.1.6).

## 2.2 Sources

The following sources were evaluated:

- NAG waste rock.
- Ex-Pit PAG waste rock.
- Ore stockpiles.
- Pit backfills.
- Pit walls.
- Ore processing.

- Tailings.

CGMs for each source are described below.

## 2.3 Ex-Pit NAG Waste Rock and Construction Fills

Ex-pit NAG waste rock is produced by operational segregation of waste rock into PAG and NAG components using an NP/AP of 2. NAG rock was primarily placed in ex-pit subaerial dumps but has and continues to be used for construction of fills at the TSF.

Nominally, NAG waste rock contains an excess of acid neutralizing minerals over acid generating sulphide minerals and will generate pH basic water for perpetuity. General weathering processes will include:

- Oxidation of sulphides (pyrite, chalcopyrite and bornite) to release iron, acidity, sulphate and trace elements contained in the sulphides. Copper is expected to be primarily released by oxidation of chalcopyrite and bornite.
- Weathering of silicates by dissolved carbon dioxide in infiltrating waters. This process results in release of alkali earth and alkali metals, silicon and bicarbonate. Copper (whether incorporated in the mineral structure at the ionic scale, or native, see Section 1.1.2) could conceivably be released from chlorite by this process but chlorite has relatively low susceptibility to weathering by meteoric waters compared to sulphides and carbonates.
- Neutralization of acidity by reaction with calcium carbonate minerals or mixing with alkaline waters resulting in basic pHs, and precipitation of metals as various secondary minerals, including gypsum, metal oxides and metal carbonates. From observation of natural weathering, copper may form malachite and chrysocolla and be sorbed with iron oxides.
- Dissolution of secondary minerals produced by weathering processes. The more soluble forms are expected to be copper oxides.
- Dissolution of rock components independent of acid generation and neutralization (for example, natural secondary minerals such as malachite and chrysocolla).
- Control of trace elements forming cations by lower mobility at high pH (e.g. copper).
- Higher mobility of trace elements forming anions at high pH (e.g. selenium, molybdenum, arsenic).

Due to the solubility control exerted by secondary minerals, contact water chemistry is expected to be constrained so that chemical loadings are directly proportional to infiltrating water volume. Therefore, loadings will tend to increase as footprint area increases rather than as total mass increases. The exceptions are parameters that do not readily form secondary minerals such as selenium which may therefore leach in proportion to the mass of waste rock.

Operationally, the NAG waste rock can be expected to contain PAG components due to inefficiencies in segregation. Potential for ARD or accelerated metal leaching due to the presence of PAG would be controlled partly by the mass balance of AP and NP, but also the extent of contiguous PAG rock placed in the waste rock dumps. If the PAG rock is well-distributed through

the dump, the potential for water quality effect is reduced. The absence of minerals hosting metals that remain somewhat mobile at carbonate-buffered pHs (such a cadmium and zinc) also limits the potential for water quality effects at MPM.

## 2.4 Ex-Pit PAG Waste Rock

Segregated and exposed ex-pit PAG waste rock is present in the Temporary NW PAG Stockpile located adjacent to the Springer Pit. The distinguishing feature of PAG rock at MPM is that it contains an excess of sulphide over carbonate minerals (in terms of ABA units) rather than being from a particular rock type. Sulphide content is higher than NAG waste rock.

Due to the higher sulphide content of PAG waste rock, the overall oxidation rate of PAG waste rock is expected to be greater than NAG waste rock. However, before acidification occurs, PAG and NAG weathering conditions are expected to be similar with secondary minerals exerting solubility controls. For example, the solubility of sulphate is expected to be controlled by gypsum which will be similar regardless of the sulphide oxidation rate. The source terms for NAG and PAG waste rock are not expected to be sufficiently different to warrant developing different terms.

Acidification is expected to take decades to progress with early contact waters remaining basic and having metal concentrations controlled by the solubility of secondary minerals.

As higher proportions of the rock acidify, the drainage can be expected to become acidic. Metal concentrations will increase as secondary minerals formed at higher pHs dissolve. In the longer term, metal concentrations will decrease due to depletion of acid soluble secondary minerals and reduction in the available sulphide.

The timeframe for acidification effects is expected to be of the order of decades (See Section 1.1.5.5) and therefore will be avoided by timely (i.e., at the end of the currently anticipated life of mine) re-handling back to the Springer-Cariboo Pit.

## 2.5 Ore Stockpiles

Ore stockpiles will perform the same as NAG and PAG waste rock depending on composition. The presence of more copper sulphides than waste rock will result in more leachable copper being generated but similar solubility controls are expected for the elements of interest.

## 2.6 Pit Backfill

Existing backfilled pits are the Bell Pit (completely full), the Southeast Zone Pit (completely full), the Pond Zone Pit (completely full), the Wight Pit (partially full), and Cariboo Pit (partially full). PAG rock from Temporary NW PAG Stockpile will be backfilled into the Springer-Cariboo Pit at completion of mining. Backfilling of currently filled pits occurred during operation so that run-of-mine waste rock was directed immediately to a backfill location. The water level has risen in most of these pits resulting in complete submergence of PAG rock and partial submergence of NAG rock. PAG rock in the Cariboo Pit and Wight Pit remains unsubmerged due to drawdown of the water table as operations continue in these pits.

Waste rock in backfilled pits will behave the same as waste rock in external waste rock dumps until it is submerged by rising pit waters after which oxidation will effectively occur very slowly due to low oxygen concentrations in the backfill. During submergence, flushing of weathering products formed while the rock is exposed will likely occur but concentrations will be constrained by the same secondary minerals formed under subaerial conditions. Pore water will equilibrate with the secondary minerals in the waste rock.

Leaching effects due to low oxygen conditions such as reductive dissolution of oxides is not likely to occur because reactive carbon needed to provide electrons for reducing processes does not occur in the rock.

## 2.7 Pit Walls

Exposed pit walls will remain in the Springer-Cariboo Pit, Wight Pit and Boundary Pit. All other pits have been backfilled resulting in pit wall reactive surfaces becoming part of the backfill.

Pit walls are composed of fractured walls and rubble resulting from over-blast and physical weathering. Localized wall failures will contribute additional talus. Reactive surface area for pit walls is contained primarily in the broken rock rather than fractured walls.

For source terms, pit walls are assumed to perform the same as waste rock dumps composed of PAG and NAG waste but flow paths are much shorter.

During flooding of pit walls, accumulated soluble weathering products will be flushed into pit walls. Following submergence, oxidation of walls will effectively be stopped due to reduction in availability of oxygen. Highwalls above final flood levels will continue to weather.

## 2.8 Ore Processing

Ore processing results in crushing and grinding of ore in contact water. Soluble components of the ore are dissolved and become part of the process water. Modification of process water chemistry may occur in the cleaner circuit where lime is added to increase pH. The change in pH may cause copper to precipitate.

The ore source term is expressed as mass leached per mass of ore. Except for the possible effects of pH adjustment described above, process water concentrations are expected to be too low to be controlled by secondary minerals.

The ore processing terms will depend on the degree of oxidation of the ore. Freshly blasted ore will contribute less load than ore re-handled from stockpiles, and deep fresh ore will contribute less load than near surface ore that has been naturally oxidized.

## 2.9 Tailings Solids

During operations, tailings are deposited by spigotting from the TSF embankments, resulting in tailings beaches and slimes migrating to the centre of TSF. Cycloned tailings were also used for dam construction.

Under normal operational conditions, slimes in the centre would be fully saturated and below the process pond. Due to the finger drains in the dam, the water table drops from surface at the edge of the pond in the centre of the facility to the finger drains. As a result, tailings near the embankments are partially saturated. Oxygen enters the unsaturated tailings in the beaches and embankments by diffusion resulting in near surface tailings oxidizing most rapidly and consuming oxygen. An oxygen concentration profile will be present in the tailings which decreases most rapidly near surface and eventually results in negligible oxygen concentrations at depth. It is probable that active oxidation at this stage extends no more than a few metres into the tailings.

Due to the acid-consuming characteristics of the tailings, the weathering environment is pH-basic and overall processes are comparable to NAG waste rock (Section 2.3). Pore water chemistry during operations is dominated by process water with less effect from weathering processes because tailings are continually deposited, resulting in re-setting of the oxidation profile.

Process water contains low levels of dissolved organic carbon from flotation process reagents (e.g., methyl isobutyl carbinol). These compounds may act as a source of reduced carbon to facilitate reductive dissolution processes in the saturated components of the tailings such as dissolution of iron oxides and release of contained trace elements. SRK (2015a) assessed this susceptibility and concluded the tailings were stable under chemically-reducing conditions.

Following the tailings dam failure in August 2014, the water table dropped, allowing more of the tailings to become unsaturated than under operational conditions. Draindown of pore waters will have occurred allowing oxidation processes to influence pore water chemistry.

Reactivation of the tailings pond will result in the water table rising again into the tailings. As the water table rises, oxidation products formed following partial draindown will be dissolved by process waters. Pore waters can therefore be expected to reflect a mixture of process water effects and flushing of oxidation products, though, due to the limited penetration of oxygen into the tailings, process water will dominate.

After operations cease, the process pond will decrease and the water table will again drop resulting in more tailings becoming unsaturated. Draindown of the tailings will result in a transition from process water dominated chemistry to oxidation effects becoming dominant. Eventual pore water chemistry will be controlled by equilibration of water chemistry with tailings weathering products which will include oxides and sulphates.

## 2.10 Sulphur Stockpile

Elemental sulphur ($S^0$) oxidizes to yield sulphuric acid through the following reaction:

$$S^0 + H_2O + 3/2O_2 \rightarrow H_2SO_4$$

Since the sulphur stockpile contains no neutralizing minerals, infiltration from the stockpile is expected to be acidic. Metal content of the pile is expected to be low relative to rock at the site resulting in acidic drainage carrying lower metal concentrations than would be expected for ARD. The foundation of the stockpile is NAG waste rock. It is expected that neutralization potential in the waste rock is neutralizing acid generated by the stockpile leading to non-acidic drainage with

chemistry comparable to weathering of waste rock. It is possible that depletion of neutralizing minerals in the NAG rock will result in the NAG rock becoming acid generating leading to a localized acidic plume in this area of the pile.

## 2.11 Magnetite Stockpiles

The magnetite stockpiles consist of sand-sized magnetite recovered magnetically from tailings. The separation process will have resulted in entrainment of non-magnetic components of the tailings.

Magnetite is resistant to oxidation under atmospheric conditions and therefore will not contribute significantly to the chemistry of drainage from the stockpiles. Drainage chemistry will be determined by the entrained minerals and will therefore be pH neutral having similar characteristics to NAG waste rock and tailings.

## 2.12 Nitrogen Leaching

Nitrogen leaching is covered separately from the foregoing conceptual models because it originates from explosives residuals rather than mineral weathering. Since the rock does not generate leachable nitrogen, the leaching of residuals provides a flush of nitrogen which occurs with water contact. It is expected that the load of nitrogen flushed is greatest initially then decaying in proportion to the remaining soluble nitrogen. The commonly used model of Ferguson and Leask (1988) assumes that all residual nitrogen is flushed in the year following placement of waste. This means that nitrogen leaching exactly tracks with waste rock placed and stops two years after placement stops. In fact, it can be expected that nitrogen leaching continues after the rock is first placed. In terms of cumulative leaching, a newly constructed waste rock dump would be expected to show increasing loads for several years then stable loads as the volume of rock added each year becomes small relative to the total volume. “Tailing off” at closure will occur. Delays and lag effects may be expected due to hydrological factors.

For a mature site such as MPM, active and long closed waste rock dumps indicate nitrogen release under operational and closed conditions. Sump waters from open pits indicate leaching from pit walls.

Leaching of explosive residual from ore will occur due to flushing in the milling process. Tailings solids themselves will not leach nitrogen because flushing during processing is very efficient. Nitrogen leaching from the TSF will reflect the influence of process water.

# 3 Source Terms

## 3.1 General Approach

MPM operations started in 1997, resulting in generation of waste rock and tailings. These full-scale waste facilities provide a more appropriate basis for predicting current and future water chemistry than scaling laboratory tests to full-scale conditions, provided that near source monitoring locations are available and appropriate allowance for local dilution effects at

monitoring locations are included. The general approach for MPM has been to use interpreted full scale monitoring data to develop source terms supplemented by laboratory data where needed. This approach removes most of the uncertainty related to predicting source term chemistry.

## 3.2 Incorporating Uncertainty

The CGMs described in Section 2 indicate that geochemical processes reflected in source terms consist of weathering of primary minerals, which is determined by rates of mineral conversions, and dissolution processes which combine rates and solubility constraints. The latter consists of the rate at which minerals dissolve and the eventual concentrations achieved when equilibrium with the contact water is reached. For example, chalcopyrite oxidizes at some rate to produce copper sulphate. The copper sulphate then dissolves at a rate adding copper and sulphate to the water until copper and sulphate concentrations in the water are in equilibrium with the solid copper sulphate.

As described in Section 3.1, the general methodology used to develop the source terms relies mainly on site monitoring data which reflects the end product of weathering and dissolution of weathering products. The assumption is that the monitoring data contain indications of the end-point solubility of the weathering products with the proviso that dilution needs to be considered. Higher end concentrations in the dataset are used as the starting point to develop source terms because these are most likely to be closest to a solubility limit. To represent uncertainty in the underlying solubility limits, the statistics from water chemistry databases used are the 95$^{th}$ and 99$^{th}$ percentile concentrations. Maximum concentrations are not used to eliminate the bias caused by spurious concentrations resulting from sampling and analytical errors. The two (2) high end percentiles are used because concentrations constrained by the solubility of minerals are not fixed but dependent on total solution chemistry including, particularly, pH.

Other approaches to incorporating uncertainty are described in the following sections.

## 3.3 NAG Waste Rock

### 3.3.1 Method

The method for the NAG waste rock source terms is as follows:

- Evaluate partitioning of reactive minerals during blasting.
- Evaluate potential for acidification due to included PAG rock.
- Evaluate seepage chemistry for geochemical controls.
- Prepare statistical summaries for seeps from major rock dumps.
- Scale-up maximum concentrations to account for dilution effects to yield source terms.

The basis for the latter step is that seepage chemistry may be diluted from true contact water and therefore needs to be scaled to remove dilution effects. Scaling was approached by assuming that gypsum is likely to exert a strong solubility control on major ion chemistry due to the interaction between oxidizing sulphides (yielding sulphate) and dissolving carbonates (yielding

calcium). It also has well-defined behaviour in which chemistry matches thermodynamic models, and is expected to be one of the most soluble secondary minerals in this setting. The high solubility indicates that it will likely be the last to reach equilibrium with contact water compared to other major primary minerals

Scaling is therefore achieved using the following equation:

$$[M]_{corrected} = \left( \frac{[SO_{4,Theoretical}]}{[SO_{4,Observed}]} \right) \cdot [M]_{observed}$$

$[SO_{4,theoretical}]$ is the maximum sulphate concentration indicated by the solubility of gypsum.

$[SO_{4,observed}]$ and $[M]_{observed}$ are the observed sulphate and element concentrations. $[M]_{corrected}$ is the scaled element concentration. $[SO_{4,observed}]$ values are the 95$^{th}$ and 99$^{th}$ percentile seep concentrations selected to be at the upper end of the distribution so that the need for correction is minimized.

$[SO_{4,theoretical}]$ depends on bulk chemistry being lowest for waters containing only calcium as the balancing cation. As other major ions (K, Mg and Na) increase in significance, $[SO_{4,theoretical}]$ increases. The ratio (Mg+K+Na)/Ca shows significant variation within MPM (Figure 12). The ratio is lowest for the Boundary Zone and highest for seeps from the two haul roads. For the purpose of determining a range of $[SO_{4,theoretical}]$s, the 50$^{th}$ and 95$^{th}$ percentiles for each dump group were used. The 50$^{th}$ percentile indicates median predicted sulphate whereas the 95$^{th}$ percentile is a conservative limit. The actual range of the ratio is fairly narrow. For the Boundary Zone, the resulting range is 1510 to 1540 mg/L whereas for the South East Dump the range is 1610 to 1670 mg/L.

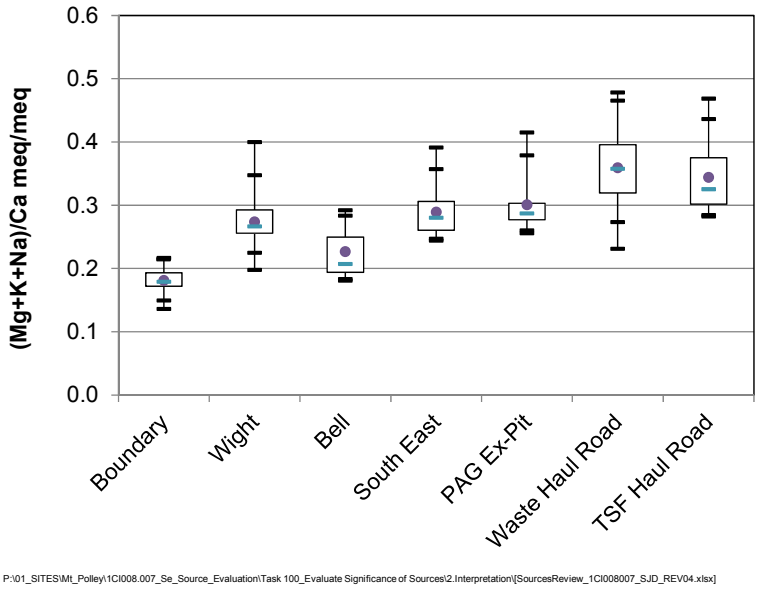

**Figure 12. Box and Whisker Distributions for the Cation Ratio**

### 3.3.2 Inputs

#### 3.3.2.1 Mineral Partitioning During Blasting

Mineral partitioning during blasting was evaluated using blast hole cuttings because this can have an effect on the classification of waste for ARD potential (Day et al. 2015). If carbonate minerals preferentially partition into the blast fines, the use of a bulk NP/AP classification factor can lead to misclassification of rock that will probably not generate acid as PAG. The reverse can also occur if sulphide minerals preferentially classify to the fines.

In 2001, blast muck samples from the Bell and Cariboo Pits were collected and the +2 mm and -2 mm fractions were tested separately for acid-base accounts. The +2 mm provides an indication of “bulk” characteristics because it contains larger rock fragments.

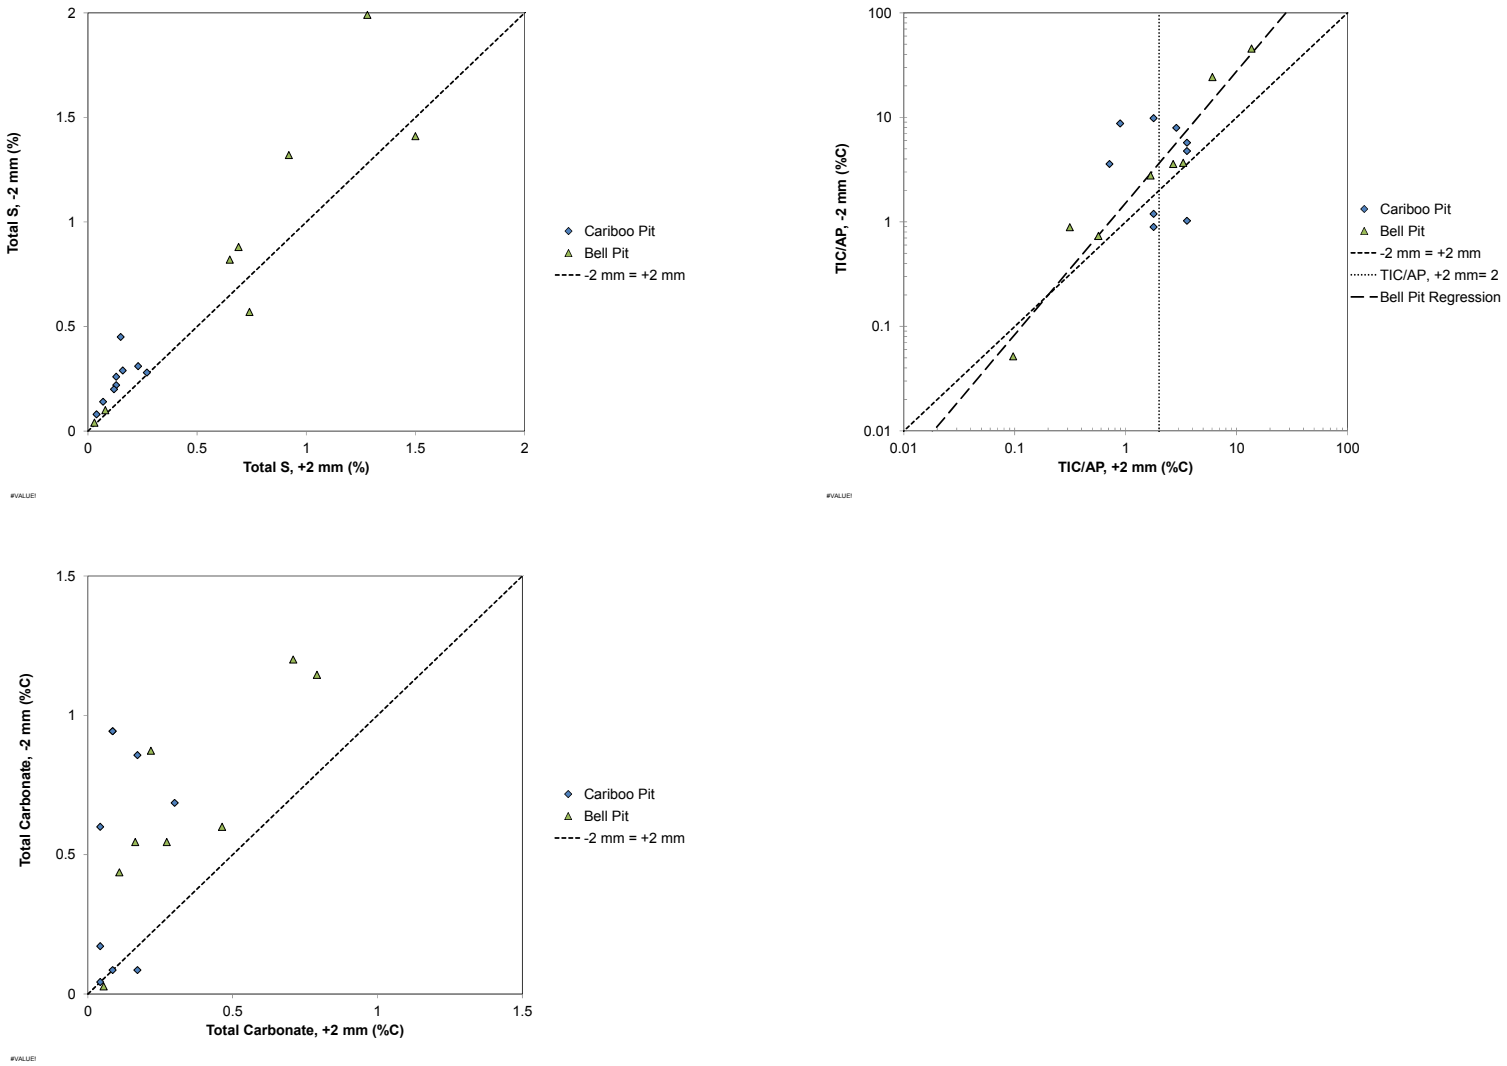

**Figure 13. Results of Testing of Blast Rock Size Fractions**

Both sulphur and carbonate preferentially partitioned into the -2 mm fraction but the effect was much stronger for carbonate (Figure 13). While there was good correlation between sulphur in the two size fractions, the correlation was absent for Cariboo Pit samples and weak for Bell Pit samples. The result of the difference in partitioning was that TIC/AP in the fine fractions was greater than in the +2 mm fractions for all but four samples. Again, for the Cariboo Pit there was no correlation between the fractions so the observed partitioning is qualitative only. For the Bell Pit, a regression equation could be derived:

$$\text{Log (TIC/AP, -2 mm)} = 1.3 \times \text{Log(TIC/AP, +2 mm)} + 0.18, r=0.97$$

The regression equation indicates that TIC/AP of 2.0 in the +2 mm fraction (i.e., approximately equivalent to bulk analysis determined in blast hole cuttings) is equivalent to 3.6 in the fines.

The equivalent regression equation:

$$\text{Log (TIC/AP, +2 mm)} = 0.75 \times \text{Log(TIC/AP, -2 mm)} - 0.10, r=0.97$$

shows that if it is assumed that the TIC/AP segregation criterion of 2 should be applied to the blast fines, the respective bulk criterion is 1.3. Based on the characteristics of NAG rock throughout MPM, about 22% of samples have TIC/AP between 1.3 and 2.

The findings of this assessment is that the classification of PAG using TIC/AP of 2 in blast hole cuttings has probably led to misclassification of some NAG rock as PAG. This finding was not used directly but primarily to confirm that under-classification of PAG rock (i.e., increased likelihood of PAG rock in NAG rock) is not a concern for MPM.

#### 3.3.2.2 Potential for Acidification

The potential for acidification of NAG rock considers:

- the likelihood that misclassified PAG waste rock occurs as large segregated volumes (resulting in hotspots); and
- the mass balance ABA resulting from misclassified PAG rock.

From operating experience, MPM geological staff have determined that PAG rock is correlated with well-defined pyritic zones (see Section 1.1.2) but also occasionally as isolated pockets. The current main pyritic zone being exposed by mining is on the southeast wall of the Springer-Cariboo Pit. A similar zone was encountered in the Bell Pit and was managed appropriately by segregation and disposal in the Cariboo Pit. The Southeast Zone was classified entirely as PAG. The Wight Pit and Boundary Zone do not appear to have distinctive pyritic zones.

Sampling effort during operations focusses the defining dig limits around the pyritic zone in Cariboo-Springer Pit and a confirmatory-type approach outside the areas of known PAG occurrence. Due to the well-defined nature of the pyritic zones, the potential for PAG rock being included with NAG rock is largely expected to be due to isolated PAG occurrences outside the known pyritic zones. MPM target for sampling is one blast hole sample per 30,000 tonnes

meaning that a PAG quantity up to this amount could be missed if surrounded by NAG blast holes. An average PAG amount in this scenario would be 15,000 tonnes which on a 15 m bench would be a 20 m x 20 m area. At the scale of mining, a PAG area this size would become mixed with surrounding NAG rock as a result of digging and placement in a rock storage area.

The acid base balance for mixing of PAG and NAG rock is shown in Figure 14. The mixing lines were calculated using average characteristics for the whole site and are based on PAG defined as TIC/AP>2 in the bulk rock. The “Best” and “Worst” envelopes were derived by combining the 95% confidence limits on the means. The “Worst Case” is the upper confidence limits for AP combined with the lowest confidence limits on NP. The “Best Case” combines the reversed limits. The overall percent PAG accounted for at MPM is 11% of the total rock mass of which 9% is in the Temporary NW PAG Stockpile located next to Springer Pit for re-handle to Springer-Cariboo Pit at closure. The remaining 2% is stored elsewhere at the site in pit backfills. As there is a good understanding of the occurrence of PAG rock based on geological controls, it is expected that unaccounted for PAG rock is probably not more than a few percent, resulting in mass balance TIC/AP exceeding 3 and probably exceeding 4.

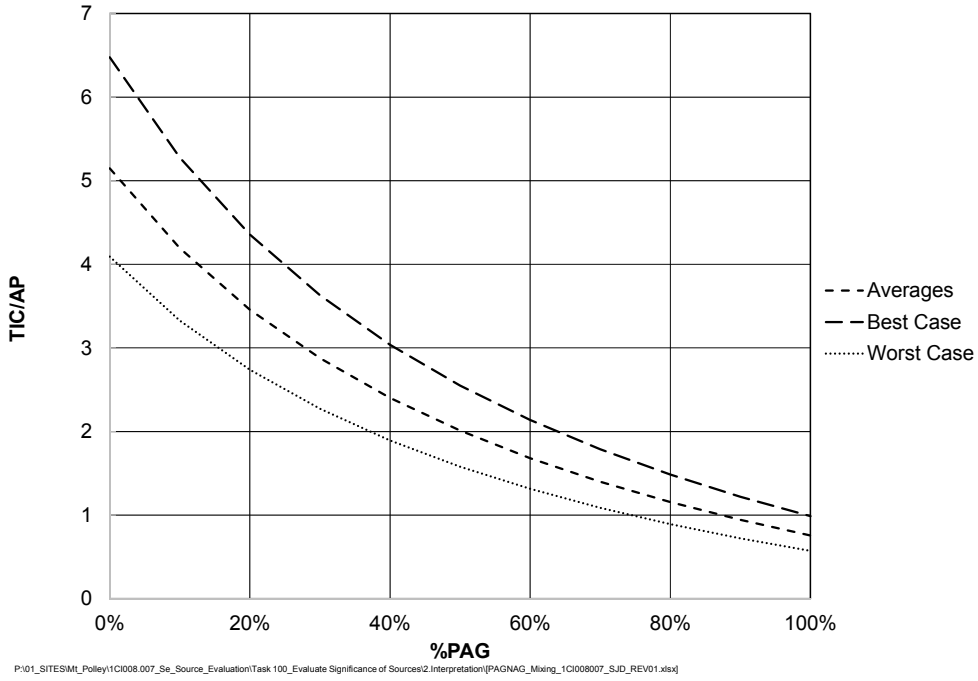

**Figure 14. Acid-Base Account for PAG-NAG Mixing**

Acidification of NAG waste rock at more than a very local scale is not expected because the percentage of PAG rock that could have been inadvertently included in the NAG waste risk is likely no more than a few percent. It was therefore concluded that NAG rock can be expected to remain permanently non-acidic and that long term changes in the NAG rock source term do not need to be considered.

#### 3.3.2.3 Waste Rock Seepage Database

The seepage database (Appendix E) was interpreted to understand what mineralogical controls may be constraining water chemistry, determine if seasonal variations are apparent, and derive statistics for input into source term derivation.

As a general interpretation effort, relationships between rock composition and seepage chemistry were evaluated. However, except for the Wight Pit (East Rock Dump and Northeast Zone Dump) and Boundary Pit waste rock dumps, waste rock from all pits has been placed in several different locations limiting the opportunity to link rock composition to seepage chemistry.

*Description of the Database*

The current database contains 314 water analyses for seeps located as shown in Figure 15. Seeps have been sampled biannually since 2013. Filtering of samples occurs at the analytical laboratory unless hold times cannot be met. Samples are analysed for a full range of major and trace ions.

*General Description of Water Chemistry*

Water chemistry statistics grouped according to the areas indicated are provided in Table 4.

All seeps are non-acidic with medians above 7 and more typically nearer 8. The major anion is sulphate followed by bicarbonate (indicated by alkalinity) which is balanced mainly by calcium and magnesium. As discussed with reference to Figure 12, some differences in major ion chemistry were reflected in the cation ratio but differences in seepage chemistry were generally absent reflecting consistencies with the geological setting and placement of waste rock from the pits at multiple locations.

Selenium to sulphate ratios were examined for comparison with ratios in the rocks (Figure 7). Rock chemistry showed some distinctive variations in the ratio with typical ratios between 0.0001 and 0.001 mgSe/mgS. Likewise, the ratio was in the same range for seeps (Figure 16). Wight Pit extended to lower ratios in both the rock and seeps. It was concluded that selenium leaching is due to oxidation of sulphides and that leaching effects are similar throughout the site.

Nitrate concentrations varied significantly by source area (Figure 17). Distinctively higher concentrations were found for the Southeast Dump, the Temporary NW PAG Stockpile and TSF Haul Road. Lower concentrations were indicated for the North Bell Dump, Wight Pit Dumps (East Rock Dump and Northeast Zone Dump) and the small Boundary Dump. The differences are linked to placement activity with lowest concentrations for dumps less recently active.

*Interpretation of Water Chemistry*

Water chemistry was interpreted by using PHREEQC to calculate mineral saturation indices thereby providing an indication possible constraining minerals.

Saturations indices for sulphate were consistent with gypsum as a strong solubility control. At higher sulphate concentrations, gypsum saturation indices approached 0. Most seeps had

sulphate concentrations well below those required to be at gypsum indicating possible dilution effects, lack of gypsum, or incomplete equilibration. Regardless, the general observation is gypsum likely controls major ion (calcium and sulphate) chemistry with pH control by carbonate. Saturation indices greater than 0 for calcite were consistent with its dissolution and partial pressures for $CO_2$ were above -3.4.

**Figure 15. Seep Sampling Locations**

**Table 4. Waste Rock Seepage Statistics**

**Figure 18. Selected Saturation Indices**

Saturation indices for malachite were well above 0 showing that copper concentrations were higher than would be predicted if malachite is controlling copper. Tenorite saturations indices were between 0 and 1 at higher copper concentrations indicating that it is more likely that a copper oxide is controlling copper concentrations. The finding that malachite does not appear to be controlling copper concentration is not consistent with the observed presence of malachite which formed by natural oxidation of the orebody. The likely controls on copper concentrations are secondary minerals resulting from oxidation of the waste rock following mining.

Other indications that higher end concentrations indicate mineral saturation included molybdenum which may be controlled by calcium molybdate (Figure 18) and barium by barite. Trace elements occurring at concentrations well below saturation in indices of 0 for their discrete minerals are probably adsorbed or co-precipitated with major secondary minerals (for example, iron oxyhydroxides).

Like the majority of trace elements, saturation indices for selenium minerals were well below 0, reflecting that discrete selenium minerals are not likely to be forming. Relationships between selenium concentrations and saturation indices for major ions that do appear to be controlling solution chemistry were examined (Figure 19). Upper limits to selenium concentrations were correlated with increasing saturation indices for gypsum and barite which may indicate co-precipitation with these minerals. The relationship with tenorite saturation indices showed that selenium concentrations appear to be constrained as copper concentrations were constrained. This may indicate that selenium is co-precipitating or adsorbing with an oxide or that the conditions resulting in copper oxide precipitation also result in selenium removal from solution. These interpretations do not provide a conclusive mechanism for constraining selenium concentrations but jointly show that higher selenium concentrations in the dataset are probably constrained. On this basis, seepage concentrations were used as the basis to calculate source terms.

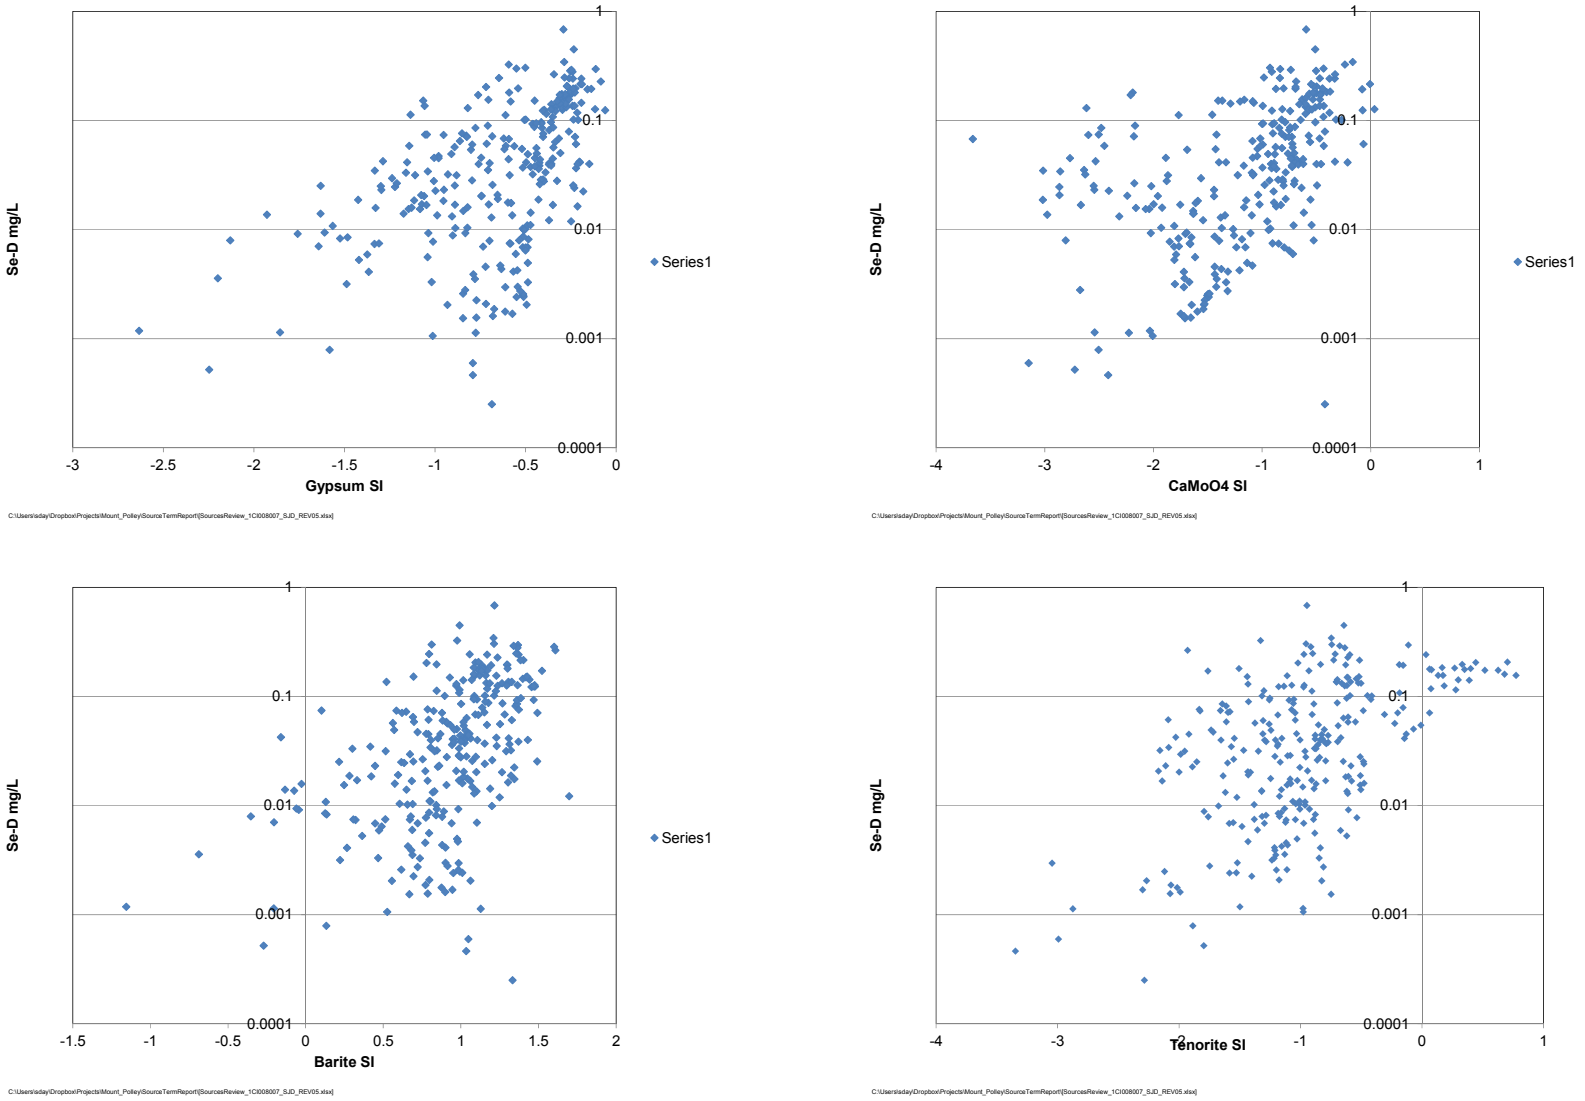

**Figure 19. Relationships between Selenium Concentrations and Saturation Indices for Gypsum, $CaMoO_4$, Barite and Tenorite**

*Seasonal Variations*

The seepage database was inspected for seasonal variations but none were identified. This may indicate that seepage chemistry does not respond to climatic variation or that the current size of the database does not allow seasonal effects to be resolved.

### 3.3.3 Results

Source terns for NAG waste rock are provided in Appendix F.

## 3.4 Ex-Pit PAG Waste Rock

Since ex-pit PAG waste rock will be re-handled to the Springer-Cariboo Pit at closure before acidification is predicted to occur, and the same solubility controls are expected as NAG, no separate PAG waste rock term was generated. The PAG waste rock term is that shown as “All-PAG Pre-acid shown in Table 4.

Acidification of PAG walls is discussed subsequently in Section 3.7.

## 3.5 Ore Stockpiles

Ore stockpiles are composed of rock with similar composition to waste rock with the exception of higher copper concentrations. Overall controls on water chemistry are expected to be similar to NAG waste rock and no separate term was developed. The effects of processing oxidized ore are considered separately in Section 3.8.

## 3.6 Pit Backfill

Exposed components of pit backfill are assigned the same source term as NAG waste rock. Following submergence, the same source term is assigned to the pore water chemistry assuming that pore waters equilibrate with the same previously formed secondary minerals. Over time, leaching of these minerals will result in decreasing concentrations; however, this process has not been quantified and it is conservatively assumed that constant pore water chemistry will be maintained in perpetuity.

## 3.7 Pit Walls

### 3.7.1 Method

Pit wall source terms prior to flooding consider the loading from weathering of rubble in exposed walls. Walls covered by waste rock backfill are not assigned a loading because the reactive surface area in waste rock far exceeds that in the rubble on pit walls.

The process of flushing walls by rising water levels was not considered because the relative volume water involved and flushing of pit walls weathering under non-acidic conditions will be small relative to ongoing flushing of exposed walls and flushing of backfilled waste rock.

Pit walls covered by water are also assumed to yield negligible loading because oxidation processes are effectively altered by a water cover. Ongoing leaching may occur (as described for waste rock backfill) but the volume involved is relatively small.

The load of parameter i released by weathering of rubble on pit benches ($W_i$) is calculated from:

$$W_i = M \cdot R_i \cdot k_O \cdot k_T \cdot k_p$$

$R_i$ is the rate of release indicated by HCTs scaled to allow for oxygen availability ($k_O$), differences in temperature ($k_T$), and differences in reactive surface area ($k_p$) and applied to a mass M. Mass is calculated on a per $m^2$ planar wall basis, using rock density (ρ) and an assumed reacting thickness (h):

$$M = 1 \cdot h \cdot \rho$$

The load leached ($L_i$) is calculated from:

$$L_i = W_i \cdot k_c$$

$k_c$ is a factor to account for incomplete leaching of weathering products.

The resulting concentration [$M_i$] in runoff from the wall area is obtained:

$$[M_i] = \frac{L_i}{I}$$

I is the infiltration over the area. Concentrations obtained for non-acidic walls are compared to those developed for NAG waste rock and constrained to the NAG waste rock if concentrations greater than for NAG waste rock are obtained. For PAG walls, concentrations were not constrained assuming that low pHs will result in high solubility of secondary minerals.

### 3.7.2 Inputs

$R_i$s for non-acidic conditions were estimated from three humidity cells (HC14, HC15 and HC16) performed on Springer Pit rock (Table 3). The average of the three tests was used to estimate R. Scaling factors used for $k_O$, $k_T$, $k_p$ and $k_c$ respectively were 1, 0.3, 0.1, and 1, and assume that oxygen is not limited, temperatures are lower under site conditions, rock is coarser than humidity cells and weathering products are completely leached.

No naturally progressing humidity cells have yielded acidic leachate for MPM but rates obtained from HCTs on Pond Zone rock forced to generate acid by stripping of carbonate (HC12 and HC13, Table 3) were used to estimate an acidic source term. Since these samples were selected to evaluate oxidation rates following carbonate depletion for samples containing lower sulphide in the Pond Zone, the HCT weathering rates $R_{i,HCT}$ were scaled to sulphide concentrations in the acidic Springer Pit walls ($S_{i,Wall}$) using:

$$R_{i,acid} = R_{i,HCT}\left(\frac{S_{acid,wall}}{S_{HCT}}\right)$$

$S_{acid,wall}$ was estimated from the blast hole cuttings database from the Springer Pit. For each PAG sample in the database, the sulphur remaining following depletion of all NP was calculated from the measured sulphide content ($S_0$) and carbonate content ($NP_{TIC,0}$) and the rate ratio for depletion of carbonate ($R_{ratio}$):

$$S_{acid,wall} = S_0 - \left(\frac{NP_{TIC,0}}{R_{ratio} \cdot 31.25}\right)$$

$R_{ratio}$ is equivalent to the PAG/NAG segregation criterion of 2. The 95$^{th}$ percentile of the resulting distribution of $S_{acid,wall}$ was calculated to be 1.7% compared to the 95$^{th}$ percentile of measured values of 2.1%. The resulting rates are shown in Table 5.

Source: C:\Users\sday\Dropbox\Projects\Mount_Polley\SourceTermReport\[SourcesReview_1CI008007_SJD_REV05.xlsx]

The weathering thickness (h) was set to 2 m to be equivalent to typical over-blast thickness. ρ was used as 2.65 t/m$^3$.

Total annual precipitation of 670 mm/year was used to estimate infiltration of 603 mm/year assuming that 90% of precipitation contacts wall rocks.

### 3.7.3 Results

Pit wall source terms of non-acidic and acidic walls are shown in Appendix G.

## 3.8 Ore Processing

### 3.8.1 Method

The mass leached from ore as it is processed was calculated from shake flask extraction test data. Concentrations in the shake flask tests (in mg/L) were converted to mass leached as (mg/t) by multiplying by factors of 3 L/kg which is the leach ratio in the test, and 1000 kg/t. The mass leached is used to determine the load added to the process water from each t of rock processed.

### 3.8.2 Inputs

Shake flask data from characterization of eight samples from four ore stockpiles were used (SRK 2015b). The data were used to calculate 5$^{th}$, 50$^{th}$ and 95$^{th}$ percentile of the loads leached. Since the rock in the stockpiles varied in age from one to nine years, they were not representative of freshly blasted ore. To account for this, the 5$^{th}$ percentile was used to indicate leaching of freshly blasted ore and the 95$^{th}$ percentile was used for processing of the stockpiles.

### 3.8.3 Results

The resulting source terms are provided in Appendix I.

## 3.9 Tailings

### 3.9.1 Method

Tailings source terms were developed for operating conditions (i.e., when tailings are being discharged) and closure conditions when contact waters are assumed to represent oxidation of tailings following draindown of process waters. Re-flooding resulting from reactivation of the impoundment would result in seepage chemistry intermediate between these conditions.

For operational conditions, observed seepage chemistry from tailings dam drains (see Appendix **H**) was assumed to be representative of future tailings contact water. Seepage chemistry is assumed to reflect mainly the influence of entrained process water with less influence from oxidation of tailings. Since localized influence from groundwater and non-contact surface can be expected, the range of concentrations assumed was the 95$^{th}$ and 99$^{th}$ percentiles.

For closure conditions, the preferred approach was to obtain direct chemistry from contact waters in the current unsaturated zone because these would likely represent the conditions when the

tailings are fully drained down. Site personnel identified two groundwater monitoring locations (Breach-1 and Upstream-1) which were felt to possibly represent the influence of tailings; however, sulphate concentrations were not different from the tailings dam drains, and higher end dissolved element concentrations were strongly influenced by suspended matter (for example, aluminum concentrations on filtered samples ranged up to 33 mg/L). It was therefore not known with confidence whether the data indicated contact water chemistry.

Interpretation of leach column data (see below) indicated that early chemistry provide a good indication of contact water chemistry reflecting the influence of oxidation processes. The following method was used to estimate contact water chemistry for drained down tailings:

- The 95$^{th}$ and 99$^{th}$ percentile concentrations of column data were calculated.
- For the majority of parameters, drain down chemistry was characterized by the column data percentiles.
- For selenium, interpretation of the column data resulted in the conclusion that attenuation of selenium may be occurring in the early stages of testing as a result of reductive process converting selenate to selenite. To address this possible effect, selenium concentrations were calculated using the sulphate statistics and the range of Se/$SO_4$ ratios indicated by later data:

$$[\mathrm{Se}] = \left( \frac{\mathrm{Se}}{\mathrm{SO_4}} \right)_{\mathrm{ratio}} \times [\mathrm{SO_4}] .$$

- The equivalent dam drain percentile was used for ammonia because it was not measured in column leachates.
- Manganese concentrations were markedly lower in column leachates compared to seepage. This difference may reflect that conditions in desaturated tailings favour lower mobility of manganese, but the seepage data were selected.

### 3.9.2 Inputs

Seepage data statistics were calculated for all seepage collection points collected between 1998 and 2015.

Seepage and column data were evaluated for solubility controls using the same approach as waste rock (see Section 3.3.2.3). Sulphate concentrations in all column data were close to 2000 mg/L and found to yield gypsum saturation indices near 0, and therefore consistent with solubility control by gypsum. Seepage saturation indices tended to be well below 0. Other parameters showing possible secondary mineral controls were copper (tenorite), molybdenum (calcium molybdate), and barium (barium sulphate). Based on similar reasoning as waste rock, the early column data appear to indicate secondary mineral solubility controls for these elements and provide a good indication of the solubility of other elements.

Figure 21 shows the ratio of Column to Seepage for the two statistics. The columns showed higher concentrations than seepage for most parameters including those linked to acid generation and neutralization processes ($SO_4$, Ca, Mg) and related heavy elements (Cu, As, Mo, Sb, Se).

Those lower in column data include nitrogen forms (which would be introduced by leaching in the process plant), and Al, Mn and Fe. Manganese and iron may be higher in seepage due to reducing conditions in drains but also may be influenced by colloidal matter. The latter may also explain why aluminum concentrations were higher in seepage compared to the column tests, and exceeded theoretical solubility of aluminum hydroxides (Figure 22).

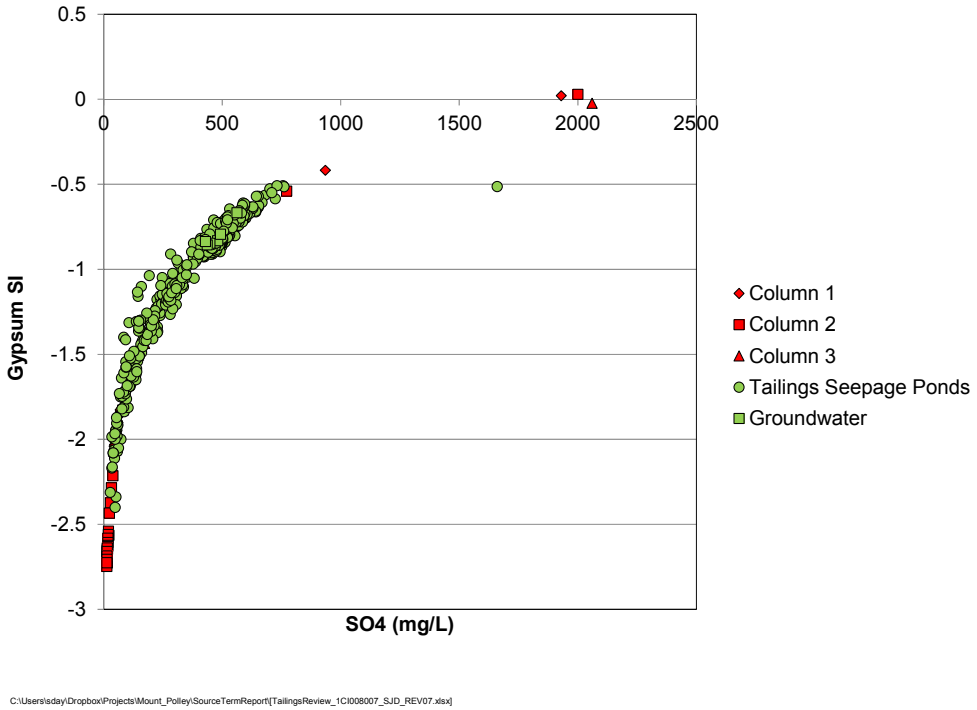

**Figure 20. Gypsum Saturation Indices for Tailings Seepage and Column Data**

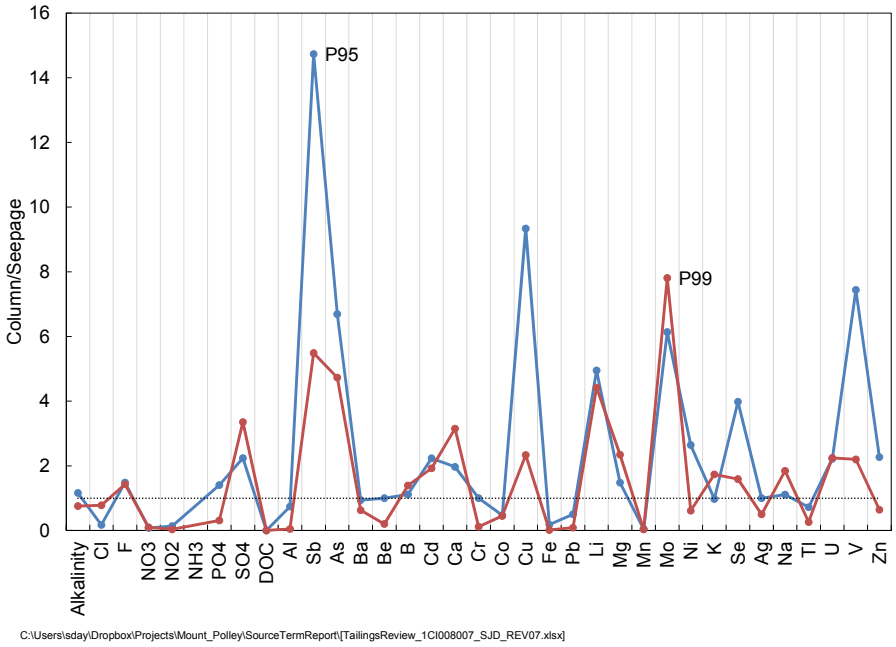

**Figure 21. Comparison of P95 and P99 Statistics for Ratio of Column/Seepage**

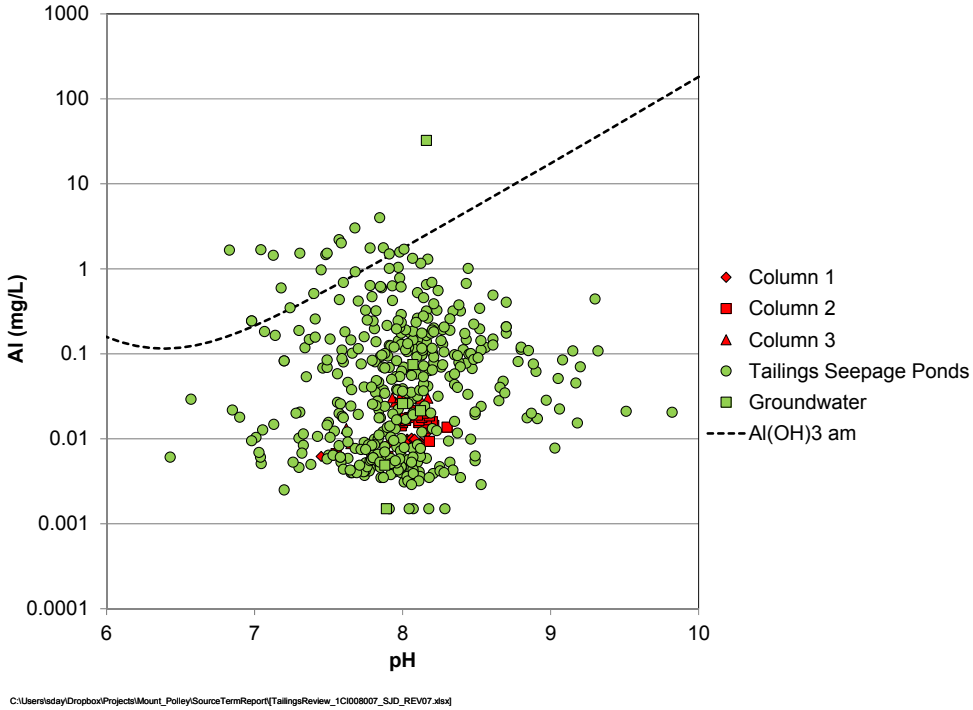

**Figure 22. Tailings Aluminum Concentrations on Log Scale Compared to pH. Ideal Solubility of Amorphous Aluminum Hydroxide is Shown**

### 3.9.3 Results

Tailings source terms are provided in Appendix I.

## 3.10 Sulphur Stockpile

No separate source term was developed for the spatially limited sulphur stockpile. As indicated in the conceptual model, it is likely that the stockpile is leaching sulphuric acid. It is assumed that the leaching effect of the stockpile is reflected in other site seeps and is therefore reflected in the NAG waste rock source terms.

## 3.11 Magnetite Stockpiles

No separate source term was developed for the magnetite stockpiles. Relative to other sources, these stockpiles are not expected to be significant sources.

## 3.12 Nitrogen Leaching

Nitrogen leaching was included for each source term as follows:

- Waste Rock. Nitrogen sources terms were developed from existing seepage by grouping waste rock dumps into active (PAG Ex-Pit and Southeast Dump), and inactive (Bell Pit and Wight Pit). For each group, mean concentrations and 95% confidence limits on the means were calculated to consider uncertainty (Table 6).

- Pit Walls. Pit walls were assumed to have zero contribution due to the small mass involved and expected results of meteoric leaching which is expected to result in any leaching effects having short duration and being insignificant relative to waste rock reporting to pit water sumps. B. Mattson, Lorax (pers. comm.), indicated that a non-zero source term should be applied but supporting data were not available.
- Backfill. Backfill source terms are the same as those for waste rock (Table 6).
- Ore Processing. Leaching of nitrogen forms by processing were based on the shake flask extraction data (Appendix I).
- Tailings. Tailings source terms are based on the observed seepage for operational conditions and column data for draindown conditions (Appendix I).

**Table 6. Waste Rock Nitrogen Source Terms**

| Phase | Statistic | Ammonia mgN/L | Nitrate mgN/L | Nitrite mgN/L |
|---|---|---|---|---|
| Inactive | Lower 95% Confidence Limit | 0 | 1.7 | 0 |
| | Mean | 0.053 | 3.4 | 0.51 |
| | Upper 95% Confidence Limit | 0.18 | 5.2 | 1.9 |
| Active | Lower 95% Confidence Limit | 0.034 | 11 | 0 |
| | Mean | 0.15 | 28 | 0.29 |
| | Upper 95% Confidence Limit | 0.27 | 45 | 0.61 |

# 4 Conclusions

This report presents source term geochemical predictions that are inputs into the site wide water quality model. The main conclusions that provided input into the source terms are:

- While several ore zones at MPM have been mined since 1997, all except the relatively small Pond Zone are alkalic porphyry mineralization centred on magmatic-hydrothermal breccia bodies with similar geological characteristics. The host rock for the mineralization is the MPIC which is mainly monzonite. The similarities of the mineralized zones, including their host rocks, indicate that source terms can appropriately be developed on a site-wide basis rather than considering significant differences between the zones.
- As a result of geochemical segregation of waste rock based on ARD potential through the mine life, PAG waste rock has been or will be placed in open pits where it will be permanently flooded thereby preventing ARD from developing.
- It is expected that operational inefficiencies will have resulted in PAG waste being incorporated into the NAG waste rock but the segregation approach was conservative and mass balance excess of acid neutralizing minerals over acid generating minerals means that future development of ARD is very unlikely. Weathering conditions are predicted to be pH-basic in perpetuity.
- Tailings are non-PAG.
- As a result of the pH-basic weathering conditions, chemistry of seepage from the existing full scale facilities reflects solubility limits for weathering minerals. Chemistry is affected by dilution which was corrected using the solubility limit of gypsum.

IMPERIAL METALS CORPORATION

# ML/ARD MANAGEMENT PROCEDURE MANUAL

## OBJECTIVE

The objective of this Metal Leaching/Acid Rock Drainage (ML/ARD) Management Procedure Manual is to provide detail on how ML/ARD potential is considered in material management at the Mount Polley Mine (MPM). This document summarizes all the various procedures and considerations related to ML/ARD potential through mine life processes.

## DOCUMENT REVISION HISTORY

This document replaces earlier versions of similar documents that directed ML/ARD Management at MPM in response to *Mines Act* Permit M-200 issued on August 3, 1995. The procedures as described have been in the place since that date.

**Document Update Summary**

| Revision Date | Author | Comment |
|---|---|---|
| June 30, 2016 | Chad Cameron<br>Ben Harding<br>Katie McMahen<br>Luke Moger<br>Ryan Brown<br>Stephen Day (SRK) | Original Document |

# BACKGROUND

Metal leaching and acid generation are naturally occurring chemical processes which may have negative impacts on the receiving environment. The potential environmental impact of ML/ARD will depend on their magnitude, the sensitivity of the receiving environment, dilution and/or attenuation, as well as any mitigation measures that are in place.

Metal leaching occurs as a result of: weathering of metal-containing minerals (i.e., exposure to water and oxygen), drainage conditions that increase solubility, and flow of water through source materials. Acid generation occurs when minerals containing reduced sulphur (e.g. sulphide and elemental sulphur) are exposed to the weathering effects of oxygen and water. In iron sulphide minerals (e.g. pyrite) acidity is also generated when ferric iron precipitates. Other minerals in the source rock, primarily calcium and magnesium carbonates can neutralize the acid. ARD occurs when the amount of acid-generation exceeds the ability of the source rock to neutralize this acid. Any surplus acid is entrained in water and can create acidic and metal-containing run-off.

Pre-mining and operational geochemical characterization has shown that ARD potential at MPM is restricted due to the abundance of acid-consuming carbonate minerals compared to acid generating sulphide minerals. In addition, the presence of natural carbonate and oxide copper minerals in the pre-mining weathering zone reinforce the expectation that weathering conditions are dominantly basic. However, due to the potential consequences of acid generation for long term management of the site, Mount Polley Mining Corporation (MPMC) actively manages waste rock based on its ARD potential as described in the following sections.

MPMC has focused on managing potential for ARD due to the link between acid generation and enhanced solubility of copper which is expected to be the primary concern for ML. Selenium leaching has also been identified as occurring at MPM. Selenium is released by oxidation of sulphide minerals but leaching is not necessarily associated with pH depression. Selenium leaching occurs regardless of whether waste rock is classified as potentially ARD generating (PAG) or non-PAG (referred to as NAG at MPM).

# UNDERSTANDING OF THE DISTRIBUTION OF ARD POTENTIAL

Like other alkalic porphyry deposits (e.g. Copper Mountain, Brenda), MPM lacks the strong hydrothermal alteration zoning that is commonly observed in calc-alkalic porphyry deposits (e.g. Highland Valley Copper, Island Copper, Gibraltar). In particular, phyllic alteration is absent at MPM. A common feature of calc-alkalic porphyry deposits is often a pronounced pyritic halo that surrounds the copper mineralization and is associated with phyllic and propylitic alteration. At MPM, discontinuous pyritic zones are present but do not appear to be mineralization halos. MPMC geological staff identified a pyritic zone in the south wall of the Springer Pit which extends into the adjacent Cariboo Pit.

This ML/ARD Management Procedure Manual applies to waste rock and ore stockpiles. Tailings are consistently NAG due to removal of copper sulphides by ore processing.

# MANAGEMENT OF PAG ROCK

Best practice for management of PAG rock is subaqueous disposal in a configuration that provides permanent and low maintenance containment. At MPM, this has been implemented by disposing of waste rock in completed open pits that will subsequently fill with water. Mine planning is carried out at MPM such that the open pits have sufficient capacity that PAG material can be re-handled into the open pits and stored subaqueously at closure. The following pits are available for subaqueous disposal (in sequence):

- Cariboo Pit
- Bell Pit
- Pond Zone Pit
- Southeast Zone Pit
- Wight Pit
- Cariboo-Springer Pit.

For the Springer Pit, backfill locations are not currently available. The PAG rock is therefore stockpiled adjacent to the open pit in the Temporary Northwest PAG Stockpile for backhauling to the Cariboo-Springer Pit upon completion of mining.

For the small Pond Zone Pit, low sulfur PAG waste rock is layered with NAG waste rock.

Onset of acidic conditions in waste rock at MPM takes at least decades as shown by humidity cells, and the lack of acidification in the natural exposure of the deposit indicates that flooding of PAG waste rock does not need to be immediate. The current approaches of backfilling into dry pits and stockpiling following by backfilling allows PAG rock to be submerged before it acidifies.

# DETERMINATION OF ML/ARD POTENTIAL

Waste rock on site is separated into two categories, NAG and PAG, using Neutralizing Potential Ratio (NPR) defined as:

$$NPR = NP/AP.$$

Acid Potential (AP) (in kg $CaCO_3$/t) is measured from:

- Total sulphur (%) x 31.25

Neutralizing Potential (NP) (in kg $CaCO_3$/t) is measured from total carbonate NP determined from:

- Total carbon (%C) x 83.33.

Due to the dominantly intrusive rock host at MPM, total carbon is an appropriate proxy for carbonate.

As required by *Mines Act* Permit M-200, PAG is defined as:

- NPR≤2 and total S>0.1%.

This *Mines Act* Permit M-200 requirement was specified in terms of NP determined by a whole-rock acid extraction and titration method; however, MPMC chose to use total carbonate which yields lower NP than the titration methods.

# MATERIAL CHARACTERIZATION OVERVIEW

This section provides an overview of characterization procedures.

The MPM program characterizes all material types that will be handled during the mine life. Analysis is completed on site by Mount Polley's LECO™ instrument , allowing MPMC to best manage mine waste by directing it to suitable storage sites, or to construction usage when required (and if deemed suitable).

On each bench, a sample of cuttings is collected from each blast hole and analyzed for total copper, non-sulphide copper, iron, and gold. Areas of ore and waste are identified by interpolation of these assay results and the economic analysis of the resulting metal grades. Ore/waste boundaries are then established based on the calculated mill head values.

In areas which have proven to be consistently NAG on previous adjacent benches in blasthole samples, the waste tonnage in each blast is divided by 40,000 in order to determine the number of ABA samples to be submitted (i.e., one per 40,000 tonnes (t) of waste). However, in areas where PAG has been modelled through either exploration sampling, or results of previous blasthole sampling on other benches, (or where NAG and PAG may coincide), the sample density is doubled to one per 20,000 t. This approach results in greater sampling density in areas of suspected NAG/PAG boundaries, and increases the certainty of defining PAG. Typically structures at MPM are vertically oriented, and relatively continuous. This provides some assurance that blasthole samples from previously mined benches have relevance for determining where additional samples should be taken on new benches.

Any ore that will be stockpiled rather than processed immediately is sampled at a frequency of one (1) per 20,000 t to determine if it is classified as PAG or NAG. Millfeed ore areas are excluded from ABA analysis, as this material is processed through the Mill.

Composite tailings samples are collected and analyzed every month when processing of ore occurs to represent the tonnage of tailings deposited.

As a QA/QC measure required by *Mines Act* Permit M-200, the Environmental Department takes random weekly grab samples from the NAG waste dump when PAG is being mined to verify that waste is being appropriately characterized and handled.

Water chemistry monitoring of seepage from rock dumps and of contact water from the site water collection systems is also conducted by the Environmental Department to inform development of geochemical source terms and long-term water quality predictions. Similarly, tailings composites and monthly random drill pulp samples are sent to a third party laboratory for metals analysis as an additional source of data for site geochemical models.

# IN-PIT SEGREGATION

Blasthole Samples:

1. After the production drill has completed and moved away from the hole, the sample may be taken.
2. Using a tube sampler, the Driller will take a representative sample of the cuttings pile.
3. Samples are to be collected in a clean plastic sample bag.
4. The Driller is to complete a Blasthole Sample Tag, tearing off the tag once completed and inserting it into sample bag.
5. The sample bag is to be tied off using ribbon.
6. In the case where multiple composite samples are to be taken from a single hole, the remaining cuttings after the sample are to be removed by the Driller so a clean new pile of cuttings can be formed.
7. Completed samples are to be left on the drill by the Driller. At the end of shift, the Mine Operations Pit Supervisor (or designate) will collect all samples and deliver them to the Bucking Room.

Bucking Room:

1. Each sample is to be transferred from the sample bag to a clean metal tray. The Blasthole Sample Tag is to be kept with the sample.
2. The sample is to be dried at 105°C.
3. The sample is then to be crushed in the Primary Crusher.
4. The sample is then to be crushed in the Fine Crusher.
5. The sample is to be split until the sample size is approximately 200 g.
    a. Reject from the sample is to be wasted.
6. The sample is then to be pulverized for 75 seconds.
7. The sample is to be placed in a pouch with the Blasthole Sample Tag stapled to the pouch.
8. If the pouch is a pit sample, it is to be sent to Assay Lab 1. If the sample is an ABA sample, it is to be sent to Assay Lab 2.

Assay Lab 1:

1. The Assay Lab is to run the sample through the atomic absorption analyzer which automatically transfers the copper (CU), non-sulphide copper (CUNS) and iron (FE) values into the LIMS database.
2. The samples for gold analysis are to be fire assayed and analyzed by atomic absorption which automatically transfers the gold (AU) value into the LIMS database.
3. The sample is then to be placed into storage. Pit samples are to be stored for 21 days.

Ore Control Technician 1:

1. Once assays have been entered into the LIMS database, the Ore Control Technician will review the data and roughly determine where in the blast any Mill Feed Ore will be located.

2. Once the Ore Control Technician drafts the Mill Feed Ore locations, the Ore Control Technician will evenly select holes in the non-Mill Feed Ore areas (including materials designated for ore stockpiles) at a ratio of one (1) sample per 20,000 t of rock. This equates to about one for every nine blast holes. Additional samples can be requested whenever additional data is desired for improving understanding of the geological conditions. An example of a sample layout is included as Figure 1.

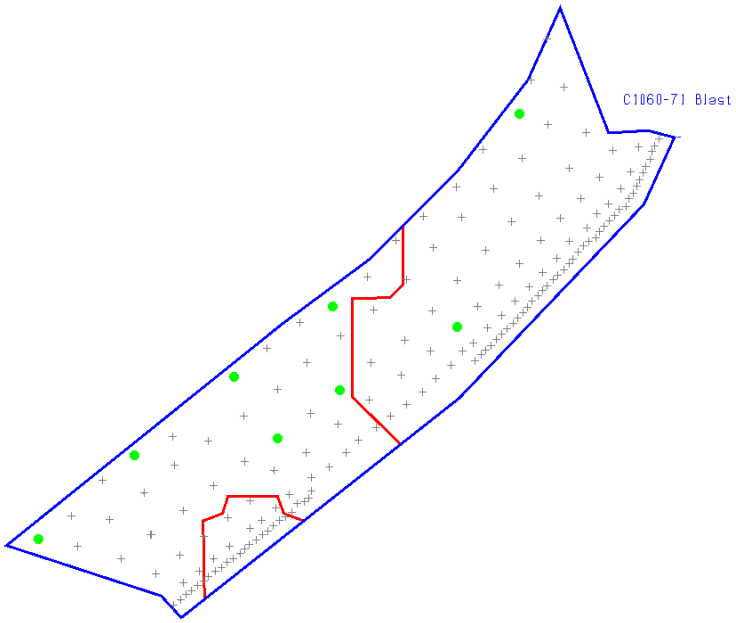

Figure 1: Location of ABA samples (green dots) within a blast. Red polygons denote mill feed ore, remainder is waste. The Ore Control Technician focuses sampling on areas which are designated waste and/or stockpile ore by the blasthole model. Reference blast = 149,173 t.

3. The Ore Control Technician is to then make an Analysis Request with the holes selected to the Assay Lab.

Assay Lab 2:

1. If the Assay Lab receives an Analysis Request, they will retrieve the sample pouch from storage, otherwise the sample will be delivered to the Bucking Room.
2. The Assay Lab will run the sample through the LECO CS230 Carbon Sulphur Analyzer.
3. Once analyzed, the machine transfers the carbon percentage (C%) and the sulphur percentage (S%) to a spreadsheet where NPR, NP and AP are calculated.
4. The NPR, NP, AP, C% and S% are transferred automatically to the LIMS database.
5. The sample is then to be placed into storage. ABA samples are to be stored for 14 days.

Ore Control Technician 2:

1. Once all the assays and ABAs have been entered into the LIMS database, the Ore Control Technician is to review the data and model the blast.
2. Modeling the blast

a. The software used is MineSight.
b. The model is based on a 5 metre (m) x 5 m x 12 m block system.
c. The block closest to the ABA sample will closely match the sample.
d. The blocks between the samples receive a weighted average of the sample carbon and sulfur grades.
e. Once each block gets the weighted C% and S%, then the AP, NP and NPR is calculated for each block.
f. Using the calculated NPR value, the model is to be coded as Ore/NAG/PAG by the Ore Control Technician and the resulting markup design is to be provided to the Surveyor.

3. The Ore Control Technician is responsible for the release of the final ore markup to the Surveyor. An example of a sample layout is included as Figure 2.

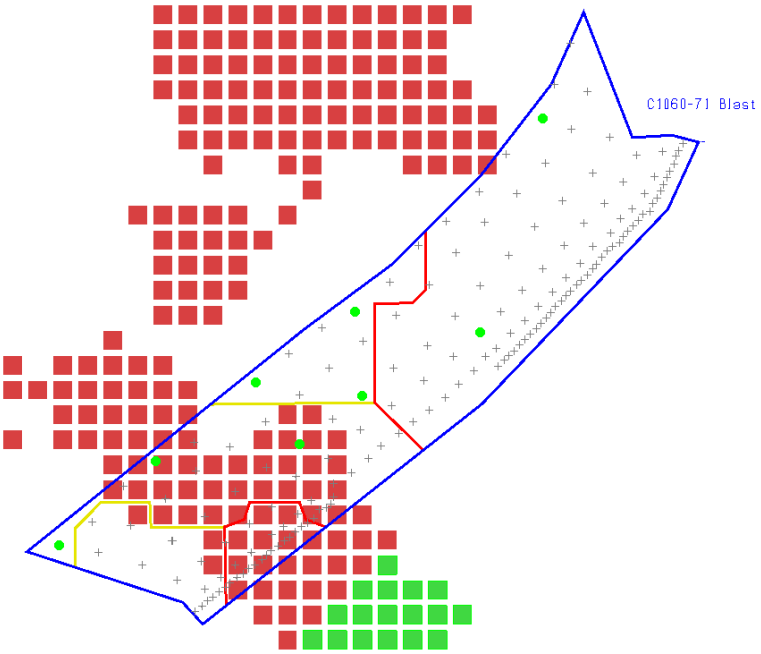

Figure 2. ABA results from samples shown in Figure 1 are used to update the blasthole PAG model item which identifies blocks which meet PAG criteria (red). The Ore Control Technician then marks up the PAG waste (yellow polygon) and the complete ore/waste markup is released to the Surveyor.

Surveyor:

1. The Surveyor will be responsible for the layout all Ore/NAG/PAG, as determined by the Ore Control Technician, in the field.

2. Using four (4) foot stakes spaced approximately 5 m apart, the Surveyor will mark out the contacts using marked placards.
   a. Red Placard = Mill Feed Ore
   b. Green Placard = Hi-Ox Ore
   c. Yellow Placard = PAG
   d. Blue Placard = NAG
   e. Pink Ribbon = High Grade Mill Feed Ore

f. Green Ribbon = Cariboo Stockpile Ore

3. Once complete, the Surveyor will print out maps of the area delineating material types for the shovel operator(s), and, if required, provide field verification of material types.

# MATERIAL HANDLING

Shovel/Haul Truck Operators:

1. The Shovel Operator will mine the rock, following the contacts laid out by the Surveyor.
2. The Shovel Operator will ensure that all material contained within the contact stakes is routed as described by the markup and that any uncertainty in material classification is resolved by seeking the assistance of either the Pit Supervisor or the Engineering Department.
3. Upon loading a haul truck, the Shovel Operator shall direct the Haul Truck Driver as to the material type being hauled, and destination, using a horn sequence. The Haul Truck Driver will then take the material to the designated area.

# IN-PIT MONITORING

Shovel Operator:

The Shovel Operator follows the staking of the Surveyor. Any material marked out as PAG is only to be hauled to approved locations. If a discrepancy is found, the Surveyor is to be called out to verify the material markup.

Pit Supervisor:

Throughout the shift, the Pit Supervisor will check in with the Shovel Operator and confirm the material type being loaded and that the destination is correct.

Haul Truck Driver:

If the Haul Truck Driver is uncertain of the material loaded, the Haul Truck Driver will confirm with the Shovel Operator or the Pit Supervisor.

Ore Control Technician:

The Ore Control Technician is to check Shovel Operator dig faces and confirm that the markup is appropriate and material is being routed appropriately.

Surveyor:

The Surveyor is to verify that material staking is visible and correct.

Environmental Department:

Once a month, the Environmental Department is to send a randomly selected drill hole pulp sample that MPMC ABA'ed to a third party laboratory (typically ALS Environmental in

Burnaby, BC) for metals analysis as an additional source of data to support site geochemical models.

Additionally, the Environmental Department takes water samples from all pit sumps to inform long-term geochemical predictions. Samples are collected as per MPMC-SOP-002: Surface Water Quality Monitoring. Monitoring locations and frequencies are regularly updated to reflect site developments and are included in the Operation, Maintenance, and Surveillance Manual.

# TAILINGS MONITORING

Mill Metallurgy

1. The Mill Metallurgy Department is to take a monthly composite sample of the tailings generated through the month.
    - Slurry is to be sampled every two (2) hours and made into a composite for the shift.
    - The shift composite is then to be added to a monthly composite.
    - At the end of the month, the monthly composite is to be given to the Bucking Room and prepared for an ABA sample.
2. The Environmental Department is to send the monthly tailings composite sample to a third party laboratory (typically ALS Environmental in Burnaby, BC) for metals analysis to provide data for site geochemical modelling.

# WASTE DUMP MONITORING

Environment Department

1. The Environmental Department is to take ABA grab samples on a weekly basis as per MPMC-SOP-016: ABA and Soil Sampling.
2. Seeps and contact water collected on site are sampled to provide data for site geochemical modelling. Samples are collected as per MPMC-SOP-002: Surface Water Quality Monitoring. The frequency and locations of these monitoring sites are updated regularly to reflect changes to the mine site and can be found in the Operation, Maintenance and Surveillance Manual.

# REVIEW OF RESULTS AND PROGRAM EFFICACY

Data collected and corresponding interpretation regarding the ML/ARD program are included in the Annual Environmental and Reclamation Report (AERR), due annually to the British Columbia Ministry of Environment and Ministry of Energy and Mines on March 31 of each year, reflective of the previous calendar year. The AERR includes sections on: waste rock characterization and disposal; drainage water quality monitoring; and, updates to long-term predictions (kinetic testing).

IMPERIAL METALS CORPORATION

# MPMC – SOP – 002:

# Surface Water Quality Monitoring

## Purpose

To monitor surface water quality in accordance with Permit11678, the Mount Polley QA/QC Binder, and the *BC Field Sampling Manual* and 2016 Comprehensive Environmental Monitoring Plan.

## Scope

This procedure outlines the surface water quality monitoring requirements that are the responsibility of MPMC Environmental Department staff.

## Introduction

All surface water sampling must be carried out in accordance with the *BC Field Sampling Manual*. This SOP outlines the procedure required to maintain compliance with the Manual and Permit 11678, including who is responsible for the sampling, and when monitoring needs to occur. A comprehensive list of all required sampling is available under Permit 11678 and 2016 Comprehensive Environmental Monitoring Plan. The specific work methods are found in *MPMC-WORK-002: Surface Water Quality Monitoring*.

Samples must be taken on or before Thursday, as they must be shipped to the laboratory in Burnaby by Thursday afternoon at the latest. Monthly and quarterly water quality samples are collected the first week of the month when possible.

At least one duplicate surface sample is taken per month along with either a field or a trip blank. The second mandatory duplicate may be taken at a far-field or groundwater site depending on sampling schedule.

# Responsibilities

## Environmental Superintendent/Coordinator:

- Ensure that the results of samples required under Permit11678 are reported in quarterly reports to MOE, in the Annual Environmental and Reclamation Report, which is submitted to MOE and MEM.
- Review sample results regularly to identify any QA/QC issues or water quality concerns.
- If a Permit 11678 or MMER discharge water quality guideline is exceeded, follow the reporting and follow-up monitoring requirements in MMER, Permit 11678, and the First Nations Communication Plan.

## Environmental Technologist/Technician:

- Coordinate the sampling schedule in accordance with the Annual Monitoring Plan (the Annual Monitoring Plan 2016 is provided in Appendix X).
- Ensure that samples are collected and handled in accordance with the *BC Field Sampling Manual*, the *MPMC-WORK-002: Surface Water Sampling*, and this document.
- Ensure samples are preserved, packed, and shipped according to *MPMC-WORK-004: Sample Preservation and Shipping*.
- Enter field data into the MP-5 database and/or spreadsheets on the Environmental network drive.

# Preparation

## Two Weeks Before Sampling:

- Make sure there is a sufficient sampling supplies and ice (for shipping) on site (refer to Appendix X – Sample Supplies Inventory Checklist).

## One Week Before Sampling:

- Arrange for second person to assist with sampling, as required.
- Plan for shipping of samples to ensure there is not a conflict with statutory holidays.

## On the Day of Sampling:

- Label all bottles and place in clear sample bags.
- Place sample bags in cooler(s) and label coolers accordingly.
- Place ice in the coolers along with the field blank set (if planned).
- Check all equipment required for sampling is functioning correctly and has sufficient battery life.
- Carry out any necessary equipment maintenance and calibrations as required by *MPMC-WORK-00:5 Data Collection Equipment*.
- Review the associated sampling Job Hazard Assessment, and complete and FLRA if necessary.
- Review safety concerns at individual sites if needed.
- Follow *MPMC-SOP-011: Check In and Check Out Procedure.*

# Procedure

## Collection:

- Collect all bottles and equipment necessary for sampling.
- Locate sampling locations using the Sample Locations Map (Appendix I), the Sample Site UTMs (Appendix II), and the Site Matrix (Appendix IV). Documents are also available in the Environmental Management System folder on the Environmental network drive.
- Carry out the in situ tests (as per *MPMC-WORK-005-1: WTW pH and Conductivity Meter* and *MPMC-WORK-005-7: NTU Meter*), preserve the samples and record keeping at each sample location in accordance with *MPMC-SOP-17: Record Keeping*.
- For each sample follow the guidelines as presented in the *BC Field Sampling Manual*.
- Place the samples in a cooler with ice.
- Upon returning to the lab, create a COC, and pack the coolers for shipping as per *MPMC-WORK-004: Water Sample Preservation and Shipping*.
- Ensure samples are collected on or before Thursday so that they may be shipped out to the lab in a timely manner.
- Enter field data into the MP-5 database and/or necessary spreadsheets on the Environmental network drive.
- Results from surface water samples required by Permit 11678 are to be submitted to MOE quarterly and annually (as part of the Annual Environmental and Reclamation Report).

For more specific surface water sample collection procedures, refer to *MPMC-WORK-002: Surface Water Sampling*.

# Documents and Records

- Surface water sample results are stored in the MP-5 database and on the Environmental network drive.
- Surface water sample results are to be submitted to MOE on a quarterly and annual basis.

IMPERIAL METALS CORPORATION

# MPMC – SOP – 016:
# ABA and Soil Sampling

## Purpose

To monitor the operational MPMC ARD/ML sampling and segregation program by collecting weekly waste rock samples (when PAG material is being mined), as per Permit M-200, and to assess the variability and suitability of reclamation materials on site, as per Permit M-200 and the *MPMC Soil Management Plan*.

## Scope

This procedure outlines the ABA and soil sampling requirements that are the responsibility of MPMC Environmental Department staff.

## Introduction

ABA grab samples are taken from active rock dumping sites; typical sample sites include, but are not limited to, active rock disposal sites, new road construction and road surfaces, and TSF construction. These samples are a randomized audit of detailed geological mapping done by MPMC geologists to ensure proper segregation and management of acid generating, PAG, and NAG materials. While Permit M-200 requires weekly samples only when PAG material is being mined, MPMC takes ABA grab sample weekly, regardless of the material being mined.

Soil samples are taken from stockpiles to monitor soil degradation and for characterization purposes prior application of soil to reclamation sites. All new soil stockpiles are to be sampled upon creation, and a site wide soil stockpile sampling program is to be carried out every 5 years. Additional soil sampling may be completed on progressive reclamation sites to monitor soil development.

Site specific soil surveys must be completed by a qualified professional for areas schedule to be disturbed by mine expansion. This is discussed in the *MPMC Soil Management Plan* and is beyond the scope of this document.

# Responsibilities

### Environmental Superintendent/Coordinator:

- Ensure that sampling is completed on a regular schedule, as required.
- Ensure that results are reported in the Annual Environmental and Reclamation Report, which is to be submitted to MOE and MEM.

### Environmental Technologist/Technician:

- Coordinate sampling schedule.
- Ensure that samples are collected and handled in accordance with *MPMC-WORK-016: Acid-Base Accounting and Soil Sampling*, and this document.

# Preparation

### On the Day of Sampling:

- Pre-select area(s) for soil samples to be taken (refer to *MPMC-WORK-016: Acid-Base Accounting and Soil Sampling* for details).
- Call Pit-Shifter and ask if any rock waste is being hauled, its location and if it is safe to enter the area (refer to *MPMC-WORK-016: Acid-Base Accounting and Soil Sampling* for details).
- Review the associated Job Hazard Assessment, and completed a FLRA if necessary.
- Ensure all workers have appropriate PPE and are fit for the task.
- Follow *MPMC-SOP-011: Check In and Check Out Procedure*.

# Procedure

### ABA Grab Sampling:

- Take a composite sample of a minimum of 1 kg of randomly selected material, as described in *MPMC-WORK-016: Acid-Base Accounting and Soil Sampling*, and place in clean sample bag.
- Record the GPS Coordinates, elevation and sample information in the field notebook as per *MPMC-SOP-17: Record Keeping.*
- Enter sample information into the spreadsheet on the Environmental Network Drive and submit an analysis request in LIMS.
- Tag and date sample bag.
- Deliver sample(s) to the Bucking Room.

### Soil Stockpile Sampling:

- Take a photo of the stockpile to document characteristics, including size and vegetative cover.
- Collect a composite sample from a minimum of three sub-sample locations in a clean, labelled, plastic sample bag, taking soil from the surface and at depth at each subsample location.
- Record the sample location GPS coordinates and record sample information in the field notebook as per *MPMC-SOP-17: Record Keeping.*
- Store samples in the refrigerator until they can be shipped to the analytical laboratory.

The detailed procedure is outlined in *MPMC-WORK-016: Acid-Base Accounting and Soil Sampling*.

### Soil Sampling of Reclamation Sites:

- Pre-select soil sample locations and record GPS coordinates.
- Collect a composite sample from minimum three locations at each site in a clean, labelled plastic sample bag, taking a representative sample from the entire soil profile at each location.
- Record sample information in the field notebook as per *MPMC-SOP-17: Record Keeping.*
- Store samples in the refrigerator until they can be shipped to the analytical laboratory.

A detailed procedure is outlined in *MPMC-WORK-016: Acid-Base Accounting and Soil Sampling;* however, it may need to be adapted for specific sampling objectives.

# Documents and Records

- ABA analysis results are recorded in the MPMC LIMS and into the spreadsheet on the Environmental Network Drive.
- All soil sample results are recorded on the Environmental network drive.
- ABA and Soil results are reported to MOE and MEM in the Annual Environmental and Reclamation Report.
