|---|---|---|---|
| **To:** | Ron Martel, Mount Polley | **Date:** | August 27, 2010 |
| **cc:** | | **From:** | Stephen Day |
| **Subject:** | Delay to Onset of Acidic Conditions for Springer Zone PAG Waste Rock<br>DRAFT | **Project #:** | 1CI008.000 |

## 1 Background

The proposed expansion of mining in Mount Polley Mine's Springer Pit will result in generation of PAG rock. A number of options are under consideration for management of this rock one of which would involve placement in a temporary stockpile prior to re-handling and permanent subaqueous disposal in the Springer Pit following completion of mining. It is important that the PAG waste rock is placed underwater before it becomes acidic so that ARD from the stockpile does not need to be managed, and the Springer Pit lake is not affected by acidic salts in the PAG waste rock as it becomes inundated.

This memorandum describes calculation of the delay to onset of acidic conditions for Springer Zone PAG waste rock.

## 2 Method

The delay to onset depends on two factors:

- The amount of acid neutralizing minerals; and
- The rate at which the acid neutralizing minerals are consumed.

The latter is dependent on the rate of acid generation from sulphide oxidation is proportional to the sulphide content. The ratio of consumption of acid neutralizing minerals compared to sulphate generation is also the critical NPR ($NPR_{crit}$).

These concepts can be brought together in the following equation:

$$t_{onset} = \frac{NPR_{rock}}{k.NPR_{crit}}$$

where k is the slope of the line (in $week^{-1}$) relating sulphide content (in mgS/kg) to oxidation rate (in mgS/kg/week).

## 3 Results

### 3.1 Calculation of $NPR_{crit}$

Site-specific values of $NPR_{crit}$ have previously developed using humidity cell data. Earlier estimates were hampered by a lack of testing on samples oxidizing fast enough to indicate the effect of acid

generation. Figure 1 shows the average ratio of release of calcium and magnesium (reflecting carbonate dissolution) to sulphate release (reflecting sulphide oxidation) compared to sulphate release for each test. The pattern of decreasing ratio as oxidation rate increases reflects the increasing influence of acid generation on carbonate dissolution. At lower oxidation rates, carbonate dissolution occurs by simple dissolution due to the high water volumes applied to humidity cells. The theoretical range of ratios is 1 to 2 which the trend approaches and is crossed for the Springer Zone sample with the highest oxidation rate.

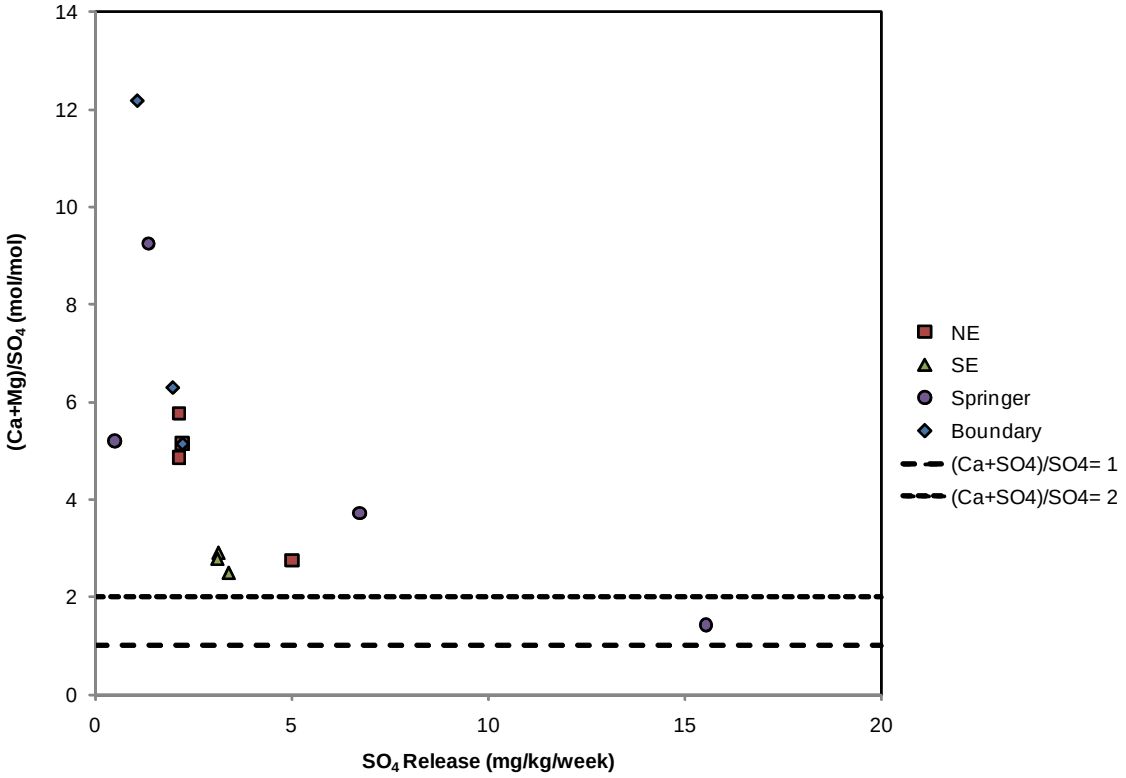

**Figure 1. Estimation of $NP_{crit}$ Values from Mount Polley Humidity Cells**

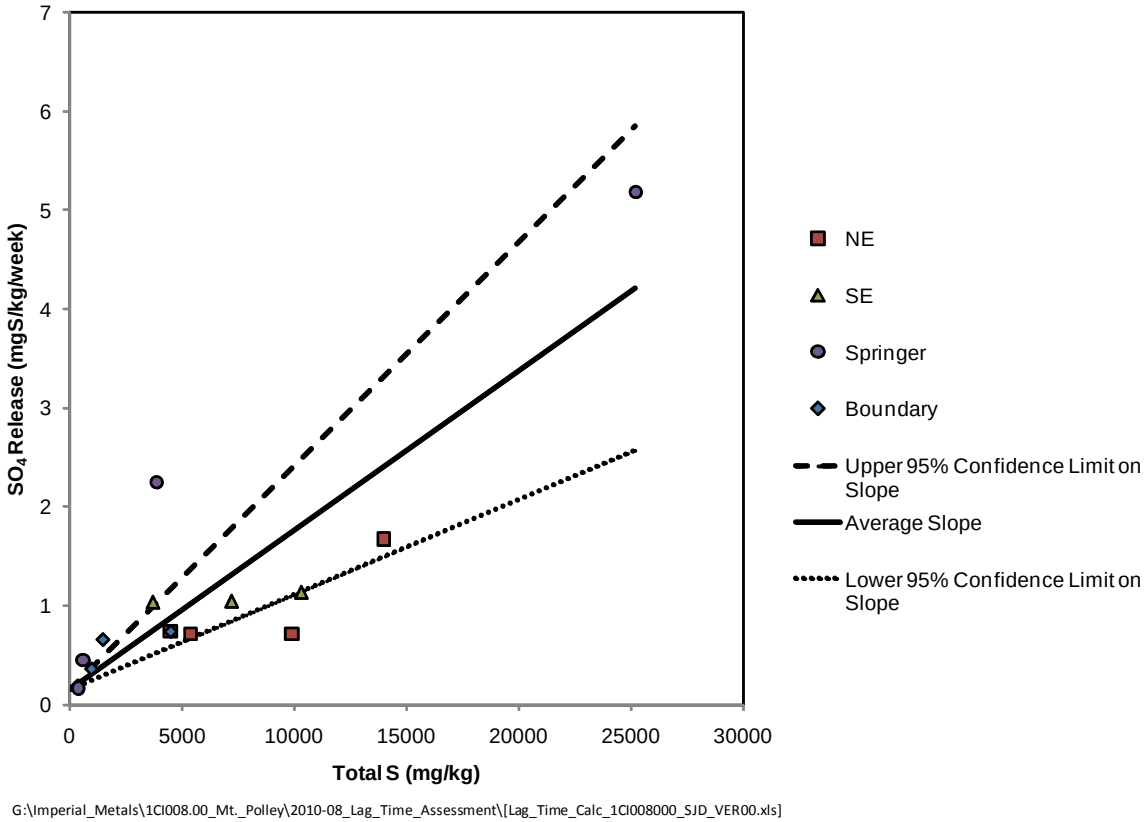
This evaluation supports the permit-specified value of $NPR_{crit}$ of 2 which is the upper end of the theoretical range. This value was adopted for subsequent calculations. Note that in the $t_{onset}$ calculation, higher values of $NPR_{crit}$ result in more rapid onset due to higher relative rates of NP consumption.

## 3.2 Calculation of k

The value of k is estimated from the average rates of sulphide oxidation indicated by the humidity cells compared to sulphide content (Figure 2). Overall data from Mount Polley show a strong positive correlation (r=0.85). The regression equation for the best fit is:

$$R_{SO_4} = 0.00016 \cdot S + 0.16$$

The intercept is non-negative but the 95% confidence limit for the intercept includes 0 mg/kg/week indicating the expected condition that when sulphur content is zero, the rate is also zero. The additional dashed lines indicate the 95% confidence limits on the regression slope of 0.00016 $week^{-1}$ which is 0.000096 to 0.00023 $week^{-1}$.



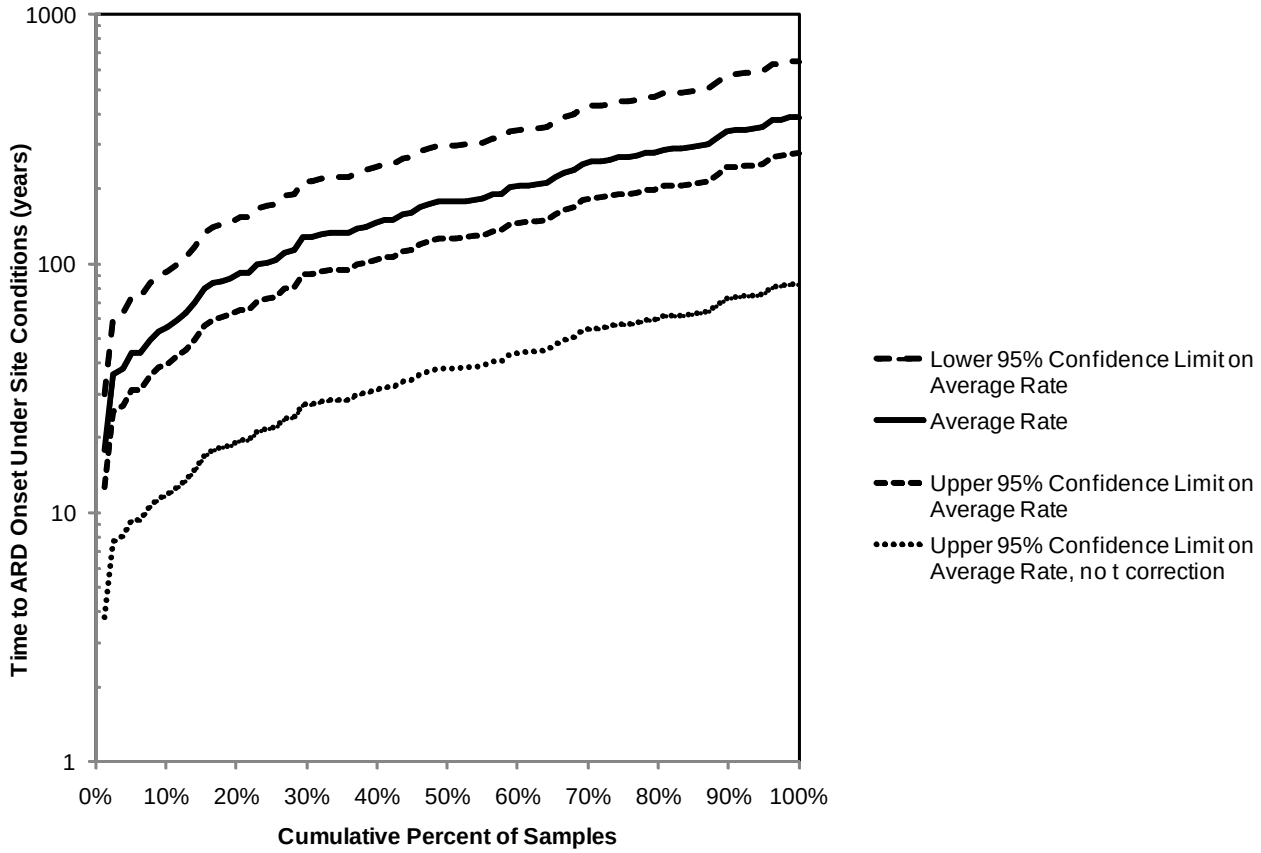


**Figure 2. Sulphur Content Compared to Oxidation Rate.**

## 4 Calculation of $t_{onset}$

The range of NPR indicated by blast hole and drill hole samples in the Springer Pit was used to estimate the distribution of $t_{onset}$ for PAG waste (Figure 3). The calculation is based on an $NPR_{crit}$ value of 3, the range of k values indicated above and a temperature correction of 0.3 to reflect slow reaction rates under cooler site conditions. For reference, the distribution at room temperature with the highest value is also shown. This line indicates the delay to onset for humidity cell tests.

G:\Imperial_Metals\1CI008.00_Mt._Polley\2010-08_Lag_Time_Assessment\[Lag_Time_Calc_1CI008000_SJD_VER00.xls]

**Figure 3. Distribution of $t_{onset}$ for PAG Waste Rock in Springer Pit**

The distribution for faster-reacting components represented by the lower dashed line indicates that about 2% of the rock might become acidic in 20 years, and 10% after 40 years. The majority of the rock with higher NPR might take over 100 years to become acidic. A number of factors complicate the actual estimate for higher NPR materials. Increasing acidification along with heating would result in accelerated oxidation and NP depletion though decreasing oxidation rates due to sulphide depletion and formation of secondary mineral coatings would result in lower oxidation rates and greater time to onset of acidic conditions.

## 5 Conclusion

This calculation indicates that PAG rock placed in stockpiles for a few years is not likely to become significantly acidic due to buffering provided by carbonate minerals.

Nitrogen Forms:

Assume 0 mg/L

Explanatory Notes

1 MPMC estimates PAG rock about 1050 masl is 18%. Acidification will be progressive.

2 Concentrations are "annual". Seasonal variation can be expected but these concentrations are intended to reflect seasonal worst for each case.

3 Concentations are dissolved.

4 Probabilities cannot be attached to the terms. Use the terms to assess proximity to trigger levels but not to assess probability of exceedance.

# Executive Summary

The Mount Polley Mining Corporation (MPMC) built four ore-grade rock stockpiles that are intended for processing to recover copper. *Mines Act* Permit M-200 contains a new condition to characterize the metal leaching and acid rock drainage (ML/ARD) potential of the stockpiles.

SRK Consulting (Canada) Inc. was retained by MPMC to develop a plan to characterize the geochemical stability of the ore stockpiles, including the following considerations:

- ARD potential using acid-base accounting data.
- Evaluation of element enrichment relative to other stockpiles.
- Evaluation of whether stockpile seepage chemistry can be expected to differ from existing drainage chemistry, using shake flask data as a proxy for stockpile seepage.

This report provides the results and interpretations from implementation of the ore stockpile geochemical characterization plan, which indicated that:

- The ore stockpiles have low ARD potential. It is not expected that acid conditions will develop in the stockpiles in the long term should they not be processed.
- Some differences between stockpiles were apparent (lower sulphide content of high oxide stockpile), but the bulk characteristics of the stockpiles are generally not significantly different from waste rock at the site with the exception of copper content which is elevated in the ore stockpiles.
- Contact water chemistry for the ore stockpiles is expected to be similar to waste rock with both being pH basic and chemistry controlled by secondary gypsum, primary calcite, iron oxides and copper oxides. Selenium may be more leachable from the ore stockpiles than waste rock though this depends on the mineralogical association of selenium.
- The presence of leachable selenium is a consideration for processing of the stockpiled ore. Operating conditions may result in a flush of selenium into process waters.

# 1 Introduction

The Mount Polley Mining Corporation (MPMC) built four ore-grade rock stockpiles at the Mount Polley Mine (MPM), located approximately 55 km north-east of Likely, British Columbia, between 2006 and 2014. The ore stockpiles total about 8 million tonnes and the MPMC plans to process these stockpiles to recover copper. *Mines Act* Permit M-200 contains a new condition to characterize the metal leaching and acid rock drainage (ML/ARD) potential of the stockpiles.

SRK Consulting (Canada) Inc. was retained by MPMC to develop a plan to characterize the geochemical stability of the ore stockpiles. The outcomes of implementation of the plan were to consider:

- ARD potential using acid-base accounting data.
- Evaluation of element enrichment relative to other stockpiles.
- In the absence of specific seepage from the stockpile, interpretation of shake flask data to determine if seepage chemistry for the stockpiles can be expected to be different from other existing drainage chemistry on site.

This report provides the results and interpretations from implementation of the plan by MPMC personnel.

# 2 Background

## 2.1 Solids Geochemistry

The ore characterization plan provided a summary of the geological and geochemical characteristics expected in the ore stockpiles (SRK 2015). In summary, the main features of the Mount Polley deposit are:

- The deposit is classified as an alkalic porphyry copper gold deposit (BC MINFILE No. 093A 008).
- The host rocks for porphyry mineralization are intrusions into the Nicola Volcanics varying in composition from diorite to syenite.
- Sulphide mineralization is predominantly chalcopyrite ($CuFeS_2$) and pyrite ($FeS_2$), with lesser bornite ($Cu_5FeS_4$), covellite (CuS), and digenite ($Cu_9S_5$).
- Carbonate mineralization is principally calcite, with occurrences of malachite ($Cu_2CO_3(OH)_2$); iron carbonates have not been reported.
- A significant portion of the copper at the MPM is not associated with sulphides (upwards of 50% in the upper portions of each pit).

The characteristics of the four ore stockpiles as provided by MPMC are summarized in Table 2-1. The relative locations of the stockpiles are shown in Figure 2-1. More than 50% of stockpiled ore is contained in the High-Oxide Stockpile which originated from the oxide cap of the Springer Zone. Stockpile #1 also originates from the Springer Zone but has lower copper grade dominated by copper sulphide (oxide ratio 18%). The other two stockpiles (#3 and Cariboo) originated from the Cariboo and Bell Zones. The maximum age of the stockpiled rock is 9 years.

SRK's current assessment of site data is that there is no correlation between copper grade and ARD potential. ARD potential at Mount Polley reflects the balance between sulphide as pyrite and calcite which is not correlated with the presence of copper sulphide. For this reason, the designation of rock as ore means that its ARD potential is not expected to be different from waste rock.

**Figure 2-1: Location of Ore Stockpiles. The figure is approximately 1.7 km across (Source: MPMC)**

**Table 2-1: Description of Ore Stockpiles**

| Stockpile | Primary Source | Approximate Construction Time | Mass tonnes | Total Copper (%) | Oxide Copper (%) | Oxide Ratio |
|---|---|---|---|---|---|---|
| #1 Stockpile | Springer - Low Oxide | 2008-2014 | 1,200,000 | 0.26 | 0.047 | 18% |
| #3 Stockpile | Cariboo/Bell | 2006-2007 | 1,900,000 | 0.26 | 0.12 | 44% |
| High-Oxide Stockpile | Springer - Oxide Cap | 2007-2009 | 4,100,000 | 0.35 | 0.26 | 76% |
| Cariboo Stockpile | Cariboo | 2014 | 730,000 | 0.19 | 0.066 | 36% |
| *Total* | | | *8,000,000* | *0.30* | *0.18* | *56%* |

Note: values rounded to two significant figures.

## 2.2 Aqueous Geochemistry – Seep Sampling

Results from seep sampling from across the site (not specifically ore stockpiles) at seven different locations between 2010 and 2014 were provided to SRK as part of this assessment. Table 2-2 is a statistical summary of results for parameters with guidelines for the protection of freshwater aquatic life in British Columbia (BC FAL guidelines) and also concentrations above detection limits in the seep samples and laboratory testing.

**Table 2-2: Statistical Summary of Selected Parameters in Mount Polley Seep Samples.**

| Statistic | pH (field) | Alkalinity mg $CaCO_3$/L | Sulphate mg/L | Nitrate mg/L | As mg/L | Ba mg/L | Ca mg/L | Cu mg/L | Fe mg/L | Mo mg/L | Se mg/L |

# 3 Methods

## 3.1 Sample Collection

Samples were collected from test pits in each of the ore stockpiles by MPMC personnel under direction by SRK. Six test pits per stockpile were spread evenly over the dump platform of each of the three smaller stockpiles (#1, #3 and Cariboo). Twelve test pits were sampled in the larger oxide stockpile. Thirty-three samples were collected using a backhoe to excavate to a depth of approximately two metres. Each sample was 5 kg.

During excavation, MPMC geologists documented distinctive features such as differences in rock types and degree of oxidation. Distinctive materials were segregated into piles by the test pit, photographed and logged for:

- Sulphide content.
- Copper oxide content as indicated by green and blue colours.
- Iron oxide content as indicated by red-brown colouration.
- Reaction of rock fines with 10% hydrochloric acid (degree of fizz) rated as none, moderate or strong.
- Any other mineral precipitates (such as gypsum).

Field observations are provided in Appendix A.

## 3.2 Laboratory Analysis

Samples were shipped by MPMC to ALS Environmental in Burnaby, BC.

Following drying, each sample was split into two parts. One part was sieved to yield the -2 mm fraction which is assumed to represent the more reactive component of the rock. This fraction was analysed as follows:

- Moisture content.
- Rinse pH and conductivity.
- Total sulphur and sulphur as sulphate (hydrochloric acid leach).
- Total carbonate and modified neutralization potential.
- Ultra-trace level 51 element scan by ICP-MS and ICP-AES following aqua regia digestion.

Based on review of the results obtained, a sub-set of samples were selected by SRK for shake flask extraction (SFE) tests as per the MEND (2009) method. Two samples per stockpile were selected on the basis of high selenium content and high electrical conductivity values within their stockpile. Samples with high selenium content were chosen in order to obtain conservative results for leachable components.

SFE leachates were analysed for:

- pH
- Conductivity
- Leachable anions and nutrients
  - Alkalinity
  - Nitrate
  - Sulphate
  - Chloride

  - Total phosphate
- Leachable Metals
  - 33 element scan by collision reaction cell (CRC) ICP-MS
  - Mercury by CVAFS

Laboratory reports are provided in Appendix B.

## 3.3 Interpretation Methods

### 3.3.1 ARD Potential

ARD potential was evaluated using the neutralization potential ratio (NPR) calculated from total inorganic carbon (TIC) as a proxy for reactive (calcium and magnesium) carbonate content, and acid potential (AP) calculated from sulphide content:

$$\text{NPR} = \frac{\text{TIC}}{\text{AP}}$$

Potentially ARD generating (PAG) rock is indicated by NPR≤2.

### 3.3.2 Element Enrichment

Element enrichment relative to other waste rock stockpiles (as indicated by previous analysis of drill cores) was evaluated by calculating confidence limits on mean concentrations for selected parameters and considering overlap in the resulting ranges. 95% confidence limits were calculated conventionally using standard error and a Student's t-statistic.

### 3.3.3 Interpretation of Shake Flask Leachate Chemistry

Concentrations in shake flask leachate chemistry must be corrected to address the high dilution factor (3 L/kg) relative to full-scale conditions. To interpret concentrations obtained by the method, it was assumed that natural moisture in the sample is in equilibrium with sample solids, and that the extraction test dilutes this contact water. Using this assumption, concentrations in the contact water ($[C]_{contact}$) can be calculated from the moisture content of the sample using the following equation:

$$[C]_{\text{contact}} = \frac{[C]_{\text{SFE}}\,(\text{mg of C/L of water}) \times V_{\text{SFE}}\,(\text{L of water})}{M_{\text{SFE}}\,(\text{kg of rock})} \times \frac{1000\ \text{g of water/L of water}}{u(\text{g of } H_2O/100\ \text{g of rock}) \times 10(100\ \text{g/ kg})}$$

$[C]_{SFE}$ is the concentration of an ion in the SFE leachate obtained by leaching $M_{SFE}$ rock using $V_{SFE}$ of water. The gravimetric water content is u expressed as a percentage.

The resulting up-scaled concentrations were evaluated using PHREEQC (Parkhurst and Appelo 1999) to determine mineral saturation indices (SIs). If the resulting SIs are near 0, it is likely the contact water is in equilibrium with the secondary minerals. If the SIs are well above 0, it is interpreted that the extraction test is leaching additional load from the solids during the procedure.

## 3.4 Quality Assurance and Quality Control

The QA/QC checks and their associated outcomes are outlined in Table 3-1. SRK's assessment was that the quality of the analytical data was acceptable, pending duplicate outcomes (described in Table 3-1).

**Table 3-1: Summary of QA/QC Checks and Outcomes**

| Parameter | Criterion | Result |
|---|---|---|
| Sulphur balance | Total Sulphur ≥ Sulphate Sulphur, for samples >10X DL. | Passed |
| Neutralization potential consistent with fizz test | NP does not exceed maximum NP indicated by acid strength and acid volume indicated by fizz. | Passed |
| Neutralization potential consistent with carbonate content | NP correlated with carbonate and values near parity. | Passed |
| Field Duplicates | Relative percent difference (RPD) better than about ±30% for levels >10 times limit of detection (LOD). | In-progress. |
| Leachate Ion Balance | Imbalance not greater than ±10%. | Passed |

Source: P:\01_SITES\Mt_Polley\1CI008.005_2015_ReStart_Source_Terms\!080_Deliverables\2015-08_Stockpile_SFE\[StockpileSFE_1CI008005_REV02.xlsx]

# 4 Results and Discussion

## 4.1 Test Pit Sampling

The majority of test pits showed homogeneous material and there was no segregation into distinctive material types. There were three exceptions that showed two distinct materials, and two samples were taken at the following locations:

- Cariboo SP-14
- #1 SP-21
- High Oxide SP-7

A duplicate was taken from the Cariboo, #1, and High Oxide stockpiles as part of quality assurance and quality control measures.

Overall, material properties were comparable between the piles. The main rock type as described by MPM geologists was monzodiorite with variations to monzonite. Sulphides were generally absent and only observed some of the time in minor amounts. Secondary minerals included malachite in minor to moderate amounts in all samples, with iron oxide distribution following a similar distribution. All samples showed moderate to strong HCl fizz test reaction. This was consistent with calcite observed in all but one sample.

## 4.2 Assessment of ARD Potential

### 4.2.1 Sulphur Form

Sulphate-sulphur concentrations were near or below the limit of detection for all samples, therefore; total sulphur was used to represent sulphide content in the stockpiles, which is consistent with the known mineralogy at the site.

Sulphur content ranged from a minimum of 0.01% to a maximum of 0.62%, with an overall average value of 0.15% (Table 4-1). The High Oxide Stockpile had the lowest average sulphur content (0.04%) which was statistically different from the #1 and #3 stockpiles (Table 4-1). These latter stockpiles had higher sulphur contents which were not statistically different from each other.

**Table 4-1. 95% Confidence Limits on Means for Selected Parameters**

### 4.2.2 Carbonate Content and Neutralization Potential

Carbonate and neutralization potential (NP) results are summarized in Table 4-2.

Total inorganic carbon (TIC) ranged from a minimum of 4.2 to a maximum of 93 kg $CaCO_3$/t, with an average value of 29 kg $CaCO_3$/t. The High Oxide Stockpile had the lowest average TIC

(21 kg $CaCO_3$/t), whereas as the #1 Stockpile had the highest average TIC (43 kg $CaCO_3$/t). TIC averaged 31 kg $CaCO_3$/t for the Cariboo Stockpile and 29 kg $CaCO_3$/t for the #3 Stockpile.

Modified NP determined by titration was always greater than TIC as shown in Figure 4-1. The higher modified NP compared to TIC is attributed to weakly reactive silicates that would consume acid during testing, but may not provide neutralization capacity under field conditions. TIC was used for buffering potential in this assessment because it is a proxy for acid neutralizing carbonate minerals. Iron carbonates, which do not consume acid, have not been documented at the MPM.

P:\01_SITES\Mt_Polley\1CI008.005_2015_ReStart_Source_Terms\!080_Deliverables\2015-08_Stockpile_SFE\[StockpileSFE_1CI008005_REV01.xlsx]

**Figure 4-1: Comparison of Modified NP and Total Inorganic Carbon**

### 4.2.3 Acid Rock Drainage Potential

Paste pH values (Table 4-2) for all samples taken were basic, indicating that net acidity had not developed in any of the samples at the time of sampling. This is also consistent with the presence of abundant calcite and malachite observed during test pit sampling.

Based on NPR calculated as described in Section 3.3.1, all but one sample (#3 Stockpile-27, with NPR = 1.4) were determined to be non-PAG.

Based on the samples collected in this assessment, the ARD potential for the ore stockpiles is low.

## 4.3 Element Enrichment

Confidence limits on mean concentrations for selected elements are shown in Table 4-1 by stockpile and compared to other zones. For the stockpiles, a statistically significant difference is apparent for #1 which has distinctively higher selenium concentrations. The lower confidence limit is 3.9 mg/kg compared to the highest upper confidence limit of 3.7 mg/kg for the Cariboo stockpile.

Compared to other zones waste rock samples, copper concentrations are clearly enriched, which is consistent with the classification of the stockpiles as ore. Other than for copper, the Southeast Zone and Pond Zone had lower average selenium concentrations than the #1 and #3 stockpiles. There is some indication of subtle differences for arsenic, such as the lower arsenic concentrations for the Southeast Zone compared to the Cariboo stockpile. However, there is a lack of strong (e.g. order-of-magnitude) differences for any of the parameters. Variability in element content is not expected to generally influence drainage chemistry.

## 4.4 Contact Water Chemistry

### 4.4.1 Shake Flask Results

Shake flask extraction (SFE) test results for parameters with BC FAL guidelines and above analytical detection limits are shown in Table 4-3.

The SFE leachates had pHs near 9 for most samples, which is higher than is typical of carbonate-buffered waters in equilibrium with the atmosphere (closer to pH 8.6). The elevated pHs may reflect abrasion of silicate minerals during sample processing (drying and sieving) and shaking in the extraction procedure. Hydrolysis of abraded silicate surfaces yields hydroxyl ions ($OH^-$) that result in higher pHs. The higher pHs are potentially important for interpreting leaching of oxyanions such as selenium and arsenic.

Leachate chemistry was dominated by sulphate, alkalinity and calcium, with lesser amounts of sodium, silicon, potassium and magnesium. Sulphate was significantly correlated with bulk rock sulphur content at the 99% confidence level (r = 0.87) implying that it is derived from oxidation of pyrite rather than a primary sulphate mineral.

### 4.4.2 Interpretation

#### Upscaled Concentrations

Results of applying the SFE upscaling methodology described in Section 3.3.3 yielded the results shown in Table 4-4.

Raw SFE sulphate concentrations were in the tens of mg/L (Table 4-3) which, based on concentration factors of about 100, became scaled up concentrations in the thousands of mg/L. PHREEQC indicated that these concentrations were generally consistent with moisture being in equilibrium with gypsum (calcium sulphate dehydrate) because saturation indices were close to 0. Barite (barium sulphate) saturation indices in contrast were well above 0, implying that raw

barium concentrations in the SFE leachates resulted from equilibration of weakly soluble barite with the SFE leachates, and therefore that barium concentrations in the contact water are not at the levels indicated by the calculation.

Following similar interpretation approaches, alkalinity and calcium concentrations in the raw SFE leachates reflect dissolution of calcite during the procedure because up-scaled concentrations yielded saturation indices well above 0. Scaled up copper concentrations appear to realistically reflect rock moisture equilibration with copper carbonate (malachite) and oxide (tenorite) as shown by saturation indices near 0.

Scaled up concentrations for three elements occurred as oxyanions (As, Mo, Se) are shown. Molybdenum concentrations were assessed using saturation indices for calcium molybdate. Since saturation indices were typically between 0 and 1, upscaled molybdenum concentrations may realistically reflect molybdenum concentrations in pore waters. In addition, since upscaled calcium concentrations are probably in reality controlled by calcite, $CaMoO_4$ saturation indices would decrease.

Arsenic and selenium concentrations are not readily assessed with respect to known secondary minerals in this geological setting because they occur as trace elements. Mobile arsenic probably occurs as a trace component of secondary iron oxides or adsorbed to the secondary oxides; however, iron oxides have low solubility at these pHs as shown by undetected iron concentrations in the shake flask leachates (<0.03 mg/L). Saturation indices for iron oxides are not shown in Table 4-4 but are well above 0. Scaled up arsenic concentrations therefore do not realistically represent concentrations in contact water and pore water arsenic concentrations are not expected to exceed those shown in the raw SFE leachates (Table 4-3).

Scaled up selenium concentrations approached 3 mg/L. Selenium may occur as a trace component of secondary sulphate (gypsum, barite) or in association with iron oxide (either adsorbed or co-precipitated). If associated with gypsum, the up-scaled selenium concentrations reflect concentrations in the contact water because the water chemistry appears to be controlled by gypsum dissolution. If barite is the host, the low solubility of barite would limit Se concentrations to those observed in the raw SFE leachates (approximately two orders of magnitude below those indicated by scale-up).

If selenium is being leached by de-sorption, concentrations may be controlled by several factors (pH, kinetics of de-sorption, distribution coefficients for the solutions). Due to the elevated pH, selenium leaching may be unrealistically accelerated compared to natural conditions resulting in elevated raw and upscaled concentrations.

**Comparison with Observed Seepage Chemistry**

Raw (Table 4-3) and upscaled pore water (Table 4-4) concentrations for selected parameters were compared to observed seep chemistry (Table 2-2). For the latter, concentrations at the 95$^{th}$ percentile and higher probably reflect the least dilution and are therefore the relevant comparison point for the SFE data.

**Table 4-3: Summary of SFE Leachate Concentrations**

Source: P:\01_SITES\Mt_Polley\1CI008.005_2015_ReStart_Source_Terms\!080_Deliverables\2015-08_Stockpile_SFE\[StockpileStatics_1CI008005_REV03_SJD.xlsx]

Observed sulphate concentrations in seeps are comparable to up-scaled concentrations. Highest seep concentrations were above 1000 mg/L which approaches gypsum saturation though some dilution is indicated. Likewise, pH and alkalinity concentrations are consistent with control by calcite dissolution. Iron has been generally undetected (<0.03 mg/L) in seeps with 95th percentile concentrations at 0.06 mg/L. These concentrations are consistent with the low solubility of iron oxides at basic pHs.

95$^{th}$ percentile copper concentrations in seeps are 0.04 mg/L ranging up to 0.5 mg/L as a maximum concentration compared to 0.1 to 1 mg/L for upscaled concentrations. Considering that seeps reflect some dilution (as indicated by sulphate concentrations), the upscaled concentrations are comparable to the seeps.

Higher arsenic concentrations in seeps show a narrow range from 0.001 to 0.003 mg/L which are comparable to the raw concentrations from SFE (0.002 to 0.007 mg/L) indicating control by the low solubility of secondary iron oxides as described above.

Higher molybdenum concentrations likewise show a narrow range from 0.1 to 0.3 mg/L. This concentration range is between that of the raw SFE leachates (0.02 to 0.05 mg/L) and upscaled concentrations (1 to 7 mg/L). Molybdenum concentrations in the stockpile rock averaged 9 mg/kg and are therefore probably associated with iron oxides rather than discrete mineral phases. Leaching of molybdenum may therefore be controlled by iron solubility rather than solubility of calcium molybdate.

Likewise, seep selenium concentrations of about 0.1 to 0.2 mg/L are between the range indicated for the raw SFE leachates (0.002 to 0.02 mg/L) and the upscaled concentration range of 0.2 to 3 mg/L. At these pHs, and oxidizing conditions, selenium is expected to be mobile as the selenate ion ($SeO_4^{2-}$) resulting in the conclusion that the ore stockpiles may leach selenium at higher concentrations than waste rock. The presence of leachable selenium is also a consideration for the influence of processing oxide ore on process water chemistry.

# 5 Conclusions

The following are concluded:

- The ore stockpiles have low ARD potential. It is not expected that acid conditions will develop in the stockpiles in the long term should they not be processed.
- Some differences between stockpiles were apparent (lower sulphide content of high oxide stockpile) but the bulk characteristics of the stockpiles are generally not significantly different from waste rock at the site with the exception of copper content which is elevated in the ore stockpiles.
- Contact water chemistry for the ore stockpiles is expected to be similar to waste rock with both being pH basic and chemistry controlled by secondary gypsum, primary calcite, iron oxides and copper oxides. Selenium may be more leachable from the ore stockpiles than waste rock though this depends on the mineralogical association of selenium.
- The presence of leachable selenium is a consideration for processing of the stockpiled ore. Operating conditions may result in a flush of selenium into process waters.

# CERTIFICATE VA15101982

Project: One Stockpile Project 2015

This report is for 33 Sediment samples submitted to our lab in Vancouver, BC, Canada on 7-JUL-2015.

The following have access to data associated with this certificate:

| | | |
|---|---|---|
| MCLEAN DONOHOE | COLLEEN HUGHES | |

## SAMPLE PREPARATION

| ALS CODE | DESCRIPTION |
|---|---|
| WEI-21 | Received Sample Weight |
| LOG-22 | Sample login - Rcd w/o BarCode |
| OA-GRA10b | Moisture - Bulk Samples |
| PUL-QC | Pulverizing QC Test |
| PUL-31 | Pulverize split to 85% <75 um |
| SCR-51 | Screening |
| SPL-21 | Split sample - riffle splitter |

## ANALYTICAL PROCEDURES

| ALS CODE | DESCRIPTION | INSTRUMENT |
|---|---|---|
| S-GRA06a | Sulfate Sulfur (HCl leachable) | WST-SEQ |
| S-CAL06 | Sulfide Sulfur (calculated) | LECO |
| C-GAS05 | Inorganic Carbon (CO2) | |
| OA-ELE04 | Specific Conductivity 1:10 | |
| ME-MS41 | 51 anal. aqua regia ICPMS | |
| OA-VOL08mn | NP MEND 1991 | |
| S-IR08 | Total Sulphur (Leco) | LECO |
| OA-ELE07 | Paste pH | |
| S-GRA06 | Sulfate Sulfur-carbonate leach | WST-SEQ |

To: **MOUNT POLLEY MINING CORPORATION**

# CERTIFICATE OF ANALYSIS VA15101982

## CERTIFICATE COMMENTS

### ANALYTICAL COMMENTS

Applies to Method: Gold determinations by this method are semi- quantitative due to the small sample weight used (0.5g).
ME- MS41

### LABORATORY ADDRESSES

Applies to Method: Processed at ALS Vancouver located at 2103 Dollarton Hwy, North Vancouver, BC, Canada.

# Reference Information

**QC Samples with Qualifiers & Comments:**

| QC Type Description | Parameter | Qualifier | Applies to Sample Number(s) |
|---|---|---|---|
| Matrix Spike | Calcium (Ca)-Leachable | MS-B | L1672948-1, -2, -3, -4, -5, -6, -7, -8 |
| Matrix Spike | Magnesium (Mg)-Leachable | MS-B | L1672948-1, -2, -3, -4, -5, -6, -7, -8 |
| Matrix Spike | Silicon (Si)-Leachable | MS-B | L1672948-1, -2, -3, -4, -5, -6, -7, -8 |

**Qualifiers for Individual Parameters Listed:**

| Qualifier | Description |
|---|---|
| MS-B | Matrix Spike recovery could not be accurately calculated due to high analyte background in sample. |

**Test Method References:**

| ALS Test Code | Matrix | Test Description | Method Reference** |
|---|---|---|---|
| **ALK-SHKFLSK-PCT-VA** | Soil | Alkalinity by PCT (SHAKEFLASK) | BC MINISTRY OF ENERGY AND MINES |

TThis analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter and analysed using procedures adapted from APHA Method 2320 "Alkalinity".

**CL-SHKFLSK-IC-VA** Soil Chloride by IC (SHAKEFLASK) BC MIN. OF ENERGY AND MINES/APHA 4110 B.

This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter. The analysis is carried out using procedures adapted from APHA Method 4110 B. "Ion Chromatography with Chemical Suppression of Eluent Conductivity" and EPA Method 300.0 "Determination of Inorganic Anions by Ion Chromatography". Anions routinely determined by this method include: bromide, chloride, fluoride, nitrate, nitrite and sulphate.

**EC-SHKFLSK-PCT-VA** Soil EC by PCT (SHAKEFLASK) BC MINISTRY OF ENERGY AND MINES

This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter and analysed using procedures adapted from APHA Method 2510 "Conductivity".

**HG-SHKFLSK-CVAFS-VA** Soil Mercury by CVAFS (SHAKEFLASK) BC MINISTRY OF ENERGY AND MINES

This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter and analysed using cold vapour atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).

**MET-SHKFLSK-MS-VA** Soil Metals by ICPMS (SHAKEFLASK) BC MINISTRY OF ENERGY AND MINES

This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter and analysed using inductively coupled plasma - mass spectrophotometry (EPA Method 6020A).

**MOISTURE-VA** Soil Moisture content ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

**NO3-SHKFLSK-IC-VA** Soil Nitrate by IC (SHAKEFLASK) BC MIN. OF ENERGY AND MINES/APHA 4110 B.

This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter. The analysis is carried out using procedures adapted from APHA Method 4110 B. "Ion Chromatography with Chemical Suppression of Eluent Conductivity" and EPA Method 300.0 "Determination of Inorganic Anions by Ion Chromatography". Anions routinely determined by this method include: bromide, chloride, fluoride, nitrate, nitrite and sulphate.

**PH-SHKFLSK-MAN-VA** Soil pH by Manual Meter (SHAKEFLASK) BC MINISTRY OF ENERGY AND MINES

This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently analysed using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode.

**SO4-SHKFLSK-IC-VA** Soil Sulfate by IC (SHAKEFLASK) BC MIN. OF ENERGY AND MINES/APHA 4110 B.

This analysis is based upon the extraction procedure outlined in "Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND Report 1.20.1)" (William A. Price, 2009). In summary, a sample is extracted with deionized water at a 3:1 liquid to solids ratio for 24 hours. The extract is then allowed to settle and subsequently filtered through a 0.45 micron membrane filter. The analysis is carried out using procedures adapted from APHA Method 4110 B. "Ion Chromatography with Chemical Suppression of Eluent Conductivity" and EPA Method 300.0 "Determination of Inorganic Anions by Ion Chromatography".

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

*The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:*

## Appendices

Appendix A Heap Leach Facility Geochemical Characterization Plan

# 1 Introduction

Mount Polley Mining Corporation (MPMC) retained SRK Consulting (Canada) Inc. (SRK) to develop a plan to decommission the Test Heap Leach Facility at Mount Polley Mine. The plan is a requirement under MPMC's amalgamated Mines Act Permit M-200 (EMLI 2020) s. D3(c)(v) and must be submitted to the BC Ministry of Energy, Mines and Low Carbon Innovation (EMLI) by June 30, 2021. Specifically, the M-200 condition reads:

> *The Permittee shall provide a report that includes a detailed plan and timeline for the removal of the test heap leach facility and all stockpiled sulphur by June 30, 2021, to the satisfaction of the Chief Inspector. The Permittee shall ensure the plan includes, but is not limited to, the removal and disposal of the leached ore, sulphur stockpile, waste rock, contaminated soil, reagents or chemicals, and all associated infrastructure.*

The plan should also include an approach to identify and remediate any contaminated material beneath the facility. No timeline for disposal is provided in the M-200 Permit.

Results from testing were not available in time for the June 30, 2021 submission deadline. In the interim, the geochemical characterization program, detailed in SRK (2021) and provided as Appendix A, was submitted.

## 1.1 Development of the Plan

Management strategies for each material were established based on Geochemical Conceptual Models (GCMs) developed for each of the waste types currently stored in the Test Heap Leach Facility. They were developed using existing information, geochemical first principles, and experience. GCMs are an effective way to capture the key geochemical reactivity considerations for the Test Heap Leach Facility and how its reactivity may be impacting water quality on site now, and how it may do so in the future under various long-term storage scenarios.

Material characteristics and reactivity were evaluated through observations, sampling, testwork, and interpretation. Results were presented during a virtual options analysis with Mount Polley Mine personnel and SRK geochemists in attendance. Potential disposal options were discussed based on short- and long-term impacts, as well as time and cost considerations.

Disposal options selected during this workshop formed the basis for the management plan of each material.

## 1.2 Structure of the Plan

Section 2 describes the location, background, and materials inventory of the Test Heap Leach Facility.

Geochemical characterization for each material stored on the Test Heap Leach Facility is described in Section 3. The geochemical characterization program was detailed in SRK (2021) and was designed to address data gaps identified during the development of the GCMs for each material. Remedial and

disposal options for each material are presented in Section 6. Potential risks identified are presented along with mitigation strategies.

Material disposal and management criteria are presented in Section 7. Reagents, chemicals, and all associated infrastructure, including the leach pad liner, that need to be removed were not considered in the geochemical characterization program, as this program focused on material reactivity and disposal. Disposal of these components is also presented in Section 7.

# 2 Overview of the Test Heap Leach Facility

## 2.1 Location

The Test Heap Leach Facility is located on top of the East Rock Disposal Site (East RDS) and includes the lined heap leach pad, operations building, and former sulphur stockpile footprint (Figure 1).

## 2.2 Background

The pilot-scale high-density polyethylene (HDPE) double-lined Test Heap Leach Facility was constructed in 2007 for research into leaching non-sulphide copper ore. From 2006-2008, approximately 11,000 $m^3$ of elemental sulphur was procured for sulphuric acid production for the heap leach trial. Between 2007 and 2012, different layering and blending techniques of ore and sulphur were tested to optimize leaching. In 2012, the Test Heap Leach Facility was placed into Care and Maintenance due to economic considerations but was not loaded out prior to shut down. Roughly 7,000 $m^3$ of ore mixed with elemental sulphur remain on the leach pad. The heap leach pad also contains metal-contaminated soils from an off-site disposal clean-up. Approximately 19,000 tonnes of the metal-contaminated soil were loaded out and processed in the mill in 2019. An estimated 30,000 t remains on the heap leach pad.

Excess sulphur was stored in a nearby stockpile, first in the Cariboo Pit (2006-2009) and then moved to a crushed rock pad beside the heap leach pad (2009-2018) when mining resumed in the Cariboo Pit. In 2018, the excess sulphur was relocated on top of the lined leach pad after evidence showed that water quality on the mine may be affected by contaminated drainage from below the sulphur stockpile. The affected drainage is seepage from the NEZ Dump, located east of the Test Heap Leach Facility. Approximately 1 m thickness of waste rock was removed from the sulphur stockpile pad footprint (about 9,200 tonnes) and was relocated to the TSF after the sulphur stockpile was moved to the Test Heap Leach Facility as clean-up.

Leachate from within the lined heap leach pad facility is managed by treatment with lime at the ore processing plant and conveyance to the TSF. A copper recovery system using sodium hydrosulfide (NaHS) to precipitate copper sulfide in the tailings thickener is being developed by MPMC within the concentrator building.

Data exist for 21 leachate samples from the heap leach pad that were collected between 2017 to 2021 (Table 1). Element concentrations in the leachate reflected the acidic pH and sulphate is above 10,000 mg/L.

**Table 1: Summary Statistics of Leachate Chemistry from the Heap Leach Pad (2017 – 2021)**

| Statistic (n = 21) | pH[1] | Sulphate (mg/L) | Aluminum (mg/L) | Copper (mg/L) | Iron (mg/L) |
|---|---|---|---|---|---|
| Min | 2.9 | 12,000 | 1,000 | 260 | 15 |
| P50 | 3.3 | 13,000 | 1,400 | 710 | 130 |
| Max | 3.4 | 25,000 | 2,800 | 1,400 | 230 |

Notes: Drawings are for illustrative purpose and not drawn to scale. Lines A-A' and B-B' are shown on Figure 1.

**Table 2: Inventory of Materials Stored at the Heap Leach Facility**

| Material | Earlier Placement | Current Storage Location | Estimated Tonnage Stored on Leach Pad (t) |
|---|---|---|---|
| Elemental sulphur | Placed on top of waste rock pile on crush pad | Stored on top of leached ore on leach pad | 23,000 |
| | Stored in sulphur stockpile before loaded onto leach pad | Stored in layers between ore on leach pad | Unknown amount |
| Leached waste rock from beneath sulphur stockpile | Beneath sulphur stockpile | Stored on top of leached ore on leach pad | 9,200 |
| Leached ore | Placed on leach pad, layered with elemental sulphur | Stored on top of leach pad | 19,000 |
| | Placed on leach pad, layered with elemental sulphur | Stored on top of leach pad | |
| Crush Rock | Waste rock sourced from pits | Stored on leach pad surrounding and underneath contaminated soils | 20,000[1] |
| Metal-contaminated soils | Metal-impacted soils clean-up of lead-zinc concentrate from Kinder Morgan/Vancouver Wharves | Stored on top of leached ore on leach pad | 30,000 |
| ***Facility Construction Materials*** | | | |
| Anchor rock for liner | Waste rock sourced from pits during construction | Outside of heap leach pad footprint | 5,400[1,2] |
| Berm | Waste rock sourced from pits during construction | Around leached ore on leach pad, within heap leach pad footprint | 22,000[1] |
| Drainage material | Waste rock sourced from pits during construction, crushed on-site | Drainage rock above and between liner layers | Unknown amount |
| Till liner (Zone S) | Borrow Source #3 | Underneath heap leach facility | Unknown amount |
| Liner[3] | - | Bottom of heap leach pad | - |

Notes: Estimated material amounts were provided by MPMC.

[1] Estimated based on volume estimates

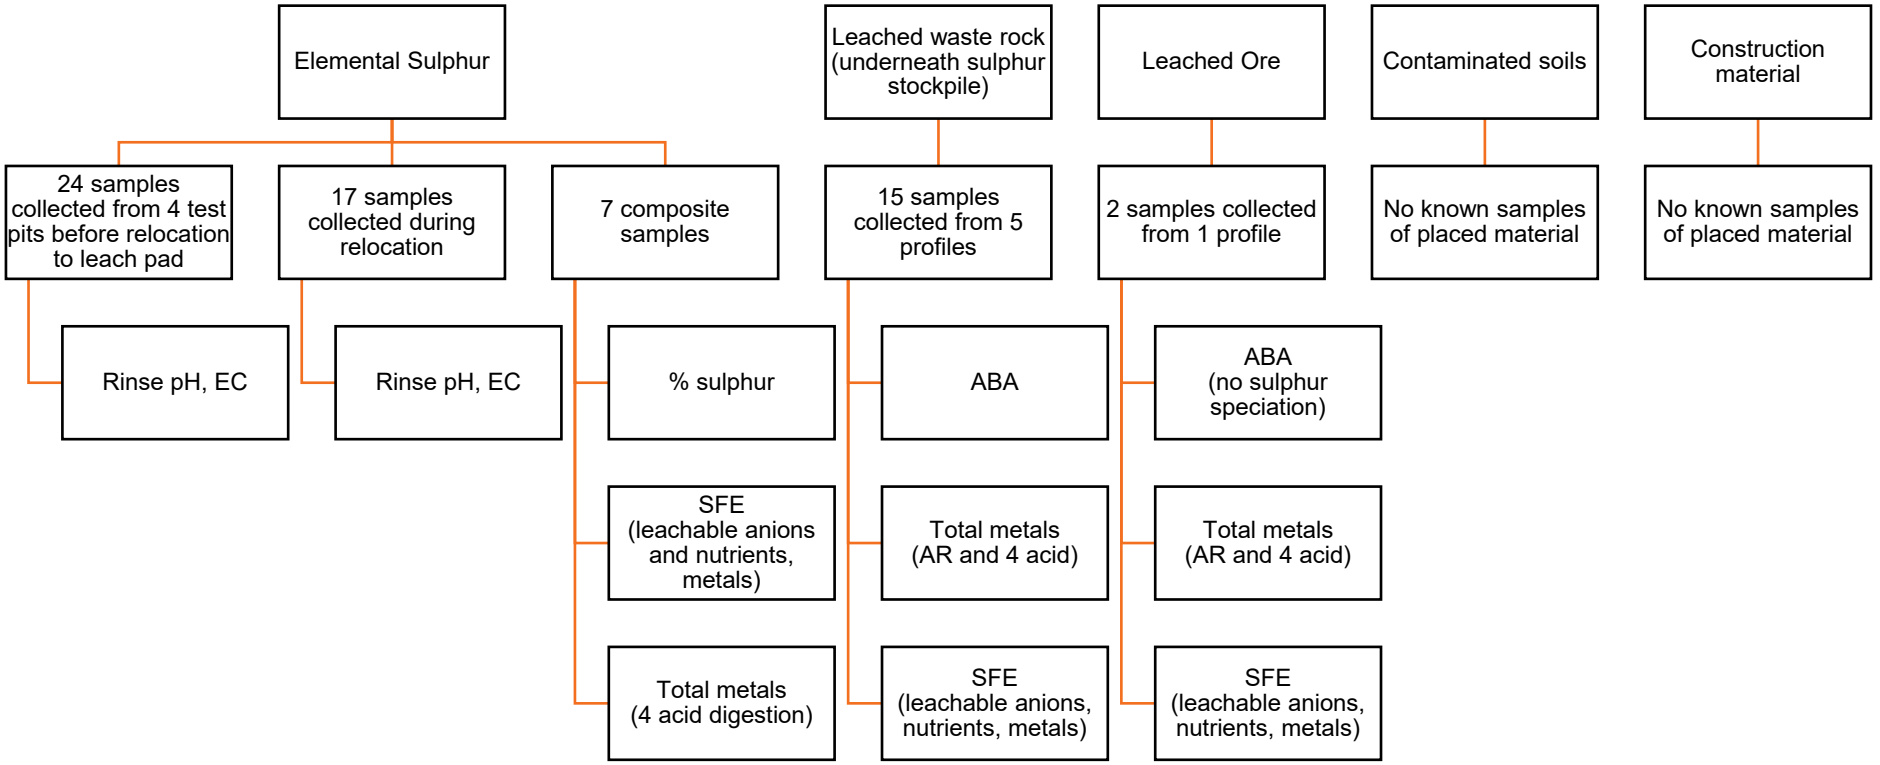
[2] Stored outside of leach pad footprint

[3] Liner comprises two HDPE liners that are 19,000 $m^2$ with one geonet placed between.

# 3 Regulatory Context

SRK understands from MPMC that these materials are considered mine wastes and are therefore managed under the requirements of Mines Act permit M-200, and EMLI's policies and guidance. SRK assumes that all materials will have approval from regulatory agencies for disposal on-site.

# 4 Geochemical Characterization Program



## 4.1 Characterization Program

The Decommissioning Plan required geochemical characterization of the materials stored on the Test Heap Leach Facility. The geochemical characterization program designed to address data gaps identified during the development of the GCMs for each material was detailed in SRK (2021) and is provided as Appendix A. An overview of this program is provided in the following sub-sections.

## 4.2 Data Collected Prior to 2021

Previous data were available for elemental sulphur, leached waste rock from beneath the sulphur stockpile, and leached ore (Figure 3). These data were included in the interpretation as appropriate.

**Figure 3: Summary of Existing Datasets Available by Material Stored in the Test Heap Leach Facility**

Sources: \\van-svr0.van.na.srk.ad\Projects\01_SITES\Mt_Polley\1CM017.010_Heap_Leach_Facility_Decomissioning\!060_Presentations\GCM_SamplingPlan_1CM017.010_Rev02_SJL.pptx

Notes: EC: electrical conductivity; ABA: acid-base accounting; SFE: shake flask extraction; AR: aqua regia

## 4.3 Characterization Program in 2021

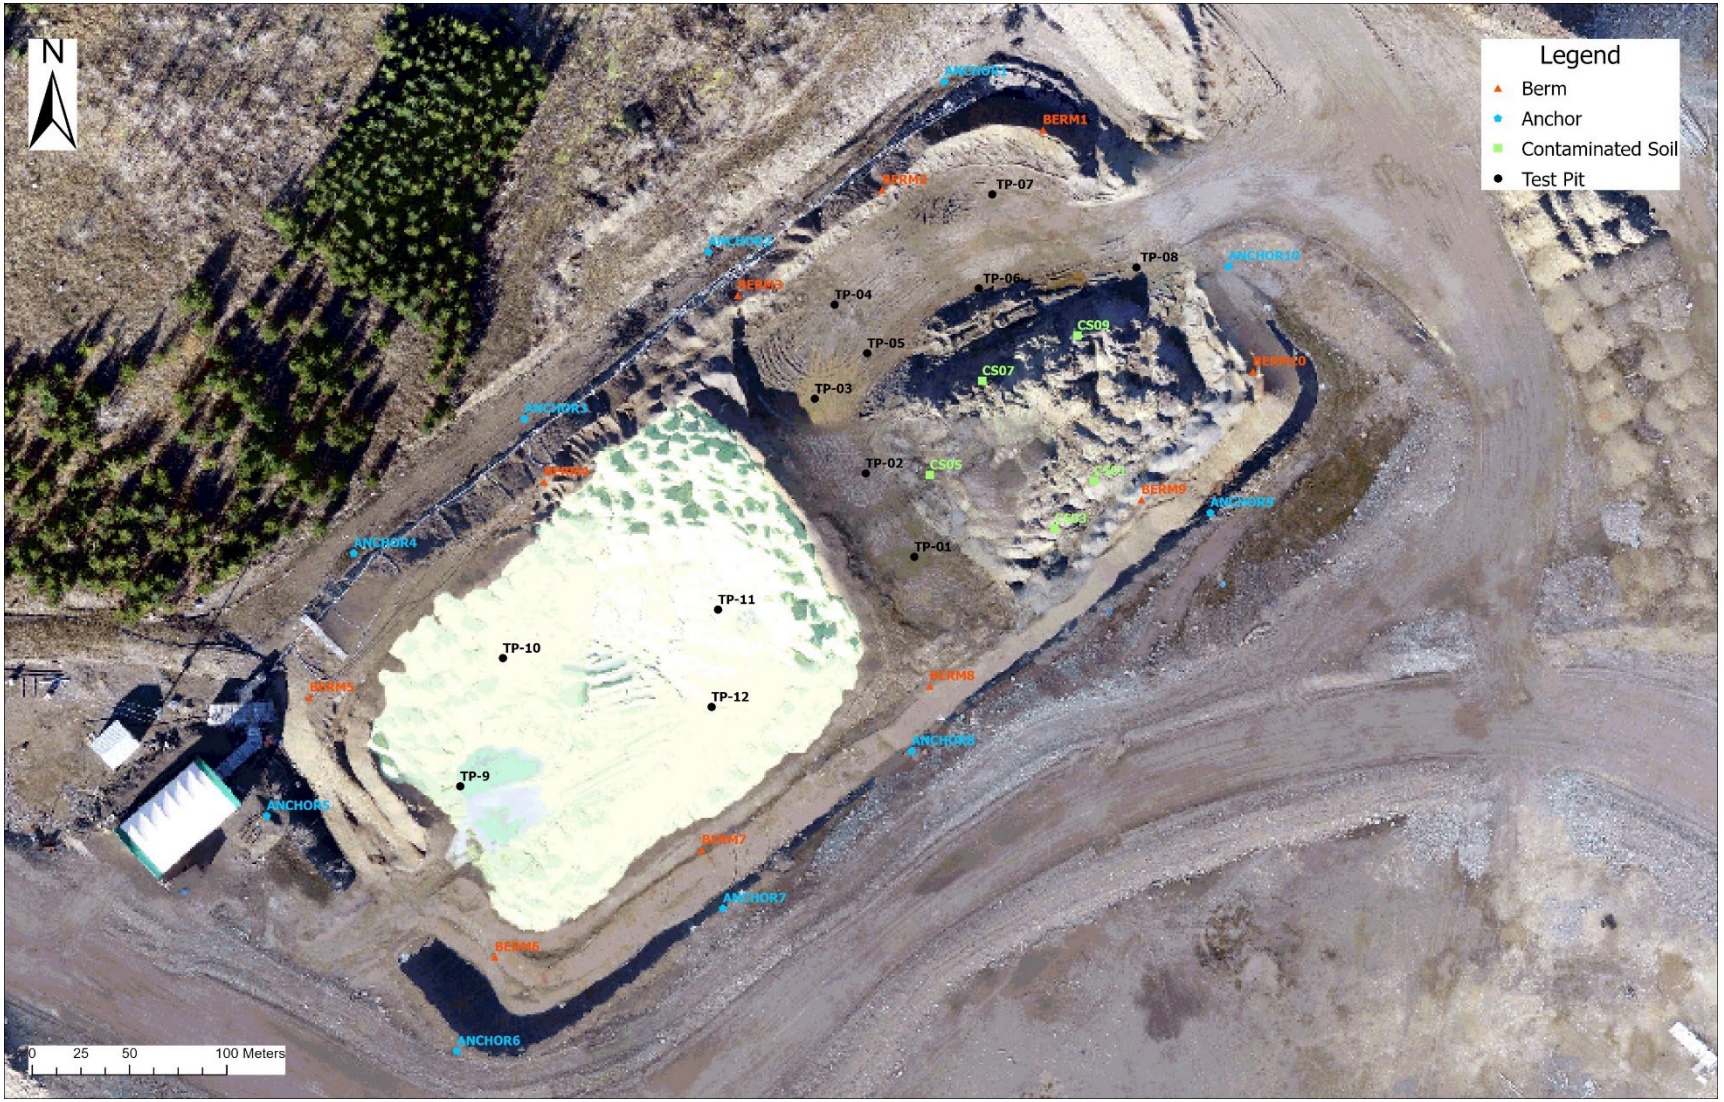
SRK geochemist Shauna Litke, PEng, sampled materials stored on the Test Heap Leach Facility from May 5 – 6, 2021 after snow melt. To ensure the liner was not punctured during sampling, the depth to liner was estimated at each sampling location using historical survey data.

Elemental sulphur, leached ore, crush rock, and contaminated soils samples were collected using an excavator. Test pits were dug at each sampling location using an excavator. Each test pit was logged after excavation.

Construction materials were collected as one composite approximately every 25 m. This includes the anchor rock and berm materials. Drainage materials and the compacted till liner can not be sampled before decommissioning because they are below the HDPE liner, so no samples of these materials were collected. Instead, a sampling and analysis plan is provided in Section 6.6 to guide management decisions.

Table 3 summarizes the samples submitted for analysis as part of the characterization program.

**Table 3: Summary of Samples Submitted for Analysis During the Current Characterization Program**



| Material | Current Storage Location | Number of Samples Collected |
|---|---|---|
| Elemental Sulphur | Stored on top of leached ore on leach pad | 2 (+1 duplicate) |
| | Stored in layers between ore on leach pad | 2 |
| Leached Ore | Stored on the leach pad, beneath the elemental sulphur, contaminated soils, and leached waste rock | 9 (4 profiles) (+1 duplicate) |
| Crush Rock | Stored on the leach pad | 9 (3 profiles) |
| Metal-Contaminated Soils | Stored on the leach pad | 11 (+2 duplicate) |
| Anchor Rock for Liner | Stored outside leach pad footprint | 10 (+1 duplicate) |
| Berm | Berm | 10 (+1 duplicate) |

### 4.3.1 Sample Locations

Sample locations are shown on Figure 4.

**Figure 4: Leach Pad Sample Locations**

Sources: Photo provided by MPMC; https://srk.sharepoint.com/sites/NA1CM017.010/Internal/!020_Project_Data/010_SRK/Leach%20Pad%20Site%20Map.pptx

Notes: Flyover photo taken October 21, 2019.

### 4.3.2 Analytical Methods

All samples were shipped to Bureau Veritas Laboratory in Richmond, BC. All samples were air dried.

Elemental sulphur samples were analyzed for the following:

- Metals by aqua regia digestion with ICP-MS finish
- Shake Flask Extraction (SFE) test (MEND method) on as-received particle size
  - Leachate analyzed for: pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS
- Total sulphur by Leco furnace (performed at ALS Minerals in North Vancouver, BC)

Rock samples were analyzed the following:

- Total carbon
- Total inorganic carbon
- Acid Base Accounting: paste pH, total sulphur (Leco), sulphate sulphur (HCl method), sulphate sulphur (by pyrolysis), and modified Sobek NP
- Metals by aqua regia digestion with ICP-MS finish
- SFE test (MEND method) on -2 mm fraction
  - Leachate analyzed for: pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS

### 4.3.3 Interpretation Methods

#### Sulphur Speciation

For leached ore, crush rock, metal-contaminated soils, and berm samples, three types of sulphur analyses were performed on all samples in the 2021 Characterization Program and were interpreted as follows to provide a basis for calculating acid potential (AP):

- Total sulphur ($S_{Total}$)
- Hydrochloric acid soluble sulphur indicates sulphur in the form of sulphates ($S_{HCl}$)
- Sulphate sulphur by pyrolysis ($S_{Pyro}$)
  - In case of the presence of insoluble sulphate salts (e.g., barite), the pyrolysis method volatizes the sulphide and elemental sulphur. The residue contains sulphur as sulphate.

Sulphide and elemental sulphur concentrations could not be differentiated using these methods and are reported together. For consistency, sulphide + elemental sulphur concentrations ($S_{sulphide+}S^0$) were calculated for all materials as follows:

$$S_{sulphide+}S^0 = S_{Total} - S_{Pyro}$$

The pyrolysis method was not analyzed on samples collected prior to the 2021 Characterization Program. Therefore, sulphide concentrations were calculated using $S_{HCl}$ instead of $S_{Pyro}$. This may over-predict the sulphide + elemental sulphur content for these samples.

Sulphide and elemental sulphur generate 2 moles of acid per mole of sulphur. Acid potential (AP) was therefore calculated for all rock samples as:

$$AP\ (kg\ CaCO_3/t) = 31.25 \times (S_{sulphide} + S^0)\ (\%)$$

### Neutralization Potential

Neutralizing rock components for other materials were evaluated by the Mod Sobek NP method and total inorganic carbonate (TIC) analysis. Since carbonate mineralization is principally calcite and iron carbonates have not been reported at Mount Polley, carbonate content indicates calcite.

### Acid Rock Drainage Potential

Acid rock drainage (ARD) potential was assessed using NP/AP. An NP/AP greater than 3 indicates negligible potential for ARD (not potentially acid generating, Non-PAG), whereas an NP/AP equal or less than 3 indicates the material has potential to generate ARD. Materials with an NP/AP ratio equal or less than 3 are classified as potentially acid generating (PAG).

In addition to the NP/AP ratio classification described above, an additional parameter was used to classify ARD potential. At low sulphide concentrations, interpretation of ARD potential using NP/AP ratios may not be meaningful because oxidation of small concentrations of sulphide produces low amounts of acid that are readily neutralized by other rock components in addition to carbonate. An $S_{Sulphide}$ concentration less than 0.1% was selected to represent low sulphur concentrations (AP = 3.1 kg $CaCO_3$/t). Below 0.1% $S_{Sulphide}$, rock was classified as NAG regardless of the NP/AP ratio.

### Metal Leaching Potential

Trace element concentrations provide an indication of the degree to which rock may contain elevated concentrations compared to global average values. Enrichment of trace elements was evaluated by comparison with global average values in similar rock types (Price 1997).

All samples were compared to 10 times the high calcium granitic rock global values. Values exceeding 10 times the global value average were considered “enriched.” Enrichment of trace elements compared to global averages may or may not be correlated with leaching potential but is the basis for initial screening of metal leaching potential.

### Assessment of Current Metal Leaching and Acid Rock Drainage

To determine current available acidity and ARD onset, the following assessment was used.

Measurements of paste pH less than 5.5 and Mod Sobek NPs that are less than 0 indicate the immediately available acidity upon contact with water.

SFE tests provide an indication of readily soluble acidity and metals. Measurements of leachate pH less than 5.5 also indicate the immediately available acidity upon contact with water. If the paste or leachate pH was less than 5.5, the material was classified as acidic.

### 4.3.4 Quality Assurance and Quality Control

Table 4 provides the QA/QC summary for samples collected during the 2021 Field Program. Field duplicates had relative percent differences above the acceptable criteria, indicating heterogeneity. SRK considers these data acceptable.

**Table 4: QA/QC Summary of Samples Collected as Part of the 2021 Field Program**

| QC Test | SRK QC Criteria | Results |
|---|---|---|

# 5 Results

## 5.1 Elemental Sulphur

Elemental sulphur stored on top of leached ore on the leach pad contained higher sulphur content than elemental sulphur stored in layers between ore on the leach pad and were similar to the composite samples collected in 2018 (Table 5). The solids analysis indicated the majority of these samples were sulphur by weight, with the balance made up of aluminum, calcium, iron, potassium, and sodium. Layered elemental sulphur samples contained higher metal concentrations (e.g., aluminum, copper, and iron were all greater than one order of magnitude), which may indicate metals that have leached from the ore and accumulated on in these sulphur layers.

Notes:

[1] Where a result was less than the detection limit, the detection limit was used for statistical calculations.

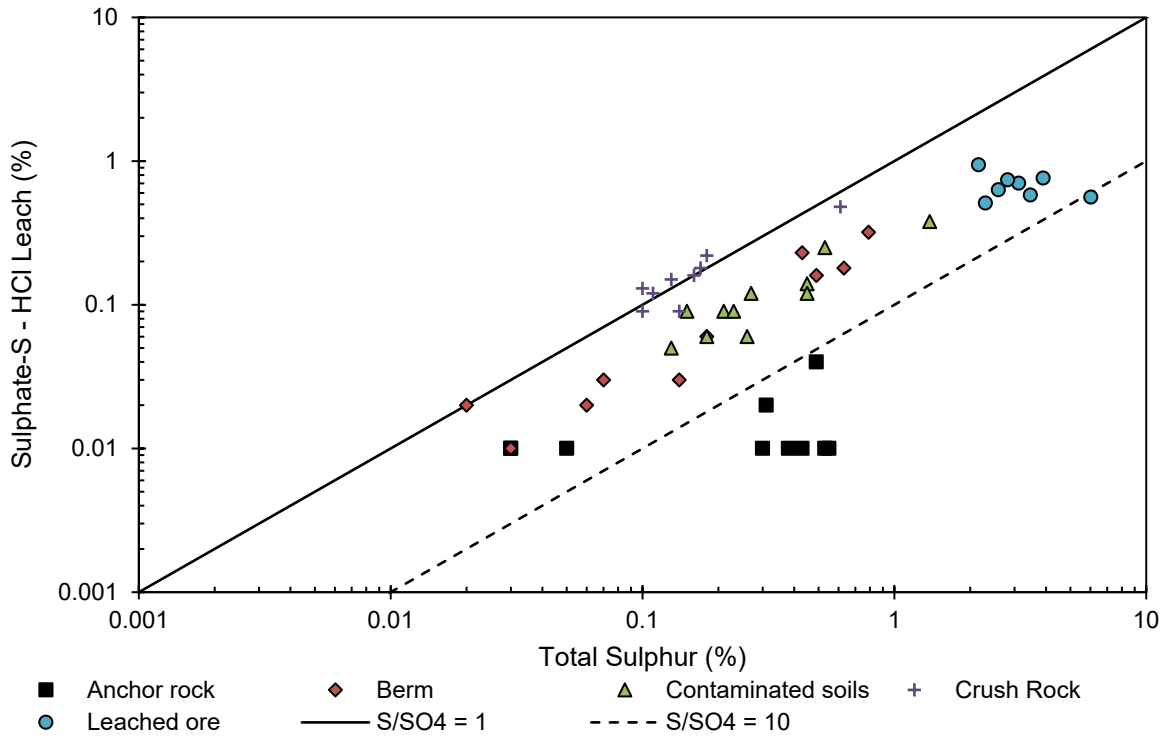
[2] Analysis not performed on samples collected in 2018.

Elemental sulphur had some of the highest leachable sulphate concentrations of the materials stored on the leach pad. Leachable metal concentrations were high in the elemental sulphur due to the low pH of the leachate (Figure 9). Elemental sulphur contained the highest leachable iron concentrations of any material, but other leachable metal concentrations, although high, were lower than other materials. Solid phase concentrations of trace elements were lower compared to other materials but were within the same order of magnitude.

The elemental sulphur characteristics can be summarized as follows:

- Elemental sulphur samples were assumed to have no neutralization potential.
- The elemental sulphur is composed of about 90% sulphur. The balance of 10% are impurities which create a leachable source of other elements including iron and aluminum. Smaller amounts of elemental sulphur are stored in layers between ore on the leach pad. These layers contain less sulphur than the elemental sulphur stored on top of the facility and more impurities.

- Oxidation of the sulphur has generated sulphuric acid, which has markedly increased the solubility of metals in the surrounding materials that would not otherwise be leachable at neutral pH.



## 5.2 Rock-Containing Materials

### 5.2.1 General Findings

#### Sulphur Species and Acid Potential

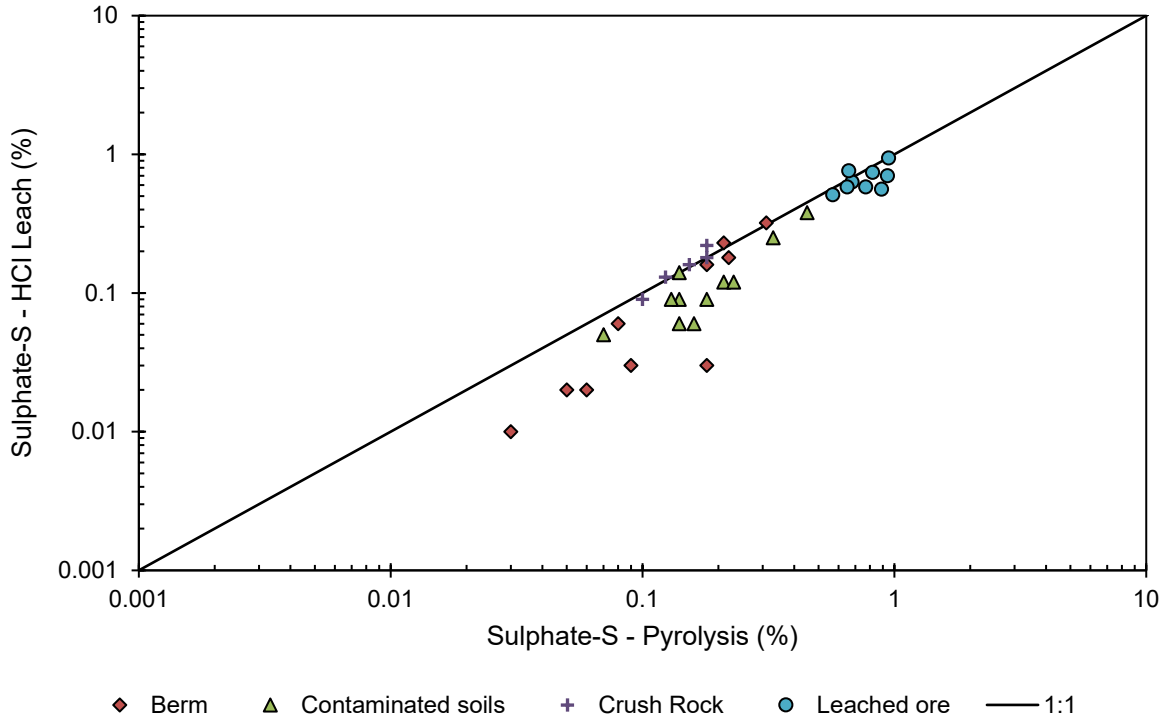


Figure 5 compares $S_{HCl}$ to $S_{Total}$ for the rock samples, indicating that not all total sulphur components are acid generating. Figure 6 shows the comparison between the two sulphate methods for samples four different rock materials collected from the leach pad. The HCl leach method under-predicted the sulphate content for contaminated soils and berm samples, indicating the presence of some insoluble sulphate salts. Sulphate content from both methods were similar for crush rock and leached ore samples.

**Figure 5: Sulphate (HCl Leach) Concentrations Compared to Total Sulphur**

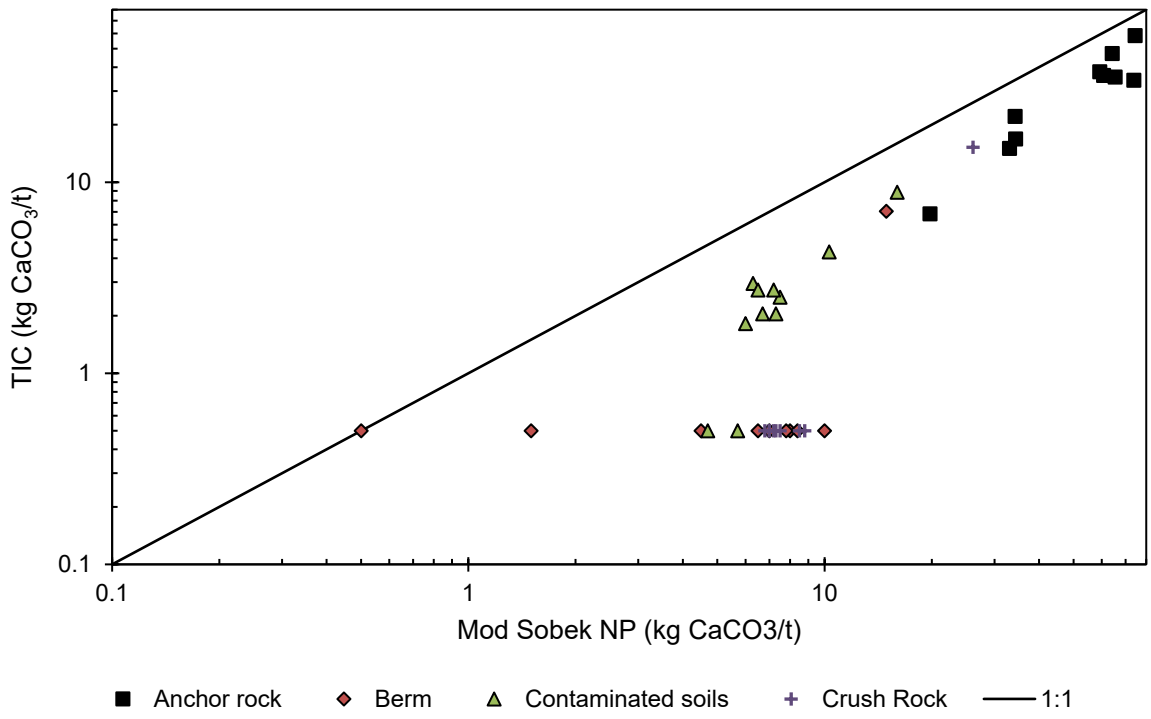
**Figure 6: Comparison of Sulphate Content by HCl Leach Versus Pyrolysis**

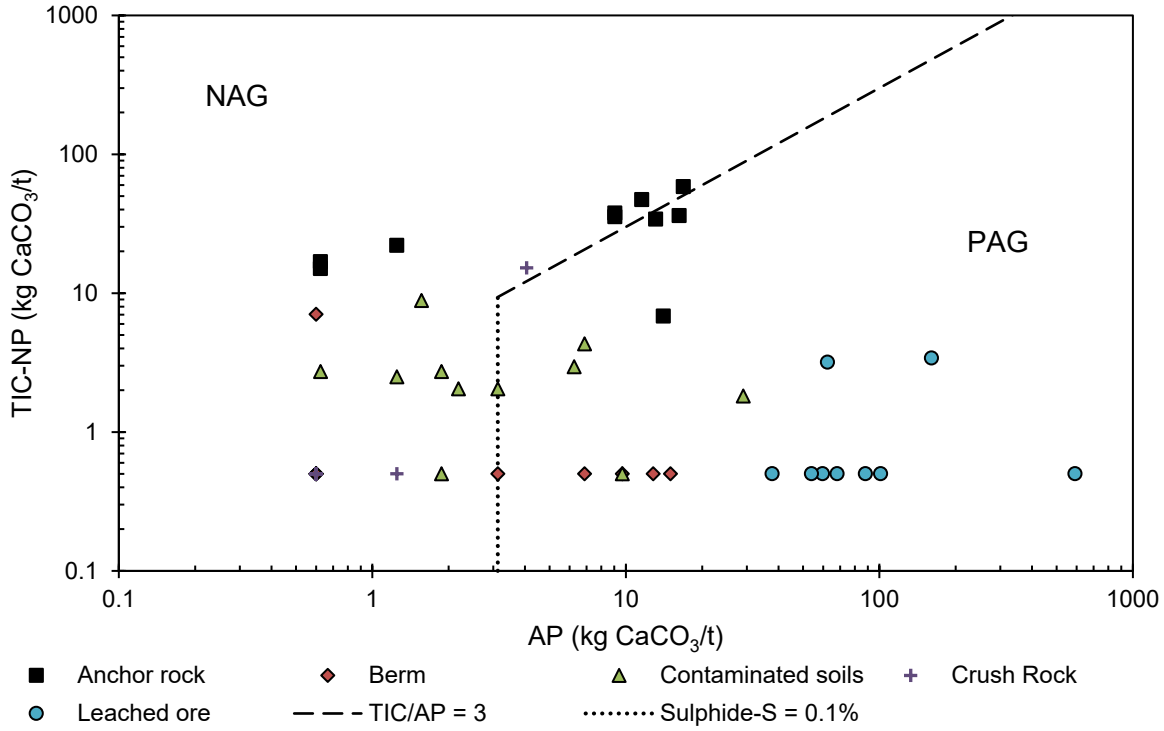


Sources: \\van-svr0.van.na.srk.ad\Projects\01_SITES\Mt_Polley\1CM017.010_Heap_Leach_Facility_Decomissioning\Task300_Material_Testing_Program\SubTask330_DataInterpretation\Leach_Decom_Compiled_data_1CM017.010_Rev01_NK_SJL.xlsx

## Neutralization Potential

Results show that for all materials that carbonates were detected, TIC was lower than Mod Sobek NP (Figure 7), indicating the presence of minerals other than carbonates that provide some neutralization (e.g., silicates). TIC was therefore used in subsequent calculations for classification of ARD potential.

**Figure 7: Total Inorganic Carbon Compared to Modified Sobek Neutralization Potential**



Sources: \\van-svr0.van.na.srk.ad\Projects\01_SITES\Mt_Polley\1CM017.010_Heap_Leach_Facility_Decomissioning\Task300_Material_Testing_Program\SubTask330_DataInterpretation\Leach_Decom_Compiled_data_1CM017.010_Rev01_NK_SJL.xlsx

## Acid Rock Drainage Potential

Calculated NP/AP ratios indicate future potential for ARD if sulphides oxidize through exposure to atmospheric oxygen. As discussed above, TIC was compared to AP represented by acid potential measured from the sulphide content of the sample (Figure 8).

### 5.2.2 Assessment of Current Metal Leaching and Acid Rock Drainage

Leachable metal concentrations of all materials were pH-controlled (Figure 9). Elemental sulphur had the highest leachable iron concentrations and had similar leachable aluminum concentrations to leached ore. Although elemental sulphur had the lowest leachate pH of all materials tested, it did not have the highest leachable concentrations of other trace elements (e.g., cobalt, copper, nickel, etc.). This is likely because the elemental sulphur is mostly sulphur while other materials contain higher solid content of these trace elements. For example, leached ore had the highest leachable copper content while the contaminated soils had the highest leachable zinc concentrations.

**Figure 9: Leachable Element Concentrations versus pH**

### 5.2.3 Leached Waste Rock from Beneath Sulphur Stockpile

Material that was previously underneath the sulphur stockpile was well characterized, as documented in Litke (2019) and Litke et al. (2019). No additional static testwork of this material was recommended in 2021. Leached waste rock is currently stored on the southwest corner of the leach pad, surrounded by contaminated soils. Table 6 provides distribution statistics (minimum, 5$^{th}$ percentile, 25$^{th}$ percentile, median, 75$^{th}$ percentile, 95$^{th}$ percentile, and maximum) for acid base accounting (ABA) parameters and selected elemental concentrations. Table 7 provides distribution statistics for selected leachable constituents.

Litke et al. (2019) and Litke (2019) showed pH-controlled weathering fronts developed in the material underneath the sulphur stockpile. Acidification was observed at one sampling profile location, but the amount and degree to which the waste rock was acidified was variable underneath the sulphur stockpile. Jarosite was observed at this location, which typically forms under acidic conditions and needs iron. This is possibly an indication that the acid generated from the sulphur pile was interacting with the waste rock underneath and was contributing to accelerated weathering of this rock. Carbonate depletion was apparent at all locations, but excess carbonate to maintain neutral pH was observed at some sampling locations below the sulphur stockpile. The leached waste rock was NAG based on sulphide content or AP calculated from sulphide and NP from remaining carbonate (Table 6). Sulphur prills were observed interspersed in the material.

Because of the wide range of leachate pH in the leached waste rock samples (ranging from 3.2 to 7.8), leachable metal concentrations varied (Table 7). The acidic conditions are currently resulting in accelerated metal leaching (Figure 9).

### 5.2.4 Leached Ore

Leached ore is currently stored on the leach pad, beneath the elemental sulphur. The majority of the leached ore is stored on the southwest end of the leach pad, beneath the elemental sulphur. Table 8 provides distribution statistics for ABA parameters and selected elemental concentrations. Table 9 provides distribution statistics for selected leachable constituents.

Data from samples collected prior to 2021 were not included because they were collected before the elemental sulphur was moved for storage on the leach pad in 2018/2019. Results were not consistent with current data because the storage conditions had changed and altered the material. A previous study by Henry (2009) showed precipitation of copper sulphide minerals was occurring in water-saturated and anaerobic microenvironments in the leach pad. This is also reflected in the higher sulphide content in the leached ore compared to other rock at Mount Polley.

Sulphur prills were observed mixed with the leached ore on the heap leach pad and results indicate carbonates are depleted and the material is classified as PAG. Acidification is evident in all samples, where the paste pH ranges from 3.6 to 4.3. All leached ore samples had leachable acidity and associated metal concentrations (Figure 9).

### 5.2.5 Crush Rock

Crush rock is currently stored on the leach pad, some beneath the contaminated soils and leached waste rock. This was previously classified as leached ore in SRK (2021), but upon receipt of results, this material was more similar to leached waste rock than leached ore, based on copper concentrations, but was more acidified than leached waste rock.

Table 10 provides distribution statistics for ABA parameters and selected elemental concentrations for the crush rock material. This material contains low sulphide (all samples < 0.13 %) and the majority of sulphur occurs as sulphate, most likely from sulphate precipitates. Table 11 provides distribution statistics for selected leachable constituents. Leachate pH ranged from 4.2 to 7.4 (median = 4.5), indicating leachable acidity and associated metal concentrations.

## 5.3 Metal-Contaminated Soils

Metal-contaminated soils are currently stored on top of the leached ore on the northeast end of the leach pad. Some samples of the contaminated soils were collected and tested before the material was brought to Mount Polley Mine and placed on the heap leach pad. This material was sourced from various soil clean-up sites and no sampling of placed material occurred during initial placement. The sampling and testing methods were not provided, and the data were not able to be related with the remaining material on the leach pad.

Table 12 provides distribution statistics for ABA parameters and selected elemental concentrations for the contaminated soils collected during the 2021 Characterization Program. Table 13 provides distribution statistics for selected leachable constituents. Because of the wide range of leachate pH in the contaminated soils samples (ranging from 4.2 to 7.4), leachable metal concentrations varied (Figure 9). Leachable lead and zinc concentrations were highest in the contaminated soils.

## 5.4 Construction Materials

### 5.4.1 Anchor Rock

This material was waste rock sourced from pits and is possibly similar to other NAG waste rock from Mount Polley. Anchor rock is currently stored outside the main footprint of the leach pad. Table 14 provides distribution statistics for ABA parameters and selected elemental concentrations for anchor rock. Table 15 provides distribution statistics for selected leachable constituents.

Anchor rock is mostly NAG with some PAG components, due to low sulphide content and the presence of carbonates. No acidification was identified. Samples collected near the contaminated soils storage location had higher Pb and Zn content, while samples collected near the elemental sulphur load out contained higher AP and lower leachate pH, indicating some contamination with other materials stored on the leach pad.

### 5.4.2 Berm Materials

This material was waste rock sourced from pits but is currently stored inside the footprint of the leach pad. It is contaminated with leachate and dust from elemental sulphur. Table 16 provides distribution statistics for ABA parameters and selected elemental concentrations for the berm materials. Table 17 provides distribution statistics for selected leachable constituents.

Berm materials were PAG with some components classified as NAG due to low sulphide content. Carbonates were depleted and acidification was evident for the majority of the material. Higher Pb and Zn content was observed in samples collected near the contaminated soils storage location on the leach pad, indicating some contamination with this material.

### 5.4.3 Drainage Material and Compacted Till Liner

No geochemical data exists for this material and sampling of these materials will not be possible until decommissioning. The amount of drainage material and till is small in proportion to other materials, so sampling and analysis is for inventory development and estimating potential amendments. It is also unknown if acidic drainage broke through the till liner, resulting in contamination of the flow path underneath the facility.

A sampling and testing plan to characterize this material as the facility is decommissioned and determine if treatment of the flow path beneath the facility is required is provided in Section 6.6.

# 6 Material Management

## 6.1 Overview

Table 18 summarizes the ML/ARD current conditions and potential of each material stored on the leach pad.

**Table 18: ML/ARD Current Conditions and Potential of Materials Stored on Leach Pad**

| Material | ARD Potential[1] | ML Potential[2] | Current ML/ARD Conditions[3] | Rinse pH | | Comments |

[3] Low = no acidic components, Medium = some acidic components, High = > P50 acidic components.

## 6.2 Disposal Options

A virtual options analysis workshop was conducted on October 8, 2021, with Mount Polley Mine personnel and SRK geochemists in attendance. Potential disposal options were discussed based on short- and long-term impacts (Table 19). Time and cost for each disposal option were also considered.

**Table 19: Impacts and Considerations for Disposal Options**

| Impacts and Considerations | Disposal Options | | |
|---|---|---|---|
| | Transport and dispose materials off-site | Store on surface in existing facility | Submergence in TSF |
| Short-Term Impacts | ■ Immediate removal of material | ■ Continual release of acidity and associated metals<br>■ Can be managed in the short-term by addition of neutralization amendments | ■ Initial flush of soluble acidity and associated metals<br>■ TSF is largest water reservoir on-site<br>■ Can be managed by addition of neutralization amendments |
| Long-Term Impacts | ■ Moves long-term risk off-site | ■ Continual release of acidity and associated metals<br>■ May require a cover for material with high ML/ARD potential (high long-term care and maintenance) | ■ Disposal underwater can be expected to arrest oxidation, providing a long-term solution for material with high ML/ARD potential<br>■ Material in TSF will remain submerged into closure<br>■ Long-term sulphate leaching |
| Time Consideration | ■ Materials can be transported off-site immediately<br>■ Fastest option | ■ Materials can be amended and stored at the same time | ■ Materials need to be added gradually due to initial flush<br>■ Slowest and most time-consuming option |
| Cost Consideration | ■ Most expensive | ■ Starts low, but costs will increase depending on required amendments and potential need for cover | ■ Costs from material transport to TSF and other logistical considerations<br>■ Possible long-term sulphate treatment |

Sources: Compiled in text

The potential disposal options by material are summarized in Table 20. Considerations for each material were as follows:

- Only materials that were not sourced from site were considered for transport and management off-site.
- Materials that had low ARD potential, similar ML potential to Mount Polley NAG waste rock, and low to medium current ML/ARD conditions were considered for amendments and storing on surface.
- Submergence in TSF will achieve objective of isolating material from atmospheric oxygen and effectively prevent further oxidation and generation of sulphuric acid from elemental sulphur prills and remaining sulphides. This was the best disposal option for materials with medium to high ML/ARD potential, but all materials can be disposed with this option. However, this would result in

a source of $CaSO_4$ that may result in long-term sulphate leaching perhaps leading to long-term sulphate treatment.

**Table 20: Disposal Options by Material**

| Material | Disposal Options | | |
|---|---|---|---|
| | Transport and dispose materials off-site | Amend and store on surface | Submergence in TSF |
| Elemental Sulphur | ✓ | × | ✓ |
| Leached Waste Rock | × | × | ✓ |
| Leached Ore | × | × | ✓ |
| Crush Rock | × | × | ✓ |
| Contaminated Soils | ✓ | × | ✓ |
| Berm Materials | × | × | ✓ |
| Anchor Rock | × | ✓ | ✓ |

Sources: Compiled in text

Notes: ✓ - Material considered for disposal option; × - Material not considered for disposal option

## 6.3 Selected Disposal Options

Based on the material characterization, and time and cost considerations described above, submergence of elemental sulphur, leached waste rock, leached ore, crush rock, contaminated soils, and berm materials in the TSF was selected as the disposal option.

The disposal option selected for anchor rock was amend (if required) and store on surface.

## 6.4 Scheduling and Disposal Considerations

Disposal underwater can be expected to arrest oxidation but will rapidly leach the soluble acidity. The acidity may be neutralized by contact with tailings or could be amended with lime during disposal.

As described in Table 19, submergence in the TSF was the most time-consuming option considered. Therefore, this option drives scheduling considerations. To allow for a cover of tailings over disposed materials in the TSF and sufficient blending with neutralizing amendments, disposal should be started during operations and completed before the last year of processing.

## 6.5 Effects on TSF Water Quality

### 6.5.1 Background

“Source terms” refer to predicted concentrations for waters in contact with geologically-sourced waste and surfaces under the expected disposal or exposure conditions at the site. These predictions

become inputs (or terms) which can be used to evaluate the influence of material disposal into the TSF on the water chemistry in the TSF.

Predicted loads from each material during submergence were calculated to estimate the influence of material disposal on the water chemistry in the TSF. All source terms are considered upper limit estimates.

### 6.5.2 Conceptual Model

Materials excavated from the heap leach pad are deposited into the ponded area of the TSF. Mixing of different materials from the leach pad was not considered.

All materials have undergone prior oxidation resulting in accumulation of potentially soluble weathering products. In most cases, these are expected to be sulphates which might include sulphuric acid (in the case of elemental sulphur), iron, and other metal sulphates (acidic wastes such as contaminated soil) or gypsum (non-acidic rock). For non-acidic rock, oxidation products may include oxides and carbonates.

Upon contact with the water in the TSF, the soluble load will be flushed until solubility limits are reached and will react with the pond water and existing tailings. In general, these processes can be expected to result in neutralization of acidity resulting in precipitation of sulphates, oxides, and hydroxides. Leached sulphuric acid can be expected to be neutralized leading to precipitation of gypsum. Metal in metal sulphates will be hydrolyzed to form oxides and hydroxides. As submergence occurs, residual soluble solids will continue to dissolve as pore waters are displaced and replaced by diluted water. For example, gypsum will likely continue to dissolve adding sulphate to pore waters. Under the expected non-acidic conditions, oxides and hydroxides should be stable unless reducing conditions develop allowing reductive dissolution of iron oxyhydroxides.

Submergence will also essentially arrest oxidation of elemental sulphur and sulphide-containing wastes. The rate of oxidation under these conditions will depend on the availability of oxygen dissolved in water.

### 6.5.3 Approach

To evaluate the influence of the disposal of each material into the TSF, two scenarios were considered (Table 21).

**Table 21: Summary of Disposal Scenarios Considered for Calculation Loadings in the TSF**

| Scenario | Description |
|---|---|
| 1 | The entire stockpile of each material is disposed into the ponded area of the TSF all at once. This scenario represents an upper limit estimate of potential water quality changes in the TSF and did not consider the addition of neutralizing amendments. |
| 2 | One truck per day of a material is disposed into the ponded area of the TSF. This scenario represents an estimate of potential water quality changes in the TSF based on a more likely loading rate during disposal. A lime addition rate per truckload was also calculated for this scenario (see Section 6.5.6). |

Sources: Compiled in text

The approach and assumptions used to calculate loadings to the TSF during submergence were as follows:

- Mixing of different materials from the leach pad was not considered.
- Calculate a conservative water to solid ratio:
  - The volume of TSF water was assumed to be the minimum required in the TSF for processing (1,000,000 $m^3$), as provided by MPMC.
- Water-rock contact factor was assumed to be 100% since all material is in contact with water when submerged.
- The trucking rate for Scenario 2 assumed a CAT 785 haul truck, capable of hauling a maximum of 135 tonnes of material per load. The maximum loading rate per day considered for each material was 135 tonnes/day for Scenario 2.
- Upper limit estimates were only considered using the P95 SFE leachate results for each material.
  - Sulphate concentrations in the majority of SFE tests for all materials except elemental sulphur and contaminated soils were solubility constrained by dissolution of gypsum, so were not used to estimate sulphate loadings. Instead, the sulphate loading from these materials was estimated by assuming all sulphate content (from ABA results) dissolve into the TSF supernatant.
- Anchor rock was not considered because it will not be submerged in the TSF.
- The flushed loadings assume that the soluble load completely dissolves into the TSF pond water.

### 6.5.4 Screening Parameters

The following methods were used to flag potential changes in the water quality of the TSF from the disposal of each material.

- The scaled P95 acidity loading for each material was added to the P25 alkalinity load of the TSF (calculated using monitoring data from the TSF Barge Station E1a collected from 2015 – 2020). The material was flagged if acidity load added was greater than alkalinity load in the TSF.
- Other parameters were compared to discharge limits listed in MPMC's *Environmental Management Act* Permit 11678 for screening (Table 22). If the calculated concentration of the parameter in the

TSF was above the permitted limit, the parameter was flagged as a parameter of interest (POI) for the material.

- Solubility constraints in the TSF were not considered for the screening-level test.

**Table 22: Permit Limits and P75 Concentration of the TSF Supernatant**

| Parameters | Units | Permit Limits[1] |
|---|---|---|
| pH | pH units | 6 < pH < 9.5 |
| Total Acidity | mg $CaCO_3$/L | No limit |
| Total Alkalinity | mg $CaCO_3$/L | No limit |
| Sulfate | mg/L | 1100 |
| Total Ammonia | mg-N/L | 1.3 |
| Nitrate | mg-N/L | 34 |
| Nitrite | mg-N/L | 0.78 |
| Total Phosphorus | mg/L | 0.09 |

Sources: https://srk.sharepoint.com/sites/NA1CM017.010/Internal/Task300_Material_Testing_Program/SubTask330_DataInterpretation/Loadings_Calc_1CM017.010_Rev01_SJL.xlsx?web=1

Notes:

[1] From Section 1.2.3 in EMA PE-11678 (April 7, 2017); used dissolved concentration limits where available and total concentrations if no dissolved concentration limits are specified.

[2] Lead limit is chronic BC Water Quality Guideline for aquatic life using TSF Supernatant P75 hardness concentration for calculation.

### 6.5.5 Calculations

#### Sulphate Loadings using Solid Sulphate Content

For leached ore, leached waste rock, crush rock, and berm rock, the soluble mass of sulphate ($m_{SO4,material}$) was calculated using the solid sulphate content ($c_{SO4,material}$) and mass of material deposited ($M_{material}$):

$$m_{SO4,material}[mg] = c_{SO4,material}\ [mg/kg] \times M_{material}\ [kg]$$

#### Loadings using SFE Concentrations

The soluble mass of all other parameters, i ($m_{i,material}$), was calculated using the concentration from the SFE ($c_{i,material}$), mass of material deposited ($M_{material}$), and the SFE dilution factor ($DF_{SFE}$):

$$m_{i,material}[mg] = c_{i,material}\ [mg/L] \times M_{material}\ [kg] \times DF_{SFE}\ [L/kg]$$

#### Estimated TSF Concentrations

The soluble mass was then added to the TSF pond water ($V_{TSF}$) in addition to the calculated mass already in the TSF pond based on the P75 concentration for each parameter ($c_{i,TSF}$) to calculate the concentration of the TSF after submergence ($c_{i,submerge}$):

$$c_{i,submerge}[mg/L] = \frac{m_{i,material}[mg] + (c_{i,TSF}[mg/L] \times V_{TSF}[L])}{V_{TSF}[L]}$$

### 6.5.6 Inputs

Table 23 summarizes the inputs used in the calculations. The background water quality for the TSF supernatant was calculated using the P75 concentration of the TSF supernatant (E1a). For conservatism, the P25 concentration for total alkalinity was used instead.

**Table 23: Summary of Inputs**

| Inputs | Units | Value |
|---|---|---|
| **SFE Dilution Factor** | L/kg | 3 |
| **Physical Inputs** | | |
| Pond Volume | $m^3$ | 1,000,000 |
| Mass of Elemental Sulphur | t | 22,880 |
| Mass of Leached Waste Rock | t | 9,200 |
| Mass of Leached Ore | t | 18,900 |
| Mass of Contaminated Soils | t | 30,000 |
| Mass of Crushed Rock on Leach Pad | t | 20,000 |
| Mass of Berm Material | t | 21,600 |
| Mass per Truckload | t | 135 |
| **Pond Water Chemistry (TSF Supernatant – P75 2015 – 2020)** | | |
| pH | pH units | 7.7 |
| Total Acidity | mg $CaCO_3$/L | - |
| Total Alkalinity | mg $CaCO_3$/L | 49[2] |
| Sulfate | mg/L | 542 |
| Total Ammonia | mg-N/L | 0.050 |
| Nitrate | mg-N/L | 6.8 |
| Nitrite | mg-N/L | 0.13 |
| Total Phosphorus | mg/L | 0.028 |
| Fluoride | mg/L | 0.82 |
| Aluminum | mg/L | 0.039 |

Notes:

[1] P25 concentration

### 6.5.7 Results

Table 24 summarizes concentration estimates for Scenario 1 using the upper limit material estimates for all materials. Loadings for Scenario 2 are shown for comparison (i.e., soluble mass added per truckload) in Table 25. All concentrations are estimated as “dissolved”.

Elemental sulphur and leached ore were the only materials that had a greater acidity loading compared to alkalinity. Leachable acidity results were not available for leached waste rock, so the acidity loading was calculated based on $H^+$, iron, aluminum, and copper concentrations.

The P95 copper concentrations in the TSF already surpass the Permit limits. Leachable aluminum and zinc were flagged for most materials (Table 24). Elemental sulphur contained the largest estimated loads per truckload for most constituents, but leached ore contained the highest estimated load for copper (Table 25). Contaminated soils contained the highest estimated loads for cadmium, lead, and zinc.

**Table 24: Estimated TSF Concentrations for Scenario 1**

| Parameters | Permit Limits[1] | TSF Supernatant (P75 2015 – 2020) | Materials | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | Elemental Sulphur | Leached Ore | Leached Waste Rock | Crush Rock | Contaminated Soils | Berm |
| Total Acidity (mg $CaCO_3$/L) | No limit | - | **93** | **84** | 23 | 5.0 | 12 | 13 |

Sources: https://srk.sharepoint.com/sites/NA1CM017.010/Internal/Task300_Material_Testing_Program/SubTask330_DataInterpretation/Loadings_Calc_1CM017.010_Rev02_SJL.xlsx?web=1

Notes: **Bolded** values indicate material will the highest load per truckload for each parameter (lowest for alkalinity).

### 6.5.8 Lime Addition Rate

If materials are crushed and blended during disposal, there will be better contact between sources of acidity and neutralization. The TSF supernatant will also provide neutralization during disposal. Lime may also be added as an amendment to neutralize the soluble acidity. Using the scaled average acidity measurements for each material, a lime addition rate per truckload (assuming 135 tonnes of material per truckload) was estimated (Table 26). Further refinement of these rates may be required depending on disposal methods.

**Table 26: Estimated Lime Addition Rate by Material (Fixed Truck Mass: 135 Tonnes)**

| Material | Average Soluble Acidity (mg $CaCO_3$/L) | Estimated Lime Addition Rate per Truckload (kg) |
|---|---|---|
| Elemental Sulphur | 930 | 300 |
| Leached Ore | 760 | 200 |
| Leached Waste Rock | 190[1] | 90 |
| Crush Rock | 52 | 20 |
| Contaminated Soils | 32 | 10 |
| Berm | 78 | 20 |

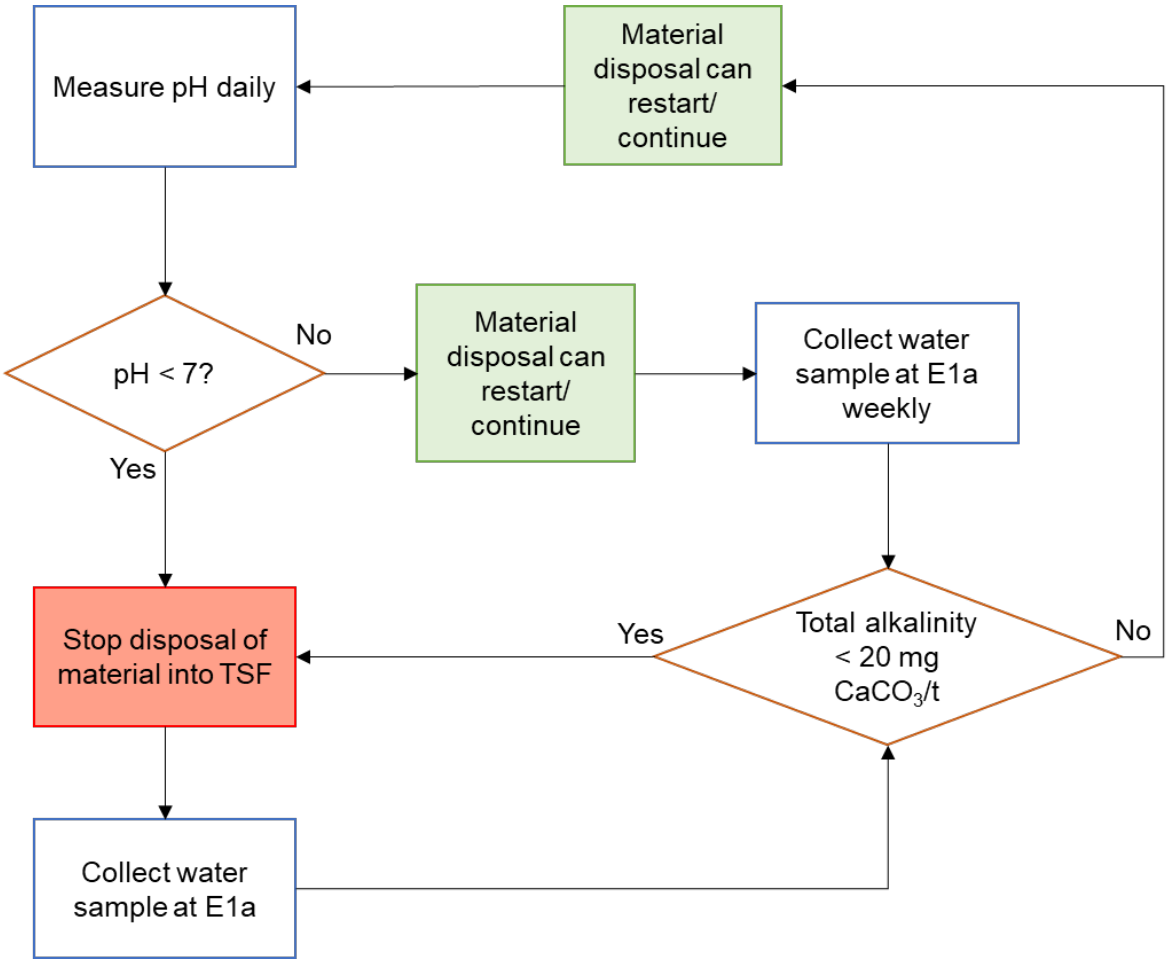
### 6.5.9 Monitoring of TSF Supernatant during Material Disposal



During disposal of any material into the TSF, monitoring of the TSF supernatant (E1a) will be conducted as summarized in Table 27. The purpose of this monitoring is to identify if the water chemistry of the TSF significantly changes during material disposal. A trigger response plan was also developed to determine when material disposal can continue or should cease based on field measurements (i.e., pH) for instant feedback and laboratory analyses (i.e., total alkalinity) (Figure 10).

**Table 27: Monitoring Overview of TSF Supernatant during Disposal**

| Parameter Group | Location | Analyses | Frequency |
|---|---|---|---|
| Field Parameters | In-situ | pH | Daily |
| Physical Parameters | External laboratory | pH, conductivity, total acidity, total alkalinity | Weekly |
| Anions | External laboratory | Sulphate | Weekly |
| Metals | External laboratory | Dissolved | Weekly |

## 6.6 Drainage Materials and Till Liner Monitoring

Representative samples of the drainage materials and till should be collected during decommissioning and analyzed as described in Section 4.3.2.

It is anticipated that drainage materials will be similar to crush rock since they are from similar sources and would have been exposed to acidic drainage since commissioning. If sampling confirms this hypothesis, these materials can be managed similar to crush rock. If testing shows drainage materials are not similar to previously characterized material, then further assessment may be warranted including assessing effects on TSF water quality and potential amendments.

Till materials are underneath liner and therefore the amount of acidification and ML/ARD potential is unknown. Till material should be assessed by ML/ARD potential as well as current ML/ARD condition before disposal option is selected.

# 7 Material Disposal and Management Criteria

Table 28 summarizes the disposal and management criteria for all materials currently stored on the heap leach pad as well as other associated infrastructure and reagents.

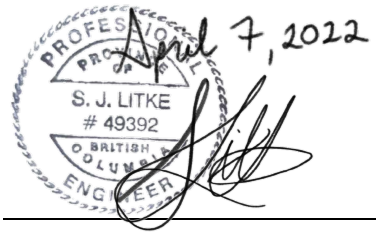

**Table 28: Material Disposal Summary and Other Associated Infrastructure and Reagents Management**

| Material | Management Criteria | Disposal Location | Disposal Method | Monitoring During Disposal |
|---|---|---|---|---|
| **Materials Stored on Leach Pad** | | | | |
| Elemental Sulphur | All managed as material with high ML/ARD potential and high current ML/ARD conditions | Submerged in TSF | Blend in hopper with lime. Dispose in tailings line. | TSF Supernatant (see Section 6.5.9) |
| Leached Waste Rock | All managed as material with high ML/ARD potential and high current ML/ARD conditions | Submerged in TSF | Crush and blend in hopper with lime. Dispose in tailings line. | TSF Supernatant (see Section 6.5.9) |
| Leached Ore | All managed as material with high ML/ARD potential and high current ML/ARD conditions | Submerged in TSF | Crush and blend in hopper with lime. Dispose in tailings line. | TSF Supernatant (see Section 4.5.8) |
| Crush Rock | All managed as material with high ML/ARD potential and high current ML/ARD conditions | Submerged in TSF | Crush and blend in hopper with lime. Dispose in tailings line. | TSF Supernatant (see Section 4.5.8) |
| Contaminated Soils | All managed as material with high ML/ARD potential and high current ML/ARD conditions | Submerged in TSF | Process through mill or crush and blend in hopper with lime. Dispose in tailings line. | TSF Supernatant (see Section 4.5.8) |
| Berm | All managed as material with high ML/ARD potential and high current ML/ARD conditions | Submerged in TSF | Crush and blend in hopper with lime. Dispose in tailings line. | TSF Supernatant (see Section 4.5.8) |
| Anchor Rock | Managed as either NAG or PAG, depending on sampling before placement | **If Non-PAG:**<br>Stored on surface<br>**If PAG:**<br>Submerged in TSF | **If Non-PAG:**<br>Store on waste rock dump. Can be used as fill material for heap leach pad hole left after other materials are disposed.<br>**If PAG:**<br>Follow disposal described for Berm Materials. Crush and blend in hopper with lime. Dispose in tailings line. | One composite is collected every truckload.<br>Sample is screened to -2 mm and +2 mm fractions. The -2 mm fraction is analyzed for total carbon and total sulphur at on-site laboratory. ARD classification of each fraction follows MPMC ML/ARD Management Procedure Manual (MPMC 2016 or most recent version). |
| **Associated Infrastructure and Reagents** | | | | |
| Heap Leach Pad Excavation | Once material has been removed from the heap leach pad, the exposed hole should be filled with Non-PAG rock. | - | - | Sampling of placed rock should follow MPMC (2016) (or most recent version) to confirm ARD potential of placed material. |
| Leach Pad Liner | - | Heap leach excavation | Folded in place and covered with Non-PAG rock. | - |
| Reagents and Chemicals | The only reagent or chemical related to the leach pad is the leach pad leachate. | TSF | Continually manage leach pad level by pumping down to mill or TSF. | - |
| Remaining Infrastructure | - | - | Auxiliary buildings should be dismantled and disposed as per other management plans. They can be re-used for other reclamation activities as required | - |

# 1 Introduction

Mount Polley Mining Corporation (MPMC) retained SRK Consulting (Canada) Inc. (SRK) to develop a plan to decommission the Test Heap Leach Facility at Mount Polley Mine. The plan is a requirement under MPMC's amalgamated Mines Act Permit M-200 (EMPR 2020) s. D3(c)(v) and must be submitted to the BC Ministry of Energy, Mines and Low Carbon Innovation (EMLI) by June 30, 2021. Specifically, the M-200 condition reads:

> *The Permittee shall provide a report that includes a detailed plan and timeline for the removal of the test heap leach facility and all stockpiled sulphur by June 30, 2021, to the satisfaction of the Chief Inspector. The Permittee shall ensure the plan includes, but is not limited to, the removal and disposal of the leached ore, sulphur stockpile, waste rock, contaminated soil, reagents or chemicals, and all associated infrastructure.*

The plan also should include an approach to identify and remediate any contaminated material beneath the facility. No timeline for disposal is provided in the M-200 Permit.

The Test Heap Leach Facility is located on top of the East Rock Disposal Site (East RDS) and includes the lined heap leach pad, operations building, and former sulphur stockpile footprint. Background of the facility is provided in Section 2.

The Decommissioning Plan requires geochemical characterization of the materials stored on the Test Heap Leach Facility. This document provides the geochemical characterization program that is currently underway to address data gaps identified during the development of the Geochemical Conceptual Models (GCMs) for each material. Results from the characterization program are not yet available in time for reporting and management options will be selected after the additional characterization is completed.

Reagents or chemicals and all associated infrastructure that need to be removed have not been considered as the Geochemical Characterization Plan focuses on material reactivity and disposal.

To finalize the Decommissioning Plan, the results from the geochemical characterization program will be used to update the GCMs and develop a management plan for each material. This will comprise an options analysis for potential remedial options for each material. The options analysis will be based on the updated GCMs and include considerations for site (e.g., disposal during operations versus closure, tailings deposition plan into the Tailings Storage Facility (TSF), Life of Mine Plan and scheduling, etc.).

The final Decommissioning Plan, which will include all components listed above, is expected by the end of Q3 2021.

# 2 Overview of the Test Heap Leach Facility

## 2.1 Background

The pilot-scale Test Heap Leach Facility was constructed in 2007 for research into leaching non-sulphide copper ore. From 2006-2008, approximately 11,000 $m^3$ of sulphur was procured for sulphuric acid production for the heap leach trial. Between 2007 and 2012, different layering and blending techniques of ore and sulphur were tested to optimize leaching. In 2012, the Test Heap Leach Facility was placed into Care and Maintenance due to economic considerations but was not loaded out prior to shut down. Roughly 7,000 $m^3$ of ore remain on the leach pad. The heap leach pad also contains contaminated soils from an off-site disposal clean-up. Approximately 19,000 tonnes were loaded out and processed in the mill in 2019. An estimated 30,000 t remains on the heap leach pad.

Excess sulphur was stored in a nearby stockpile, first in the Cariboo Pit (2006-2009) and then moved to a crushed rock pad beside the heap leach pad (2009-2018) when mining resumed in the Cariboo Pit. In 2018, the excess sulphur was relocated on top of the lined leach pad after evidence showed that water quality on the mine may be affected by contaminated drainage from below the sulphur stockpile. The affected drainage is seepage from the NEZ Dump, located east of the Test Heap Leach Facility. Approximately 1 m of material was removed from the sulphur stockpile pad (about 9,200 tonnes) and was relocated to the TSF after the sulphur stockpile was moved to the Test Heap Leach Facility.

Leachate from within the lined heap leach pad facility is managed by treatment with lime at the plant and conveyance to the TSF. A copper recovery system using Sodium Hydrosulfide (NaHS) to precipitate copper sulfide in the tailings thickener is being developed by MPMC within the concentrator building. The sprinkler system over top of the facility is operational.

## 2.2 Materials Inventory

Materials stored at the Test Heap Leach Facility are shown in Figure 1 and summarized in Table 1. The plan view will be updated after sampling if the location of materials become better delineated and a cross-section will be developed to be included in the Decommissioning Plan.

**Figure 1: Plan View of Heap Leach Facility Showing Location of Different Materials Stored on Leach Pad**

**Table 1: Inventory of Materials Stored at the Heap Leach Facility**

| Material | Earlier Placement | Current Storage Location | Estimated Tonnage Stored on Leach Pad (t) |
|---|---|---|---|
| Elemental sulphur | Placed on top of waste rock pile on crush pad | Stored on top of leached ore on leach pad | 22,880 |
| | Stored in sulphur stockpile before loaded onto leach pad | Stored in layers of between ore on leach pad | Unknown amount |
| Leached waste rock from beneath sulphur stockpile | Beneath sulphur stockpile | Stored on top of leached ore on leach pad | 9,200 |
| Leached ore | Placed on leach pad, layered with elemental sulphur | Stored on top of leach pad | 18,900 |
| | Placed on leach pad, layered with elemental sulphur | Stored on top of leach pad | |
| Contaminated soils | Metal-impacted soils clean-up from Kinder Morgan/Vancouver Wharves | Stored on top of leached ore on leach pad | 30,000 |
| ***Construction Materials*** | | | |
| Anchor Rock | Waste rock sourced from pits during construction | Outside of heap leach pad footprint | 0[1] |
| Berm | Waste rock sourced from pits during construction | Around leached ore on leach pad, within heap leach pad footprint | Unknown amount |

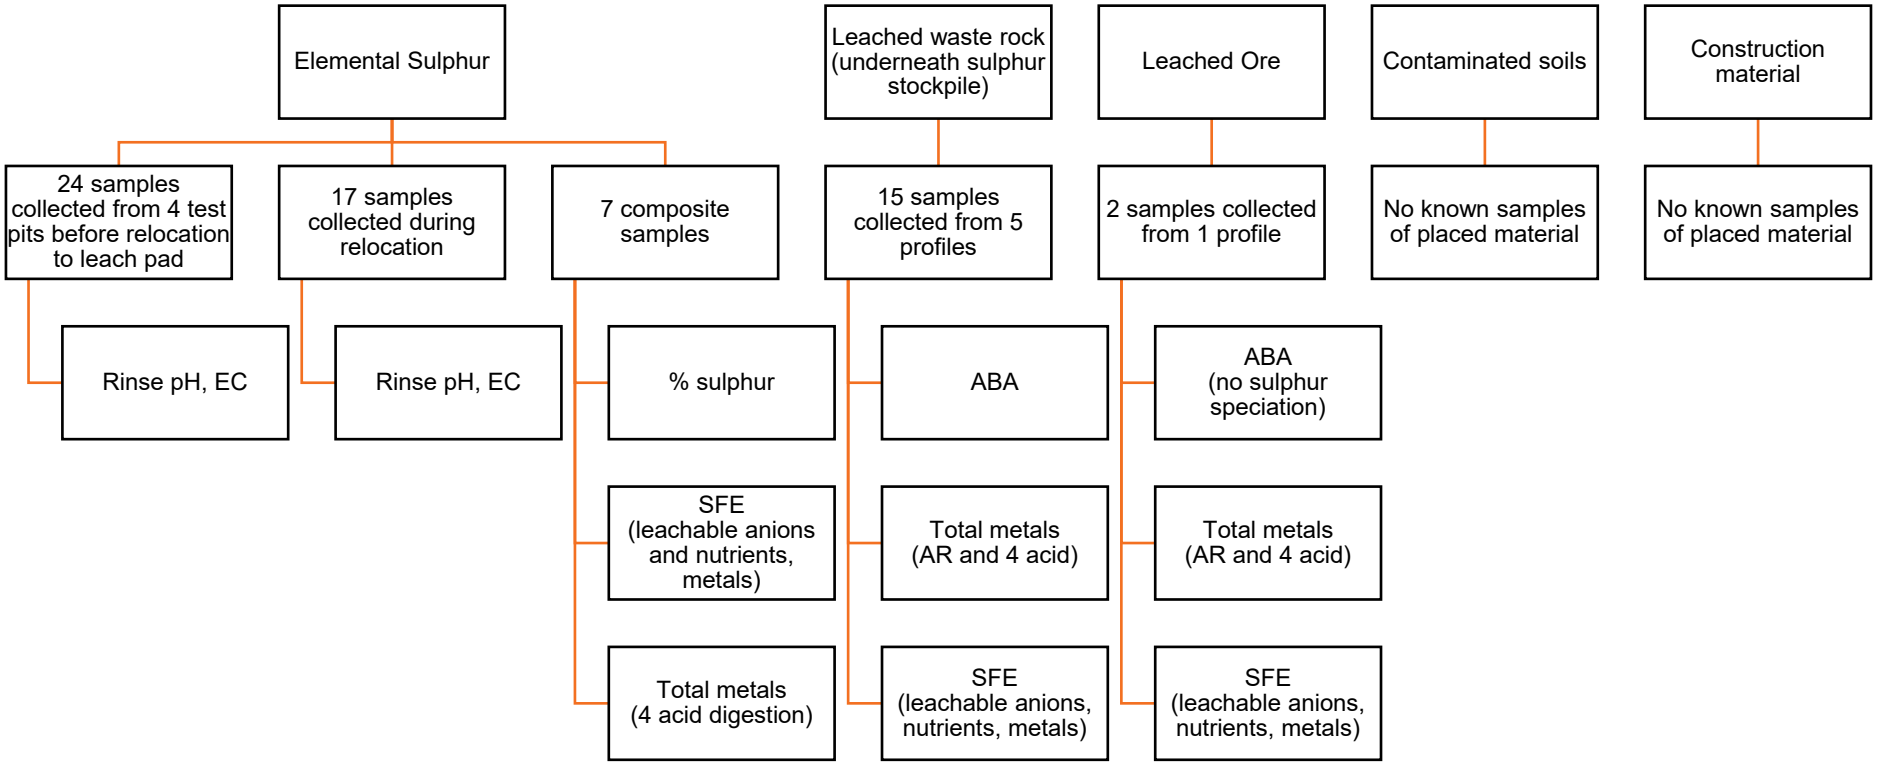
Notes: Estimated material amounts were provided by MPMC.



[1] Stored outside of leach pad footprint

[2] Liner comprises two HDPE liners that are 19,000 $m^2$ with one geonet placed between.

## 2.3 Existing Data

Available data are summarized in Figure 2. Data exist for elemental sulphur, leached waste rock from beneath the sulphur stockpile, and leached ore.

**Figure 2: Summary of Existing Datasets Available by Material Stored in the Test Heap Leach Facility**

Sources: \\van-svr0.van.na.srk.ad\Projects\01_SITES\Mt_Polley\1CM017.010_Heap_Leach_Facility_Decomissioning\!060_Presentations\GCM_SamplingPlan_1CM017.010_Rev02_SJL.pptx

# 3 Geochemical Conceptual Models

GCMs were developed for each of the waste types currently stored in the Test Heap Leach Facility using existing information, geochemical first principles, and experience. GCMs are an effective way to capture the key geochemical reactivity considerations for the Test Heap Leach Facility and how its reactivity may be impacting water quality on site now, and how it may do so in the future under various long-term storage scenarios.

The GCMs effectively represent hypotheses about material characteristics and reactivity which are subsequently evaluated through observations, sampling, testwork, and interpretation. A gap analysis was performed to inform need for additional testing, which is described in the following section. The results from additional characterization will test the assumptions in the GCM concerning the reactivity of the materials stored in the Test Heap Leach Facility and ultimately be used to develop management options. The characterization program currently underway is described in Section 4.

## 3.1 Elemental Sulphur

Prior to relocation onto the Test Heap Leach Facility, elemental sulphur was stored on top of the East RDS on a crush pad in a stockpile (see Figure 1). The elemental sulphur was previously sampled and tested in 2018 prior to and during its relocation to the heap leach pad, as summarized in SRK (2019). The following was found:

- The elemental sulphur in the stockpile was composed of about 90% sulphur. Some impurities were present which created a leachable source of other elements including iron and aluminum.
- Oxidation of the sulphur has generated sulphuric acid which is readily soluble.
  - pH of Shake Flask Extraction (SFE) leachates ranged from 1.4 – 1.9.

Elemental sulphur is currently stored in two locations: on top of the leached ore on the leach pad and stored in layers between ore on the leach pad. It is expected that elemental sulphur currently stored on top of the leached ore is similar to the previously characterized material. No existing data are available for elemental sulphur stored in layers between ore on the leach pad, but it is expected to be similar to the bulk pile.

The GCM for elemental sulphur for both storage locations is shown in Figure 3 and summarized in Table 2. A potential decommissioning option and unknowns identified in the gap analysis are also included in Table 2. Additional testwork to address these unknowns is described in Section 4.1.

The potential decommissioning option that was considered for the elemental sulphur was submergence. Disposal underwater can be expected to arrest oxidation but will rapidly leach the soluble acidity. The final location for submergence (e.g., TSF, flooded pit, etc.) has not yet been considered.

**Figure 3: Geochemical Conceptual Model – Elemental Sulphur**

Sources: \\van-svr0.van.na.srk.ad\Projects\01_SITES\Mt_Polley\1CM017.010_Heap_Leach_Facility_Decomissioning\!060_Presentations\GCM_SamplingPlan_1CM017.010_Rev02_SJL.pptx
Notes: Left: Elemental sulphur stored on top of leached ore on leach pad. Right: Elemental sulphur stored in layers of between ore on leach pad.

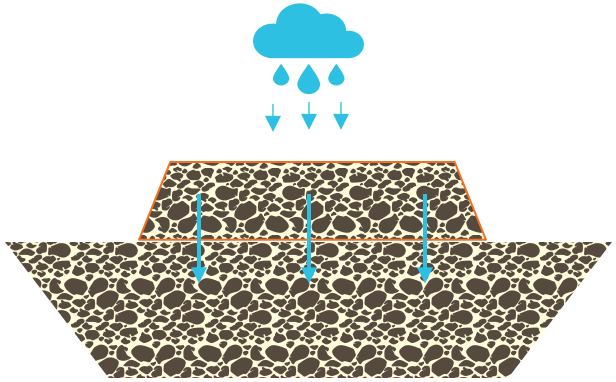
## 3.2 Leached Waste Rock from Beneath Sulphur Stockpile

Litke et al. (2019) and Litke (2019) showed pH-controlled weathering fronts developed in the material underneath the sulphur stockpile. Acidification was observed at one sampling profile location, but the amount and degree to which the waste rock was acidified was variable underneath the sulphur stockpile. Jarosite was observed at this location, which typically forms under acidic conditions and needs iron. This is possibly an indication that the acid generated from the sulphur pile was interacting with the waste rock underneath and was contributing to accelerated weathering of this rock. Carbonate depletion was apparent at all locations, but excess carbonate to maintain neutral pH was observed at some sampling locations below the sulphur stockpile. The leached waste rock was dominantly potentially acid generating (PAG), based on acid potential (AP) calculated from sulphide and neutralizing potential (NP) from remaining carbonate. Sulphur prills were observed interspersed in the material.



Material that was previously underneath the sulphur stockpile was well characterized, as documented in Litke (2019) and Litke et al. (2019). No additional static testwork of this material was recommended.

The GCM for leached waste rock from beneath sulphur stockpile is shown in Figure 4 and summarized in Table 3. Two potential decommissioning options and unknowns identified in the gap analysis are also included in Table 3.

One potential decommissioning option that was considered for the leached waste rock was submergence. Disposal underwater can be expected to arrest oxidation but will rapidly leach the soluble acidity and associated metals. The final location for submergence (e.g., TSF, flooded pit, etc.) has not yet been considered.

The other potential decommissioning option considered was disposal on surface with lime amendment. The final location and management approach has not yet been considered.

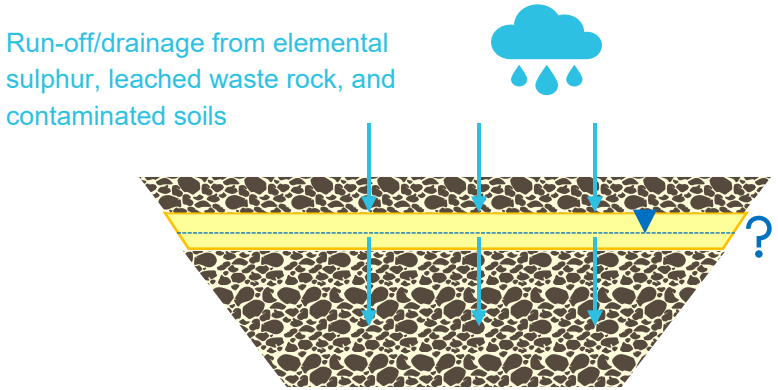
## 3.3 Leached Ore



Data from two samples collected for one depth profile exist, as previously documented in Litke (2019). Carbonates were depleted and sulphur prills were observed mixed with the leached ore on the heap leach pad and acidification was evident along the profile (Litke 2019). Henry (2009) showed precipitation of copper sulphide minerals was occurring in water-saturated and anaerobic microenvironments in the leach pad.

Leached ore is currently stored on the leach pad, beneath the elemental sulphur, contaminated soils, and leached waste rock. The majority of the leached ore is stored on the southwest end of the leach pad, beneath the elemental sulphur.

The GCM for leached ore is shown in Figure 5 and summarized in Table 4. A potential decommissioning option and unknowns identified in the gap analysis are also included in Table 4. Additional testwork to address these unknowns is described in Section 4.4.

The potential decommissioning option that was considered for the leached ore was submergence. Disposal underwater can be expected to arrest oxidation but will rapidly leach the soluble acidity and associated metals. The final approach for decommissioning has not yet been determined.

Sources: Compiled in text

## 3.4 Contaminated Soils

Contaminated soils are currently stored on top of the leached ore on the northeast end of the leach pad. Some samples of the contaminated soils were collected and tested before the material was brought to Mount Polley Mine and placed on the heap leach pad. This material was sourced from various soil clean-up sites and no sampling of placed material occurred during initial placement. The sampling and testing methods were not provided, and the data were not able to be related with the remaining material on the leach pad.

The GCM for contaminated soils is shown in Figure 6 and summarized in Table 5. Unknowns identified in the gap analysis are also provided in Table 5. Potential decommissioning options could not be considered until key aspects are determined and additional testwork to address these unknowns is described in Section 4.5.

**Figure 6: Geochemical Conceptual Model – Contaminated Soils**

## 3.5 Construction Material

### 3.5.1 Anchor Rock

This material was waste rock sourced from pits and is possibly similar to other NAG waste rock from Mount Polley. Anchor rock is currently stored outside the main footprint of the leach pad. No geochemical data exists for this material.

The GCM for anchor rock is summarized in Table 6. A potential decommissioning option considered was to leave material on the East RDS as part of the NAG waste rock pile, depending on the ARD potential of the anchor rock. However, there may be possible contamination of the anchor rock with dust from the elemental sulphur due to its proximity to the leach pad and former stockpile location. Additional testwork to address this is described in Section 4.5.

### 3.5.2 Berm

This material was waste rock sourced from pits but is currently stored inside the footprint of the leach pad. It is contaminated with leachate and dust from elemental sulphur. No geochemical data exists for this material.

The GCM for berm material is summarized in Table 7. Two potential decommissioning options and unknowns identified in the gap analysis are also included in Table 7.

One potential decommissioning option that was considered for the berm material was submergence. Disposal underwater can be expected to arrest oxidation but will rapidly leach the soluble acidity and associated metals. The final location for submergence (e.g., TSF, flooded pit, etc.) has not yet been considered.

The other potential decommissioning option considered was disposal on surface with lime amendment. The final location for disposal has not yet been considered.

### 3.5.3 Drainage Material and Compacted Till Layer

No geochemical data exists for this material; however sampling of these materials will not be possible until decommissioning. The amount of drainage material and till is small in proportion to other materials, so sampling and analysis is for inventory development and estimating potential amendments. A sampling and testing plan to characterize this material as the facility is decommissioned will be provided in the final Decommissioning Plan.

**Table 6: Geochemical Conceptual Model – Anchor Rock**

| Current Storage Location | Current Storage Environment | Reactivity and Impacts on Current Water Quality | Potential Decommissioning Option | Reactivity and Impacts on Future Water Quality | Unknowns |
|---|---|---|---|---|---|
| Stored outside leach pad footprint on top of East RDS | ■ Exposed to precipitation (rain and snowmelt)<br>■ Atmospheric oxygen exposure<br>■ Possibly contaminated with dust from elemental sulphur | ■ Sulphide oxidation occurring<br>■ Carbonate buffering pH | Leave in place as part of East RDS | ■ Depends on ARD potential with remaining sulphide content<br>■ Carbonate in rock neutralizes generated acid<br>■ Neutral pH run-off | ■ Degree of contamination with elemental sulphur dust due to proximity to leach pad and former sulphur stockpile location |

# 4 Current Characterization Program

## 4.1 Overview

Sampling of material stored on the Test Heap Leach Facility was done by SRK personnel from May 5 – 6, 2021 after snow melt. To ensure the liner was not punctured during sampling, the depth to liner was estimated at each sampling location using historical survey data.

Elemental sulphur, leached ore, and contaminated soils samples were collected using an excavator. Test pits were dug at each sampling location using an excavator. Each test pit was logged after excavation. Elemental sulphur, leached ore, and contaminated soils samples were collected using this method.

Construction materials were collected as one composite approximately every 25 m. This includes the anchor rock and berm materials. Drainage materials and the compacted till liner can not be sampled before decommissioning because they are below the HDPE liner, so no samples of these materials were collected.

Table 9 summarizes the samples submitted for analysis as part of the characterization program.

**Table 9: Summary of Samples Submitted for Analysis During the Current Characterization Program**

| Material | Current Storage Location | Number of Samples Collected | GCM Section | Characterization Program Section |
|---|---|---|---|---|
| Elemental Sulphur | Stored on top of leached ore on leach pad | 2 | 3.1 | 4.2 |
| | Stored in layers between ore on leach pad | 2 | 3.1 | 4.2 |
| Leached Ore | Stored on the leach pad, beneath the elemental sulphur, contaminated soils, and leached waste rock | 9 (4 profiles) | 3.3 | 4.4 |
| Contaminated Soils | Stored on the leach pad | 11 | 3.4 | 4.5 |
| Anchor Rock | Stored outside leach pad footprint | 10 | 3.5.1 | 4.6.1 |
| Berm | Berm | 10 | 3.5.2 | 4.6.2 |

## 4.2 Elemental Sulphur

Further sampling and testing of the elemental sulphur was completed as follows:

- Four confirmatory samples from material placed on leach pad were collected. The number of samples were based on heterogeneity of material. The samples were analyzed for:
  - Rinse pH and EC in field.
  - Subset (n=2) submitted for:
    - Total sulphur
    - Metals by aqua regia digestion with ICP-MS finish
    - Readily soluble forms testing: SFE (MEND method) on as-received particle size. Leachate analyzed for pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS
- Two samples were collected from layered sulphur in leach pad. The number of samples were based on heterogeneity of material and sampling access (i.e., present within safe depth of test pit). The samples were analyzed for:
  - Rinse pH and EC in field.
  - Subset (n=2) submitted for:
    - Total sulphur
    - Metals by aqua regia digestion with ICP-MS finish
    - Readily soluble forms testing: SFE (MEND method) on as-received particle size. Leachate analyzed for pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS

## 4.3 Leached Waste Rock from Beneath Sulphur Stockpile

No further sampling of this material was recommended, but pulps and rejects from the previous characterization work by Litke (2019) are available for further analysis if required.

## 4.4 Leached Ore

Further sampling and testing of the leached ore was completed as follows:

- Four test pits were excavated and nine samples in total were collected. The number of samples were based on heterogeneity of material. The samples were analyzed for:
  - ABA
    - paste pH, total sulphur, sulphate sulphur by HCl leach, sulphate sulphur by pyrolysis, total carbon, total inorganic carbon, modified Sobek NP)
  - Metals by aqua regia digestion with ICP-MS finish

- Readily soluble forms testing: SFE (MEND method) on as-received particle size. Leachate analyzed for pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS
- A subset may be submitted for mineralogy once results are received

## 4.5 Contaminated Soils

Further sampling and testing of the contaminated soils was completed as follows:

- In total, 11 samples were collected. The samples were analyzed for:
  - ABA
    - paste pH, total sulphur, sulphate sulphur by HCl leach, sulphate sulphur by pyrolysis, total carbon, total inorganic carbon, modified Sobek NP
  - Metals by aqua regia digestion with ICP-MS finish
  - Readily soluble forms testing: SFE (MEND method) on as-received particle size. Leachate analyzed for pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS
  - A subset may be submitted for mineralogy once results are received

## 4.6 Construction Material

### 4.6.1 Anchor Rock

Further sampling and testing of the anchor rock was completed as follows:

- In total, 10 composite samples of the anchor rock were collected. The samples were analyzed for:
  - ABA
    - paste pH, total sulphur, sulphate sulphur by HCl leach, sulphate sulphur by pyrolysis, total carbon, total inorganic carbon, modified Sobek NP)
  - Metals by aqua regia digestion with ICP-MS finish
  - Readily soluble forms testing: SFE (MEND method) on as-received particle size. Leachate analyzed for pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS
  - A subset may be submitted for mineralogy once results are received

### 4.6.2 Berm

Further sampling and testing of the berm material was completed as follows:

- In total, 10 composite samples of the berm material were collected. The samples were analyzed for:
  - ABA
    - paste pH, total sulphur, sulphate sulphur by HCl leach, sulphate sulphur by pyrolysis, total carbon, total inorganic carbon, modified Sobek NP
  - Metals by aqua regia digestion with ICP-MS finish
  - Readily soluble forms testing: SFE (MEND method) on as-received particle size. Leachate analyzed for pH, conductivity, ORP, acidity, alkalinity, sulphate, chloride, nitrate, nitrite, ammonia, fluoride, dissolved organic carbon, dissolved metals by ICP-MS
  - A subset may be submitted for mineralogy once results are received

### 4.6.3 Drainage Material and Compacted Till Layer

Sampling of these materials will not be possible until decommissioning and no samples could be collected.

# 5 Summary

Table 10 summarizes the potential decommissioning options for components of the Heap Leach Facility. Options will be selected after the GCMs are updated and an options analysis is completed.

**Table 10: Heap Leach Facility Decommissioning Inventory**

| Material | Current Storage Location | Potential Decommissioning Options | Estimated Tonnage Stored on Leach Pad (t) |
|---|---|---|---|
| Elemental sulphur | Stored on top of leached ore on leach pad | Submergence | 22,880 |
| | Stored in layers of between ore on leach pad | Submergence | Unknown amount |
| Leached waste rock from beneath sulphur stockpile | Stored on top of leached ore on leach pad | Submergence<br>Amendment with lime | 9,200 |
| Leached ore | Stored on top of leach pad | Submergence | 18,900 |
| Contaminated soils | Stored on top of leached ore on leach pad | None yet considered | 30,000 |
| ***Construction Materials*** | | | |

| **Subject** | Review of Geochemical Source Terms – Mount Polley Mine | | |

## 1 Introduction

Mount Polley Mining Corporation (MPMC) is applying to extend its Environmental Management Act (EMA) authorization (Permit 11678) to allow discharge of treated water to Quesnel Lake beyond the current expiry date of December 31, 2022. The original authorization issued in 2016 was based on a site wide water quality model inputs to which were geochemical source terms developed by SRK Consulting (SRK 2016). To support the application, SRK was requested by MPMC to review the basis for the source terms and provide commentary on the need for an update to the model to reflect changes in source water chemistry.

This memorandum provides results of the review.

## 2 Background

SRK (2016) described development of the original geochemical source terms beginning with conceptual geochemical models to describe the anticipated performance of each source of contact water. The main sources of chemical load are the waste rock dumps and tailings. Numerical source terms were developed by statistically summarizing water chemistry monitoring data for near source seeps. The higher concentrations in the monitoring datasets were assumed to represent contact water with minimal dilution. This approach avoids the limitation of interpreting laboratory test data. The main assumption when using monitoring data is that the wastes are geochemically stable.

SRK (2016) did not recommend separate source terms to indicate chemical loads originating from two small sources (elemental sulphur stockpile and magnetite stockpile) based on the assumption that the loads were reflected in the waste rock dump seep monitoring. In 2018, the sulphur stockpile was relocated to a lined pad already containing waste rock mixed with elemental sulphur. Acidic drainage from the pad is pumped to the tailings storage facility (TSF).

# 3 Method

SRK evaluated whether a statistically significant change in near source concentrations had occurred between data collected up to December 2015 and subsequent data collected from January 2016 to December 2021. December 2015 was the cutoff for data used by SRK (2016). 95% confidence limits on geometric averages for the two data periods were compared. If the ranges overlapped, it was concluded that no change in near source concentrations had occurred.

For selected parameters, box and whisker plots were prepared to examine the distributions in more detail.

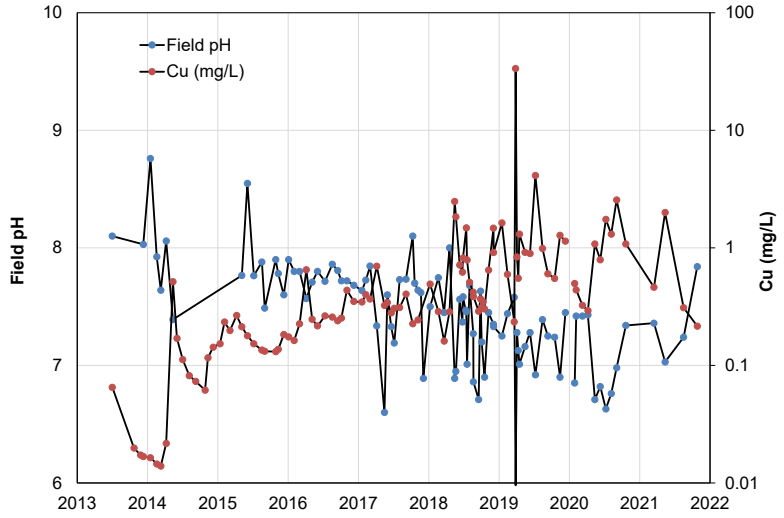
# 4 Results

## 4.1 Waste Rock

Table 1 summarizes findings on statistically significant changes in seepage chemistry of waste rock and tailings seeps. All metals and related elements are expressed as dissolved concentrations. For waste rock, the difference is shown by decrease in pH and increased concentrations of elements neutralizing sulphuric acid by reaction with calcium and magnesium carbonates and potassic silicates. The depression in pH increased the solubility of several heavy metals (Cd, Cu, Ni and Zn).

**Table 1: Summary of Statistically Significant Changes in Seepage Chemistry**

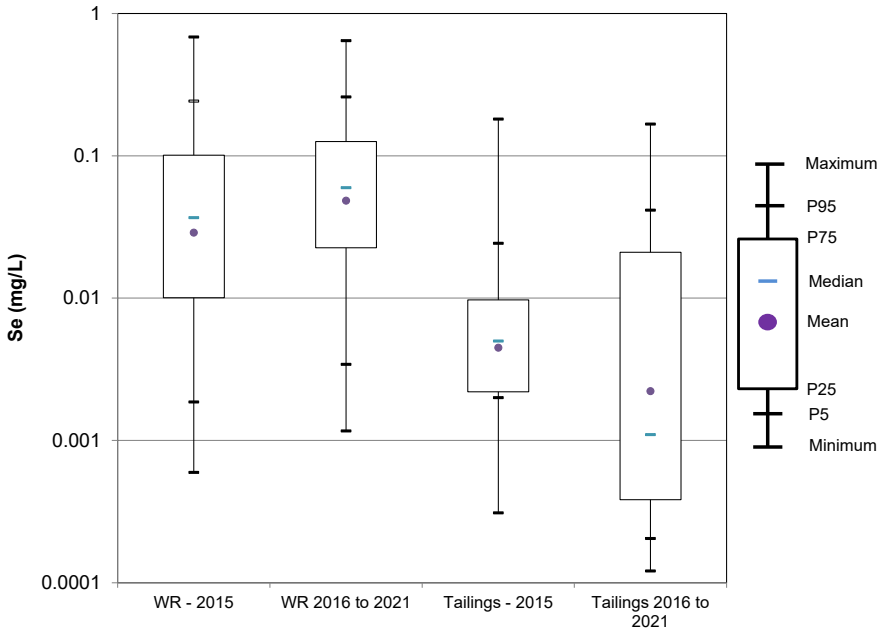
| Waste Rock Seeps | | Tailings Seeps | |
|---|---|---|---|
| **Significant Decrease** | **Significant Increase** | **Significant Decrease** | **Significant Increase** |
| Alkalinity, $NH_3$, As, Ba, Cl, DOC, Mn, $NO_3$, $NO_2$, $PO_4$, V | $H^+$, **Cd**, Ca, Cu, **Li**, Mg, Mo, Ni, K, **Se**, Na, $SO_4$, Zn | Al, Sb, Ba, DOC, Ni, $NO_3$, $NO_2$, Se, V | $H^+$, alkalinity, $NH_3$, As, B, Ca, Co, Fe, Li, Mg, Mn, Mo, K, Na, $SO_4$, U, Zn |



Source: https://srk.sharepoint.com/sites/NACAPR001713/Internal/2022-02_SourceTermReview/[SourceTermDataReview_CAPR001713_SJD_R0.xlsx]

Notes: Parameters shown in bold show significant increases in average concentrations when seeps influenced by the sulphur stockpile are removed from the geometric mean.

For the most part, these differences can be accounted for by increased sulphate and metal concentrations at NEZ Seep 1 and 2, which are believed to be influenced by oxidation and leaching of the elemental sulphur. Monitoring of the drainage from the leach pad containing ore, waste rock and elemental sulphur showed average pH, sulphate and copper of 3.3, 15 g/L and 750 mg/L, respectively. Parameters shown in bold still showed a significant increase after removal of these seeps from the calculation of averages. At Seep 1, pHs declined below 7 sporadically in 2017 and one reading was just below 6 in 2019 (Figure 1). The decline in pH and increase in copper concentrations appears to have plateaued as would be expected since the sulphur pile was removed in 2018.



While average selenium concentrations increased as shown in Table 1, the statistics used to define the source term ($95^{th}$ and $99^{th}$ percentiles) did not change markedly.

## 4.2 Tailings

Table 1 shows statistically significant increases for a number of parameters in the tailing seeps. Statistics for this period reflect the long-term record of monitoring prior to the tailings breach in August 2014, the subsequent period when the tailings were drained following the breach and re-activation of the TSF after the dam was reconstructed. Of those parameters shown in Table 1, the greater increases were apparent for sulphate and molybdenum. Seepage concentrations for these two parameters are correlated which is consistent with the expectation that they both originate by oxidation of pyrite since molybdenite is uncommon in the mineralization at Mount Polley.

Inspection of sulphate and molybdenum trends for individual seeps shows the upward trend but also stabilization of the trend in recent years (Figure 3). The explanation for the trends is not clear. It may reflect dewatering of the tailings following the breach resulting in greater oxidation of tailings. pHs have declined (Table 1) but remain above 7 which might indicate greater acid generation with neutralization by carbonates. A second explanation is that acidic water from the leach pad containing elemental sulphur is pumped to the tailings pond, but molybdenum is not detected in the leach pad water and sulphate and molybdenum are strongly correlated. It seems unlikely that the acid drainage from the leach pad would be affecting the chemistry of seepage from the TSF. The apparent flattening of the trend may indicate that the solubility of secondary minerals is controlling concentrations. Sulphate concentrations in these seeps are below the solubility limit resulting from the formation of gypsum (typically near 1500 mg/L in waters dominated by calcium and sulphate) but this is expected because seeps are not pure contact waters. At these pH conditions, molybdenum concentrations may be controlled by the solubility of calcium molybdate (powellite).

**Figure 3: Sulphate and Molybdenum Trends for East Main Toe Drain**

Source: https://srk.sharepoint.com/sites/NACAPR001713/Internal/2022-02_SourceTermReview/[SourceTermDataReview_CAPR001713_SJD_R0.xlsx]

Selenium shows a statistically significant but small (0.002 mg/L) decrease in average concentrations, but the dataset has become more variable particularly as shown by the spread in quartiles (Figure 2). Trends for individual seeps are variable.

# 5 Discussion

Seepage from the waste rock dumps has been mostly stable for key parameters (pH, sulphate, copper and selenium) over the monitoring period with the exception of localized influence of sulphuric acid waters likely originating from oxidation of the elemental sulphur pile. The acidity has been neutralized by reaction with carbonate and silicate minerals in the waste rock but it resulted in depressed pHs and occasional breakthrough of acidic waters to waste rock seeps. The removal of the elemental sulphur pile seems to have arrested the downward trend in pH and upward trend in copper.

There was a risk that depletion of acid neutralizing minerals from the waste rock could have triggered acidification of the waste rock on the infiltrating water flowpath but this does not seem to have occurred based on sampling of the foundation materials (Litke et al. 2019). It is expected that the seeps influenced by the sulphur stockpile will show a downward trend in parameters such as sulphate and copper.

Based on the current dataset, the waste rock source terms do not need to be modified because the source term method would result in source terms that are biased by these localized effects. However, monitoring of these seeps should continue and a sector-specific term developed if warranted.

Seepages from the TSF have shown significant increases in some parameters which may be a result in greater exposure of tailings due to dewatering of the tailings following the breach. It appears that trends in sulphate and molybdenum have stabilized over recent years which might be due to control by known secondary minerals (gypsum and powellite) in the tailings. The possible effect of secondary mineral solubilities means that current seepage chemistry should be a good indication of future water chemistry.

# 6 Conclusions

As a result of this review, SRK finds:

- Recent seepage chemistry statistics are influenced by seeps affected by leaching of sulphuric acid from the elemental sulphur stockpile which has now been relocated to the lined pad. Seepage chemistry is expected to improve as acidic waters are flushed from the pile. As a result, the source terms should not be updated to reflect the influence of these seeps.
- Upward trends in tailings seepage chemistry for some parameters appear to have stabilized over recent years which may reflect the influence of secondary mineral solubility. On this basis, higher concentrations would not be expected in the future.

# 1. SOILS

## 1.1. Terrain

Using airphoto interpretation, Blashill (1995a) conducted a preliminary terrain analysis of the Mount Polley project area. The principal terrain units are blankets and veneers of glacial atill (Mb and Mv), colluvial veneers (Cv), and gently to steeply sloping bedrock knobs (Rj to Rk). He also identified units of organic terrain (Ob and Obv) overlying glaciolacustrine materials ($L^G$). There are many small outcrops of bedrock, most of which are covered by thin veneers of glacial till, colluvium, or mixtures of the two. Even where soils are deeper, bedrock is usually found at depths of approximately 3 to 7.6m.

Veneers (less than 50cm thick) and blankets (more than 50cm thick) of morainal material are the most extensive landforms in the Mount Polley area. These morainal materials, also known as glacial till, were laid down by glacier ice, and they show little evidence of any subsequent reworking by water. Tills are generally poorly sorted, so that they contain a wide range of particle sizes, and the particles are often rounded and derived from a variety of rock sources. The morainal deposits at Mount Polley correspond to the Lanezi soil association of Lord (1984). Lanezi soils are loams oils developed on morainal materials deposited along the boundary zone of the Quesnel Highland. Parent materials range from load to clay loam with an acid to neutral reaction, and with moderate amounts of stones and gravel. In the Mount Polley are, Lanezi soils often occur in complexes with the Dragon soil association, which is described below. Soils mapped as Lanezi-Dragon units may contain 30 to 50% inclusions of the colluvial soils of the Dragon Association.

Veneers of colluvium, less than 1m thick, are the second most common landform in the project area. They are best expressed on the bedrock knobs and ridges in the Bell Pit and Springer/Cariboo Pit areas, as well as near the summit of Mount Polley itself, in Terrain Units #1 and #3 (Blashill, 1995a). “Colluvium” refers to soil materials that have been redistributed by gravity. Colluvium sometimes shows a degree of sorting by size, with the larger particles occurring farther downslope than the smaller ones. In contrast to till, coluvial particles often have rougher, more angular edges and they have the same lithology as the betrock occurring upslope from a colluvial deposit. The colluvial units recognized by Blashill (1995a) correspond to the Dragon and Lanezi-Dragon soil associations. Dragon soils are loamy and sandy soils developed on strongly sloping terrain at elevations above 900m.

Galciolacustrin landforms ($L^G$) ar those that have originated within the basins of proglacial lakes. Although Lord (1984) did not map glaciolacustrine landforms within the Mount Pole area itself, he showed extensive glaciolacustrine areas adjacent to the upper Quesnel and lower Cariboo rivers. He assigned these units to the Bednesti soil association, which includes fine loamy soils developed on silty, stratified glaciolacustrine deposits. These soils generally have a low stone content, are fine-textured, and often have a varved or layered appearance. Blashill (1005) reported that deep excavations by

engineering staff found glaciolacustrine deposits beneath a surficial till in the proposed tailings area, although the glaciolacustrine deposits were not continuous. IN that area, the sediments were up to 20m thick over bedrock.

Glaciofluvial landforms include both erosion and depositional landforms that have been formed by the water from melting glaciers. Lord (1984) did not recognize any glaciofluvial deposits within the Mount Polley area itself, although he mapped two such areas nearby. One such area ws int eh valley northwest of Polley Lake, and a second in the valley containing Prior and Little Lakes. He assigned these units to the Ptarmigan-Catfish Creek soil complex, which referes to sandy-sekeltal soils developed on glaciofluvial material at elevations from 900 to 1200m, which also contain significant inclusions of sedge fen peat. Blashill (1995a) did no note any glaciofluvial landforms within the Mount Polley area.

Organic landforms are the result of biological activity. In the Moutn Polley area, organic landforms are the result of the centrurues if accumu.ation sedge or moss peat. Lord (1984) assigned these units to the Catfish Creek-Spakwaniko (CC-SW) soil landscape complex, and mapped two such units in the Mount Polley area. The units are the small wetland at the south end of Polley Lake, and that within the southern portion of the tailings area. Blashill (1995a) mapped a small area of organic terrain northeast of the Main Pit (Terrain Unit #5), and two small organic unites within the tailings area.

A terrain classification map for the site and a soil/landform classifications map are provided as Figures 2.1 and 2.3[1] (extracted from Hallam Knight Piésold Ltd., 1996a).

Detailed soil and landform inventories have been completed across the site prior to development of the mine (Blashill, 1995a; Blashill, 1995b; Meister, 1998; Meister, 2001; Meister, 2004; Meister, 2005; Meister 2006; Meister, 2010), and can be referenced for further details.

### 1.2. Soil Land Capability

The Land Capability for Agriculture in BC contains 7 classes differentiated on the basis of the inherent capability of soils and climate to support agricultural crops. There was no agriculture practiced in the area and agriculture is not planned as an end land use at mine closure; however, agriculture land capability was assessed in soil and landform inventories completed across the site (Blashill, 1995a; Blashill, 1995b; Meister, 1998; Meister, 2001; Meister, 2004; Meister, 2005; Meister 2006; Meister, 2010). There is no climatic moisture deficit (CMD) number for the Mount Polley area, but the climatic capability for most of the site was mapped as 3GF. The CMD was estimated to be the minimum for the Class 3 unit, 116 mm, and based on average site soil conditions, the soil moisture deficit (SMD) was estimated to be 56.5 mm. This places the mine site in Class 2A for moisture limitations. The SMD calculated for each soil pit does not improve or increase the moisture limitations beyond Class 2A. Improved ratings were based on topographic changes due to bedrock removal, stone picking and improved drainage, although classes 6 and 7 normally have no improved rating. The depth to bedrock (R) and the climatic capability (3C) (limited by a short frost-free period and low thermal class) remain the

[1] MPMC is currently working to develop digitized versions of these map.

limiting factors for agricultural production. Overall the agricultural capability for the site is poor. None of the land in the project area is included in the Agricultural Land Reserve.

The soil map units are rated as suitable for forestry. The Ministry of Forests and Range site index estimates by site series for Mount Polley are 24 meters for Douglas-fir and lodgepole pine, and 21 meters for spruce. This site index provides a numeric description of site productivity for a particular target species; this is the height of the largest diameter (at breast height) site tree on a 0.01 ha plot at age 50, provided the tree is suitable for measurement (Ministry of Forests and Range, 2006). Due to favorable climatic and soil conditions, this site is very productive in terms of timber for a B.C. Interior site.

## 2. VEGETATION CLASSIFICATION

Biogeoclimatic maps of the Cariboo Forest Region indicate that the Mount Polley site is located within the Horsefly Moist Cool variant of the Interior Cedar-Hemlock Biogeoclimatic Zone (ICHmk3), which occurs between Quesnel and Horsefly Lakes, in the valley of McKinley Creek, and near Canim Lake. Table 2.1 provides a summary of the ICHmk3 site series. The dominant trees on upland sites in the ICHmk3 are Douglas-fir, Western red cedar, hybrid spruce, and subalpine fir. Lodgepole pine, trembling aspen, and paper birch are also present in the early stages of forest succession. The forests in lower valley bottoms are often dominated by hybrid spruce and black cottonwood.

Field surveys of the Mount Polley site have found that the dominant trees in mature and old growth stands are Western red cedar, Douglas-fir, and subalpine fir. Subalpine fir usually dominates the seedling regeneration in mid-seral, mature, and old forests. Black cottonwood dominates the early stages of forest succession after logging, while trembling aspen and paper birch are usually secondary species. Western hemlock is present in the area, but rare. Large portions of the project area have been selectively logged to remove the largest Douglas-firs and Western red-cedars, and some clearcut sites have been replanted with lodgepole pine seedlings. Hybrid spruce occur sparingly on lower, middle and upslope positions in the Mount Polley site area, and is most common near streams and lakeshores.

*Table 2.1 Interior Cedar Hemlock Horsefly Moist Cool Variant vegetation summary*

| Site Association | Moisture Regime | Slope Position | Gradient (%) | Aspect | Parent Material | Vegetation |
|---|---|---|---|---|---|---|
| ICHmk3/01 | mesic, submesic | middle | 0 - 20 | variable | gravelly, loamy morainal blanket | western redcedar, subalpine fir, falsebox, black huckleberry, bunchberry round-leaved violet, foamflower, rosy twistedstalk, red stemmed feathermoss |
| ICHmk3/02 | xeric, subxeric | crest | 0 - 10 | variable | loamy gravelly moraina veneer over | Douglas-fir, western redcedar, saskatoon, soopolallie, pussytoes, wild strawberry, white hawkweed, juniper haircap moss, lichens |
| ICHmk3/03 | subxeric, xeric | upper | 50 - 70 | variable | gravelly loamy colluvial veneer over morainal blanket | Douglas-fir, western redcedar, saskatoon, soopolallie, rough-leaved ricegrass, wavy-leaved moss, Peltigera sp. Mosses not forming carpet-like ground cover. |
| ICHmk3/04 | subhygric, mesic | lower, middle | 10 - 35 | variable | loamy morainal blanket | western redcedar, falsebox, devil's club, (10% cover or less), foamflower, oak fern (average cover 30%), leafy mosses, red-stemmed feathermoss |
| ICHmk3/05 | subhygric | middle, lower | 10 - 35 | variable | loamy morainal blanket, silty fluvial blanket | hybrid white spruce, subalpine fir, thimbleberry, black twinberry, red-osier dogwood, fringed aster, sweet-cicely, ragged moss. Shrubs diverse and abundant up to 70% cover. |
| ICHmk3/06 | subhygric, mesic | lower, middle | 0 - 25 | variable | loamy morainal blanket, loamy to silty fluvial blanket | hybrid white spruce, subalpine fir, devil's club (up to 40% cover), black gooseberry, lady fern, oak fern, enchanter's nightshade, stream violet, leafy mosses. Trees and shrubs show good to excellent vigour. |
| ICHmk3/07 | hygric | toe or depression | 0 | level | loamy morainal or fuvial blanket | hybrid white spruce, western redcedar, red-osier dogwood, black twinberry, devil's club (average 10% cover), horsetails, soft-leaved sedge, American brooklime, leafy mosses, ragged moss. Thallose liverworts in depressions and moss layer very diverse. |
| Non-forested unit | subhygric | depression | 0 | level | organic blanket | hybrid white spruce and lodgepole pine, when present occur as stunted trees. Scrub birch, Labrador-tea, hardhack, sedges, sphagnum mosses. |

### 2.1. Zonal Site Series (ICHmk3/01)

"Zonal" sites are those of average moisture and nutrient conditions, on moderate to gentle slopes. This site series occurs on gentle slopes of 0 to 50°, generally on till blankets, which are sometimes mantled with colluvial veneers where slopes range from 35 to 50°.

According to Steen (1989), mature and old stands on zonal sites are dominated by Western red cedar and subalpine fir, with an understory of falsebox, black huckleberry, bunchberry, round-leaved violet, and foamflower. The herb and shrub layers are relatively poorly developed (especially on north and northeastern aspects), and the forest floor tends to be carpeted with feather mosses, especially red-stemmed feather moss.

Baseline field studies found that the vegetation of zonal sites to be much richer and more diverse. Much of the project area was selectively logged in the 1970's, when the larger, merchantable Douglas-firs and Western redcedars were removed. Selective logging removed the tallest trees in the canopy, but left smaller conifers, advance seedling regeneration by subalpine fir, and large back cottonwoods in place. Much of the mine development area now supports a mixed forest with a sparse canopy of veteran conifers; a moderately dense pole sapling cover of subalpine fir, Western red cedar, and Douglas; and a dense tall shrub canopy of black cottonwood, Sitka alder, Douglas maple, Scouler willow and Bebbian willow. Most cut-over stands have a luxuriant low shrub understory dominated by red elderberry, black huckleberry, black twinberry, various willows, thimbleberry, western mountain-ash, prickly currant, and wild red raspberry. The herb layer in cut-over areas is also well-developed on zonal sites and is dominated by fireweed, bluejoint, and other grasses, Solomon's seal, twinflower, and bunchberry.

### 2.2. Xeric to Subxeric Site Series (ICHmk3/02, ICHmk3/03)

The driest sites on steep south-facing slopes and ridge crests belong to the ICHmk3/02 and ICHmk3/03 site series. Such sites are dominated by open to closed forests of Douglas-fir and Western red cedar. Common shrub species in the understorey are Saskatoon, soopalallie, and common herbs, including pussytoes, wild strawberry, white-flowered hawkweed, and rough-leaved rice grass. Juniper hair cap moss and lichens dominate the forest floor on very dry sites, while rough-leaved rice grass, wavy-leaved moss, and dog's-tongue lichen are characteristic species of slightly moisture sites (Steen, 1989).

Baseline field surveys found the driest sites (on ridge crests) with thin, rapidly drained soils conforming to 02 and 03 site series. The 02 site series is found on south- or west-facing ridge crests where soil depths less than 20 cm and it has a very localized distribution. They are dominated by an open forest of lodgepole pine and Douglas-fir. The tall shrub understorey is dominated by an advance regeneration of subalpine fir seedlings, but is otherwise poorly developed. The low shrub understory is dominated by black huckleberry, birch-leaved spiraea, falsebox, prickly rose and prince's pine. Common juniper is very scarce at Mount Polley. The herb layer is generally poorly developed, usually making up less than 1% of the groundcover. Twinflower, white hawkweed, and hear-leaved arnica are the most prominent herbs. The common mosses are red stemmed feather moss, juniper hair cap moss and dog's tongue lichen. Though usually present with low cover, coral lichen is never dominant.

Stands conforming to the 03 site series are more widespread, generally where soils are 20 to 50 cm deep, on upper slope positions. These sites are distinguished from the 02 by:

- A somewhat more vigorous growth of Douglas-fir, lodgepole pine, and subalpine fir;
- The presence of occasional Western red cedar;

- The presence of Sitka alder, Saskatoon, Western mountain-ash, and tall willows in the tall shrub understory;
- Higher coverage and greater species diversity in the low shrub and herb understory;
- Fair to good development of bear's hair and witches' hair lichens in the epiphyte layer.

An 03 site immediately west of the mill area was selectively logged in the 1970's, resulting in the removal of some very large Douglas-firs and Western red cedars with stump diameters of 70 to 100 cm. The cut-over area was slash-burned, and the natural vegetation was allowed to regenerate. The resulting forest provides excellent summer range for mule deer and moose. This stand has a very variable, patchy cover by Western red cedar, subalpine fir, black cottonwood, alder, and willow, and a very rich shrub understory with several very palatable species, such as Western mountain-ash, Saskatoon, wild rose, and willows. Many of the common shrub species are berry-producing, and important factor for black bears and birds, such as cedar waxwing, bohemian waxwing, America robin, and other thrushes.

### 2.3. Mesic to Moist Nutrient-Rich Site Series (ICHmk3/04, ICHmk3/05)

These sites occupy middle and lower slopes, with gradients of 10 to 35°. They often receive inputs of moisture and nutrients from overland seepage, and are usually associated with deep blankets (soil depths greater than 50 cm) of glacial till or fluvial deposits.

According to Steen (1989), site series 04 is dominated by western red-cedar, oak fern (30% cover), falsebox, foamflower, and red-stemmed feather moss. Devil's club has a cover of less than 10%. On the slightly moisture 05 site series, hybrid spruce and subalpine fir become increasingly dominant in the tree canopy. The shrub layer is much better developed than on zonal sites, and is dominated by thimbleberry, black twinberry, black gooseberry, and red-osier dogwood. The herb layer is also much lusher, and is dominated by species such as oak fern, fringed aster, wild sarsaparilla, lady fern and sweet-cicely. Leafy mosses and ragged mosses become increasingly important in the moss layer as moisture and nutrient levels increase.

Field studies at Mount Polley found many sites that generally conform to the 04 and 05 series, however many of these sites have been selectively logged, then slash-burned, so that the actual vegetation is atypical. Selectively logged areas are dominated by a mixed forest of black cottonwood, Douglas-fir, and subalpine fir. These sites typically have a very well-developed tall shrub understory dominated by black cottonwood seedlings, aspen poplar, Sitka alder, Douglas maple, Scouler willow, and Bebbian willow. The low shrub understory is also well developed, and often includes thimbleberry, black huckleberry, oval-leaved blueberry, red elderberry, black twinberry, black gooseberry, and wild raspberry. The herb understory is often very rich, and usually includes oak fern, lady fern, false Solomon's-seal, star-flowered Solomon's –seal, rosy twisted stalk, bunchberry, fireweed, and one-leaved foamflower. Some 04 and 05 sites near Bootjack Lake have been set back to a very early stage of succession, and are dominated by black cottonwood, alder, willows, fireweed, pearly everlasting, dandelion and various tame grasses, legumes, and weeds.

Mature and older forests in the 04 and 05 site series tend to be dominated by species that are of relatively low palatability to ungulates, the main exception being red-osier. These mature stands almost always have excellent growths of arboreal lichens, notably witches' hair and bear's hair, growing in thick beards up to 30 cm long. These arboreal lichens may provide an important forage source for mule deer, particularly in the early spring. Many of the dominant shrub species are good berry-producers, a feature that may be important to black bears and some songbirds.

Forest regeneration following logging has had varying degrees of success in the Mount Polley area. In some areas, selective logging has actually improved the area's capability as summer habitat for moose and mule deer by removing the tree canopy and allowing more light on the herb and shrub understory. Removal of the coniferous tree canopy has increased the cover of several highly palatable forage species, notably black cottonwood, trembling aspen, Scouler and Bebbian willow, Western mountain-ash, Saskatoon, red-osier dogwood, and red elderberry.

### 2.4. Moist, Very Rich Sites (ICHmk3/06, ICHmk3/07)

They are found at the toes of long slopes in riparian habitats and in topographic depressions. These sites are associated with deep blankets of morainal or fluvial materials. They are often dominated by forests of hybrid spruce and Western red cedar, with an understory of red-osier, black twinberry, devil's club, horsetails, soft-leaved sedge, American speedwell, and various mosses. Tree growth is good to excellent in these sites, and the shrub cover is usually lush and diverse.

At Mount Polley, site series 06 is readily recognized by the devil's club cover of up to 40%. Other prominent plant indicators include oak fern, spiny wood-fern, lady fern, foamflower, false Solomon's-seal, rosy twisted stalk, and clasping twisted stalk. As good example, is SE of the mill site. Another is adjacent to the Bootjack Lake Recreation Site. A small tract of mature forest of the 06 site association occurred in the north-central portion of the Tailings Storage Facility (TSF) area, and extensive areas of large stumps indicate that it may have been much more extensive before clear-cutting in the 1970's.

Site series 07 is not found within the mine development area itself, although a good example of this vegetation occurs in the riparian zone of Hazeltine Creek, about 3 km east of the tailings area. That area supports very tall, vigorous stands of hybrid spruce and black cottonwood. Smaller examples may occur near the shores of Bootjack and Polley Lakes. These areas may be important foraging areas for bears, and wintering for moose and mule deer. Horsetail, sedges and red-osier dogwood are particularly important forage species.

### 2.5. Non-Forested Organic Sites

There was a wetland in the south-western portion of the tailings area. The vegetation adjacent to the pond is dominated by poor-fen sphagnum, common green sphagnum, and narrow-leaved cottongrass, and it had many plant indicators of true bog conditions, such as Labrador-tea, buck-bean, narrow-leaved sundew, bog laurel and sphagnum mosses. The pond itself was surrounded by floating mats of sphagnum and cotton grass, but there is no emergent zone of sedges, cattails, or bulrushes. The

submergent zone is also poorly developed, consisting of a single plant of yellow pond lily. A shrub wetland northeast of the pond was dominated by dense thickets of hardhack, Sitka alder, and tall willows. Where willows were a significant component of the vegetation, these shrub carrs may be important wintering areas for moose. In this wetland, scrub birch, Sitka alder, Labrador-tea, and hardhack were the only important shrub species, and its value for ungulates was low.

# 3. WILDLIFE AND WILDLIFE HABITAT

Baseline wildlife and wildlife habitat reconnaissance was completed in 1995 by Knight Piésold to guide reclamation activities for optimising wildlife habitat after mine closure. The major findings of this study were:

1. The project will have negligible effects on local and regional populations of raptors, waterfowl, other water birds, and shorebirds.
2. The songbirds found in the mine development area also found outside the mine development area in large populations.
3. The project will not cause any wildlife population to disappear from the local area or from the surrounding region.
4. So far as can be determined, the project will not result in the loss of mineral licks, winter yarding areas, migration corridors, or rutting areas used by ungulates.
5. The project will not affect specialized wildlife habitats such as caves, cliffs, or canyons.
6. The wetland in the tailings area has a small area of less than 10 ha, and it has a low capability for waterfowl, shorebirds, wetland songbirds and moose. Mine development will displace one colony of beavers in this wetland.
7. The project will not affect the ability of wildlife to use or gain access to Polley or Bootjack Lakes.
8. Although most mine development will take place on the areas that have been selectively logged or clear-cut, the project will displace small areas of mature forest habitat.
9. The project will displace small numbers of mule deer and moose from summer and autumn rages that they currently use. However, alternate ranges of comparable quality exist in adjacent areas and improved grazing will be available in reseeded areas.

## 3.1. Wildlife Species Present

The baseline wildlife study identified 44 bird species and 10 mammal species in the project area, with another 18 bird species identified in the surrounding region. These species are listed in Table 3.1.

*Table 3.1 Checklist of the wildlife of the Mount Polley Mine and adjacent areas near Likely, B.C.*

**Notes:**

| BIRDS | |
|---|---|
| * Common Loon | *Gavia immer* |
| *Green-winged Teal | *Anas crecca* |
| *Mallard | *Anas Pltyrhynchos* |
| *Bufflehead | *Bucephala albeola* |
| *Bald Eagle | *Haliaeetus leucocephalus* |
| *Sharp-shinned Hawk | *Accipiter striatus* |
| *Blue Grouse | *Dendragapus obscurus* |
| Spruce Grouse | *Dendragapus Canadensis* |
| Ruffed Grouse | *Bonasa umbellus* |
| *Sharp-tailed Grouse | *Tympanuchus phasianellus* |
| White-tailed Ptarmigan | *Lagopus leucurus* |
| *Killdeer | *Charadrius vociferus* |
| *Greater Yellowlegs | *Tringa melanoleuca* |
| Spotted Sandpiper | *Actitis macularia* |
| *Common Snipe | *Gallinago gallinago* |
| *Sandhill Crane | *Grus Canadensis* |
| *Great Blue Heron | Ardea herodias |
| Belted Kingfisher | *Ceryle alcyon* |
| *Northern Flicker | *Colaptes auratus* |
| *Yellow-bellied Sapsucker | *Sphyrapicus varius* |
| Downy Woodpecker | *Picoides pubescens* |
| *Three-toed Woodpecker | *Picoides tridactylus* |
| *Black-backed Woodpecker | *Picoides arcticus* |
| *Pileated Woodpecker | *Dryocopus pileatus* |
| *Western Wood-Pewee | *Contopus sordidulus* |
| *Olive-sided Flycatcher | *Contopus borealis* |
| *Hammond's Flycatcher | *Empidonax hammondii* |
| *Willow Flycatcher | *Empidonax traillii* |
| Violet-green Swallow | *Tachycineta thalassina* |
| Cliff Swallow | *Hirundo pyrrhonota* |
| *Barn Swallow | *Hirundo rustica* |
| *Gray Jay | *Perisoreus Canadensis* |
| Steller's Jay | *Cyanocitta stelleri* |
| *Common Raven | *Corvus corax* |
| *Common Crow | *Corvus brachyrhynchos* |
| Black-capped Chickadee | *Parus atricapillus* |
| *Mountain Chikadee | *Parus gambeli* |
| *Boreal Chikadee | *Parus hudsonicus* |
| *Red-breasted Nuthatch | *Sitta Canadensis* |
| *Winter Wren | *Troglodytes troglodytes* |
| *Golden-crowned Kinglet | *Regulus strapa* |
| *Ruby-crowned Kinglet | *Regulus calendula* |
| *Townsend's Solitaire | *Myadestes townsendi* |
| *Swainson's Thrush | *Catharus usstulatus* |
| *American Robin | *Turdus migratorius* |
| *Varied Thrush | *Ixoreus naevius* |
| European Starling | *Sturnus vulgaris* |

| BIRDS (continued) | |
|---|---|
| *Warbling Vireo | *Vireo gilvus* |
| *Solitary Vireo | *Vireo solitaries* |
| *Orange-crowned Warbler | *Vermivora celata* |
| Nashville Warbler | *Vermivora ruficapilla* |
| *Yellow-rumped Warbler | *Dendroica coronate* |
| *Magnolia Warbler | *Dendroicamagnolia* |
| *Blackpoll Warbler | *Dendroicastriata* |
| *Townsend's Warbler | *Dendroica townsendi* |
| *MacGillivray's Warbler | *Oporornis tolmiei* |
| *Common Yellowthroat | *Geothlypis trichas* |
| *Wilson's Warbler | *Wilsonia pusilla* |
| *Common Redstart | *Setophaga ruticilla* |
| *Western Tanager | *Piranga ludoviciana* |
| *Chipping Sparrow | *Spizella passerine* |
| *Lincoln's Sparrow | *Melospiza lincolnii* |
| *Song Sparrow | *Melospiza melodia* |
| *Dark-eyed Junco | *Junco hyemalis* |
| Red-winged Blackbird | *Agelaius phoeniceus* |
| Brown-headed Cowbird | *Molothrus ater* |
| *Pine Siskin | *Carduelis pinus* |
| *Evening Grosbeak | *Coccothraustes vespertinus* |

| MAMMALS | |
|---|---|
| *Snowshoe Hare | *Lepus americanus* |
| *Northwestern Chipmunk | *Tamias amoenus* |
| *Red Squirrel | *Tamiasciurus hudsonicus* |
| *Beaver | *Castor Canadensis* |
| *Coyote | *Canis latrans* |
| *Gray Wolf | *Canis lupus* |
| Red Fox | *Vulpes vulpes* |
| *Marten | *Martes americana* |
| Fisher | *Martes pennanti* |
| *Long-tailed Weasel | *Mustela frenata* |
| River Otter | *Lontra canadensis* |
| Wolverine | *Gulo gulo* |
| * Cougar | *Felis concolor* |
| * Lynx | *Lynx canadensis* |
| *Black Bear | *Ursus americanus* |
| * Grizzly Bear | *Ursus arctos* |
| *Mule Deer | *Odocoileus hemionus* |
| *Moose | *Alces alces* |

1) Asterisk (*) indicates the species has been recorded in the Mount Polley Mine area. Note that some bird species without an asterisk have likely been observed, but not recorded.
2) Species names follow the system of scientific names currently used in British Columbia (Luttmerding et al., 1991).

### 3.1.1.*Amphibians*

During field studies in the mine development area in May-June 1995, only one adult frog or toad was seen, which escaped before it could be identified. Frog tadpoles, which could not be identified to species, were recorded in a beaver pond outside the project area, near “Ditch Road” Forest Service Road.

### 3.1.2.*Waterfowl, Shorebirds and other Water-Oriented Birds*

The Mount Polley project area has a relatively diverse land bird fauna, but relatively few species of waterfowl, shorebirds and other water-oriented birds. There is a greater diversity of aquatic habitats outside the project area, at Bootjack, Polley, Morehead, Prior and Quesnel Lakes, and at Hazeltine Creek and the Quesnel River. There is a correspondingly greater diversity of water birds and wetland species outside the project area.

Within the project area itself, potential habitat for waterfowl and shorebirds is limited to a small 3-ha bog pond in the southwestern portion of the proposed tailings area, the surrounding 2-ha wetlands, and to short sections of the tributary to South Edney Creek. In May-June 1995, the known waterfowl population of the mine development area consisted of one pair of green-winged teal, and a trio of a male and two female buffleheads. At most, the shorebird population may have amounted to one or two pairs of killdeer, greater yellowlegs and common snipe.

Two sandhill cranes were recorded in the tailings area on 27 July 1989, and a greater blue heron was recorded at the Upper Hazeltine Bridge on 15 August 1989 (Imperial Metals Corporation 1990). Neither of these species was recorded in the project area in May-June 1995, and their present status in the project area is uncertain.

The only other water-oriented birds recorded in the project area in May-June 1995 were songbirds that characteristically occur in wetlands, such as willow flycatcher, common yellowthroat, song sparrow and Lincoln’s sparrow.

### 3.1.3.*Upland Game Birds*

The only grouse record for the mine area is one of a pile of winter grouse droppings in the Maine Pit area, in a cut-over tract of red cedar-Douglas-fir forest. However, according to Mr. Robert Toupin, a long-time resident, five grouse species occur in the Likely area. These are the ruffed grouse, blue grouse, spruce grouse, sharp-tailed grouse and white-tailed ptarmigan. Of these species, the ruffed grouse is usually found in deciduous and mixed-wood forest, and the blue grouse is usually found in mature to old coniferous forests dominated by western red cedar and Douglas-fir. Mr. Toupin reports that a flock 10-20 sharp-tailed grouse regularly frequents the East corner of the tailings area.

### 3.1.4.*Birds of Prey*

Though they actively looked for them, Hallam Knight Piésold staff did not record any birds of prey in the mine development area during field studies in May-June 1995. Though they searched for them intensively in the mine area, HKP did not find any large stick nests, large nesting cavities, "whitewashed" cliffs or rock outcrops, which could indicate potential nest sites for a variety of raptors.

An unidentified hawk was recorded at Bootjack Creek on 15 October 1989 (Imperial Metals Corporation 1990). Only two species of raptors were recorded during field studies in May-June 1995, both well outside the proposed mine development area. These records were of a sharp-shinned hawk at Km 11 on the "Ditch Road", and of a pair of barred owls heard calling at Likely in the early morning of 30 May 1995.

Robert Toupin states that there was a pair of bald eagles on Polley Lake in 1995, although he did not record a nest location. HKP did not record any eagles on Polley, Bootjack or Morehead Lakes during field studies in May-June 1995. There appears to be little or no foraging habitat for bald eagles within the mine development area. The bog pond does not contain fish, while the small creeks draining the mine and mill area dry up by mid-summer. There may be a small amount of fish habitat in the tributary to South Edney Creek, which could provide a limited amount of foraging habitat for eagles.

### 3.1.5.*Woodpeckers and Songbirds*

Five woodpecker species were recorded in the mine development area, and a sixth was recorded in the village of Likely. None of these species is considered rare in British Columbia. The yellow-bellied sapsucker is often associated with deciduous woodlands, particularly those dominated by aspens or birches. The northern flicker is a common and widespread species, found in both deciduous and coniferous forests, as well as in aspen parkland. The downy woodpecker, which was recorded twice at Likely, is more characteristic of deciduous or mixed forests. Pileated woodpecker diggings were found in large western red cedars at four locations in the mine development area. Both the black-backed woodpecker and its close relative, the three-toed woodpecker, occur in mature cedar and Douglas-fir forests in the mine development area. An active nest of three-toed woodpeckers was found on 10 June 1995 in an old growth western red cedar – Douglas-fir forest, east of the North Pit area.

Between 29 May and 12 June 1995, nearly 30 species of songbirds were recorded in the mine development area, and another 10-15 species were recorded between Mount Polley and Likely. Songbirds were the most numerous and frequently recorded wildlife group in the Mount Polley area. From 8-12 June 1995, Hallam Knight Piésold used call counts to index the relative abundance of songbirds in the project area. Twelve locations in the mine development area were sampled, over a total of 17.6 km of transect length. Results of call counts are discussed in Section 3 of Hallam Knight Piésold (1995b).

Songbirds that are typically associated with young clear cuts and recent burns include chipping sparrow, dark-eyed junco, Hammond's flycatcher, western wood-pewee, warbling vireo, orange-crowned

warbled and American robin. As clear cuts and burns mature, they become increasingly dominated by thickets of deciduous trees and shrubs. At this stage, the pioneer bird species are joined by gray jay, Swainson's trush, yellow-rumped warbler and pine siskin. Typical songbirds of shrub thickets in wet areas are willow flycatcher, Wilson's warbler, common yellowthroat, song sparrow and Lincoln's sparrow.

Common bird species in mixed forests of deciduous trees and conifers include: Hammond's flycatcher, olive-sided flycatcher, ruby-crowned kinglet, American robin, Swainson's trush, varied trush, warbling vireo, solitary vireo, orange-crowned warbler, yellow-rumped warbler, Wilson's warbler, MacGillivray's warbler, chipping sparrow, dark-eyed junco and pine siskin. Typical species in dry forest of lodgepole pine and Douglas-fir include dark-eyed junco, chipping sparrow, yellow-rumped warbler, pine siskin, red-breasted nuthatch, Swainson's thrush and gray jay.

Characteristic songbird species in mature and old growth stands at Mount Polley include: Hammond's flycatcher, western-wood-pewee, red-breasted nuthatch, golden-crowned kinglet, Swainson's thrush, American robin, varied thrush, solitary vireo, yellow-rumped warbler, blackpoll warbler, magnolia warbler, Wilson's warbler, Townsend's warbler, chipping sparrow, dark-eyed junco and pine siskin. Of these species, the blackpoll, Townsend's and Magnolia warblers appear to be more common in mature and old forests than in any other habitat type.

#### 3.1.6.*Small Mammals (Insectivores, Hares and Rodents)*

No shrews, moles or bats were recorded in the Mount Polley project area in 1989 or 1995.

Snowshoe hare sign, such as droppings and girdled shrubs, were relatively common in most forested habitats in the Mount Polley project area. However, hare droppings were not abundant enough to develop a reliable relative index of hare abundance in the various habitat types.

Hallam Knight Piésold recorded only three northwestern chipmunks in the Mount Polley project area in May-June 1995. Analysis of call-count data indicated low densities of 10 to 31 chipmunks/ 100 ha in the tailings area. No chipmunks were recorded on call-count transects in other parts of the mine area.

During 29 May to 12 June, Hallam Knight Piésold obtained only five records of red squirrels in the Mount Polley project area, including visual observations, calls and middens. Red squirrels were recorded on only 2 of the 12 call-count transects, at densities estimated at 6 to 8 squirrels /100ha. The Observer considered red squirrels numbers at Mount Polley to be low in comparison to other parts of the B.C Interior.

Fur harvest summaries do not distinguish between red squirrel and flying squirrel, and both species are reported simply as "squirrel". Squirrel is in fourth place among the species reported in fur harvest returns from Registered Trapping Area no. TR0502T056, which includes the Mount Polley area. The largest fur harvest of squirrels in this trapping area was in 1985, when 22 squirrels were trapped. Two or three squirrels were reported in each of the years 1986 to 1989, but none were reported from 1990 to

1994. In other trap lines in the region (TR0502T032, TR0502T037, TR0502T043 and TR00515T008), squirrel is in third position in terms of the total number of fur bearers harvested.

The beaver was recorded at only one location in the project area, in the small bog pond in the southwestern corner of the tailings area. Two beaver lodges, and one medium-sized adult were seen there between 29 May and 12 June 1995. Beaver sign (girdled or felled trees, beaver dams or beaver lodges) were not found anywhere else in the project area. There is an active beaver colony outside the project area, in a small wetland near Km 11 on the "Ditch Road". Next to marten, beaver is the second-most important fur-bearer in the five trap lines in the region surrounding Mount Polley. In trapping area TR0502T056 (which includes the Mount Polley project area), from 7 to 15 beaver per year were harvested in 1985-89, none were harvested from 1989 to 1993 and 4 were taken in 1994. Fur returns do not specify exactly where beaver were harvested within this large trapping area.

No muskrat were recorded during field studies in May-June 1995, although they were actively searched for. Neither muskrat nor muskrat lodges were found in the small bog pond in the southwestern part of the proposed tailings area, and little or no potential muskrat habitat exists elsewhere in the mine development area. However, from 11 to 24 muskrat were harvested annually from 1984 to 1988 from trapping area TR0502T056, the trap line that surrounds the mine development area. No muskrat have been harvested there in the years 1989 to 1994. Fur returns do not specify where the muskrats were harvested in this large trapping area.

There is no information on which species of mice and voles occur in the Mount Polley area, or on their status. The deer mouse, northern red-backed vole and meadow vole are expected to be the most common mice in the project area.

#### 3.1.7.*Carnivores*

Red fox, coyote and grey wolf have been trapped in several of the registered trapping areas surrounding Mount Polley, from 1985 to 1994. On most of these trap lines, one or two animals were harvested per trap line per year. However from 1985 to 1994, only one fox and no wolves or coyotes were taken from TR0502T056, the trap line which includes Mount Polley.

There are a few sight records of wolves and coyotes in or near the project area. One wolf was seen in the Morehead Lake area on 19 November 1989 (Imperial Metals Corporation 1990). No wolves or wolf sign were recorded during field work on May-June 1995. One coyote was seen in the proposed tailings area on 26 July 1989 (Imperial Metals Corporation 1990). Four coyote tracks and scats were recorded in the proposed tailings area in May-June 1995, but none were recorded elsewhere in the mine development area. One fox was recorded at Bootjack Creek on 2 November 1989 (Imperial Metals Corporation 1990).

The Ministry of Environment Lands and Parks believe that gray wolves are regularly present in the Mount Polley area (P. Deilman to M. Demers, 17 Oct 1995). A few years ago, the Ministry monitored a radio-collared pack of five wolves, whose home range may have been centred around Antoine Lake. This

radio-collared pack was subsequently destroyed, so that by November 1995, there was no longer any radio-collared wolves in the Mount Polley are (Pat Deilman pers. Comm to D. Karasiuk).

Black bears appear to be relatively common in the area surrounding Mount Polley, while grizzly bears are either very scarce or absent. Mr. Robert Toupin, a long-time resident of Likely, believes that black bears are quite common in the Likely area generally, and in the Mount Polley project area specifically. The ministry of Environment Lands and Parks believes that the Mount Polley project area has a healthy black bear population, and that numbers are stable (P. Deilman letter to M. Demers, 17 October 1995).

Imperial Metals Corporation (1990) compiled nine black bear records for the Mount Polley area in 1989, consisting of at least two males, one female and four cubs. These records did not appear to be grouped around any single location. No grizzly bears were recorded in 1989. Hallam Knight Piésold recorded six bear scats in the project area, mainly on abandoned roads to the north and northeast pf the open pits. HKP recorded another scat near Morehead Lake, where black bears are regularly seen, and a sight record of a three-year-old black-phase bear on the “Ditch Road” near Polley Lake. All of the sightings and scats were from black bear, and no grizzly or grizzly sign were recorded.

The Ministry of Environment Lands and Parks completes a Compulsory Inspection data (CID) Form for every grizzly bear kill that comes to its attention (A. Bowser, pers Comm to D. Karasiuk). During the years 1983 to 1995, only one CID form has been completed for a grizzly kill in Wildlife Management Unit 5-02, which includes Mount –Polley. This kill took place at Edwards Lake, far to the south of the project area, in September 1983. In contrast, 28 CID forms were completed for Wildlife Management Unit 5-15, which lies east of Quesnel Lake and the Quesnel River. The nearest CID kill was for an animal control action at the community of Likely in June 1992. When the location of CID kills is plotted, it appears that grizzly bears are scarce in the Mount Polley area, but much more common in the highlands and mountains farther to the east.

The marten is probably the most important mustelid species at Mount Polley. No mustelids were recorded during field studies in 1989 (Imperial Metals Corporation). Field studies in May-June 1995 yielded a few additional records of weasels and marten, but none for other mustelids. In May 1995, Mr. Wayne Blashill reported a long-tailed weasel in the project area. In May-June 1995, Hallam Knight Piésold obtained a sight record of a marten near the mill area, and recorded two marten scats in the North Dump area. There are no sight records of other weasels, mink, fisher, otter, skunks or wolverine within the footprint of the mine development area.

Mount Polley is in the northern part of trapping area TR0502T056. From 1985 to 1994, more marten were trapped in this trapping area than any other fur-bearer, but few weasel and mink were taken. Small numbers of river otter, fisher and wolverine were trapped in neighbouring trapping areas (TR0502T056, TR0502T043 and TR0515T008) but none of these species were trapped in TR0502T056 from 1985 to 1994.

There is little information on the occurrence of the fisher in the Mount Polley project area. No fishers were recorded during filed investigations of the project area in 1989 or 1995, and no fishers were

reported in fur returns from TR0502T056 from 1985 to 1994. Mount Polley is about 10-15 km east of the study area where Richard Weir (1995) investigated of the diet, spatial organisation and habitat preferences of a transplanted, radio-collared population of fishers. None of these fishers established permanent home ranges in the Mount Polley area, although there were no obvious geographic barriers to prevent them from doing so. All of these fishers established permanent home ranges in the Sub-Boreal Spruce zone, in the area of Beaver Creek, Beedy Creek, Sheridan Creek and Moffat Creek. Perhaps the fishers preferred to establish permanent home ranges in the zone of lower snow accumulation, which is 5-10 km west of the project area.

No wolverine or wolverine signs were recorded during fields investigations of the project area in 1989 and 1995, and no wolverine have been reported in fur returns from TR0505T056, which includes the project area, from 1985 to 1994. No wolverine were reported in fur returns for this periods from the adjacent trap lines in Management Zone 5-02 (TR0502T032, TR0502T037 and TR0505T043). Five wolverine were taken from TR0515T008, which is east of Quesnel Lake and Quesnel River in Management Zone 5-15. Because they often maintain large home ranges, it is possible that wolverine may enter the project area from time to time, but would probably do so very infrequently.

No cougar, lynx or bobcat were recorded during the field studies of the project area in 1989 or 1995 (Imperial Metals Corporation 1990, Hallam Knight Piésold 1995). Only one lynx was trapped in TR0502T056 from 1985 to 1994. The lynx harvest in the neighbouring trapping areas TR0502T037, TR0502T043 and TR0515T008 was also low. In contrast, 16 lynx were harvested from TR0502T032 between 1985 to 94, though there was some year-to –year variation in the number of animals trapped.

Compulsory Inspection Data (CID) forms are completed by the Ministry of Environment Lands and Parks for every cougar kill that comes to its attention (A. Bowser, pers. Comm. to D. Karasiuk). There is only one CID form for cougar in Management Unit 5-15 for the year 1982-95, compared to 51 records for Management unit 5-02 for the same period. This suggests that the cougar is much less common in the Quesnel Highlands Ecosection than it is at lower elevations in the Cariboo Plateau Ecosection. The only CID record for Management Unit 5-15 refers to a female cougar that was trapped at Cariboo Lake in 1987. No CID forms have been completed for cougar in the immediate area of Mount Polley. The nearest CID location is Gavin Lake, where a male cougar was killed by hunters in December 1987. When the 51 CID records for cougar are plotted on a map, they are concentrated in an axis along the Beaver Creek valley, which extends from Gerimi Creek to the village of Horsefly. Most of these records within the Cariboo Plateau Ecosection, and the Sub-Boreal Spruce zone.

#### 3.1.8.*Ungulates (Hoofed Animals)*

Moose and mule deer are the only ungulates that have been recorded during wildlife studies in the Mount Polley area. There does not appear to be any suitable habitat for either the bighorn sheep or mountain goat at Mount Polley. Neither elk nor mule deer are listed by the Technical Working Group (1993) as species of special management interest for the Cariboo Region. There is a herd of 200-300 caribou in the Quesnel Highland and Cariboo Mountains east of Quesnel Lake, but there is little information on caribou use of the Mount Polley area.

Hallam Knight Piésold (1995b) conducted pellet group counts and range surveys at 12 locations in the Mount Polley project area. Pellet counts were counted on 60 plots, each measuring 5 x 5 m, and forage preferences were assessed on each plot. Section 4 of Hallam Knight Piésold (1995b) discusses these results in detail.

Aerial surveys of the project area in March 1995, when the snow pack was still more than 1 m deep, found no moose or moose tracks at higher elevations in the project area (that is, near the open pits, waste rock dumps, and the mill area). Low numbers of moose tracks and feeding craters were recorded at lower elevations with less snow, especially near Bootjack and Hazeltine Creeks. Although no moose were seen in the project area during field investigations in May-June 1995, moose signs were common throughout the project area. Moose droppings were found in low to medium densities throughout the project area, and in higher densities along abandoned logging trails. Most of the droppings were the so-called “winter pellets”.

Selective logging appears to have been especially favourable for moose, as it has decreased the cover of the coniferous tree canopy, and thereby fostered the growth of a wide variety of palatable browse species. Unlogged mature and old stands tend to have a poorly developed shrub understorey, which is often dominated by species of lower palatability to moose. The interior of such stands typically have very low densities of moose pellets, and show little evidence of browsing. Areas with large amounts of deadfall are typically lightly utilized.

Wetlands vary greatly in the amount of moose utilization they receive. Wetlands that are dominated by tall willows, herbs and sedges appear to be well used by moose, particularly if they are located near patches of coniferous forest that are used as bedding areas. Wetlands dominated by hardhack, Sitka alder and scrub birches are little used. The most heavily used part of the project area is a well-drained gravel ridge west of the mill area, which formerly supported an open forest of Douglas-fir and western red cedar. The area was selectively cut and slash-burned, and now supports a mixed forest with rich and diverse tall shrub, low shrub and herb understoreys. It has exceptionally high concentration of moose scats and browsed bushes.

Eleven mule deer were seen during field studies in May-June 1995, eight of which were in the mine area. The largest group was five animals, about 600 m north of the tailings area. Most observations were of single animals. Deer tracks were common in the project area, especially near the main pit and in the tailings area. Tracks were most commonly observed near mud puddles in roads, and the tracks sometime followed abandoned roads for several hundred meters. Pellet group counts found that deer pellet were less numerous than moose pellets.

### 3.2. Species at Risk

SNC Lavalin (SNC; Golder, 2015) compiled an updated list of at-risk species for the ICHwk2 and ICHmk3 Cariboo Region that are potentially in the Mount Polley area (Table 3.2). Species presence and the timing and duration of their residence time in the project area will vary with habitat characteristics and other factors, such as social interactions, timing of life history events, seasonal and inter-annual

variation in habitat use, population cycling, immigration routes and timing, and weather. The following is an excerpt from SNC's assessment (Golder, 2015) which outlines possible use of the project area.

- Hagen's bluet (*Enallagma hageni*) is a blue damselfly that inhabits marshy lake edges, slow streams, and ponds. It is associated with marsh and fen wetland types (Wm01-02, Wm04-07, and Wf01) and flies in June and July (Royal British Columbia Museum and the Spencer Entomological Museum, 2004).
- The magnum mantleslug (*Magnipelta mycophaga*) has rarely been detected in Canada (COSEWIC, 2012a). Only 13 records of the species exist for BC, and the closest occurrence to Mount Polley Mine is in Wells Gray Park. COSEWIC (2012a) does not list any surveys for terrestrial gastropods completed near Quesnel Lake. The magnum mantleslug has been found in moist microsites in heavily shaded coniferous forests in the ICH and ESSF biogeoclimatic zones. Individuals have been located both on the ground surface and under bark, logs or rocks. Important habitat features may include seepage sites, coarse woody debris, and undisturbed forests with intact duff layers (COSEWIC 2012a).
- The western toad (*Anaxyrus boreas*) is an amphibian that is widely distributed across the province (COSEWIC 2012b). Adult western toads may be found in a variety of habitats including grasslands, forests, shrublands, riparian areas, and wetlands. Adult toads congregate to breed communally in the spring and exhibit fidelity to their breeding sites. Females lay strings of eggs in stream margins, wetlands, river backchannels, ponds, and human-made sites such as ditches, road ruts, and tailings ponds (COSEWIC 2012b). The eggs hatch into tadpoles that metamorphose in 4-12 weeks and leave the water by late July or August. Adults may move up to several kilometres away from breeding sites, and show a strong fidelity to summer foraging sites. Adult western toads feed on invertebrates including worms (Clitellata), slugs (Gastropoda), spiders (Arachnida), bees (Hymenoptera), beetles (Coleoptera), sow bugs (Isopoda), grasshoppers (Orthoptera), caddisflies (Trichoptera), moths and butterflies (Lepidoptera), flies (Diptera), true bugs (Hemiptera), and ants (Formicidae) (reviewed in COSEWIC 2012b). Larvae eat organic detritus, filamentous algae and carrion (ibid). Adult toads hibernate underground during the winter.
- The Great Blue Heron (*Ardea herodias*) is a large wading bird that feeds on fish, amphibians, small mammals, snakes, and aquatic insects (Gebauer and Moul 2001). The *arodias* subspecies is provincially Blue-listed and is the subspecies present in the Cariboo region. Herons are present in the Cariboo region between April and November (Roberts et al. 2013). During the rest of the year, they winter in southern BC or further south. Herons are colonial nesters and build bulky stick nests in coniferous or deciduous trees. The closest known colony to the study area is the Big Lake Forest Service Road colony (Colony 502-005), which was active between 1997 and 1999 and was located 2.4 km west of the north end of Polley Lake (Great Blue Heron Management Team 2015).
- The Common Nighthawk (*Chordeiles minor*) is a brown, black and grey-mottled bird that forages aerially for flying insects. Nighthawks are migratory and may be present in the Cariboo region between the beginning of June and mid-September (Roberts et al. 2013). Nighthawks lay their eggs

on the ground in sparsely-vegetated areas and may nest in disturbed sites such as roadsides, gravel pits and recent clear-cuts.

- The Olive-sided Flycatcher (*Contopus cooperi*) is a robin-sized songbird that frequents forest edges. It forages from a perch on a tree or snag from which it makes short flights in pursuit of flying insects. Olive-sided Flycatchers are migratory and are present in the Cariboo region between May and mid-August (Roberts et al. 2013).
- The wolverine (*Gulo gulo*) is a large mustelid that feeds on a wide variety of prey from small mammals to ungulates. The *luscus* subspecies is provincially Blue-listed and is the subspecies present in the Cariboo region. Although it is associated with high-elevation forests and large areas of wilderness, wolverine distribution is governed more by food supply than by particular habitats. It is both a generalist and an opportunist and will readily scavenge carrion. Wolverines range widely (50-100 $km^2$ for females and up to 1580 $km^2$ for males) and may become nomadic if food is scarce (COSEWIC 2014).
- The little brown myotis (*Myotis lucifugus*) and northern myotis (*M. septentrionalis*) are small insectivorous bats that roost in tree cavities, under loose bark, in buildings, and in rock fissures. Although the little brown myotis has been described as the most common and widely distributed Canadian bat species (van Zyll de Jong 1985), both it and the northern myotis are now listed under SARA as endangered due to a fungal disease known as white-nose syndrome (Government of Canada 2014). The disease is not currently present in western Canada, but is spreading westward from the eastern provinces. The northern myotis is very difficult to distinguish from similar species in the field and its identification must be confirmed via DNA typing. Little brown myotis and one individual field-identified as a northern myotis were captured in 2012 near Spanish Lake (approximately 11 km northeast of the mouth of Hazeltine Creek) (data file at http://a100.gov.bc.ca/pub/siwe/details.do?id=5044). A species model for little brown myotis and northern myotis is presented in Golder (2015).
- The fisher (*Pekania pennanti*) is a large mustelid or weasel. Fishers are forest-dwellers that feed primarily on small mammals. Females require cavities in large deciduous trees for use as reproductive dens. There are large-diameter *Populus balsamifera* present along Hazeltine Creek that are potential natal den sites for fishers. A fisher species account is presented in Golder (2015).
- Grizzly bears (*Ursus arctos*) are considered by the province to be extirpated in the area west of the west arm of Quesnel Lake (Province of BC 2014). A viable grizzly population (the Quesnel Lake North grizzly bear population unit) is present east of the west arm of Quesnel Lake.
- Mountain caribou (*Rangifer tarandus*) was removed from consideration within this assessment as caribou have been extirpated from the area west of the west arm of Quesnel Lake (Province of BC 2014).

*Table 3.2 Species at risk potentially present in the Mount Polley area*

| Scientific Name | Common Name | BC List | Other List |
|---|---|---|---|
| *Enallagma hageni* | Hagen's Bluet | Blue | - |
| *Magnipelta mycophaga* | Magnum Mantleslug | Blue | - |
| *Anaxyrus boreas* | Western Toad | Blue | SARA Schedule 1 –Special Concern |
| *Ardea herodias herodias* | Great Blue Heron, *herodias* subspecies | Blue | - |
| *Chordeiles minor* | Common Nighthawk | Yellow | SARA Schedule 1 - Threatened |
| *Contopus cooperi* | Olive-sided Flycatcher | Blue | SARA Schedule 1 - Threatened |
| *Gulo gulo luscus* | Wolverine, *luscus* subspecies | Blue | - |
| *Myotis lucifugus* | Little Brown Myotis | Yellow | SARA Schedule 1 - Endangered |
| *Myotis septentrionalis* | Northern Myotis | Blue | SARA Schedule 1 - Endangered |
| *Pekania pennanti* | Fisher | Blue | - |
| *Ursus arctos* | Grizzly Bear | Blue | SARA Schedule 1 – Extirpated |
| *Rangifer tarandus* | Mountain Caribou | | SARA Schedule 1 – Threatened |

## 3.3. Wildlife Habitat Classification

At the time that wildlife studies were being planned for the Mount Polley Project, there was no formal system of wildlife habitat classification for the Cariboo Forest Region. The only available wildlife habitat mapping for the surrounding region was a generalized draft map at 1:250,000 scale, showing winter habitat capability for moose, deer and bear. An *ad hoc* wildlife habitat classification for the Mount Polley area was carried out based on the habitat classifications of the ICH Biogeoclimatic Zone, the Prince Rupert Forest District, and of the wildlife branch for the Omineca Sub-Region of the Prince George Region.

With an elevation range of 920 m (Polley Lake) to 1260 m (the summit of Polley Mountain), all of the project area is in the ICH. There are no alpine or subalpine habitats, and the summit of Polley Mountain is below the lower elevation limits of the Engelmann Spruce – Subalpine Fir Zone. There are no avalanche tracks, talus slopes, or other mountain features that would be considered significant wildlife

habitats. There are no cliffs or canyons, and no arable agricultural land. Man-made habitats include logging clear-cuts and the network of roads for logging.

Before European contact, the primeval vegetation of the project area was probably a continuous closed forest of Douglas-fir and lodgepole pine on drier sites, and of western red cedar, hybrid spruce and black cottonwood on riparian sites. Much of the mine development area was selectively logged or clear-cut in the 1970s, and is now covered by open, young seral forests. The different baseline habitat types are delineated in Figure 2.18[2] (extracted from Hallam Knight Piésold Ltd., 1996a), and described in the following sections.

A summary of habitat types present at Mount Polley is provided in Table 3.3.

*Table 3.3 Habitat types at the Mount Polley Mine*

| **Habitat Grouping** | **Habitat Type** | **Present in the Mount Polley Area?** |
|---|---|---|
| 1 | Alpine Habitats | No |
| 2 | Habitats of the Engelmann Spruce-Subalpine Fir Zone | No |
| 3 | Forest Habitats of the ICH Zone | |
| | 3.1 Clearcuts and burns (0-20 years +) | Yes |
| | 3.2 Young stands (20-40 years) | Yes |
| | 3.3 Mid-seral stands (40-120 years) | Yes |
| | 3.4 Mature and old growth stands (120+ years) | Yes |
| | 3.5 Douglas-fir – Lodgepole Pine Forest (south slopes and ridge crests) | Yes |
| | 3.6 Rocky cliffs and talus | No |
| 4 | Wetland and Aquatic Habitats | |
| | 4.1 Riparian forest complex | No |
| | 4.2 Riparian habitats near small streams | No |
| | 4.3 Shrub carr/sedge fen habitat complex | Yes |
| | 4.4 Marsh/shallow open water habitat complex | No |
| | 4.5 Small and medium-sized lakes (<1000 ha) | Yes |
| | 4.6 Large lakes and reservoirs (>1000 ha) | No |
| 5 | Man-Made Habitats | |
| | 5.1 Urban areas | No |
| | 5.2 Transportation / Transmission Corridor | No |
| | 5.3 Agricultural areas | No |

### 3.3.1.*Clear-cuts*

Clear-cutting, followed by moderate to intense slash burning, has been practiced in several locations on the Bootjack Lake road, and throughout much of the Tailings Storage Facility Area. Although harvested at approximately the same time, clear-cut areas have reverted to a much earlier stage of forest succession than those that were selectively logged, and the existing vegetation is quite different. In

[2] MPMC is currently working to develop a digitized version of this map.

general, clear-cutting followed by slash burning has removed most of the advance regeneration by subalpine fir and western red cedar, and the area has not been sufficiently restocked from natural sources. Cover by conifer seedlings in such areas is well under 5%. Black cottonwood, aspen, Sitka alder, and paper birch have re-sprouted in a few favoured spots, but much of the clear-cuts in the tailings area are dominated by low shrubs, grasses and herbs. Typical herbs and legumes are bluejoint, tame wheatgrasses, broom, dandelion, fireweed, big-leaved avens, fescues and thistles. North of the tailings area, some clear-cut areas have been hand-planted with lodgepole pine plantations, which are now 3 – 4 m tall, with 20 to 30% ground cover. Portions of the tailings area have been replanted with spruce seedlings, in an area that once supported well-grown stands of western red cedar and Douglas fir. Re-stocking of clear-cuts in the tailings area has generally been unsuccessful, as the spruce seedlings are widely spaced, with poor vigour and high mortality.

Pellet counts and general observations in the tailings area indicate that ungulates make little use of open areas in the centres of large clear-cuts, where there is little cover. However, ecotonal areas at the boundaries of clear-cuts and mature forests appear to be quite heavily used by both moose and mule deer. Such areas offer a combination of thermal and predator avoidance cover (in the forests), as well as palatable forage (in the clear-cuts). Small bird densities appear to be very low in the clear-cut areas, where chipping sparrow and dark-eyed junco are the principal species. Warbling vireo, orange-crowned warbler and Hammond's flycatcher are strongly associated with dense thickets of black cottonwood, trembling aspen, tall willow and Sitka alder. Varying hare and northwestern chipmunk were the only small mammals recorded in clear-cuts. Coyote tracks and scats were also recorded in the tailings area.

#### 3.3.2.*Mid-Seral Forests*

Mid-seral stands at Mount Polley have many of the same species as mature and older stands discussed below. The number of individuals and the diversity of species may increase somewhat as mid-seral stands mature, and as the complexity and structural diversity of the habitat increases; however, species that prefer open woodlands and herb- or shrub-dominated habitats tend to decrease.

#### 3.3.3.*Selectively Logged Areas*

Much of the mine development area was selectively logged during the mid-1970s. During selective logging, most of the large Douglas-firs and western red cedars were removed from the site, but smaller conifers were left in place, as were both large and small black cottonwoods. During the 25 years prior to mining, this advanced regeneration matured, resulting in a complex and variable mixed-wood forest, with a diverse and well-developed tall shrub, low shrub and herb understorey. The height, crown cover and species composition of the tree canopy are quite variable in selectively logged areas. Typically, the tree canopy is 10 – 15 m high, with a crown cover of 10 to 20%, and it is dominated by a mixture of western red cedar, subalpine fir, Douglas-fir and black cottonwood. A few veteran black cottonwoods and western red cedars reach heights of 20 – 25 m. The tall shrub understorey is dominated by a variable mixture of black cottonwood and subalpine fir saplings, Sitka alder, trembling aspen, Scouler willow, Bebbian willow and unidentified willows. The low shrub understorey is lush and diverse, and is typically dominated by thimbleberry, black twinberry, western mountain-ash, red elderberry, black

currant, black huckleberry, and falsebox. There is also a rich and diverse her understorey, where fireweed, bunchberry, twinflower, foamflower, star-flowered Solomon's-seal, false Solomon's-seal, rosy twisted stalk and queen's cup are typical species.

At Mount Polley, areas that were selectively logged in the 1970s now support a complex, patchy vegetation that provides fair to good spring and summer habitat for mule deer, moose and black bears. Removal of the continuous, dense and shady canopy of western red cedar and Douglas fir has favoured the development of deciduous trees and shrubs, some of which are highly palatable to moose and deer. It has also increased the cover of a wide variety of berry-producing shrubs, which is favourable for bears and fruit-eating birds such as thrushes. Dense thickets of tall shrubs provide good escape cover for mule deer. MacGillivray's warbler, Wilson's warbler, orange-crowned warbler and the warbling vireo are all strongly associated with this second-growth vegetation.

#### 3.3.4.*Mature and Old Growth Forests*

According to Ketcheson et al. (1991), moose, mule deer, black bear, wolverine, marten, southern red-backed vole, various owls, pileated woodpecker, Steller's jay, gray jay, varied thrush, golden-crowned kinglet, Townsend's warbler, bohemian waxwing, red crossbill, winter wren, and mountain chickadee are representative species of mature and old growth forests in the ICH Zone in general. Some of these species have been recorded in the Mount Polley project area, although they are not restricted to mature or old growth forests.

#### 3.3.5.*Forests on Southern and Western Aspects*

These slopes may be significant for moose and mule deer in the late winter, spring, and summer. Due to favourable insolation, these slopes are likely to have a lighter snow cover than average during the winter. These slopes are likely to be snow-free earlier in the season, and to green up earlier than most other habitats. Even with a favourable insolation regime, south-facing slopes in the project area are likely to be too deeply covered with snow to be suitable for mule deer in the winter. However, in spring, these slopes may be important for mule deer, due to rapid snowmelt and early green-up. For the same reasons, they may also be important for bears emerging from winter hibernation. Ketcheson et al. (1991) list several other species that they consider to be closely associated with south-facing slopes in the ICH Zone (e.g. yellow bellied marmot, rubber boa, elk), but it is doubtful that these species occur in the Mount Polley area.

#### 3.3.6.*Non-forested Rock Cliffs and Talus*

There are no rocky cliff or talus habitats in the Mount Polley project area.

#### 3.3.7.*Riparian Forest Habitat Complex*

There are no riparian forest habitats in the Mount Polley project area, such as would be associated with rivers or large creeks with channel widths greater than 5 m. The project area does not contain any landscape features that are typically associated with large streams, and which may be significant to

wildlife, such as: alluvial fans, alluvial terraces, braided channels, oxbows, meander scrolls, backwaters, floodplains, canyons or gallery forests.

### 3.3.8.*Riparian Habitats near Small Streams*

There are five riparian areas associated with small streams in the Mount Polley project area: Hazeltine Creek; Bootjack Creek; Mine Drainage Creek; W20 Creek; and North Dump Creek. All of these are small creeks, with channels less than 5 m wide. Bootjack Creek is entrenched in a ravine for much of its length with two small wetlands near its inlet and one near its outlet. The riparian zone of Hazeltine Creek is somewhat more conspicuous on aerial photographs than that of Bootjack Creek. Hazeltine Creek has an area of shrub carr and sedge meadow near its mouth in Polley Lake, and smaller areas of shrub carr in its upper reaches. No lakes or backwaters are associated with any of the creeks, and all of the creeks except North Dump Creek are fish-bearing. Beaver and mink are the main wildlife species that are likely to be found in the riparian zones of these small creeks. The streamside vegetation may provide above-average habitat for black bears, moose, and mule deer.

### 3.3.9.*Shrub Carr/Sedge Fen Habitat Complex*

The only example of this habitat complex within the mine development area is a 5 to 10 hectare area located in the southwest part of the tailings area, about 300 m northeast of the bog pond. The centre of this wetland is a sedge meadow, dominated by beaded sedge, and dead spruce snags, and standing water from 20 to 50 cm deep. The sedge meadow is surrounded by dense thickets of hardhack, black twinberry, and Sitka alder, where shrub clumps grow on elevated hummocks, and where standing water occupies the intervening low spots. Surveys prior to mine construction show no evidence of moose browsing or pellets in the thicket. None of these shrubs are considered to be palatable to ungulates. In June 1995, this wetland had one or two pairs each of willow flycatcher, orange-crowned warbler, Wilson's warbler and song sparrow. These are all common and widespread songbird species typical of wet shrub carrs. No waterfowl or shorebirds were recorded within the shrub carr.

Additional examples of this complex are found outside the mine development area, southeast of Morehead Lake, near the outlet of Bootjack Lake, about 500 m downstream from the outlet of Bootjack Lake, and along Hazeltine Creek. The largest shrub carr and fen complex in the local area is at the south end of Polley Lake. No large ponds are associated with this complex. At the southern end of Polley Lake, fen and shrub carr grade into a swamp forest. There are a few widenings of Hazeltine Creek, which may be due to beaver damming.

A few moose tracks were seen in these habitats during aerial surveys of the mine area in March 1995, but no moose were seen. For the present analysis, riparian habitats along Bootjack and Hazeltine Creeks can be considered Class 3 or Class 4 winter range, and Class 3 summer range for moose. Due to heavy winter snow accumulations, these habitats should be considered Class 5 or Class 6 winter range for deer.

### 3.3.10. *Marsh/Shallow Open Water Habitat Complex*

If a marsh is defined as a permanently flooded wetland dominated by tall emergent plants, such as cattails, bulrushes, or *Phragmintes* reeds, then there are no marshes in the project area. If a shallow open water habitat is defined as an area dominated by lush beds of submergent plants, such as yellow pond lily, hornwort, milfoil, or pondweeds, then there are not shallow water habitats in the project area.

### 3.3.11. *Small and Medium-sized Lakes (< 1000 hectares)*

Both Polley and Bootjack Lakes support a good to very good sport fishery based on rainbow trout. Bald eagles and the common loon have been observed on both lakes, however; there is no foraging or nesting habitat for either species within the mine development area. The Canada Land Inventory assigned a rating of 6-JZ to both lakes. This rating implies severe limitations to waterfowl production. The major limitations being excessively deep waters and a limited area of marsh edge development.

The only lake within the mine development area is a bog pond of approximately 3 ha located in the south-western corner of the tailings area. During a survey on May 30, 1995, the waterfowl population of this pond amounted to one male green-winged teal, and two females and one male bufflehead. One greater yellowlegs, and one common snipe were also seen. On June 9, 2005, a female green-winged teal with five young were present on the lake, as well as the trio of buffleheads. A common snipe was heard, but the yellowlegs was no longer present. The lake had two beaver lodges, and one beaver was observed during these surveys. One or two pairs of willow flycatcher, common yellowthroat, Wilson's Warbler and song sparrow were recorded in shrub thickets near the lake. These are all common and widespread songbird species, which are also present in shrub-dominated wetlands near Morehead and Bootjack Lake. Development of the tailings area would not cause significant losses of habitat for local or regional populations of any of these species.

A single frog or toad, which swam away before it was accurately identified, was recorded at the pond. No amphibian egg masses or tadpoles were recorded in either survey.

### 3.3.12. *Large Lakes and Reservoirs (>1000 hectares)*

There are no large lakes in the project area, although the site is within the Quesnel Lake Watershed. Quesnel Lake is located approximately 10 km east of the mine.

### 3.3.13. *Urban Areas*

The Wildlife Branch (1994) defines urban areas as man-made habitats, such as residential, commercial and industrial areas. Agricultural lands are considered a distance habitat type. There were no urban areas in the Mount Polley project areas prior to exploration and mine development.

### 3.3.14. *Transportation/Transmission Corridors*

Transportation and transmission corridors are linear facilities that carry people, goods, and services from one point to another. There are no major roads or power line corridors in the project area;

however, there is a large network of logging and skid roads throughout the area, and a further network of trails to reach exploration drilling sites.

Roads typically occupy a small proportion of the land area, but they may be significant to wildlife. Early stages of forest succession often include plants that are palatable to wildlife, such as willows, prickly rose, fireweed, and elderberry. Commercial seed mixes are sometimes sown to stabilize roadsides and ditches, and they often contain plants that are palatable to wildlife, such as Kentucky bluegrass, red fescue, timothy and red clover. Consequently, moose, deer and black bear sometimes forage preferentially along transportation and transmission corridors. Where winter snows are deep, moose coyotes and wolves sometimes used plowed roads as travel routes, and may be killed in collisions with vehicles. Forest road networks make the back-country more accessible to outdoor recreationists. Unregulated hunting and wildlife harassment become a concern for wildlife managers.

Moose, deer, coyotes, and bears regularly use roads and trails in the project area as travel routes. During surveys in June 1995, animal tracks appeared to follow roads, rather than crossing roads by the shortest and most direct route. There were substantially more moose and deer pellet groups on roads than in the nearby natural vegetation, particularly if there were large amounts of deadfall.

# 4. FISHERIES AND AQUATIC RESOURCES

## 4.1. Limnology

There are four major lakes in Mount Polley area: Bootjack Lake, Polley Lake, Morehead Lake, and Kay Lake (also known locally as Fry Pan). Morehead Lake is a man-made and relatively shallow reservoir. The other three are all natural, accessible to the public. Bootjack and Polley Lakes have been manipulated for water storage and diversion.

Bootjack Lake is essentially a long and narrow basin, with two depressions over 15m deep. Polley Lake is a long narrow lake that is almost twice as deep and has almost twice the surface area and four times the volume of Bootjack Lake. Polley Lake does not have multiple depressions. Shoal areas occur at both ends of the lake but are severely restricted along the steep sides of the basin. One permanent stream enters Polley Lake from the north draining Kay Lake. Kay Lake is smaller, but is very deep for its surface area. Its shoreline resembles a bog with floating vegetation mats. There is no distinguishing inlet stream and the outlet is impounded by beaver dams. This small stream between these two lakes flows through swamp and meadow and is heavily braided with numerous beaver dams and minimal recognized surface flow. The steep slopes on either side of Polley Lake are drained by intermittent drainage channels, but no permanent streams. Polley Lake is some 64m lower in elevation than Bootjack and has a maximum depth of 35m.

The outlet of Polley Lake forms Hazeltine Creek, which flows a distance of 7,900m to its confluence with Edney Creek drainage, 500m upstream of the discharge to Quesnel Lake. Bootjack Creek is a 2,800m long tributary of Hazeltine Creek, which flows in an easterly direction to its confluence 450m downstream of Polley Lake outlet.

Morehead Lake was created by damming Morehead Creek. It is a shallow lake, usually less than 6m deep (Ron Williams, personal communication). Small tributary streams flowing into Morehead Lake include Morehead Creek, which contains the discharge from Bootjack Lake, Trio Lake, 4K Creek and other intermittent drainages off the hill sides. A concrete culvert and long spillway control the downstream from Morehead Lake. A ditch on the east side of the lake, which was once used to carry lake discharge to the placer mines, has now been abandoned and blocked.

In Bootjack Lake, both basins thermally stratify with the epilimnion extending down to a depth of six meters. The two basins exhibit similar patterns of stratification with only minor indications of differences in the hypolimnion in the vicinity of 10m depth. Surveys in June and October 1989 indicate that the lake was probably unstratified at those times. In mid-summer, the hypolimnion of both basins exhibits some reduction in dissolved oxygen. These patterns reflect productive lake conditions, and probable light attenuation in maximum depths. These observations indicate that Bootjack Lake is a mesotrophic lake that does not become anoxic.

In Polley Lake, thermal stratification is apparent with the epilimnion extending down to a depth of approximately 7 m. The hypolimnion extends from around 14m to the bottom. In late fall thermal stratification was still evident but was being eroded by decreasing temperatures in the epilimnion. The

narrow, deep, north-south orientation of Polley Lake and the steep slopes surrounding it probably shield it from wind action and results in a somewhat different stratification pattern from Bootjack Lake. The hypolimnion of Polley Lake is better oxygenated than Bootjack Lake, both in mid-summer and late fall, suggesting Polley Lake is slightly less productive.

In Kay Lake strong stratification is apparent with the epilimnion extending to approximately 4m depth mid-summer. By late fall, stratification broke down with the epilimnion extending to a depth of about 8m. The lake surface is protected from the strong winds that dissipate stratification. The hypolimnion extends from a depth of approximately 8 or 9m to the bottom. Dissolved oxygen is markedly depressed in the hypolimnion in the summer, although it is not anoxic. Kay Lake is probably mesotrophic, and perhaps, more dystrophic than either Bootjack or Polley Lakes. The heavily organic deposits on the lake margins and the peaty souks surrounding it support dystrophic characterization.

In 1995, a total of four limnology stations were established: two in Bootjack Lake and two in Polley Lake (Figure 2.8[3], extracted from Hallam Knight Piésold Ltd., 1996a). Dissolved oxygen and temperature profiles were collected at 1m intervals from each station once a month from May until October of 1995. In addition, one set of profiles was completed in January, 1996. The results are summarized by Hallam Knight Piésold Ltd. (1996b).

Results from the 1995 sampling season showed that for Bootjack Lake, stratification began in May. Water temperatures were colder during this month and consequently, oxygen concentration were higher than those measured later in the year. From June to September, the thermocline dropped in the water column, reaching a maximum depth of 8 to 12m in September. Water temperatures were highest in July (20.0$^{o}$C at the surface), and dissolved oxygen concentrations reached their seasonal low during this month. In October, the thermocline had completely disappeared, indicating that the fall overturn had occurred in the previous months. Water temperatures in January were the lowest recorded during the year, and dissolved oxygen concentrations were similar to those recorded in May.

Profiles collected from Polley Lake in 1995 indicate thermal stratification throughout the summer and into the fall. Beginning in May, surface warming established a minor thermocline at about 2m depth. Average water temperatures were coldest during this month (except for January), and concentrations f dissolved oxygen were higher than those measured later in the year. As surface temperatures increased, the thermocline became more pronounced, reaching a maximum in July when the difference between surface (21.8$^{o}$C) and bottom (4.9$^{o}$C) temperatures was more than 15.0$^{o}$C. From August to October, surface temperatures dropped and the thermocline sank in the water column, reaching its maximum depth of 15 to 17m in October. Water temperatures below 17m depth were relatively constant between 4.0$^{o}$C to 5.5$^{o}$C throughout all months (except January). Oxygen profiles indicated only minor stratification during all months. A surface layer with relatively constant concentrations of dissolved oxygen indicated near complete mixing in that zone. Below the mixed layer, dissolved oxygen concentrations slowly decreased down through the water column. Oxygen concentrations were lowest in September, when DO at the lake bottom dropped to 2.1ppm.

[3] MPMC is currently working to develop a digitized version of this map.

## 4.2. Fisheries Resources

### 4.2.1.*Regional*

Fisheries resources in the Quesnel River and Quesnel Lake system consists of diverse populations of sport fish including anadromous chinook and coho salmon and resident kokanee, rainbow and lake trout, Dolly Varden char, whitefish and several forage species. In addition, large populations of Horsefly sockeye salmon annually migrate from the Fraser River to spawn in tributary streamswhich drain into Quesnel Lake. Salmonoid enhancement facilities have been constructed by the Department of Fisheries and Oceans on the Horsefly River for sockeye and on the Quesnel River for chinook to improve survival of upper Fraser River stocks. The lakes in the vicinity of Mount Polley provide good recreational angling for rainbow trout. These trout populations are natural and maintained without stocking. A summary of creel surveys carried out on Bootjack and Polley Lake is presented in section 2.8.5.2.

### 4.2.2.*Local Fisheries*

***1989 Surveys***

No streams flow into Bootjack Lake that would support spawning. Thus its rainbow trout must spawn downstream in Morehead Creek, with fish from Trio and Morehead Lakes. The storage dam and spillway at the outlet of Morehead Lake prohibit the return of any fish or their offspring that migrate down the spillway. In addition, an active beaver dam also restricts movement of both to and from Bootjack Lake. Given this, it would appear that fish production in these three lakes may be limited by spawning area available. Large numbers of juvenile trout were captured with baited Gee traps in the streams in June, August and October. This suggests the streams may be the principal nurseries where trout rearing occurs. Recruitment into the lake population depends on the rearing and successful returns to the lake of the offspring. Because of their apparent success in coexisting with rough fish, Bootjack Lake rainbow trout populations are being investigated as a potential source of brood stock for the provincial fish culture program (Demers, M., personal communication). Fisheries biophysical inventory is presented on Figure 2.15[4] to (extracted from Hallam Knight Piésold Ltd., 1996a) show the habitat characteristics and species distribution.

Rearing salmonoid populations ranged from 0.071/$m^2$ (Upper Hazeltine Creek) to 1.50/$m^2$ in Bootjack Creek, the highest density of rearing juvenile rainbow trout in the entire study area. The results illustrate the importance of Bootjack Creek and Hazeltine Creek for rearing of Polley Lake rainbow trout populations. Reconnaissance along the streams revealed numerous locations where trout were actively spawning at the time. The greatest frequency of spawning was in the upper reaches of Morehead Creek and Hazeltine Creek but spawning was common in all creeks.

The Edney /Hazeltine Creek system is physically divided by topography which creates water velocity barriers in a steep gradient canyon located 1,650m upstream of Edney Creek confluence. This canyon

[4] MPMC is currently working to prepare a digitized version of this map.

barrier isolated the rainbow trout populations in the headwater lakes and streams and prevents encroachment by the mixed residents and anadromous salmonoid and forage fish populations found in the lower reaches. In lower Hazeltine and Edney Creeks mixed populations of rainbow trout, mountain whitefish, burbot, suckers, rearing juvenile chinooks, and adult sockeye salmon were documented in 1989. The lower reaches of Hazeltine and Edney Creeks are low gradient streams consisting of deep pools and riffles, large log jams and areas with excellent spawning gravels for salmon. On the Morehead Creek system barrier is even more dramatic. A waterfall exists about 1,500m upstream of the confluence with the Quesnel River and the spillway at the outlet of Morehead Lake further divides the system to migrating fish. Watercourses located at higher elevations such as Bootjack Creek, upper Hazeltine Creek, upper Edney Creek, upper Morehead Creek, 4K Creek and 6K Creek are also relatively low gradient streams associated with the lake systems and are used mainly by rainbow trout populations for spawning and rearing.

The lower reaches of Morehead Creek, near the Quesnel River, were investigated on October 20, 1989 with baited Gee traps. The creek contained good populations of rearing chinook salmon. The lower reaches of Hazeltine Creek and Edney Creek sampled in May, August and October 1989 always contained rearing populations of rainbow trout. Juvenile chinook salmon (greater than 1 year old) were found there in August and October, suggesting they entered the stream from Quesnel Lake. Lower Edney Creek provided good spawning habitat for sockeye salmon when it was inventoried in October 1989, coinciding with record runs to the Horsefly River System. Heavy spawning activity by sockeye was evident in this reach at that time.

Headwater lakes in the vicinity of Mount Polley were historically used for water storage in connection with early placer mining. The redirection of flow from Bootjack Lake by the construction of an earth-filled dam in about 1913 at the southern end of the lake prevented further use of important spawning and nursery areas in Bootjack and Hazeltine Creeks by the trout populations from Bootjack Lake. The outlet of Bootjack Lake presently consists of a large excavated channel which redirects flow to Morehead Lake. A beaver dam at the outlet of Bootjack Lake restricts movement of rainbow trout both to and from the steam habitat particularly during the summer low flow period. Nevertheless, during the fish inventory of May 31 – June 2, 1989 rainbow trout populations were observed in large numbers spawning in the vicinity of the Morehead Creek bridge crossing when the water temperature was 14.5$^{o}$C. It is not certain which lake they came from. The spawning habitat between Morehead, Bootjack and Trio Lakes is probably used by spawners from all three systems.

***1995 Surveys***

A fisheries assessment of the two Edney Creek tributaries was implemented in 1995, to determine the potential fish habitat losses and develop corresponding compensation options in accordance with federal government policy. Survey sites are shown in Figure 2.16[5] (extracted from Hallam Knight Piésold Ltd., 1996a). The only fish captured during sampling in the Edney Creek watershed were rainbow trout. Surveys were conducted during the peak spawning time for Bootjack and Polley Lakes fish (May 12-21)

[5] MPMC is currently working to develop a digitized verson of this map.

and again during base flow conditions, well after rainbow trout fry emergence (July 31-August 4). Hallam Knight Piésold (1996c) discusses these results in detail.

An additional objective of the May sampling program was to characterize the adult rainbow trout populations using the potentially impacted tributaries. The distributions of rainbow trout in Edney Tributary 1, Edney Tributary 2, and the Edney Creek mainstem are presented in Figure 2.16[6] (extracted from Hallam Knight Piésold Ltd., 1996a), as are the locations of presence/absence sampling sites.

The largest specimen captured had a fork length of 17cm (from Edney Tributary 2), but most were much smaller. This may reflect the size adult fish can be expected to attain in these small tributaries.

Only male fish were captured, suggesting that the population of adults use these tributaries for spawning and earl life history phases only, and that they have migrated from a larger stream or lake (Edney Creek/Edney Lake). The utilization of these streams by large, Quesnel Lake resident rainbow trout may be ruled out because the habitat structure is simply too small.

During the August field trip, spot-check electrofishing revealed that the upstream extent of fish distribution in Edney Tributaries 1 and 2 had not changed since May, even though stream discharges had been greatly reduced. An important result was that fish were still present in the upstream section of Edney Tributary 1, even though flow was subsurface for approximately 50% of the distance at that location. These fish appear capable of surviving in pools with no surface of the distance at that location. These fish appear capable of surviving in pools with no surface inflow, although their presence appeared to be dependent on good cover and depth (20cm achieved somewhere in the pool). Because there was no measurable discharge at several of these locations, fish presence cannot be correlated to a threshold minimum discharge, and therefore this parameter cannot be used to predict post-impact distribution in these tributaries.

Presence/absence electrofishing was also conducted on Edney Creek above Edney Lake. Importantly, Edney Creek was found to be barren of all species at two road-accessible locations above the lake (Sites F3, P/A 11, shown in Figure 2.16[7], extracted from Hallam Knight Piésold Ltd., 1996a), even though the rearing habitat at these locations was of high quality. A series of falls in a short canyon was later discovered between Edney Lake and the road crossing approximately 1km upstream, and is an absolute barrier to fish migration.

A summary of the fry and juvenile density estimates from the August survey is presented in Table 4.1 (Hallam Knight Piésold 1996c). Fry densities ranged from 0 fish/$m^2$ at site F3 to 1.02 fish/$m^2$ at site F2. The high densities at site F2 may be due to very high nitrate levels at the site, or due to a recent extensive fry emergence at this site, as habitat appeared highly suitable from spawning (Hallam Knight Piésold 1996c).

Visual estimation of critical habitat types in August revealed that Edney Tributary 1 provides totals of 3554$m^2$ of fry rearing, 1045$m^2$ of juvenile rearing, and 92$m^2$ of spawning habitat over the 3604m of its

[6] MPMC is currently working to develop a digitized version of this map.
[7] MPMC is currently working to develop a digitized version of this map.

useable length. Edney Tributary 2 was found to provide totals of 7059m$^2$ of fry rearing, 1696m$^2$ of juvenile rearing, and 15m$^2$ of spawning habitat over the 5073m of its useable length (Hallam Knight Piésold 1996c). These two streams are obviously highly suited to rainbow trout fry production at base flow conditions, mainly because water velocities are typically low across the entire wetted width.

A maximum 46% reduction in discharge s predicted for the Edney Tributary 1, and 12% for Edney Tributary 2 (see section 3.5.6) based on reduction in catchment area. Following mine closure, reclamation activities will restore the diverted flows to their pre-impact native channels, restoring the habitat capability to pre-impact levels. Post-closure reclamation planning specifies the return of the pre-impact flow regime to these channels.

*Table 4.1 Rainbow trout density estimates (fish/m$^2$) for August, 1995 Edney Creek watershed survey*

| Sampling Site Location | F1 (lower Edney) | F1 (replicate) | F2 (below Edney Lake) | F3 (upper Edney) | F4 (Edney Tributary 1) | F6 (Edney Tributary 2) |
|---|---|---|---|---|---|---|
| Capture density (fry) | 0.015 | 0.015 | 3.43 | 0 | >1.09 | 1 |
| Capture density (juvenile) | 0.075 | 0.075 | 1.02 | 0 | >0.29 | 0.26 |
| Capture density (total) | 0.09 | 0.09 | 4.45 | 0 | >1.38 | 1.26 |

### 4.2.3.*Fish Tissue Analysis*

***1989 Sampling***

In October 1989 nine sexually mature rainbow trout were captured using a 2.0 inch monofilament gill net in Bootjack Lake. Metal analysis was conducted of muscle and liver tissues from these fish to establish baseline conditions prior to mining operations. Metal concentrations varied among fish. Metals that were above the detection limits are presented in Table 4.2.

*Table 4.2 Fish tissue metals above detection limit in Bootjack Lake (1989)*

| | Tissue | Liver |
|---|---|---|
| Copper | 0.83 – 1.86 mg/kg | 205 mg/kg |
| Iron | 14.7 – 33.5 mg/kg | 1042 mg/kg |
| Manganese | 0.49 – 1.31 mg/kg | 4.66 mg/kg |
| Lead | 0.05 – 0.30 mg/kg | 0.10 mg/kg |
| Zinc | 19.9 – 27.1 mg/kg | 162 mg/kg |

***1995 Sampling***

Fish tissue sampling in both Bootjack and Polley lakes was conducted in September and October, 1995 in order to establish a baseline for fish tissue metal content. The species targeted for this sampling effort were rainbow trout (*Oncorhynchus mykiss*) and longnose suckers (*Catostomus catostomus*). The fish tissue was analyzed for antimony, arsenic, cadmium, chromium, lead, mercury, nickel and selenium. The complete results are presented in the Mount Polley Environmental Baseline Report (Hallam Knight Piésold, 1996b).

***Bootjack Lake***

In Bootjack Lake rainbow trout, mean muscle and liver levels of antimony were found to be below the minimum detection level. However, cadmium levels exceeded the minimum detection level. In addition, mean levels of lead, chromium and selenium were well above those found in muscle tissue. In particular, mean liver selenium levels exceeded muscle levels by more than 10 times. In contrast, mean levels of mercury and nickel were slightly higher in muscle tissue. Metal levels were found to vary widely between samples for any given metal.

With the exception of mercury, the mean muscle metal content of Bootjack Lake longnose suckers appeared to be very similar to that of Bootjack Lake rainbow trout. The mean mercury level, however, exceeded the equivalent rainbow trout level by more than two times. As with the rainbow trout results, antimony readings were below the detection limit, while the majority of the samples exhibited cadmium levels below the detection limit, as well. With the exception of arsenic, chromium and selenium, metal levels were found to vary between samples.

While the mean liver levels of antimony, cadmium and lead appeared similar between Bootjack Lake longnose suckers and Bootjack Lake rainbow trout, rainbow trout mean liver selenium levels are nearly three times higher than the longnose suckers levels. In addition, mean levels of arsenic, mercury, chromium and nickel appeared to be higher in longnose suckers than in rainbow trout.

With the exception of mercury, mean longnose suckers liver metal content levels exceeded those found in longnose sucker muscle tissue. Mean muscle mercury levels, however, were more than two times higher than in liver tissue. Variability in metal levels among the samples appeared high, with the exceptions being selenium and antimony.

***Polley Lake***

Mean rainbow trout muscle levels of antimony and cadmium in Polley Lake were below detection limits. Polley lake rainbow trout exhibited higher mean muscle levels of mercury and lead, and lower mean levels of chromium, nickel, and selenium than Bootjack rainbow trout. With the exceptions of lead and mercury, variation in metal levels between samples appeared to be low.

Mean Polley Lake rainbow trout levels of arsenic, cadmium, chromium, lead, nickel and selenium were all higher in liver tissue. Only mean mercury levels were higher in muscle tissue. As seen in the Bootjack Lake samples, mean liver selenium levels exceeded mean muscle selenium levels by more than ten

times. A comparison between Bootjack Lake and Polley Lake rainbow trout liver metal content reveals that Bootjack Lake rainbow trout contained higher mean levels of arsenic, lead, mercury and nickel. Mean cadmium and selenium levels were found to be higher in Polley Lake rainbow trout. The level of variability of the metal content between samples appeared high, with the exception of arsenic.

In Polley Lake longnose suckers, mean muscle antimony and cadmium levels were found to be below the detection limit. This finding is consistent with the results of rainbow trout and longnose sucker muscle analyses from Bootjack and Polley Lakes. Mean muscle levels of the remaining metals appear to be comparable to those found in most of the Bootjack Lake longnose suckers. It should be noted, however, that the mean muscle level of arsenic in Polley Lake longnose suckers was more than twice that found in Bootjack Lake fish. In addition, mean arsenic muscle levels in longnose suckers were more than three times higher, and nickel and chromium muscle levels were more than two times higher than in Polley Lake rainbow trout muscle. On the other hand, mean chromium muscle levels were nearly three times higher in rainbow trout. These results differ from Bootjack Lake results, where the only major difference between the two species appeared to be the mercury muscle levels. With the exceptions of antimony, cadmium and selenium, metal muscle levels appeared to be quite variable between samples.

As with Bootjack Lake longnose suckers, Polley Lake longnose sucker mean liver antimony levels were below detection limits. Mean liver levels of cadmium, nickel and selenium also appear to compare well with those seen in the Bootjack Lake fish. However, mean liver levels of lead and arsenic were higher in Polley Lake fish, while Bootjack Lake fish were characterized by higher mean liver levels of chromium and mercury. Mean liver levels of antimony, arsenic, lead and nickel appeared to be comparable to Polley Lake rainbow trout liver levels. However, mean liver levels of cadmium and chromium were higher in longnose suckers, while mean liver levels of mercury and selenium were higher in rainbow trout. This situation differs from that in Bootjack Lake, where mercury, arsenic and nickel liver levels were higher in longnose suckers. With the exceptions of antimony and selenium, metal liver levels appeared to be quite variable between samples.

## 4.3. Sediments

### 4.3.1. *Creeks*

On September 21 and 25, 1995 sediment samples were collected under summer low flow conditions from ten spatially-separated, normalized locations in conjunction with benthic invertebrate sampling. The objectives of the sediment program are to provide:

- Baseline benthic invertebrate habitat quality data, both physically and chemically, for benthos studies;
- Baseline characterization of sediment quality of potentially impacted streams for future monitoring purposes; and
- Baseline data to develop site-specific sediment quality guidelines

Collected samples were divided into coarse and fine fractions at the laboratory. The coarse fractions were submitted for particle size analysis (Wentworth scale). The fine fraction underwent physical tests

(loss on ignition of the minus 200 mesh fraction, as well as moisture content) as well as total metal content analysis for Sb, As, Cd, Cr, Cu, Pb, Hg, Ni, Se, Ag and Zu. Mean metal levels were compared to the BC provincial sediment quality guidelines (1994). The complete results are presented in the Mount Polley Environmental Baseline Report (Hallam Knight Piésold, 1996b)

In addition, power analyses of copper concentrations for each sampled station were carried out to determine adequate sample size to detect a 50% change in concentration.

Mean metal levels for all stations were below the lowest effect levels for cadmium, lead, selenium, silver and zinc. However, exceedances for the lowest effect levels included arsenic (eight stations), chromium (four stations), copper and manganese (all stations), iron (nine stations) and nickel (six stations). The station W5 reading exceeded the severe effect level of manganese (Hallam Knight Piésold, 1996b).

The results of the power analysis indicated that six were not sampled to level of effort required to detect a change of 50% while remaining stations were sampled to an equal, or higher, level of effort required to detect a change of 50%. Copper concentrations from stations which were not sampled to an adequate level of effort typically showed four replicate samples with fairly similar copper concentrations, while the other two replicates showed elevated levels of copper. Isolated areas of elevated copper levels would not be unexpected in an area known for copper occurrence. In addition, stations which were not sampled to an adequate level of effort were, with the exception of station W7, of narrower wetted width than the remaining stations. These smaller sites contained less available substrate for replicate sampling, and were typically more abundant in gravels and cobbles than in suitable sediment substrate. It was therefore more difficult to find enough suitable sediments for the required number of replicates at these sites, and in order to satisfy this requirement, samples may have been taken from sites which were not suitable similar with respect to substrate composition , flows and other physical parameters. This heterogeneity in substrate is further illustrated by the fact that laboratory subsamples taken from replicates from sites W6 and W10 varied considerably in copper levels (Hallam Knight Piésold, 1996b). Due to this limited supply of appropriate stream sediments at these sites, it may not be feasible to take as many replicate samples as prescribed by the power if analysis results. One solution may be to take more, but smaller volumes of sample per replicate for these sites, ie. Stratify into larger and smaller systems, and adjust sample volume appropriately.

Comparison of total copper levels to B.C. provincial guidelines show that mean levels, which ranged from 19.50 to 57.67mg/g (Hallam Knight Piésold, 1996b), are above recommended lowest effect level of 16mg/g but are less than the level of “severe effects” of 110mg/g.

#### 4.3.2.*Lakes*

Sediments were collected from Bootjack Lake and Polley Lake in 1989 and again in 1995. Sediment samples were analyzed in the laboratory for metal concentrations, distribution of particle size and relative concentration of combustible (organic) fractions. Results of the 1995 analyses are presented by Hallam Knight Piésold (1996b).

Samples collected from deep water in both lakes show relatively high concentrations of organics and low concentrations of large particle sizes. The sediment material in these circumstances is what would be expected in lakes exhibiting relatively high pelagic productivity. The continual settling of dead and dying plankton organisms to the deeper water creates these sediments characterized by high concentration of fine particles and high organics. These sediments would overlay any sand and gravel deposit that might have been left in the basin at the time of lake formation during the last glaciation.

At shallower stations these analyses illustrate transition from the deep water sediments to the shallower shoals where sand and silt composition are predominant. Wave disturbance of the shoals probably reduces accumulation of organic sediments unlike in deeper parts of the lake.

Bootjack Lake sediments have generally higher concentrations of total and dissolved copper than Polley Lake. Deep water sediments show greater accumulations or arsenic, chromium, copper, mercury, molybdenum and nickel (in addition, Polley Lake sediments are elevated in arsenic, lead and manganese). Comparison of the 1995 metals analysis results to the 1994 BC government sediment quality criteria indicated that lake sediments in both lakes are slightly acidic and naturally contain metals above government criteria levels for arsenic, chromium, copper, mercury and nickel.

### 4.4. Gravel Quality

Gravel sampling was conducted in lower Edney and lower Hazeltine Creeks in the fall of 1995 in order to document the baseline gravel quality in these systems. Withdrawal of water from the Edney tributary catchment system for mine use may affect the gravel size distribution, which in turn many affect the success of salmon spawning in the lower Edney and Hazeltine systems. A gravel quality monitoring program will be able to use the baseline results to detect any changes in gravel due to withdrawal of water for mine use.

Gravel sampling was conducted on September 18, 1995 at gravel sampling sites G1 and G2 (Figure 2.8[8], extracted from Hallam Knight Piésold Ltd., 1996a). These sites were chosen as they are located in sections of lower Hazeltine and Edney creeks which are used for salmon spawning. At each site, three replicate samples were obtained using a McNeil Sampler. Approximately 3 to 7kg of sample were obtained for each replicate site. Samples were then shipped to Golder Associates Ltd. for sieve analysis. Complete results of the sieve analysis can be found in the Mount Polley Environmental Baseline Report (Hallam Knight Piésold, 1996b).

### 4.5. Benthic Invertebrates

#### 4.5.1. *Creeks*

A baseline study of benthic macroinvertebrates was conducted at selected stations on Bootjack Creek, Edney Creek, Edney creek tributaries and Hazeltine Creek in the fall of 1995. The objective of this sampling program was to establish a master species list for each site, and to determine the baseline

[8] MPMC is currently working to develop a digitized version of this map.

species composition and abundance at each site. These baseline data will serve as a reference for comparison to future stream benthos sampling results over the life of the mine monitoring program.

The location of the sites is given in Figure 2.8[9] (extracted from Hallam Knight Piésold Ltd., 1996a). The sites were sampled over three consecutive weeks, from September 27 to October 15, 1995. A complete summary of the results of the taxonomic analyses of the samples is presented in the Mount Polley Environmental Baseline Report (Hallam Knight Piésold, 1996b).

***Abundance***

The order which contained the species with the greatest abundance throughout the sampling period was Diptera, which peaked in the third sampling week at 40,044.4 individuals/$m^2$ (Chironomidae). The taxum which contained the species with the second-greatest abundance in weeks one and two was the order Ephemeroptera, with a peak in week two of 25,644.4 individuals/$m^2$ (*Baetis sp.*), followed by the order Plecoptera, which peaked in a week three at 14,577.8 individuals/$m^2$ (Plecoptera, unidentified). In week three, abundance of *Nais sp.*in the order Oligochaeta was 31,644.4 individuals/$m^2$, making it the second-most abundant species during that week (Hallam Knight Piésold 1996b).

***Tolerance***

The general trend observed at all stations was a decrease in the number of sensitive organism, along with an increase in the number of facultative organisms. At stations W1, W5, W8 and W9, the tolerance ratio shifted predominantly sensitive organisms in week one to predominantly facultative organisms by week three. At station W8a, facultative organisms dominated throughout the sample period, while at stations W7 and W10, sensitive organisms dominated throughout the sample period (Hallam Knight Piésold, 1996b).

The sample from W6 site (Hazeltine Creek) was the only one with a tolerance ratio that indicated more tolerant organisms than sensitive organisms. The ratio of sensitive to facultative to tolerant at this site was approximately 1:10:5 (Hallam Knight Piésold, 1996b). IT should be kept in mid that this site was located in a very slow-flowing channel, and therefore represents significantly different habitat from the remaining sites.

***EPT Ratio***

This section examines the changes in the EPT ratio over the three week sample period. When examining the results presented here, it should be kept in mind that the ratios are calculated by dividing both Ephemeroptera and Plecoptera mean counts by the Trichoptera mean count.

At stations W1, W7 and W11, the EPT ratio favoured Ephemeroptera over Plecoptera over the entire sampling period. At stations W8 and W8a, the EPT ratio shifted from predominantly Ephemeroptera in week one to predominantly Plecoptera by week three. At stations W5, W9 and W10, Plecoptera were more abundant than Ephemeroptera throughout the entire sampling period. Station W6, which was

[9] MPMC is currently working to develop a digitized version of this map.

only sampled during the first week also indicated a greater abundance of Plecoptera over Ephemeroptera (Hallam Knight Piésold, 1996b).

4.5.2.*Lakes*

***1989 Survey***

As an early development of an ongoing environmental monitoring program for the Mount Polley mining operation, benthic invertebrate samples were collected in August, 1989 to document baseline conditions in the lakes. Results using diversity indices are summarized in Table 4.3.

*Table 4.3 Benthic invertebrate diversity indices for Bootjack and Polley Lakes (1989)*

| | **Bootjack Lake** | | | | **Polley Lake** | |
|---|---|---|---|---|---|---|
| **Date** | **Aug 18** | | | | **Aug 19** | |
| Sampling Stations | LN | B2 | B3 | LS | B | L |
| Depth (M) | 12 | 7 | 3 | 11 | 8 | 20 |
| Group 3 Organisms | 4 | - | - | - | - | - |
| Group 2 Organisms | 316 | 7 | 81 | 12 | 90 | 7 |
| Group 1 Organisms | 9 | 2 | 2 | 7 | - | - |
| Total No. of Organisms (N) | 329 | 9 | 83 | 19 | 90 | 7 |
| Total No. of Taxa (S) | 17 | 5 | 9 | 8 | 13 | 6 |
| Diversity (d) | 2.16 | 1.88 | 0.97 | 2.71 | 2.55 | 2.52 |
| Total No. of Organisms/$m^2$ | 6663 | 172 | 158 | 364 | 1723 | 134 |

The invertebrate populations of Bootjack Lake on August 18, 1989 consisted predominantly of Group 2 pollution facultative organism composed of Chironomidae species which are commonly associated with lake bottom substrates. Pollution tolerant Group 1 organisms were found at all sampling locations in low numbers represented by Tubificidae. Pollution sensitive Group 3 organisms were found in low numbers only at the north basin at 11.0m depth. This location contained the highest total number of organisms/$m^2$ (6663), the highest number of taxa per sample (17) and high diversity (2.61).

Benthic populations near shore (Station B2) were in low numbers (9) and diversity of species present (1.88). In the south basin, populations consisted of similar species dominated by Group 2 organisms (Chironomidae larvae) at both the shallow and deep sites. Total number of organisms/$m^2$ was higher on the shallow depth (1583) compared to (364) and the diversity was lower (0.97 compared to 2.71).

In Polley Lake August 19, 1989 the shallower sampling site contained a diverse population of benthic organisms/$m^2$ (1723) dominated by Group 2 Cammaridae, Pelecypoda and several Chironomidae species. The deeper site contained lower numbers of organisms/$m^2$ (134) represented by only a few taxonomic groups (6). Species diversity was similar for both sites.

***1995 Survey***

Results from the taxonomic analysis of the 1995 samples are presented in the Mount Polley Environmental Baseline Report (Hallam Knight Piésold, 1996b). In 1995, two stations in each of Bootjack and Polley Lakes were sampled at spring and fall overturns.

At the time of spring overturn both the number of species and abundance of benthic invertebrates found at Bootjack Lake sampling stations was very low. Abundance ranged from 43.48 to 173.91 #/$m^2$, and only three of the replicates contained more than 2 species. The most common species (found in 60% of the samples) was *Chironomus sp.* Other species detected included one species each from the taxa Hydracarina, Chaoborinae, Nematoda and Oligochaeta. Fall overturn samples appeared to contain greater abundances (43.48 to 1,086.96 #/$m^2$) and more species than the spring overturn samples. The most common species was *Chaoborus sp.* (found in 80% of the replicates), while the most abundant species were of the order Cyclopoida (86.96 to 1086.96 #/$m^2$). In contrast to the spring overturn results, species from the orders Cladocera and Copepoda were found, while species from the order Oligochaeta were absent.

Polley Lake benthos samples taken at the time of spring overturn contained a greater variety of species, as well as higher abundances (43.48 to 1913.04 #/$m^2$) than the Bootjack Lake samples. The most common species was *Chironomus sp.*, which was found in ever replicate sample from both stations P1 and P2. The most abundant species belonged to the order Cyclopoida (1913.04 #/$m^2$). In contrast to the Bootjack Lake samples, the Polley Lake samples also contained species from the orders Ephemeroptera and Ostracoda. However, species from the orders Hydracarina and Chaoborina were not detected in the Polley Lake samples. In contrast to the spring overturn samples, Polley Lake benthos samples contained fewer species and showed lower abundances (43.48 to 304.35 #/$m^2$) than the Bootjack Lake samples. The most common (found in 60% of the replicates) and abundant (43.48 to 305.35 #/$m^2$) species were of the order Harpaticoida (Copepoda). Species from the orders Ostracoda and Nematoda, which were found at spring overturn, were absent from these samples.

The low abundances and low number of species indicates that Bootjack and Polley Lakes may be very oligotrophic.

### 4.6. Zooplankton

***1989 Survey***

Zooplankton samples were collected form the water column in the lake to establish baseline conditions for the monitoring program. The data summary in Table 4.4 describes the results of the 1989 sampling program.

*Table 4.4 Zooplankton sample results for Bootjack and Polley Lakes (1989)*

| | **Bootjack Lake** | | | **Polley Lake** | | **Kay Lake** |
|---|---|---|---|---|---|---|
| **Date (1989)** | **Aug 18** | **Aug 18** | **Oct 16** | **Aug 19** | **Oct 16** | **Oct 17** |
| Sampling Location | LN | LS | LS | L | L | L |
| Tow Distance (m) | 7 | 7 | 10 | 7 | 15 | 12 |
| Total No. of Organisms (N) | 157 | 85 | 137 | 344 | 2851 | 142 |
| Total No. of Taxa (S) | 9 | 12 | 13 | 9 | 15 | 9 |
| Diversity (d) | 2.03 | 2.84 | 2.72 | 2.30 | 1.29 | 2.65 |
| Total No. Per $m^3$ | 345.4 | 1700.6 | 1412.9 | 625.7 | 2162.7 | 1785.6 |

The zooplankton community in the August 18-19, 1989 survey for Bootjack and Polley Lakes displayed wide variability in the species present, relative abundance of organisms density and species dominance between lake and also between basins in Bootjack Lake. The south basin of Bootjack Lake contained the highest number of species present (12) and highest diversity (2.84) but no species was clearly dominant and the cladoceran, *Daphnia rosea* was the most abundant zooplankton species present. In the north basin only 9 species were represented and diversity was lower (2.03). A rotifer*, Keratella quadrata* and *Cladoceran ocelli* were dominant species. In Polley Lake only 9 speices were present with a cladoceran, *Daphnia galeata mendota*, and copepods, *Cryptocyclops bicolour*, and *Ospranticum labronectum* being dominant.

The comminutes in the October survey again displayed considerable variety in species presence, relative abundance of organisms, density and species dominance as well as changes since August. The south basin of Bootjack Lake contained 13 zooplankton species with the rotifers, *Asplanchna sp*. and *Kellicottia longispina* now being dominant. Species diversity was also the highest observed (2.72). Polley Lake now contained the highest number of species present (15) dominated by a copepod, *Cryptocyclops bicolour*. The very high density of unidentifiable cladeceran naupii distorted the diversity index (1.29) and the total density estimates. The other two dominant species found in the August survey were present but at low levels. Kay Lakes contained 9 species in the October survey with two copepods, *Ectocyclops phaleratus* and *Paracyclops fimriata poppei* the most abundant zooplankton present. Once again high naupii density created distortions in some indicators.

These differences may be reflections of differences in the basins (nutrient availability, phytoplankton productivity, physical-chemical environment, predation, etc.). Only long term trends will clarify that. The Mount Polley samples contained several species widely distributed in B.C. including *Cryptocyclops bicolour, Daphnia pulex, Daphnia rosea, Diacyclops bicuspidatus, Ectocyclops phaleratus, Leptodora kindti*, and *Tropocyclops prasinus*. Also present in the study area were several species that tend to be

found in more saline and more alkaline environments. These included *Daphnia schoedleri, Daphnia magna, Daphnia similis, Moina hutchinsoni, Paracyclops fimbriatus* (Pennack, 1989).

***1995 Survey***

In both Bootjack and Polley Lakes, vertical plankton hauls were conducted monthly from spring overturn to fall overturn (May to October) in order to establish preliminary information on zooplankton diversity and abundance. The results of the taxonomic analyses are summarized in the Mount Polley Environmental Baseline Report (Hallam Knight Piésold, 1996b).

During the May 14-15 sampling period, more species in the order Rotifera were present at the Polley Lake sites than at the Bootjack Lake sites. In addition, the Poley Lake sites had greater Rotifera abundances. While a greater number of Cladocera species were present at the Polley Lake sites, the abundances of Calonoia species were higher at Bootjack Lake. A greater number of Cyclopoida species were present at the Polly Lake sites, with abundances ranging from 0.47 to 7403.87 #/$m^3$. Insecta species were not found at Bootjack Lake sites and in only very low abundances (0.47 #/$m^3$) at Polley Lake sites. Benthic organisms such as *Hydracarina* and *Tanytarsus sp.* were present in low abundances at both Polley and Bootjack Lake sites.

Abundance data for the June 14, 1995 sampling period indicated that species from the order Protozoa were present in low abundances at both Bootjack and Polley Lakes sites. Species in the order Rotifera were present at high abundances at both Polley Lake sites (to 10416.71 #/$m^3$) and at the Bootjack Lake sites (to 26316.37 #/$m^3$). While a greater number of Cladocera species were present at the Polley Lake sites, the abundances of the Cladocera species were again higher at Bootjack Lake. Similarly, abundances of Calonoia species were higher at Bootjack Lake. A greater number of Cyclopoida species were present at the Polley Lake sites, with abundances ranging from 86.27 to 17727.54 #/$m^3$. Insecta species were found at both Polley and Bootjack Lake sites, but only in very low abundances (0.74 to 2.36 #/$m^3$). Benthic organisms such as Hydracarina, Oligochaeta, *Procladius sp.* and *Tanytarsus sp.* were present in low abundances at both Polley and Bootjack Lake sites.

For the August 24, 1995 sampling period, a different mesh haul net was used, and consequently direct comparisons to abundance from other sampling periods cannot be made. Only comparisons with regard to species presence/absence are thus warranted. There appear to be more species from the orders Rotifera (*Tetramatrix sp., Polyartha sp., Keratella cochlearis*) and Cladocera (*Leptodora kindti* and *Polyphemous pediculous*) present than in the month of June, while the species composition in the remaining taxa appears to be similar to that seen in June.

During the September 20-22, 1995 sampling species from the order Protozoa were present in low abundances at both Bootjack and Polley Lake sites. Species in the order Rotifera were present at medium abundances at but Polley sites (to 928.43 #/$m^3$) and at the Bootjack Lake sites (to 769.96 #/$m^3$). The number and abundance of Cladocera species appeared similar between the Polley Lake and Bootjack Lake sites. Abundances of Calanoia species were higher at Bootjack Lake. A greater number of Cyclopoida were present at the Polley Lake sites, with abundances ranging from 44.21 to 8400.09 #/$m^3$. Insecta species were found at both Polley and Bootjack Lake sites, but only in very low abundances (2.30

to 30.56 #/$m^3$). Benthic organisms such as Hydracarina, Oligochaeta, *Prodcladium sp.* and *Tanytarsus sp.* were present in low abundances at both Polley and Bootjack Lake sites.

Results from the October 16-17, 1995 sampling showed that species from the order Protozoa were present in low abundances at only the Polley Lake site P2. Species in the order Rotifera were present at medium abundances at both Polley Lake sites (to 373.78 #/$m^3$) and at the Bootjack Lake sites (to 979.44 #/$m^3$). While a greater number of Cladocera species were present at the Polley Lake sites, the abundances of the Cladocera species were higher at Bootjack Lake (to 4979.93 #/$m^3$). While the number of Calanoia species was low at both Polley and Bootjack Lake sites, the abundances at the Bootjack Lake sites was slightly higher (to 631.20 #/$m^3$). Cyclopoida species were more abundant at the Polley Lake sites, with abundances ranging from 373.78 to 1997.70 #/$m^3$. Insecta species were found at both Polley and Bootjack Lake sites, but only in very low abundances (0.53 to 1.88 #/$m^3$). Benthic organism such as Naididae, Hyrdacarina and *Procladius sp.* were present in low abundances at both Polley and Bootjack Lake sites.

### 4.7. Phytoplankton

***1989 Survey***

Phytoplankton samples were also collected from the lakes in August and October in conjunction with limnology studies. The data summary in Table 4.5describes the result of the 1989 sampling program.

*Table 4.5 Phytoplankton sample results for Bootjack and Polley Lakes (1989)*

| | **Bootjack Lake** | | | **Polley Lake** | | **Kay Lake** |
|---|---|---|---|---|---|---|
| **Date (1989)** | **Aug 18** | **Aug 18** | **Oct 16** | **Aug 19** | **Oct 16** | **Oct 17** |
| Sampling | Ln | LS | Ls | L | L | L |
| Location Sampling | | | | | | |
| Depth (m) | 4 | 4 | 4 | 6 | 4 | 3 |
| Total No. of Organisms (N) | 264 | 275 | 140 | 502 | 402 | 331 |
| Total No. of Taxa (S) | 19 | 19 | 23 | 19 | 21 | 17 |
| Diversity (d) | 1.77 | 2.08 | 2.87 | 1.39 | 2.38 | 2.27 |
| Total No. per mL | 252.9 | 263.5 | 134.1 | 480.9 | 385.1 | 317.1 |

The august sampling of both basins of Bootjack Lake contained 19 phytoplankton taxa, and a cryptophyte species, *Chroomonas acuta* was dominant at both sites. Polley Lake also contained 19 species and the highest density (480.9 per mL) and was also dominated by *Chroomonas acuta.*

During the October survey total taxa and diversity had increased in Bootjack and Polley Lakes. The Kay Lake contained 17 species, a moderate species diversity (2.27) and moderate density (317.1 per mL). The dominant species continued to be *Chroomonas acuta* in all three lakes. In Bootjack and Polley Lakes a blue-green algae, *Aphanizomenon flos-aquae* displayed a strong seasonal response (bloom) in October but was not even present in Kay Lake.

***1995 Survey***

Bootjack and Polley lakes were sampled on a monthly basis from May to October in order to obtain information on the baseline diversity and abundance of phytoplankton in these lakes over time. Chlorophyll "a" analysis was carried out to determine phytoplankton standing crop. Results of the taxonomic and chlorophyll "a" analyses of these samples are available in the Mount Polley Environmental Baseline Report (Hallam Knight Piésold, 1996b).

All May samples were similar in the overwhelming abundance of small chrysophytes (*Ochromonas* and *Chromulina sp.*). However, Polley Lake samples differed in species composition from the Bootjack Lake samples. In Polley Lake, the diatoms *Synedra radians* and *Melosira italica* were abundant along with the chrysophytes. In Bootjack Lake, these diatoms were rare, but the cryptophyte *Rhodomonas minuta* and chrysophyte *Chrysochromulina parva* were abundant along with the chrysophytes.

The predominant species in all June samples was the chrysophyte *Uroglena Americana* accounting for between 25.6% and 46.6% of the total cells counted. Uroglena was not found in the May samples. All five June samples again had very high numbers of small chrysophytes (*Ochromonas, Chromulina spp.* and *Chrysochromulina parva*). Among the Bootjack Lake samples, *Rhodomonas minuta* (cryptophyte), *Stephanodiscus niagare* and *Asterionella formosa* (diatoms) appear common. *Mallomonas akrokomas* (chrysophyte) and *Gloeocystis sp.* (green) were common in B2. In contrast, Polley Lake samples showed high concentrations of *Aphanothece spp.* and *Anabaena flos-aquae* (blue-greens), *Eudorina elegans* (green), *Synedra radians* and *Melosira italica,* predominant in May, were much less abundant in June.

The July samples contained a much higher incidence of blue-green algae than either the May or June samples. All July samples had high numbers of small chrysophytes (*Ochromonas, Chromulina spp.* and *Chrysochromulina parva*). The colonial blue-green *Aphanothece clathrata* was predominant in both Bootjack and Polley Lake samples, accounting for between 11.9% and 23.6% of the counts. Large species *such as the diatom Asterionella formosa and dinoflagellate Ceratium hirudinella were common in the* Bootjack Lake samples. The chrysophyte *Dinobryon cylindricum* was predominant and the blue-green *Anabaena flos-aquae* was common in the Polley Lake samples.

During August, small chrysophytes (*Ochromonas spp., Chromulina spp.*) continued to dominate the cell numbers. In addition, blue-green algae continued to increase in abundance. In Polley Lake, the colonial blue-green *Aphanothece spp.* and filamentous blue-green *Aphanizomenon flos-aquae* were predominant, while the filamentous blue-green *Anabaena spp.* were common. While Bootjack Lake samples did not exhibit any clear predominant species, the most common species were the diatoms *Asterionella formosa* and *Cyclotella bodanica*, the colonial blue-greens *Gomphosphaeria lacustris,*

*Gomphosphaeria aponica,* and *Aphanothece spp.*, the filamentous blue-greens *Aphanizomenon flos-aquae* and *Anabaena spp.* and the cryptoflagellate *Rhodomonas minuta*.

The September samples were similar in comparison to the August Samples. Small chrysophytes (*Ochromonas spp.* and *Chromulina spp.*) continued to dominate the cells numbers in Bootjack Lake samples, accounting for between 50.2% and 71.9% of the total cell count. However, the blue-green algae were much more abundant in September than earlier in the season. In the Polley Lake samples, the colonial blue-green *Aphanothece spp.* were the most abundant phytoplankton, constituting from 38.8% to 42.9% off the total cell count. In Polley Lake, the colonial blue-green *Aphanothece spp.* and filamentous blue-green *Aphanizomenon flos-aquae* continued to be predominant. The filamentous blue-green *Anabaena spp.* were common. In Bootjack Lake, *Anabaena spp.* and *Aphanizomenon flos-aquae* were predominant. The common species were the diatoms *Asterionella formosa* and *Cyclotella bodanica*, the colonials blue-greens *Gomphosphaeria lacustris, Gomphosphaeria aponica,* and *Aphanothece spp.*, and the cryptoflagellate *Rhodomonas minuta*.

The October samples were fairly similar in composition to the September and August samples. Small chrysophytes (*Ochromonas spp.* and *Chromulina spp.*) continue to dominate the cell numbers, accounting for between 57.2% and 67.5% of the total count. Blue-green algae continued to be abundant, as well. In samples from all four sites, the filamentous blue-green *Aphanizomenon flos-aquae* continued to be predominant. The filamentous blue-green *Anabaena spp.* were much less abundant in September. The cryptoflagellate *Rhodomonas minuta* and varieties, blue-green *Anabaena spp.*, diatoms *Asterionella formosa and Tabellaria fenestrata* were common in all five samples. In Polly Lake, the blue-green *Aphanothece spp.* and chrysophyte *Dinobryon cylindricum* were common. In Bootjack, the blue-green *Gomphosphaeria lacustris* and diatom *Stephanodiscus niagare* were common.

Total cells numbers decreased steadily from a spring bloom high in May of 10000cells/mL to approximately 2000cells/mL for August, September and October. This decline in the total cell count appears to be due to the decline of the cell count associated with the 1000X size. In addition, the August, September and October samples were composed of colonies of small (1-5µm) cells, whereas the May samples consisted of small flagellates and large diatoms. Chlorophyll “a” measurements may show more similar quantities of phytoplankton over time than raw counts suggest. The decrease in numbers may also be related to the sampling depth of 0.5m, where surface water temperatures and light levels are high and nutrients are becoming depleted over the course of the summer.

Results from the chlorophyll “a” analysis indicated that the chlorophyll “a” content ranged from 0.28 µg/L to 4.17 µg/L, with an overall mean of 1.22 µg/L. The chlorophyll “a”content appeared to remain fairly stable from May through September, but increased greatly in October.

### 4.8. Periphyton

Periphyton sampling was conducted in mid-summer 1995 during maximum periphyton growth, in order to establish baseline periphyton diversity and abundance in selected stream within the study area. Complete results are presented by Hallam Knight Piésold (1996b).

The periphyton sample collection was carried out at water quality (W) sites 7 (Hazeltine Creek), 8 (Edney Creek tributary 1), 8a (Edney Creek tributary 2) and 9 (Edney Creek mainstem) on August 25, 1995 (Figure 2.8[10], extracted from Hallam Knight Piésold Ltd., 1996a). At each site, 3 replicate samples were randomly collected using a "Stockner sampler", a modified wide-barrelled syringe fitted with a toothbrush. In addition, samples were analyzed for chlorophyll "a" content, to determine periphyton standing crop.

The samples from site W7 contained some sediment, mostly silt and detritus with relatively little algae. All three samples had similar composition. Diatoms comprised 99% to 100% of periphyton. Empty frustules (dead cells) were common in these samples. The predominant species were *Nitzschia spp., Synedra ulna,* and *Navicula spp.*

[10] MPMC is currently working to develop a digitized version of this map.

# 5. HISTORIC LAND USES

## 5.1. Forest Resources

All of the project area is within the ICHmk3 biogeoclimatic zone, and with very few exceptions, the land is Crown owned. Under the administration of the Ministry of Forests, commercial forestry has been the predominant land use activity in the project area.

Clear-cut and selective logging occurred over a significant portion of the project area and its surroundings. Many of these cut blocks were replanted for commercial timber species, although a few blocks were replanted for a combination of silviculture and cattle grazing uses. The cut blocks planted for cattle grazing are mostly south of Polley Lake, as shown in Figure 2.20[11] (extracted from Hallam Knight Piésold Ltd., 1996a). The wildlife capability map in Figure 2.18[12] (extracted from Hallam Knight Piésold, 1996a) shows.

Forest capability varies greatly over the project area due to varying stages of regeneration from previous logging activity, mine exploration activity, and scattered marshy areas. Overall forest capability is medium to good class timber.

## 5.2. Range Management

There are two ranchers with range tenures neighbouring the site. Fred Tillitson is authorized to graze cattle to the southeast of the mine, adjacent to the TSF, and Dan Hamblin is authorized to graze cattle to the north and east of the mine site on either side of the access road (encompassing the area around Bootjack Lake and Trio Lake, stretching to Frypan Lake). Contact with each of these ranchers was established in 1988 by Imperial Metals Corporation prior to development (and infringement on grazing land) to verify grazing activities, and to discuss potential points of contact and mechanisms for avoiding conflicts between the mine and grazing. The ranchers identified a spring used by their cattle near the Gavin Lake Road south of Polley Lake, and asked to have it preserved for cattle watering. It was also confirmed that the most productive and successfully re-vegetated grazing areas are located south of Polley Lake and outside of the project area.

Areas disturbed by logging have created opportunity for cattle grazing in the area. In some cases, whole cut blocks were re-vegetated with a combination of forage species for cattle, as well as commercial timber species. Road sites, abandoned roads and tracks, and log landing areas were typically planted with species suitable for cattle grazing. The selected species include several domestic grasses and legumes. This has resulted in the creation of summer grazing areas on Crown owned lands by regional ranches. Prior to mine development, several cut blocks in the vicinity of Bootjack Creek were used for

[11] MPMC is currently working to develop a digitized version of this map.
[12] MPMC is currently working to develop a digitized version of this map.

grazing and were either re-vegetated or in a transitional state from 1970s logging, as shown in Figure 2.20[13] (Hallam Knight Piésold, 1996a).

### 5.3. Hunting, Guiding, and Trapping

There is an extensive system of logging roads surrounding the Mount Polley area, giving vehicle access to areas on both sides of Bootjack and Polley Lake. These roads also connect with north-south and east-west forestry roads, giving hunters convenient access loops. Hunting is a common recreational activity in the region, and local moose and deer populations attract both local and non-resident hunters. The roads in the areas surrounding the mine are used frequently by resident hunters during hunting season. Out-of-province hunters must hire guide-outfitters to assist them in hunting. The boundary between two guide-outfitting territories runs through the Mount Polley Mine site as shown in Figure 1. The project area was not previously an important destination for either guide-outfitter, as it does not contain substantial amounts of prime moose habitat. Both guide-outfitters were contacted by Imperial Metals Corporation prior to project development, and both confirmed that the area only formed a minor element in their annual hunting and guiding activity. They recognized that no-shooting areas around the mine would be necessary for safety, and agreed to make adjustments. Black bear have been hunted in the past from the Mount Polley project area, particularly during the spring bear hunt. Grouse and rabbits were sometimes taken by hunters seeking deer and moose. The area had low waterfowl capability and was used little by duck and goose hunters.

Marten, weasel, muskrat, beaver, and squirrel are the major fur-bearers in the region surrounding Mount Polley, although fox, lynx, mink, otter, wolf, and coyote are trapped in small numbers. The Mount Polley project area is entirely within the registered trapping area TR0502T056 as shown in Figure 1.

### 5.4. Recreation

Recreational activities in the area are centred around lake fishing, hunting, and camping. The natural populations of rainbow trout in the lakes attract both local residents and tourists.

The Forest Service maintains campgrounds that are equipped with boat launches, campsites, toilets, and picnic tables on both Bootjack and Polley Lakes, which are used steadily throughout the camping season, often by fishermen with canoes or boats. Hunters often use the campsites as well. Because no fees are collected for campsite use, no accurate utilization records exist. Hiking, nature study, cross country skiing, snowmobiling, and vehicles touring might be expected as minor components in the recreational use of the area, particularly on the network of logging roads and tracks.

Two private parcels (L11560, L11559) at the north end of Polley Lake are owned by Imperial Metals Corporation, and there is also a private cabin (L12023) at the northeast end of Bootjack Lake.

[13] MPMC is currently working to develop a digitized version of this map.

The Morehead Lake Resort on the Likely Road at the north end of Morehead Lake is the closest accommodation to the project site. Hunters, fishermen, tourists, and mining and forest industry workers stay in the cabins or use the campsites. Parcels of private land with cabins and homes can be found near Morehead Lake.

#### 5.4.1.*Creel Surveys*

BC Fisheries Branch personnel in Williams Lake indicated that during a creel survey conducted in August 1982, catch rates of rainbow trout in Polley Lake were 1.9 fish per hour (8.4 fish per angler day) and 0.94 fish per hour (6.6 fish per angler day) in Bootjack Lake. Creel survey information for Bootjack and Polley Lakes also exists for the years 1987 to 1990. During the period of June to September 1990, angler catch rates on Polley Lake ranged from 0.97 fish per hour in September to 3.37 fish per hour in June. Bootjack Lake catch rates for the same period ranged from 0.71 fish per hour in July to 1.68 fish per hour in June (Lirette and Tredger, 1991).

Judged on the basis of angler effort and success, Polley Lake is among the top three unstocked (wild) Cariboo lakes, and Bootjack Lake is among the top ten (M. Lirette, personal communication).

Imperial Metals Corporation conducted weekend boat counts and creel surveys at Polley Lake and Bootjack Lake from May 20 to September 16, 2,995. Anglers fished an estimated 1,744 weekend hours or 761 weekend days on Bootjack Lake, and 4,095 weekend hours or 1,087 weekend days on Polley Lake. For the period of May 1 to September 30 1995, anglers on Polley Lake caught an estimated 9,009 trout and kept an estimated 7,248 trout. For the same time period, anglers on Bootjack Lake caught an estimated 4,884 trout and kept an estimated 4,253 trout (Hallam Knight Piésold, 1996c).

### 5.5. Culturally and Environmentally Sensitive Areas

There are no reserves in the Mount Polley project area; however it falls on the traditional territory of the Xat'sull Cm'etem (Soda Creek/Deep Creek Band) and the T'exelc (Williams Lake Band). A traditional use study was conducted in 2012 by Points West Heritage Consulting Ltd. The report summary states:

Points West Heritage Consulting Ltd. conducted an overview assessment of the heritage resources in the project area prior to mine construction. The abstract of their report (which was filed with the Archaeology and Outdoor Recreation Branch in Victoria) states:

*"Most of the development area has a low heritage resource potential. A few isolated areas have a low-moderate potential. All have been disturbed to some degree, and involve narrow corridors. Two locations have moderate heritage resource potential. Area A is adjacent to Bootjack Lake and appears to be undisturbed. No additional studies of this site are contemplated, because it is outside of the mine development area. The other is adjacent to a potential transmission line corridor, and it appears to have been disturbed by previous land use activities. "*

No parks or protected areas fall within the project development area.

# 6. PRIOR LAND USES OF SITE RECLAMATION UNITS

## 6.1. Mill and Plant Area

The mill area was previously a gently-sloping south-facing plateau, most of which is blanketed with glacial till deposits to seven meters deep, although there was a small inclusion of organic soils in the center of the area (Blashill 1995a, 1995b). The Mill area was clear-cut in 1972, except for isolated red cedar stands, and was labelled NSR (not sufficiently restocked) on forest cover maps prior to mining. Areas to the east, north, and west of the mill area were selectively logged in 1972, and these areas have had good natural regeneration by Douglas-fir, western red cedar, and subalpine fir. In general, the mill area had a medium site class capability for commercial forestry. South and west-facing slopes, located west of the mill site, have good capability (Class 2) as summer range for moose and mule deer, but a fair to poor capability for winter range (Classes 3,4). These high-quality ranges will not be cleared for mine development. The selectively logged areas surrounding the mill have a fair capability for marten, weasel, hare, squirrel, and lynx. Breeding bird densities and bird species diversity are both high. Prior to clearing, the mill area had a very low capability for waterfowl and aquatic furbearers such as beaver, muskrat or mink. The two small intermittent streams that drained the mill area did not constitute fisheries habitat. There are no heritage resources or historic features within the mill area.

## 6.2. Open Pits

The southern portions of the Cariboo Pit were selectively logged in the 1970's, leaving a variable forest with some advance regeneration by western red cedar and subalpine fir. The remaining portion of the Cariboo Pit and the now backfilled Bell Pit were not logged, but consisted of mid-seral Douglas-fir and lodgepole pine stands which dated back to forest fires some 120 to 160 years ago. Forest cover maps indicate that most of this area had a poor to low site class rating for commercial forestry.

The area of the Springer Pit does not appear to have been logged, but consisted of mid-seral Douglas-fir and lodgepole pine stands, which date back to forest fires some 120-160 years ago. Forest cover maps indicate that most of the area for the Springer Pit has a poor (P) to low (L) site class rating for commercial forestry.

Pellet group counts and range surveys indicate that the Springer, Cariboo and Bell Pits offer poor to fair summer range for mule deer and moose, poor winter range for moose, and very poor winter range for mule deer. Better mule deer and moose habitat exists on the west-facing slopes below this, overlooking Bootjack Lake. The pit area probably has low to moderate capability as black bear habitat, due to the high cover by black huckleberry and kinnikinnick, which provide some berries in season. Habitat capability for marten, squirrel and hare appears low to moderate. Call count transects indicate that breeding bird densities are low, with few species. The pit area had no capability for waterfowl, or aquatic fur bearers such as beaver, mink, or muskrat. There were no permanent ponds, lakes, or streams in the pit area, and thus the area has no potential as fish habitat. No wildlife trees, cliffs, caves or other special wildlife features were been found in the pit area.

The Wight Pit is located in an area identified as MOG (mature and old growth habitat), CL (clear-cut) and RSS (riparian zone of small stream). It contains a mixture of Western red cedar, Douglas-fir, spruce and balsam trees. The stands were all greater than 141 years, with some greater than 251 year. Forest cover Maps indicate that the area for the Wight Pit had a poor (P), medium (M) to good (G) site class rating for commercial forestry. While there were no studies in the specific area where the Wight Pit will be located, mature and old growth forests in the Interior Cedar-Hemlock zone may be home to the following wildlife: moose, mule deer, black beer, wolverine, marten, owls, woodpeckers and several passerine species. In a field study during the spring of 2004, riparian vegetation near the creeks flowing into Polley Lake from the west were dominated by devils club, ferns, alder, huckleberry and willow species. The area of the Wight Pit will encompass the mid and upper reaches of an un-named creek. Fisheries studies in the spring of 2004 concluded that this drainage does not provide rearing or spawning habitat for the rainbow trout in Polley Lake. Further, it provided no nutrients (benthic invertebrates), as this drainage does not connect with the lake.

While the rock borrow at the TSF is included with the areas associated with the pits, all prior land uses are similar or the same as those for the TSF. Please refer to Section 6.4 on the TSF for more information.

### 6.3. Waste Rock Dumps

Most of the North Bell Dump occupies a side valley enclosed by rock knobs that was logged in 1975, and regenerated to a dense second-growth mixed forested dominated by alder, willow, cottonwood and tall shrubs, with a scattered veteran Douglas-fir and Western red cedar, and with strong advance regeneration by subalpine fir. Forest cover maps rate the site capability of this area as good (G). There was no evidence of livestock grazing in this unit prior to mining.

The North Bell Dump area had moderate densities of breeding birds, but fewer species than the East RDS, Wight RDS and Leach Pad areas. No pellet groups were found on pellet group plots, but moose dropping groups and deer tracks were found along an abandoned road. Ungulate browsing was very localized, but tall willows, Douglas maple and western mountain-ash were heavily browsed at favoured locations. Some individual alders and willows in the North Bell Dump area were girdled and killed by snowshoe hares.

The East Rock Disposal Site occupies a sloping eastward aspect plateau. Prior to mining disturbance, the vegetation was a complex mosaic of young seral, mid-seral and mature forest. Much of the area east of the mill site was selectively logged in 1972, and supported a rich and diverse patchwork of deciduous shrub thicket, veteran black cottonwoods, and vigorous advance regeneration by Douglas-fir, western redcedar and subalpine fir. Parts of the waste dump overlap stands of mature forest, dominated by large, well-grown western redcedars and Douglas-firs, with a rich a variable shrub understory, of the 05 and 07 site series. Forest cover maps rate the forest site capability as medium (M) to good (G). There is no evidence of livestock grazing in this unit prior to mining activity.

Neither of these areas had permanent lakes or ponds, although there were small seepages and swampy areas in both the North Bell Dump and East Rock Disposal Site. The creeks draining the ravines were small and intermittent, and were reduced to a trickle by mid-June. They had very low capability for

waterfowl, shorebirds or aquatic mammals, such as beaver, due to their small sizes and intermittent flows. No amphibian eggs, larvae or adults were found near any of the creeks draining these waste rock dumps. These streams did not support fish. There were no cliffs, caves, canyons, talus slopes, permanent streams, lakes, wetlands or mineral licks in either of these areas.

The areas for the East Rock Disposal Site, NEZ Dump, and North Bell Dump did not have permanent lakes or ponds, although there are small seepages and swampy areas in ravines of all four locations. The creeks draining the ravines are small, and intermittent. By mid-June, these creeks are reduced to small trickles. These creeks have a very low capability for waterfowl, shorebirds or aquatic mammals such as beach, due to their small sizes and intermittent flows. No amphibian eggs, larvae or adults were found near any of the creeks draining these existing or proposed waste rock locations. These streams do not support fish. There are no cliffs, caves canyons, talus slopes, permanent streams, lakes, wetlands or mineral licks in either of these areas.

### 6.4. Tailings Storage Facility

Large portions of the tailings area were clearcut logged in 1970, 1979 and 1983. Cut stumps indicate that the original vegetation was a closed forest of large, vigorous western red cedars and Douglas-firs. After harvest, these clear cuts were subjected to moderate to intense slash-burning. Portions of the clear cuts were re-planted with spruce seedlings, which show poor vigour and high mortality. Forest cover maps assign a poor (P) site class code to most of the tailings area. Most of the clear cuts would probably be judged NSR (not sufficiently re-stocked). There was no evidence of recent cattle grazing in these clear cuts in 1995. However, throughout the mining operations from 1997 through 2001, as well as the care and maintenance period of 2001 through 2004, the TSF area was used extensively by various herds of cattle for summer grazing.

Breeding bird densities are very low in these clearcut areas, and there are very few bird species. This habitat has moderate numbers of northwestern chipmunk. Moose and mule deer appear to make little use of open, exposed areas in the clear cuts, although use of forest edge areas with better cover may be high to very high. Several coyote tracks were seen in this habitat.

Approximately 20% of the tailings area is occupied by a stand of mature to old growth forest, dominated by western red cedar, with lesser cover by sub-alpine fir and Douglas-fir. Breeding bird densities and the number of bird species in this forested area are both high. Red squirrels are present in low densities. Neither moose nor deer appear to use the interior of this stand, as little of the available vegetation is palatable to ungulates. However, the edges of this stand appear to be heavily used by moose. Stand edges combine good thermal cover with abundant forage.

The remaining 20% is occupied by a small wetland dominated by wet shrub thickets of Sitka alder, scrub birch and hardhack, containing a 3 ha bog pond. It is the only permanent wetland in the mine development area, but it is neither unique nor important in a regional context. It supports one or two pairs of each of green-winged teal, bufflehead, common snipe, willow flycatcher, common yellowthroat, Lincoln's sparrow and song sparrow. Although the first four species are not found elsewhere in the mine development area, they are widespread and common in British Columbia. Moose and mule deer

do not appear to utilize the surrounding shrub vegetation, probably due to the low palatability of hardhack and alder, the dominant shrubs.

## TEXTURE

| Symbol | Name | Size(mm) | Other Characteristics |
|---|---|---|---|
| a | blocks | >256 | angular particles |
| b | boulders | >256 | rounded & subrounded particles |
| k | cobbles | 64–256 | rounded & subrounded particles |
| p | pebbles | 2–64 | rounded & subrounded particles |
| s | sand | .062–2 | |
| ŧ | silt | .002–.062 | |
| c | clay | <.002 | |
| d | mixed fragments | >2 | mix of rounded and angular particles |
| g | gravel | >2 | mix of boulders, cobbles and pebbles |
| x | angular fragments | >2 | mix of rubble and blocks |
| r | rubble | 2–256 | angular particles |
| m | mud | <.062 | mix of clay and silt |
| y | shells | – | shell or shell fragments |
| e | fibric | well-preserved fibre; (40%) identified after rubbing | |
| u | mesic | intermediate decomposition between fibric and mesic | |
| h | humic | decomposed organic material; (10%) identified after rubbing | |

## SURFACE EXPRESSION

| Symbol | Name | Description |
|---|---|---|
| a | moderate slope | Unidirectional surface; >15° to ≤26° |
| b | blanket | A mantle of unconsolidated material: >1m thick |
| c | cone | A cone or segment of a cone: >15° |
| d | depression | A lower area enclosed by higher surrounding terrain |
| f | fan | A segment of a cone; up to 15° |
| h | hummocky | Hillocks and hollows, irregular in plan; 15–35° |
| j | gentle slope | Unidirectional surface; >3° and ≤15° |
| k | moderately steep | Unidirectional surface; >26° and ≤35° |
| m | rolling | Elongate hillocks; 3 to 15° ; parallel forms in plan |
| p | plain | Unidirectional surface; up to 3° |
| r | ridged | Elongate hillocks; 15 to 35° ; parallel forms in plan |
| s | steep | Steep slopes; >35° |
| t | terraced | Step-like topography |
| u | undulating | Hillocks and hollows; up to ≤15° ; irregular in plan |
| v | veneer | Mantle of unconsolidated material; 10cm to 1m thick |

## SURFICIAL MATERIALS

| Symbol | Name | (Assumed Status of Formative Process) | Description |
|---|---|---|---|
| A | anthropogenic | (A) | Man-made or man-modified materials |
| C | colluvial | (A) | Products of mass wastage |
| D | weathered bedrock | (A) | In situ, decomposed bedrock |
| E | eolian | (I) | Materials deposited by wind action |
| F | fluvial | (I) | River deposits |
| $F^G$ | glaciofluvial | (I) | Ice contact fluvial materials |
| I | ice | (A) | Permanent snow, glaciers and icefields |
| L | lacustrine | (I) | Lake sediments; includes wave deposits |
| $L^G$ | glaciolacustrine | (I) | Ice contact lacustrine materials |
| M | morainal | (I) | Material deposited directly by glaciers |
| O | organic | (A) | Accumulation/decay of vegetative matter |
| R | bedrock | (–) | Outcrops/rock covered by less than 10cm |
| U | undifferentiated | (–) | Layered sequence; three materials or more |
| V | volcanic | (I) | Unconsolidated pyroclastic sediments |
| W | marine | (I) | Marine sediments; includes wave deposits |
| $W^G$ | glaciomarine | (I) | Ice contact marine sediments |

## GEOLOGICAL PROCESSES

| Symbol | Name | (Assumed Process Status) | Description |
|---|---|---|---|
| A | avalanches | (A) | Terrain modified by snow avalanches |
| B | braiding | (A) | Diverging/converging channels; unvegetated bars |
| C | cryoturbation | (A) | Sediments modified by frost heaving and churning |
| D | deflation | (A) | Removal of sand and silt by wind action |
| E | channelled | (I) | Channel formation by meltwater |
| F | slow mass movement | (A) | Slow downslope movement of masses of cohesive or non-cohesive material and/or bedrock |
| H | kettled | (I) | Depressions due to the melting of buried glacier ice |
| I | irregular channel | (A) | A single, clearly defined main channel displaying irregular turns and bends |
| J | anastamosing channel | (A) | A channel zone where channels diverge and converge around many vegetated islands |
| K | karst | (A) | Processes associated with the solution of carbonates |
| M | meandering channel | (A) | Channel characterized by a regular pattern of bends with uniform amplitude and wave length |
| N | nivation | (A) | Erosion beneath and along the margin of snow patches |
| P | piping | (A) | Subterranean erosion by flowing water |
| R | rapid mass movement | (A) | Rapid downslope movement of dry, moist or saturated debris |
| S | solifluction | (A) | Slow downslope movement of saturated overburden across a frozen or otherwise impermeable substrate |
| U | inundation | (A) | Seasonally under water due to high watertable |
| V | gully erosion | (A) | Parallel/subparallel ravines due to running water |
| W | washing | (A) | Modification by wave action |
| X | permafrost | (A) | Processes controlled by the presence of permafrost |
| Z | periglacial processes | (A) | Solifluction, cryoturbation and nivation processes occurring within a single unit |

## QUALIFYING DESCRIPTORS

| Symbol | Name | Description |
|---|---|---|
| G | glacial | Used to qualify surficial materials where there is evidence that glacier ice affected the mode of deposition of materials |
| A | active | Used to qualify surficial materials and geological processes with regard to their current state of activity |
| I | inactive | |

## MAP UNIT LETTER NOTATION

A terrain map unit symbol is composed of a combination of letters which designate different characteristics of the terrain. The relative position of letters within the symbol indicates the characteristics that they represent.

SAMPLE TERRAIN UNIT SYMBOL

This map unit consists of a gravelly glaciofluvial terrace that overlies sandy lacustrine materials and is modified by gullies that are no longer active.

Explanatory Notes

1. Units consisting of two or more types of terrain are designated by two or more groups of letters separated by slashes and/or dots

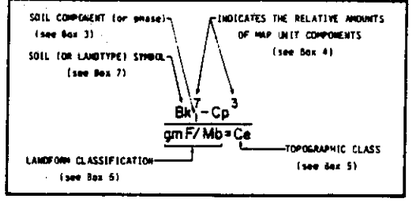
# IMPERIAL METALS CORPORATION
# MT. POLLEY PROJECT
# SOILS AND LANDFORMS MAP LEGEND



## 1. Explanatory Notes

The information contained in the following boxes explains some important characteristics of the soils and landforms that were mapped at a reconnaissance level of investigation. Each of the individual boxes is cross referenced.

The information provided in this legend is brief. Further details on the soils and their environment are provided in the soil reports and maps for adjoining soil survey areas No. 24,25,31,36 and 40. The report and maps Soils of the Horsefly Area is in preparation for printing.

This key describes all soils and landforms mapped at a scale of 1:50 000 for maps 93A/3,4,5,6,11,12,13,14

## 2. Example

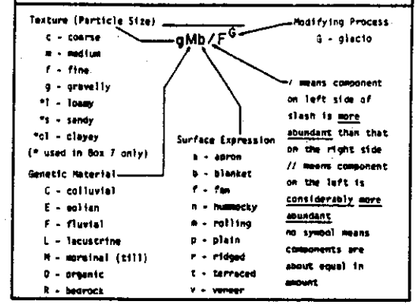
## 3. Soil Components

Where soil components are used they are shown and characterized in Box 7. Some map unit numbers refer to soil component numbers used in adjoining survey areas.

## 4. Composite Units

Composite units are employed where two or three types of map unit components are intermixed or occupy such small areas that they cannot be designated as separate units at the scale of mapping.

Numbers show the relative amounts of each soil or land type component of a map unit as: 9 (90%), 8 (80%), 7 (70%), 6 (60%), 5 (50%), 4 (40%), 3 (30%), 2 (20%), 1 (10%).



The components of the denominator are described in Boxes 5 and 6.

## 5. Topographic Classes[1]

| Simple Topography | | Complex Topography | | Slope |
|---|---|---|---|---|
| Single Slopes (regular surface) | | Complex Slopes (irregular surface) | | % |
| A | depressional to level | a | nearly level | 0-0.5 |
| B | very gently sloping | b | gently undulating | 0.5-2 |
| C | gently sloping | c | undulating | 2-5 |
| D | moderately sloping | d | gently rolling | 5-9 |
| E | strongly sloping | e | moderately rolling | 9-15 |
| F | steeply sloping | f | strongly rolling | 15-30 |
| G | very steeply sloping | g | hilly | 30-60 |
| H | extremely sloping | h | very hilly | over 60 |

## 8. Forest Zonation Symbols[1]

Biogeoclimatic zones and subzones are used instead of forest zones.

| | |
|---|---|
| AT | Alpine Tundra Zone |
| ESSFb | Engelmann Spruce - Subalpine Fir (wet subzone) |
| IWHa | Interior Western Hemlock (cedar subzone) |
| IWHb | Interior Western Hemlock (wet subzone) |
| SBSb | Subboreal Spruce (Douglas fir - white spruce subzone) |
| SBSc | Subboreal Spruce (white spruce - subalpine fir - Douglas fir subzone) |
| IDF b | Interior Douglas fir (pinegrass subzone) |

[1]Ref. Annas & Coupé 1979

## 9. Drainage Classes

| | | |
|---|---|---|
| r | Rapidly drained | The soil moisture content seldom exceeds field capacity in any horizon except immediately after water additions. |
| w | Well drained | The soil moisture content does not normally exceed field capacity in any horizon (except possibly the C) for a significant part of the year. |
| m | Moderately well drained | The soil moisture in excess of field capacity remains for a small but significant period of the year. |
| i | Imperfectly drained | The soil moisture in excess of field capacity remains in sub-surface horizons for moderately long periods during the year. |
| p | Poorly drained | The soil moisture in excess of field capacity remains in all horizons a larger part of the year. |
| vp | Very poorly drained | Free water remains at or within 12 inches (30 cm) of the surface most of the year. |

## AQUATIC BIOPHYSICAL

### STREAM SYMBOL

Rb Ch (Co)
9 8 1.5 2 3 4 1

- Fish Species: Rainbow trout (present); Chinook (migration); Cohe (probable)
- Channel Components (see Box 4): Width = 9 metres; Valley flat to channel ratio is between 2 and 5; Average reach slope = 1.5%
- Box (Substrate) Materials (see Box 5): Fines = 20%; Gravels = 30%; Larges = 40%; Bedrock = 10%

### CHANNEL COMPONENTS

1. Channel width in metres. Equal to distance between rooted vegetation, including islands.
2. Valley flat to channel ratio. The ratio between width of valley flat and width of channel.

| Map Designation | Ratio |
|---|---|
| A | 0-2 |
| B | 2-5 |
| C | 5-10 |
| D | 10+ |
| E | N/A (e.g. Fan or delta) |

3. Slope (elevation gain/reach length) calculated as an average for the reach, expressed as a percentage; measured from topographic base map.
   - >3% rounded off to the nearest percent
   - <3% rounded off to 1 decimal place.

### BED (SUBSTRATE) MATERIALS

Fines, gravels, larges and bedrock are listed in sequence to nearest 10%, expressed as an integer.

1. Fines 'F'; materials in the 0-2 mm size class
   Gravels 'G'; materials in the 2-64 mm size class
   Larges 'L'; materials greater than 64 mm
   Bedrock 'R'; consolidated materials
2. F, G, L or R used alone indicates 90-100% reach is in that size class.
3. A trace of bedrock (0-5%) may be indicated by R following the 3 material components (e.g. 253R). Traces (0-5%) of fine, gravel, or large material are indicated by a 0 (e.g. 0073).

### LAKE SYMBOL

General: Fish species | T.D.S.
Max. depth | Littoral area

1. Fish species:
2. T.D.S.: total dissolved solids, if available
3. Maximum depth: measured to nearest metre
4. Littoral area: measurement or visual estimate of % of total area <6m. When estimate is made, the symbol is placed in parenthesis.

### FISH SPECIES

1. Fish Species Abbreviations (known or inferred in this map area at time of survey).

| Map Abbrev. | Common Name | Map Abbrev. | Common Name |
|---|---|---|---|
| Ø | no fish detected at time and place of sampling | Gr | Arctic grayling |
| | | GSg | Green sturgeon |
| | | HW | Humpbacked whitefish |
| AC | Arctic char | In | Inconnu |
| Act | anad. (ana-trus) Cutthroat trout | Ko | Kokanee |
| | | LMB | Largemouth bass |
| ADV | anad. Dolly Varden char | LT | Lake (trout) char |
| | | LW | Lake whitefish |
| AEB | anad. Eastern Brook trouts (char) | MW | Mountain whitefish |
| | | NP | Northern pike |
| AGB | anad. Brown trout | OS | forage, unseen fishes |
| AS | Atlantic salmon | P | Perch, general |
| BB | Burbot (Ling) | Pk | Pink salmon |
| BCB | Black crappie | PMB | Pumkinseed |
| BS | Bass/sunfish, gen. | PW | Pigmy whitefish |

2. OS - indicates known but non-sport or non-commercial species, data bank must be consulted for complete species list.
3. Absence of any fish species symbol indicates that no sampling information was available.
4. (Co) - indicates probable but unconfirmed presence.
5. Sh!- indicates reach used by species for migration only, no resident population.
6. Ch - Underlined fish abbrev. indicates special circumstances. Refer to B.C. Aquatic Data Base for clarification.
7. Note: no specific symbol exists for a barren stream. When such a condition is suspected, it may be indicated by (Ø which is an inference that if sampling took place, fish would not be detected.

# Executive Summary

This report provides a five-year update of climate baseline at Mount Polley Mine site (the Site) owned and operated by Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation. Updated baseline statistics are presented for precipitation (total precipitation, rainfall), air temperature, relative humidity, solar radiation, evaporation, snow depths, wind speed and directions. Updated climate change projections for the Site are also provided.

The 1974 to 1993 climate records from the nearby Environment and Climate Change Canada (ECCC) Likely climate station and 1995 to 2021 climate records from the local MPMC climate stations served as the basis for developing statistics for describing precipitation and temperature conditions for the Site. Records from regional and MPMC climate stations were reviewed to assist in characterizing climate parameters, such as relative humidity and solar radiation, and to support the identification of spatial trends. Local and regional climate station data were interrogated for inconsistencies or gaps, and then infilled using regional data and translation factors.

A summary of the updated baseline climate parameters developed in this study is provided in Table 1. The trends in climate parameters at the Site are similar to those at the ECCC regional stations considered in the study. An evaluation of future climate change projections indicates future climate at the Site will likely be warmer and wetter, with larger variations throughout the months.

**Table 1: Summary of Key Mount Polley Climate Parameters**

| Parameter | Value |
|---|---|
| Mean annual total precipitation (mm) | 612 |
| 1:2-year 24-hour rainfall (mm) | 33 |
| 1:200-year 24-hour rainfall (mm) | 69 |
| Projected annual total precipitation anomaly from baseline for 2050's (%) | +5 |
| Projected annual total precipitation anomaly from baseline for 2080's (%) | +8 |
| Mean annual temperature (°C) | 3.9 |
| Average winter season (sub-zero mean monthly temperatures) | November to March |
| Projected annual air temperature anomaly from baseline for 2050's (°C) | +1.8 |
| Projected annual air temperature anomaly from baseline for 2080's (°C) | +2.7 |
| Mean annual relative humidity (%) | 68.1 |
| Mean annual solar radiation (W/m$^2$) | 135 |
| Mean annual shallow lake evaporation (mm) | 673 |
| Mean annual potential evapotranspiration (mm) | 863 |
| Mean snow water equivalent for the month of March (mm) | 185 |

Note: Statistics are based on reviewed historical records from multiple climate stations and measured and derived data (where applicable).
mm = millimetre; ˚C = degrees Celsius; W/m$^2$ = watts per square metre.

# Study Limitations

Golder Associates Ltd., a member of WSP (WSP Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings, and other documents contained herein, has been prepared by WSP Golder for the sole benefit of Mount Polley Mining Corporation (MPMC). It represents WSP Golder's professional judgement based on the knowledge and information available at the time of completion. WSP Golder is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations, and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to WSP Golder by MPMC, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations, and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings, and other documents contained herein, as well as all electronic media prepared by WSP Golder are considered its professional work product and shall remain the copyright property of WSP Golder. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration, and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

# 1.0 INTRODUCTION

## 1.1 Overview

Mount Polley Mining Corporation (MPMC), a subsidiary of Imperial Metals Corporation, owns and operates the Mount Polley Mine (the Mine). The Mine is a copper-gold mine located 56 km northeast of Williams Lake, British Columbia (BC).

## 1.2 Purpose

Guidance from the Global Industry Standard on Tailings Management (GISTM) published by the International Council on Mining & Metals (ICMM) (2020) stipulates under Requirement 2.1 that the environmental knowledge base including climate parameters should be updated every five years to capture uncertainties due to climate change.

The last climate baseline for the Mine site (the Site) was carried out by Golder Associates Ltd., a member of WSP (WSP Golder) in 2016, and MPMC has retained WSP Golder to prepare an update. The purpose of the update is to extend the existing long-term climate dataset for the Site using local and regional data collected in the last 5 years in support of design activities.

This report provides a climate baseline update for precipitation, air temperature, relative humidity, solar radiation, evaporation, wind speed and direction, and snow depths, and includes updated climate change projections for the Site.

## 1.3 Scope

The scope of work for this climate study included:

- Literature review of previous descriptions of climate conditions near the Site study area.
- Statistical analysis of historical climate records at different locations near the Site study area to develop statistics for climate variables, including precipitation (total precipitation, rainfall), air temperature, relative humidity, solar radiation, wind speed and direction, and snow cover properties.
- Mathematical modelling to calculate evaporation and potential evapotranspiration statistics for the Site study area.
- Statistical analysis of point climate data from downscaled circulation models using Shared Socioeconomic Pathways scenarios (ECCC 2022c) for future climate projections for the Site study area.

# 2.0 STUDY AREAS

The Site is located 56 km northwest of Williams Lake, British Columbia (BC) near the eastern edge of the Fraser Plateau physiographic subdivision, approximately 10 km west of its boundary with the Quesnel Highland subdivision, as defined by Holland (1976).

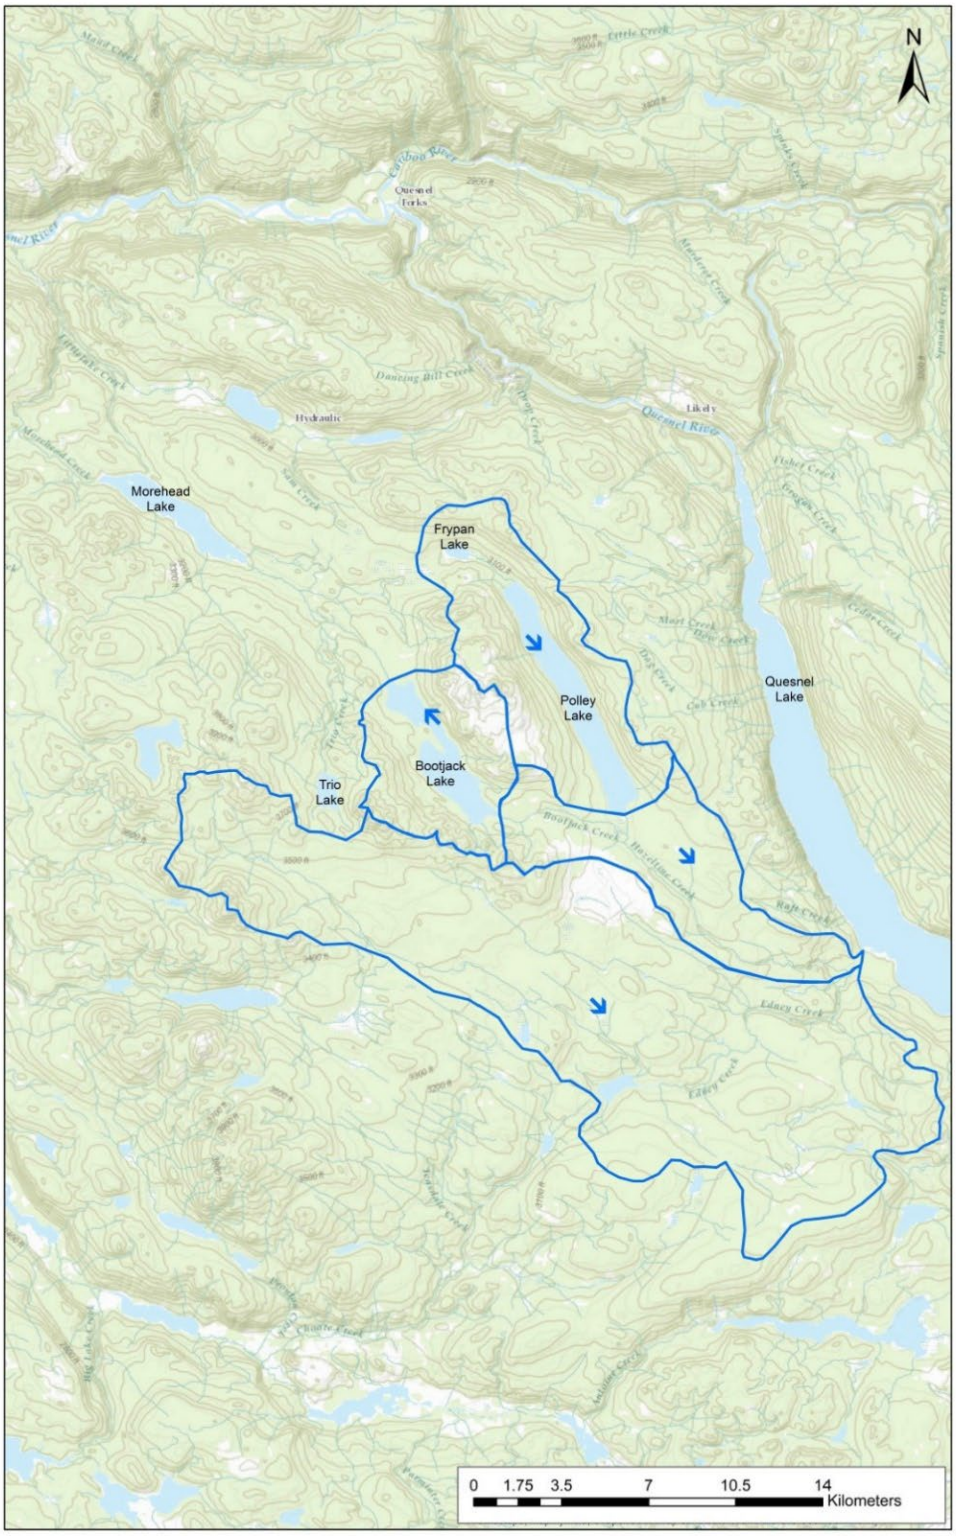
## 2.1 Local Study Area

Within the area of the Mine, the plateau has somewhat higher relief, with the Mine rising approximately 300 metres (m) above the surrounding terrain. Topographically, the Site area consists of north–south trending ridges of moderate elevation and relief. Local elevations range from 922 metres above sea level (masl) at Polley Lake to 1,266 masl at the top of Polley Mountain with an average elevation of 1,038 masl. The total surface area of the Site is 17.8 square kilometers ($km^2$).

The Site is located on the divide of two sub-watersheds within the Quesnel Lake watershed. The western watershed, which includes drainage from Bootjack Lake, discharges to the Quesnel River via Morehead Creek and drained approximately 60% of the Mount Polley area prior to Mine construction. The eastern watershed includes Polley Lake, which discharges to the east via Hazeltine Creek, Edney Creek, and the West Arm of Quesnel Lake. The Hazeltine Creek and Edney Creek watershed areas at Quesnel Lake are approximately 30.2 $km^2$ and 87.4 $km^2$, respectively. Approximately 10.5 $km^2$ that historically reported to this watershed is now within the Site contact water runoff collection system catchment.

Bootjack Creek is a small tributary of Hazeltine Creek downstream of Polley Lake. Historically, Bootjack Lake discharged into Hazeltine Creek via Bootjack Creek, but in 1913 a dam was constructed at the south end of Bootjack Lake and the flow direction was reversed in order to direct water into Morehead Lake for hydropower production. This resulted in 14 $km^2$ being diverted from the Hazeltine Creek catchment. The old Bootjack Lake Dam was upgraded by MPMC in 1997 as fulfillment of a Fish Habitat Compensation Agreement signed between MPMC and the regulating federal and provincial agencies. The Bootjack Lake watershed area is 11.2 $km^2$; approximately 2.3 $km^2$ that historically reported to this watershed is now within the Site contact water runoff collection system catchment. Currently, Bootjack Creek reports to Polley Lake.

The regional topography, water bodies, and pre-mining watersheds are shown in Figure 1. Mine Site water collection systems and catchment areas are not included in the scope of this report.



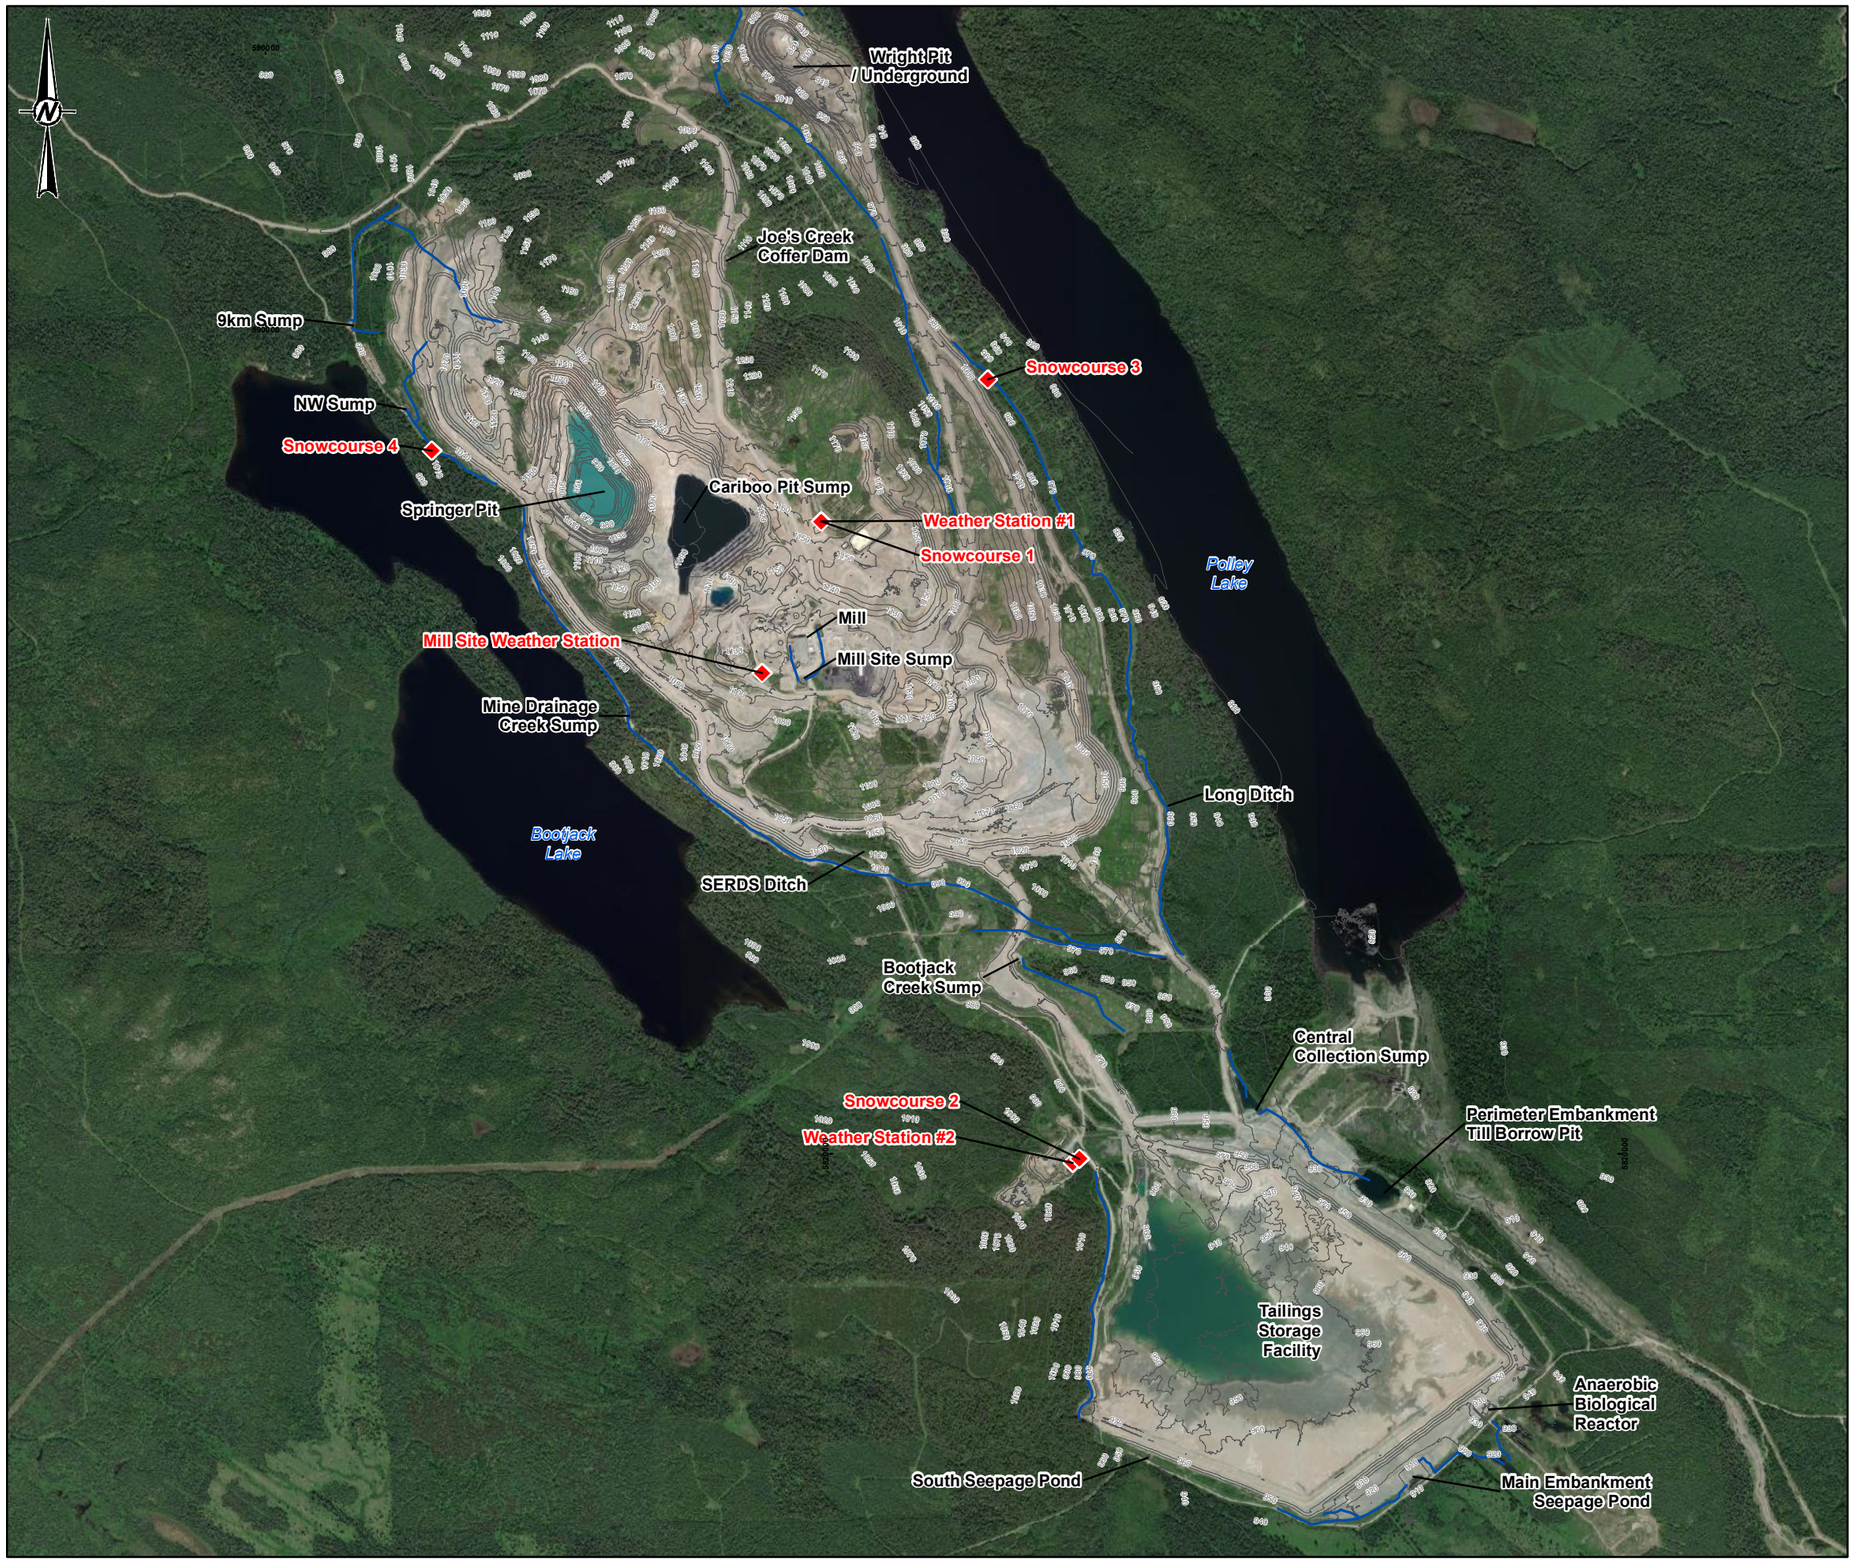


**Figure 1: Mount Polley Mine Site and Surrounding Area Water Bodies and Topography Pre-Mining Activities**

The Site study area is presented in Figure 2 The Site study area comprises the footprint of the physical infrastructure of the Mine and the tailings storage facility (TSF).

# 3.0 METHODS

## 3.1 Study Design

Climate parameters (e.g., precipitation, temperature, and evaporation) vary both spatially and temporally. They vary spatially in response to changes in elevation and/or overall circulation patterns, and temporally, across the seasons, and from year to year. Describing the climate conditions for a certain area means presenting the climate statistics that capture the variation, including both the average expected values and the extent of the variation around the average.

The summary statistics for precipitation, temperature, evaporation, relative humidity, solar radiation, wind speed and directions, and snow depths presented herein were prepared from historical measurements recorded at local climate stations, supported by data collected from nearby regional climate stations. Raw station data were interrogated for inconsistencies or gaps then infilled using regional data and translation factors to generate short duration (daily and sub-daily) and long-duration (Annual) estimates for a range of return periods (precipitation only) or percentiles (temperature, evaporation, relative humidity, and solar radiation only). Except for wind and snow cover, the datasets were extended using historical regional data and translation factors to include a range of possible weather events and climatic trends.

Future climate projections come from publicly available statistical downscaled future climate projections on a daily scale. Recognizing the inherent uncertainty with projections, multiple projections from multiple models and scenarios were included in the analysis. Therefore, the future projections are provided in terms of percentiles or exceedance probabilities. The following sections provide a summary of the climate stations used in this report.

## 3.2 Review of Existing Information

Climate conditions for the Site were estimated based on data from several meteorological stations in the region and at the Site (Figure 3). The meteorological stations are listed in Table 2 and Table 4.

### 3.2.1 Local Climate Stations

MPMC has operated climate stations on site since 1995, although the station data records are not continuous. From 1995 through 2012, MPMC maintained one climate station at the Mill Site that measured and recorded rainfall (1997 to 2012), temperature (1995 to 2012) and wind velocity and directions (1997 to 2003). In 2012, this station was replaced with two stations: one near the mill site (WS1) and one adjacent to the TSF (WS2). These new stations measure and record wind speed, relative humidity, solar radiation, temperature, and rainfall.

Rainfall was measured using a manual rain gauge from 1997 to present at each climate station, and in 2019 automated tipping rain gauges were added at WS1 and WS2. For this study, rainfall for the Site was averaged across all instruments that recorded rainfall on a given day. Relative humidity and solar radiation were recorded at WS1 and WS2 from 2019 to 2021, although records are not continuous. In addition, solar radiation was recorded at the Mill Site station from 2001 to 2003.

Details of these stations are provided in Table 2 and their locations are shown in Figure 2.

**Table 2: Local Climate Stations for the Mount Polley Mine**

| Station Name | Northing (m N)[1] | Easting (m E)[1] | Elevation (masl)[2] | Data Type | Period of Record |
|---|---|---|---|---|---|
| Mill Site Weather Station | 5822420 | 592495 | 1,118 | R, T, WS, WD | 1995-2012 |
| Weather Station #1 (WS1) [near mill] | 5822420 | 592792 | 1,171 | R, T, RH, SR, E, WS | 2012-2021[3] |
| Weather Station #2 (WS2) [TSF] | 5819955 | 594059 | 964 | R, T, RH, SR, E, WS | 2012-2021[3] |

1) UTM Coordinate system – Zone 10U.

2) Elevation for on-site climate stations measured with handheld GPS device.

3) Station still in operation.

TSF = tailings storage facility; masl = metres above sea level.

R = Rainfall; S = Snowfall; T = Temperature; RH = Relative Humidity; SR = Solar Radiation; E = Evaporation; WS = Wind Speed; WD = Wind Direction.

During the winter, snowpack is measured at four snow course sites at a minimum frequency of once per month, with more frequent measurements typically taken during the melt phase. The details of these snow course stations are provided in Table 3 and their locations are shown in Figure 2.

**Table 3: Local Snow Course Sites at the Mount Polley Mine**

| Station Name | ID | Northing (m N)[1] | Easting (m E)[1] | Approximate Elevation (masl)[2] | Period of Record |
|---|---|---|---|---|---|
| Snow Course # 1 (near mill) | N/A | 5823182 | 592792 | 1,171 | 1997–2010, 2015–current |
| Snow Course # 2 (near TSF) | N/A | 5819976 | 594092 | 964 | 1997–current |
| Snow Course # 3 | N/A | 5823895 | 593632 | 976 | 2012–current |
| Snow Course # 4 | N/A | 5823537 | 590835 | 1,112 | 2015–current |

1) UTM Coordinate system - Zone 10U.

2) Elevation for on-site climate stations measured with handheld GPS device.

masl = metres above sea level; N/A = not applicable; TSF = Tailings Storage Facility.

### 3.2.2 Regional Climate Stations

Five Environment and Climate Change Canada (ECCC) climate stations: Likely, Spokin Lake, Williams Lake, Barkerville, and Quesnel, were selected for the update due to their proximity to the Site, length of record, elevation range, and concurrent period of record with the local climate stations at the Site. In addition, the ECCC Prince George climate station was added to include an additional station with solar radiation data. Historical records were retrieved from ECCC's Historical Climate Data web server (ECCC 2022a). More recent records were compiled through e-mail correspondence with ECCC staff (ECCC 2022b). The regional climate station details are provided in Table 4, and their respective locations are shown in Figure 3.

**Table 4: Regional Climate Stations for the Mount Polley Mine**

| Station Name (ID) | Northing (m N)[1] | Easting (m E)[1] | Elevation (masl) | Approximate Distance to Site (km) | Data Type | Period of Record[2] |
|---|---|---|---|---|---|---|
| Likely (1094616) | 5828785 | 599332 | 724 | 9 | P, R, S, T | 1974-1993 |
| Williams Lake A (1098940) | 5781820 | 564666 | 940 | 50 | P, R, S, T, RH, SR | 1961-2021[4] |
| Spokin Lake 4E (1097646) | 5782274 | 589827 | 1,033 | 40 | P, R, S, T | 1983-2021[4] |
| Barkerville (1090660) | 5880996 | 599515 | 1,283 | 59 | P, R, S, T | 1888-2021[3, 4] |
| Quesnel A[5] (1096630) | 5873987 | 546720 | 545 | 80 | P, R, S, T, RH | 1946-2021[4] |
| Prince George A (1096450) | 5971423 | 521103 | 691 | 163 | P, R, S, T, RH, SR | 1973-1995 |

1) UTM Coordinate system – Zone 10U.
2) Length of record from start year to end year may not reflect the number of complete years of data.
3) Provisional data for the period January 2016 to December 2021 were provided by ECCC.
4) Station still in operation.
5) Combined record from Quesnel A and Quesnel Airport Auto stations. Stations are located at the same location.

ID = Identification; masl = metres above sea level; km = kilometre.
P = Precipitation; R = Rainfall; S = Snowfall; T = Temperature; RH = Relative Humidity; SR = Solar Radiation.

## 3.3 Data Processing

Climate parameter statistics for the Site were prepared using data from the three on-site climate stations operated by MPMC, and the five regional climate stations operated by ECCC (Sections 3.2.1 and 3.2.2). Data were interrogated for gaps and errors, and where appropriate, extended and filled with data from regional stations using translation factors derived from the available periods of record as described in Section 3.4. Local data were screened for outliers in the time series that may be indicative of errors or equipment malfunction. Potential high outliers were identified in the Mount Polley rainfall record in April 2009 but were not removed from the time series as there was insufficient evidence to support removal. In addition, climate parameter records were checked using the World Meteorological Organization (WMO) guidelines (WMO 2018) as reference. Monthly records were removed if there were more than five days missing, or more than 3 consecutive days missing. Annual records were only calculated using years with a complete dataset (twelve months).

## 3.4 Data Analysis

### 3.4.1 Precipitation

The MPMC precipitation dataset was extended and infilled using the available data record from the five regional stations as described below to derive a daily and 24-hour long-term synthetic precipitation dataset for the Site.

## Extended MPMC Precipitation Data Record

The Likely ECCC Station data were considered to extend the precipitation record for the Site given the station's length of record and proximity to the Site. As the Likely ECCC station and MPMC climate stations do not have concurrent data sets, the mean monthly April-to-November rainfall distribution for the available data records were compared to evaluate the suitability of using the Likely station data to represent precipitation conditions at the Site. As shown in Figure 4, the Likely and Site station monthly precipitation distributions show a similar trend overall, with MPMC recording notably greater rainfall in April, and notably less rainfall in June and August relative to Likely. The notable differences in monthly rainfall between the MPMC and Likely datasets for the months of April, June, and August were investigated with the following observations:

- April: the length of record for MPMC is relatively short and is not continuous, and outliers have potential to bias mean monthly rainfall. As previously mentioned, potential high outliers were identified in the Mount Polley rainfall record in April 2009 but were not removed from the time series as there was insufficient evidence to support removal. However, if the potential high outlier data were to be removed, the mean monthly April values would be more aligned between the data sets (48.8 mm for MPMC versus of 33.1 mm for Likely).
- June: review of the MPMC and concurrent regional June monthly rainfall records for Barkerville, Spokin Lake, and Williams Lake indicate that relatively low June rainfall totals (compared to average values for the complete available data set from the regional stations) were recorded in several years during the 1997 to 2021 period of record (2002, 2003, 2006, 2009, 2014, 2019, and 2021). These years represent approximately 40% of the available June records for MPMC, suggesting the MPMC mean June rainfall may be biased low (i.e., due to shorter period of record used in computing the mean) compared to Likely.
- August: review of regional rainfall records for Barkerville, Spokin Lake, and Williams Lake from 1997 to 2021 (i.e., concurrent with the MPMC precipitation data set), indicate that regional mean August monthly rainfall records were 84%, 87%, and 85% of the mean of the full period of record, respectively, indicating that there has been reduction (compared to the longer-term mean) in August rainfall regionally in more recent years. In other words, the differences between MPMC and Likely mean August rainfall values may be attributed to differing precipitation trends in the respective reporting periods.

Based on above, the historical Likely ECCC Station record was considered acceptable for extending the historical precipitation record for the Site. Owing to the elevation difference between the Site and Likely ECCC Station, a precipitation-elevation orographic factor was applied to adjust the raw precipitation data from the Likely ECCC climate station to the Site. The adjustment was based on the April-to-November rainfall ranking factor of the raw Likely ECCC climate station and Site rainfall records.

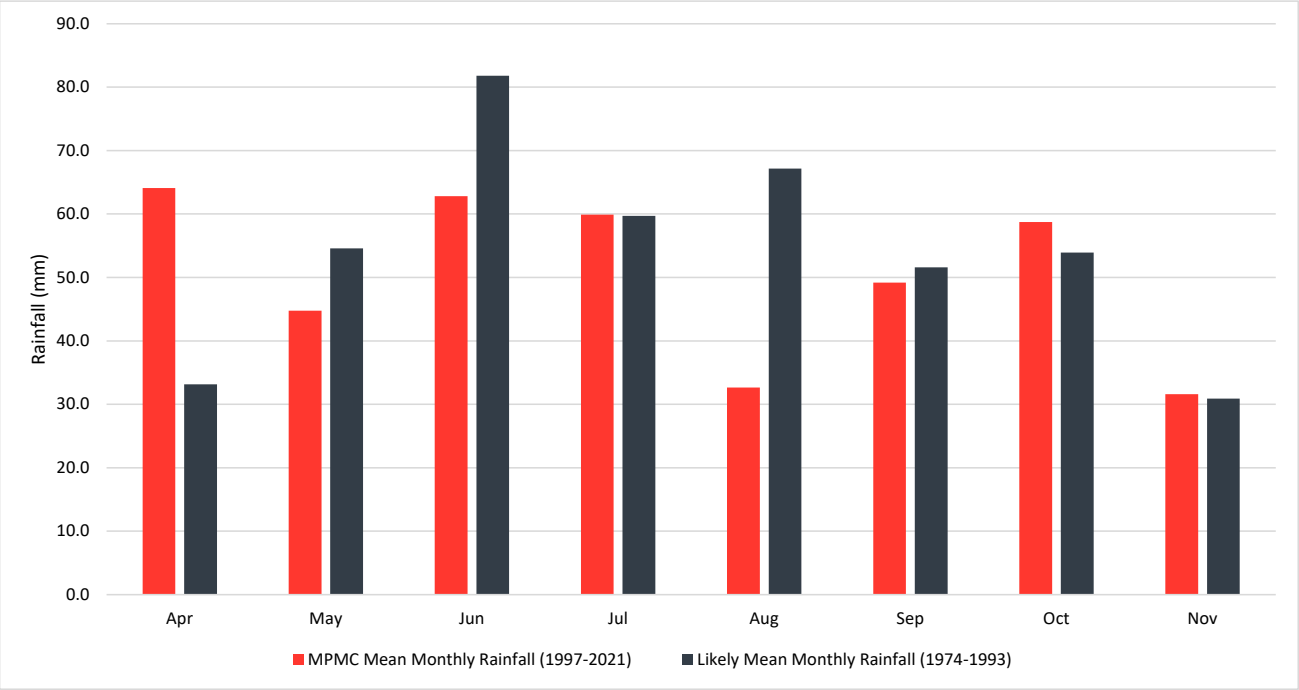

**Figure 4: April-to-November Rainfall Distributions at Mount Polley Mine and ECCC Likely Climate Stations**

## MPMC Precipitation Data Gap Infilling

The priority sequence of concurrent regional climate station data used to infill gaps in the extended Site precipitation record was determined by analyzing measured daily rainfall from April to November for all climate stations; it was assumed that precipitation occurring between December and March occurred as snowfall. The regional climate station priority sequence considered the best-fit measured concurrent daily rainfall correlation (Rainfall Correlation), rainfall ranking correlation (Rainfall Rank), and percentage of time rain was recorded on the same day (Concurrent Daily Rain) between the raw data collected at the MPMC climate stations and each ECCC climate station (Table 5). Regional climate station precipitation data replaced missing rainfall data in the extended Site data record following the priority sequence, and all precipitation data from December to March as it was assumed precipitation during this period occurs as snowfall and daily snowfall is not recorded at the Site.

**Table 5: Regional Climate Stations Priority Sequence for Precipitation Data Gap Infilling in Extended Record for MPMC**

| Priority | Station | Rainfall Correlation ($R^2$) | Rainfall Rank ($R^2$) | Concurrent Daily Rain (%) | Period of Record | Currently Active | Distance from site (km) |
|---|---|---|---|---|---|---|---|
| 1 | Williams Lake A | 0.1950 | 0.9872 | 61.8 | 1960-2021 | Yes | 50 |
| 2 | Spokin Lake 4E | 0.1829 | 0.9747 | 65.8 | 1983-2021 | Yes | 40 |
| 3 | Barkerville | 0.1579 | 0.9216 | 66.4 | 1888-2021 | Yes | 59 |
| 4 | Quesnel A | 0.0502 | 0.9556 | 23.3 | 1946-2021 | Yes | 80 |

A precipitation-elevation orographic factor was applied to adjust the raw precipitation data from the ECCC climate stations used to infill gaps. The adjustment was based on the April-to-November rainfall ranking factor of the raw ECCC climate station and Site rainfall records.

### Daily to 24-Hour, 3-day, and 10-day Precipitation

The daily long-term synthetic precipitation dataset was converted to 24-hour, 3-day, and 10-day precipitation by applying a factor of 1.13 (WMO 2009), 1.03, and 1.01 (Miller 1964), respectively.

## 3.4.2 Temperature

Similar to precipitation analysis above, the MPMC temperature dataset was extended and infilled using the available data record from the five regional stations to derive a long-term synthetic temperature dataset for the Site.

### Extended MPMC Temperature Data Record

The Likely ECCC Station data were considered to extend the temperature record for the Site given the station's length of record and proximity to the Site. As the Likely ECCC station and MPMC climate stations do not have concurrent data sets, the mean monthly air temperature distributions for the Site and Likely climate stations were compared to evaluate the suitability of using the Likely station data to represent temperature conditions at the Site. As shown in Figure 5, the monthly distributions show similar trend with MPMC and the historical Likely ECCC Station record was considered acceptable for extending the historical temperature record for the Site. Owing to the elevation difference between the Site and Likely ECCC Station, a temperature-elevation orographic factor was applied to adjust the raw precipitation data from the Likely ECCC climate station used to extend the historical record. The adjustment was based on monthly regional lapse-rates as discussed below.

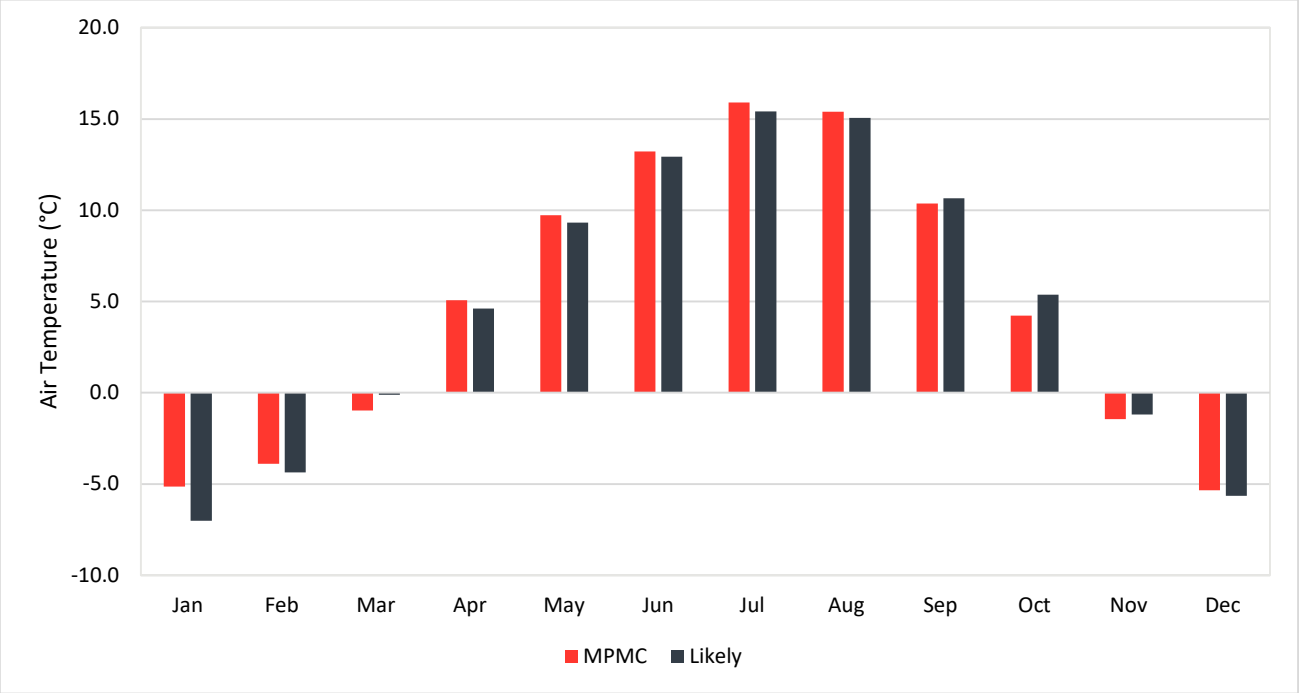

**Figure 5: Mean Monthly Air Temperature Distributions for the Site and Likely ECCC Climate Station**

ECCC Climate Normals for the regional climate stations were reviewed and are summarized in Table 6 and mean monthly air temperatures are presented in Figure 6. Comparing the Normals for the five regional ECCC Climate stations, there is an evident trend (the temperature lapse rate) of decreasing mean annual temperature with increasing elevation. The annual temperature lapse rate for the region is -0.47 °C / 100 m elevation increase. The lapse rate is larger for warmer months (April to October -0.55 °C / 100 m) and smaller for colder months (November to March -0.33 °C / 100 m). When analysed at a monthly level, the lapse rate is lowest for January (-0.09°C / 100 m) and highest for April, May, June, and July (-0.61°C / 100 m, -0.61°C / 100 m, -0.60°C / 100 m, and -0.59°C / 100 m, respectively). The $R^2$ of the linear trend is markedly lower for January (0.43) than for all the other months of the year (0.79 to 0.92), which suggests that temperature inversion may occur in the region in January. Lapse rates are presented in Table 7 and Figure 7.

**Table 6: Monthly and Annual Air Temperature Climate Normals for Regional ECCC Climate Stations**

| Station Name | Quesnel A (545 masl) | Williams Lake A (940 masl) | Spokin Lake 4E (1,033 masl) | Barkerville (1,283 masl) | Likely (740 masl) |
|---|---|---|---|---|---|
| Time period for EC Climate Normals | 1981-2010 | 1981-2010 | 1981-2010 | 1981-2010 | 1971-2000 |
| **Month** | **Temperature (°C)** | | | | |
| January | -6.9 | -6.7 | -7.6 | -7.5 | -7.0 |
| February | -3.6 | -4.1 | -5.4 | -5.9 | -4.4 |
| March | 1.3 | 0.3 | -1.2 | -2.8 | -0.1 |
| April | 6.4 | 4.9 | 3.7 | 1.4 | 4.6 |
| May | 11.1 | 9.6 | 8.0 | 6.2 | 9.3 |
| June | 14.7 | 13.3 | 11.4 | 10.0 | 12.9 |
| July | 16.8 | 16.0 | 13.4 | 12.3 | 15.4 |
| August | 16.4 | 15.3 | 12.8 | 12.8 | 15.1 |
| September | 11.5 | 10.6 | 8.5 | 8.0 | 10.7 |
| October | 5.5 | 4.6 | 3.4 | 2.4 | 5.4 |
| November | -1.4 | -2.3 | -3.2 | -4.3 | -1.2 |
| December | -5.9 | -7.3 | -7.7 | -7.8 | -5.7 |
| **Annual** | **5.5** | **4.5** | **3.0** | **2.0** | **4.6** |

masl = metres above sea level.

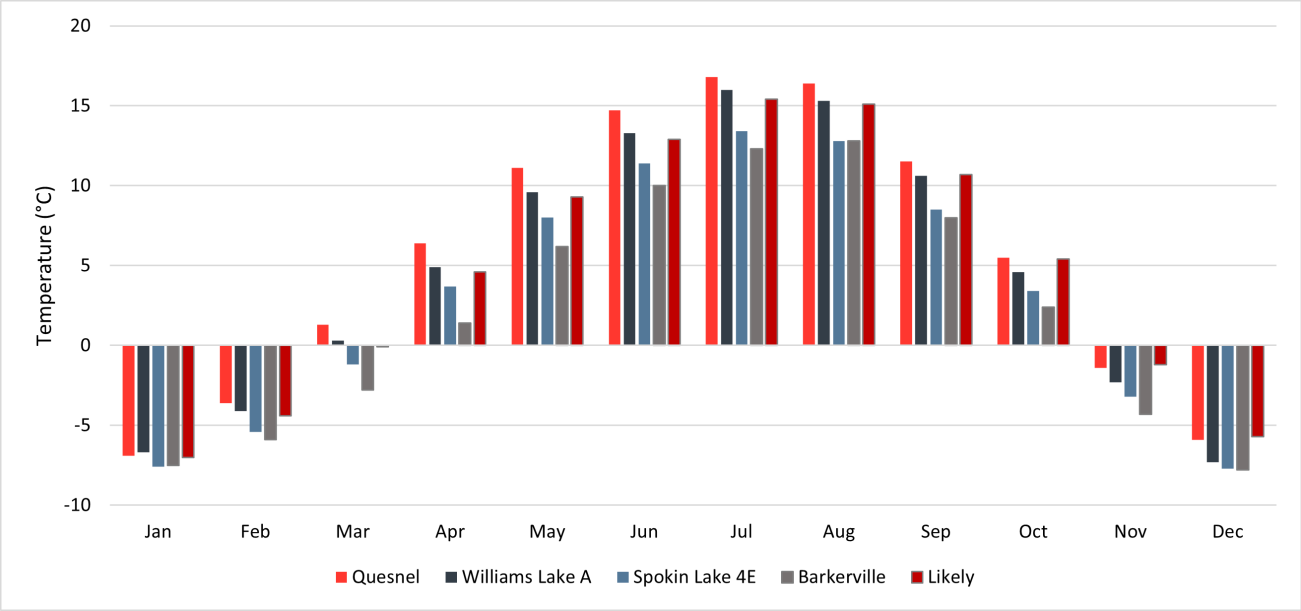

**Figure 6: Mean Monthly Air Temperature for Regional ECCC Climate Stations (1971 to 2000 period of record for ECCC Likely; 1981 to 2010 period of record for remaining stations)**

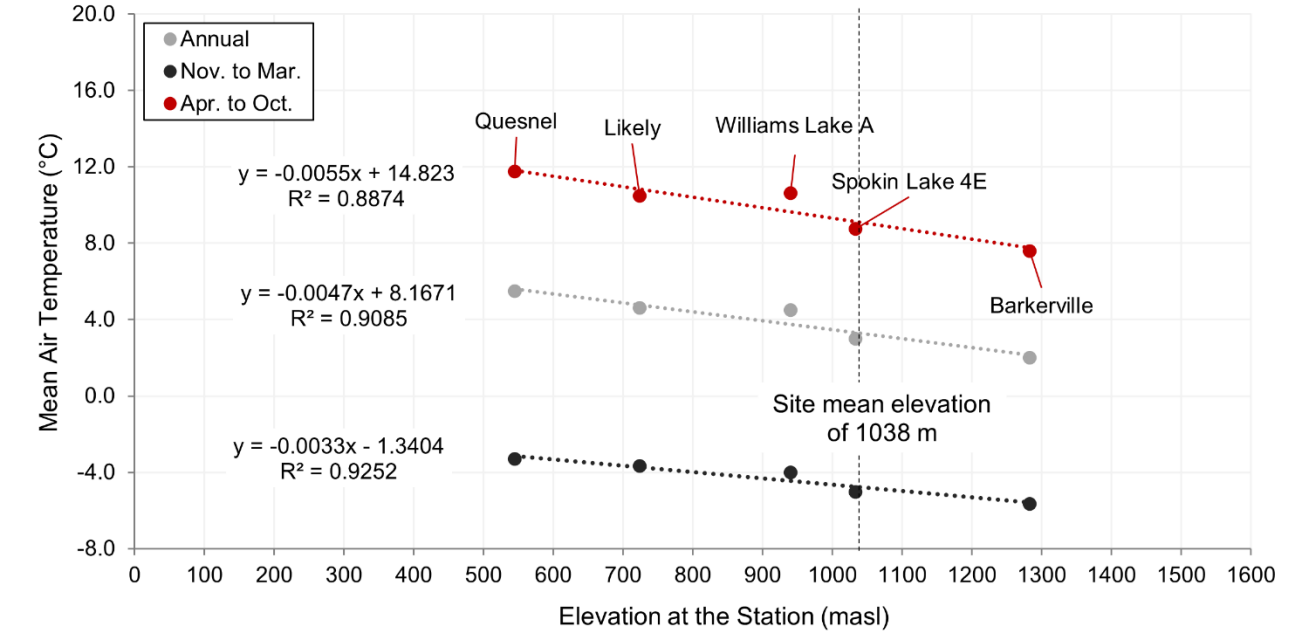

**Figure 7 : Annual, April-to-October, and November-to-March Air Temperature Lapse Rates for Regional ECCC Climate Stations (1971 to 2000 period of record for ECCC Likely; 1981 to 2010 period of record for remaining stations)**

**Table 7: Monthly Air Temperature Lapse Rate Variation Among Five Regional ECCC Climate Stations (1971 to 2000 period of record for ECCC Likely; 1981 to 2010 period of record for remaining stations)**

| Month | Lapse Rate = °C Difference / 100 m Elevation Increase | $R^2$ of the Linear Trend |
|---|---|---|
| January | -0.09 | 0.43 |
| February | -0.30 | 0.82 |
| March | -0.51 | 0.86 |
| April | -0.61 | 0.88 |
| May | -0.61 | 0.89 |
| June | -0.60 | 0.87 |
| July | -0.59 | 0.81 |
| August | -0.50 | 0.79 |
| September | -0.49 | 0.85 |
| October | -0.45 | 0.92 |
| November | -0.43 | 0.90 |
| December | -0.32 | 0.82 |
| Annual | -0.47 | 0.91 |

## MPMC Temperature Data Gap Infilling

The priority sequence of regional climate station data used to infill gaps in the extended Site air temperature record was based on the best-fit daily air temperature correlation (Temperature Correlation), air temperature ranking (Temperature Ranking), and concurrent daily temperature recordings between the MPMC climate stations and each ECCC climate station (Table 8).

**Table 8: Regional Climate Stations Priority Sequence for Temperature Data Gap Infilling in Extended Record for MPMC**

| Priority | Station | Temperature Correlation ($R^2$) | Temperature Rank ($R^2$) | Concurrent Daily Temperature (%) | Period of Record | Currently Active | Distance from site (km) |
|---|---|---|---|---|---|---|---|
| 1 | Williams Lake A | 0.8917 | 0.9942 | 93.5 | 1960-2021 | Yes | 50 |
| 2 | Barkerville | 0.8834 | 0.9951 | 99.0 | 1888-2021 | Yes | 59 |
| 3 | Quesnel A | 0.8628 | 0.9861 | 97.5 | 1946-2021 | Yes | 80 |
| 4 | Spokin Lake 4E | 0.8525 | 0.9810 | 99.5 | 1983-2021 | Yes | 40 |

Regional ECCC climate station daily air temperature data were adjusted using the monthly air temperature lapse-rate presented in Table 7 to derive representative air temperature at the Site.

### 3.4.3 Relative Humidity

Relative humidity data are available for the Site from 2019 to 2021 and for ECCC climate stations Quesnel (1953 to 2021) and Williams Lake (1961 to 2021). The MPMC WS1 relative humidity record is more complete than WS2's record; therefore, WS1 data were used for the analysis and infilled with WS2 data where necessary and if available. However, relative humidity data for the Site are insufficient for characterizing long-term climatic conditions of the Site due to the short period of record. Therefore, data from Quesnel and Williams Lake stations were reviewed and analyzed to define a representative relative humidity estimate for the Site. Comparisons between the Site data and each ECCC climate station data were made to determine which station best represents the potential relative humidity at the Site.

Figure 8 and Figure 9 present the comparison between concurrent daily relative humidity values at the ECCC Quesnel and MPMC climate stations (January 2019 to December 2021). The 15-day moving average indicates that the relative humidity is generally higher at the Site than at the ECCC Quesnel climate station. The two datasets are well correlated ($R^2$=0.96).

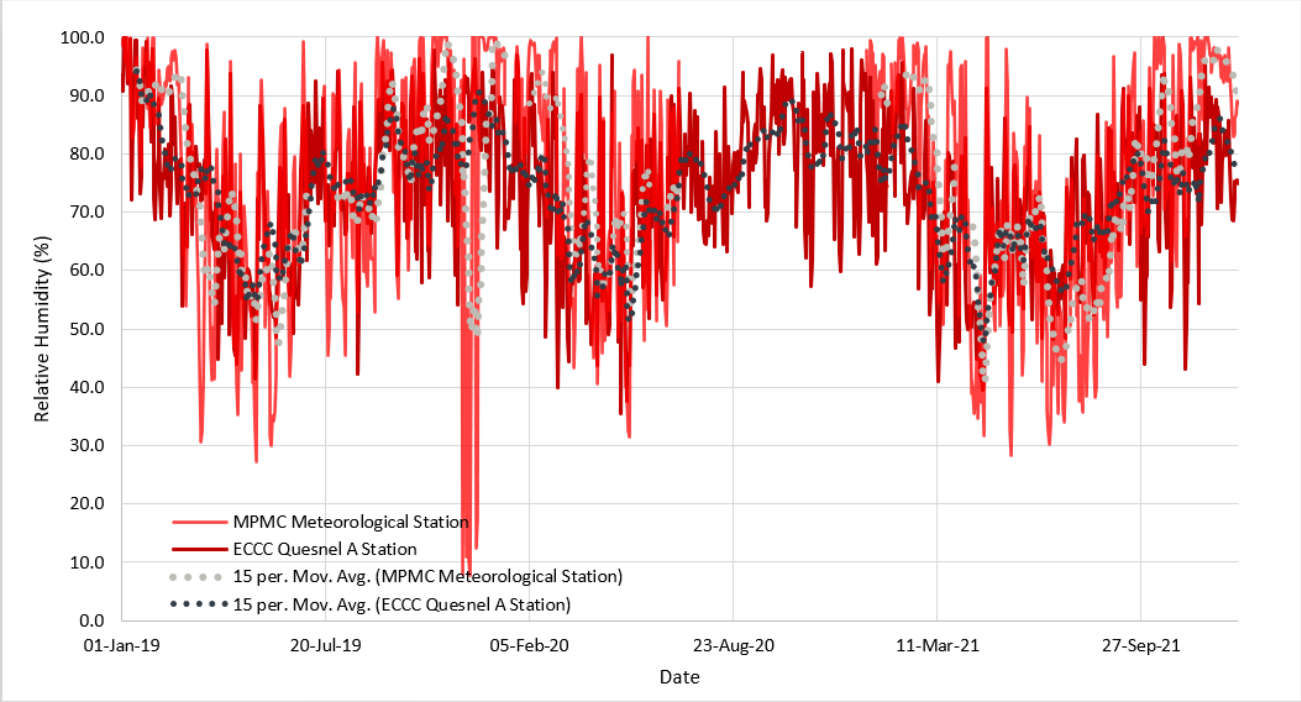

**Figure 8: Concurrent Daily Relative Humidity Values at the MPMC and ECCC Quesnel Climate Stations (2019-2021)**

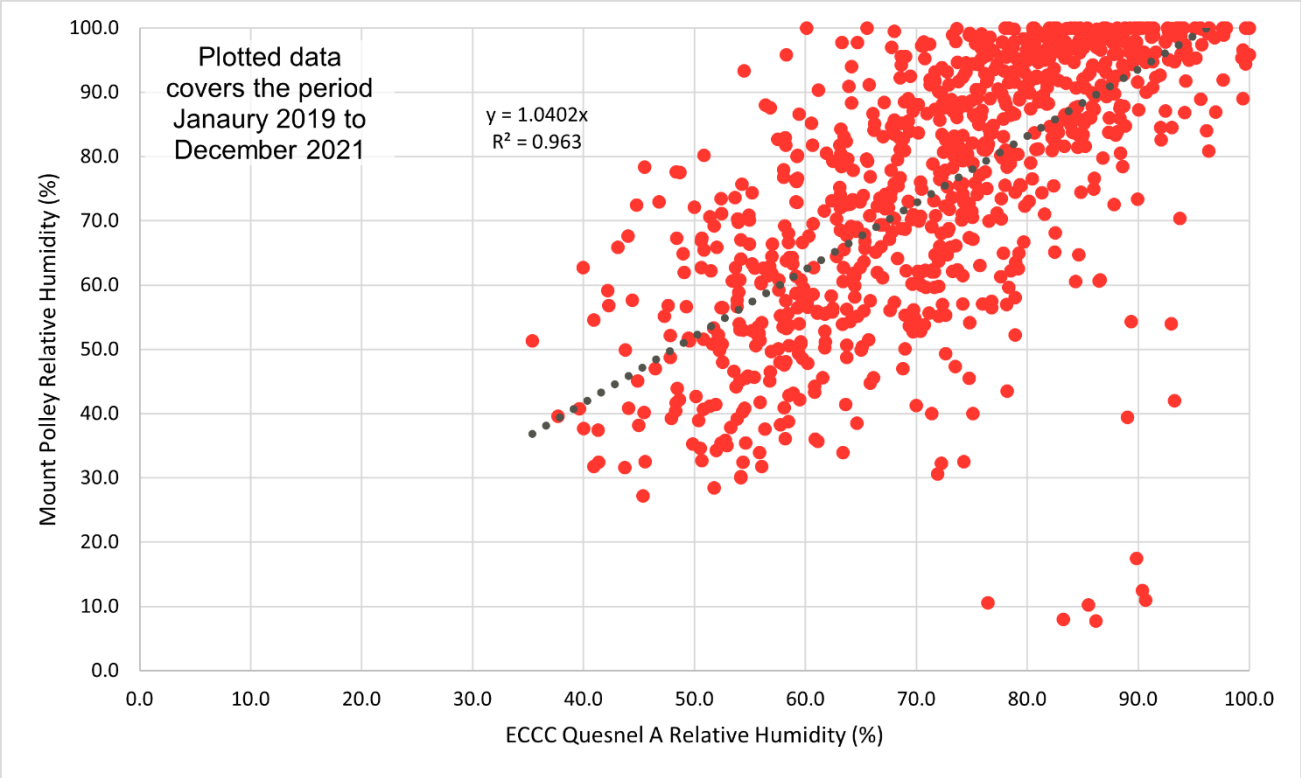

**Figure 9: Correlation Relationship of Daily Relative Humidity Values at MPMC and ECCC Quesnel Climate Stations (2019-2021)**

Figure 10 and Figure 11 present the comparison between concurrent daily relative humidity values at the ECCC Williams Lake and MPMC climate stations (January 2019 to December 2021). The 15-day moving average indicates that the relative humidity is generally higher at the Site than at ECCC Williams Lake climate station. The two datasets are very well correlated ($R^2$=0.98).

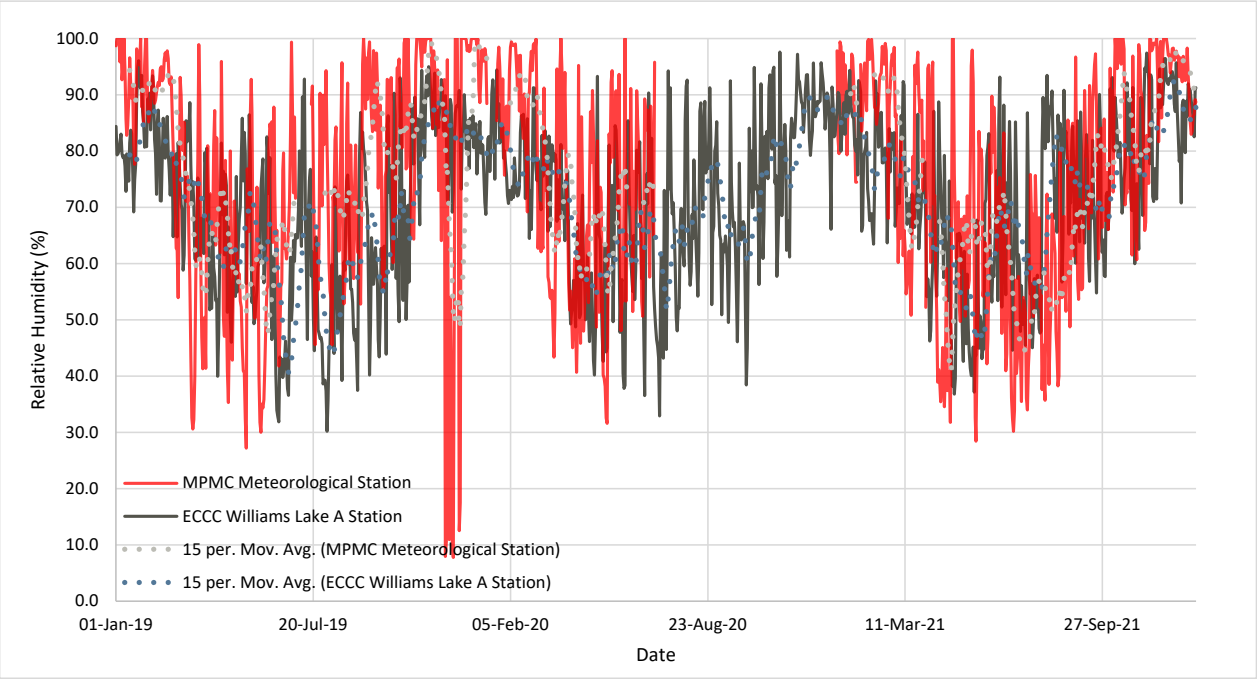

**Figure 10 : Concurrent Daily Relative Humidity Values at MPMC and ECCC Williams Lake Climate Stations (2019-2021)**

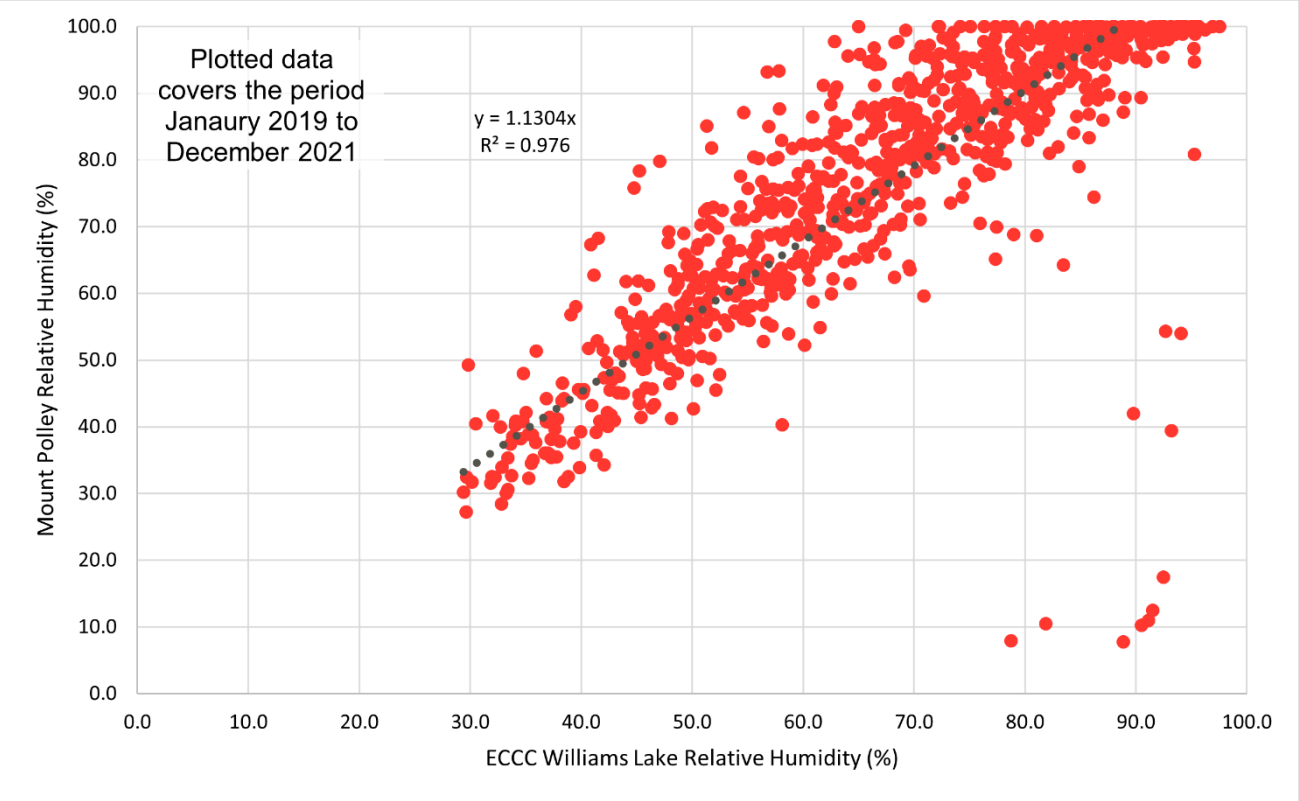

**Figure 11 : Correlation Relationship of Daily Relative Humidity Values at MPMC and ECCC Williams Lake Climate Stations (2019-2021)**

A long-term relative humidity time series for the Site was developed using ECCC Williams Lake A data infilled with ECCC Quesnel A data with an adjustment factor of 1.13 and 1.04 based on the relationships presented in Figure 11 and Figure 9, respectively.

### 3.4.4 Solar Radiation

Solar radiation data are available for the Site from 2001 to 2003 and 2019 to 2021, and for ECCC climate stations Williams Lake (1961 to 2001) and Prince George (1973 to 1995). Solar radiation data for the Site are insufficient for characterizing climatic conditions of the Site due to the short period of record, and as the data recorded in 2001 is incomplete and not concurrent with either ECCC climate station. However, as presented in Figure 12, a discernible trend in mean monthly solar radiation is apparent for MPMC solar radiation (2019 to 2021) and in data from the ECCC Williams Lake and Prince George climate stations. Figure 13 presents ECCC Williams Lake and Prince George mean monthly solar radiation correlation ($R^2$ = 0.98) from 1973 to 1995.

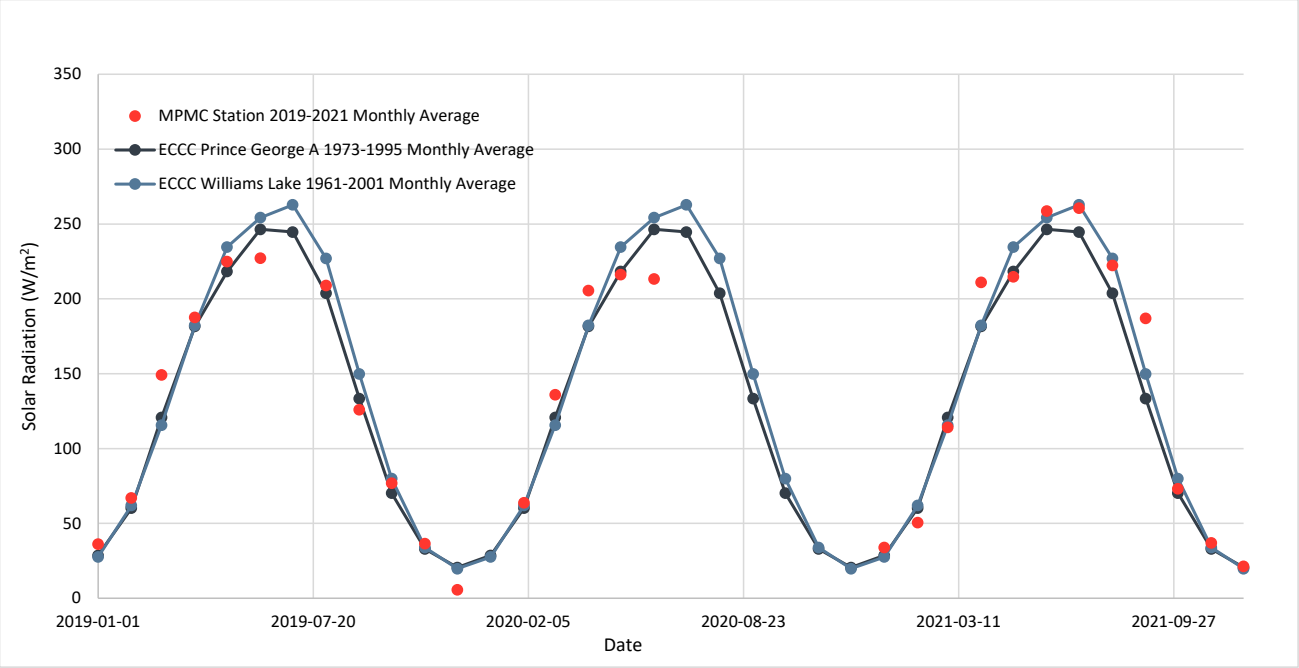

**Figure 12 : Mean Monthly Solar Radiation for MPMC and ECCC Regional Climate Stations**

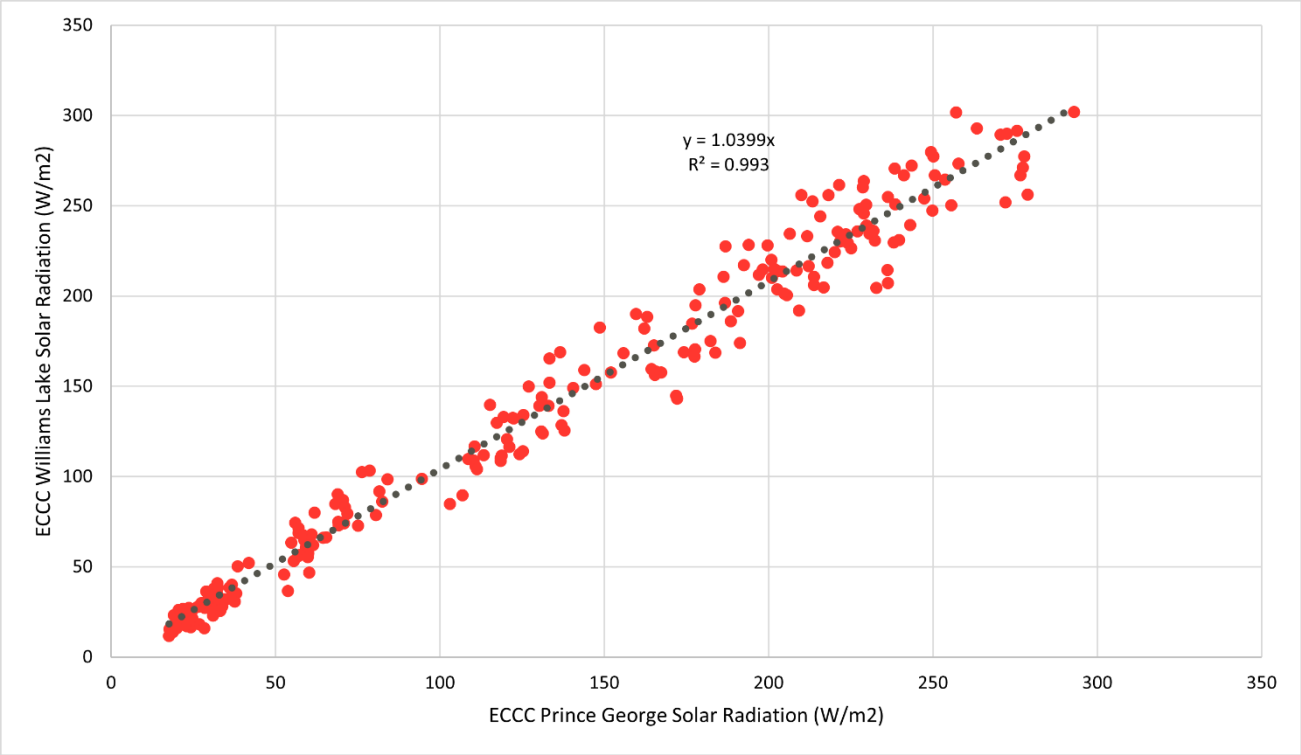

**Figure 13 : Daily Solar Radiation Correlation Between ECCC Williams Lake and Prince George Climate Stations (1973-1995)**

The strong correlation between ECCC Williams Lake and Prince George climate stations suggest there is little variation in solar radiation across the region. Based on the comparison of mean monthly solar radiation records and the proximity in distance to the Site, solar radiation statistics for the Site were determined from the ECCC Williams Lake data. Missing values were infilled by adjusting the Prince George records by a factor of 1.04 based on the relationship presented in Figure 13.

### 3.4.5 Evaporation and Evapotranspiration

Evaporation monitoring data are available for the Site from 2019 to 2021; however, the data are not continuous, and the length of record is not sufficient for characterizing the evaporation conditions at the Site. Therefore, a mathematical model (Morton 1983) was used to calculate evaporation and evapotranspiration (actual and potential) for the Site based on the long-term synthetic records for air temperature, relative humidity, and solar radiation. Evaporation in this study is defined as free water evaporation, or the amount of evaporation from open/free water surfaces (i.e., the water is returned to the atmosphere from lakes, ponds, and watercourses). Potential evapotranspiration is the water loss that occurs from a vegetated natural surface if there is no deficiency of water in the soil for use by vegetation (Thornthwaite 1948).

### 3.4.6 Wind Speed and Direction

Hourly wind speed and direction data are available for the Site from 1997 to 2003, and daily wind speed data are available from 2019 to 2021; however, the data are not continuous. The hourly wind speed and direction data available from 1997 to 2003 were used to develop wind rose plots. A wind rose depicts the relative frequency of wind from a given direction on a 16-point compass. Each ring on the wind rose represents a frequency of 2% of the data period. The length of the shaded bars on each wind rose petal represents the frequency of wind recorded from a given direction within a defined wind speed range. A wind rose is provided for the period of August 1997 to November 2003, and seasonal wind roses are presented to display seasonal variability in wind patterns, where the seasons have been defined as follows:

- Winter – December to February
- Spring – March to May
- Summer – June to August
- Autumn – September to November

Daily wind data recorded from 2019 to 2021 from WS1 and WS2 were wind speed only, no direction. The period of record for WS2 and 2020 are incomplete and are not included in the analysis. The relative frequency (%) of the magnitude of the daily wind speed data recorded at WS1 for 2019 and 2021 were compared in this study to the relative frequency (%) of wind speed magnitude of the data from 1997 to 2003.

### 3.4.7 Snow Cover Properties

Snow cover is an important climatic variable as it influences the spring freshet flow volume and distribution. Snow cover data at the Site are available monthly from manual measurements from 1997 to 2022, recorded as snow-water-equivalent (SWE). Measurements, although not continuous, are typically recorded at the beginning and end of a month, with the latter being representative of the monthly SWE.

# 4.0 RESULTS

The following section summarizes the precipitation, air temperature, relative humidity, solar radiation, evaporation and evapotranspiration, wind speed and direction, and snow cover baseline conditions at the Site.

## 4.1 Annual Precipitation

The Site experiences high summer precipitation due to summer storms, with the lowest monthly precipitation occurring in February. Precipitation typically occurs as snowfall starting in November and accumulates until March. Average annual precipitation at the Site is estimated to be 612 mm with a standard deviation of 118 mm. Frequency analyses of the derived long-term precipitation time series for the Site were undertaken to generate the variability in monthly and annual precipitation of the Site. Estimated annual wet and dry precipitation depths for a range of return periods are shown in Table 9, Figure 14, and Figure 15.

**Table 9: Annual Precipitation Depths for the Site (1974-2021)**

| Return Period (yr) | Wet (mm)[1] | Dry (mm)[1] |
|---|---|---|
| 5 | 714 | 508 |
| 10 | 768 | 459 |
| 25 | 825 | 412 |
| 50 | 861 | 386 |
| 100 | 893 | 366 |
| 200 | 922 | 349 |
| Average | 612 | |

1) Weibull distribution was selected based on the statistical distribution goodness-of-fit-test.

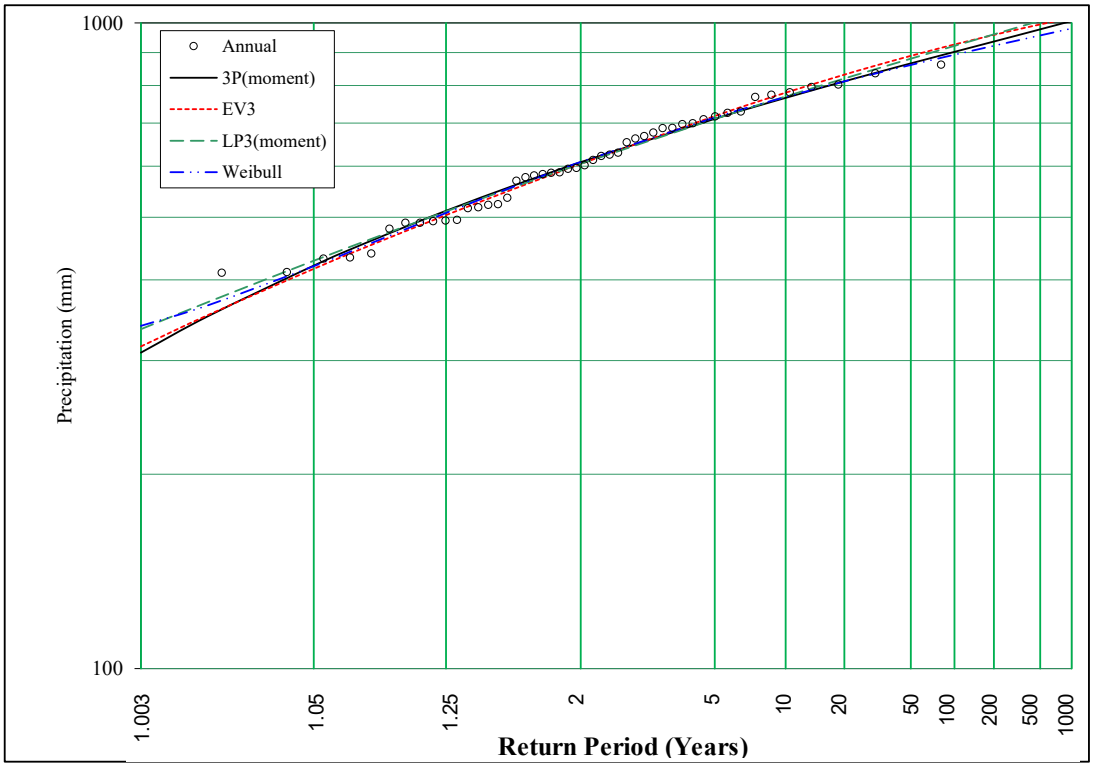

**Figure 14 : Annual Precipitation Frequency Analysis – Wet Results**

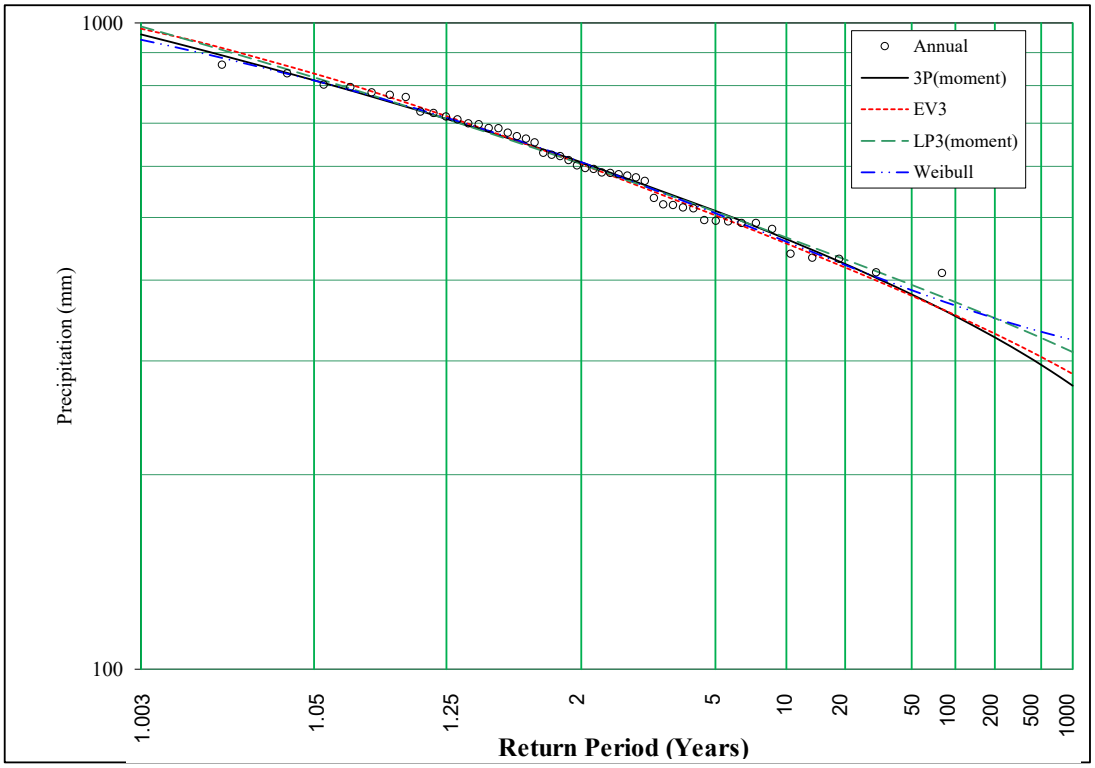

**Figure 15 : Annual Precipitation Frequency Analysis - Dry Results**

Monthly values for the 25- and 200-year return periods for wet and dry precipitation depths are presented in Table 10. Monthly values for the 1:25 year dry and wet precipitation for the 1:200 year dry and wet precipitation were assumed to follow the same monthly distribution as the average precipitation.

**Table 10: Monthly Precipitation Depths for the Site (1974-2021)**

| Month[1] | Precipitation (mm) | | | | |
|---|---|---|---|---|---|
| | Average | 1:200 Year Wet | 1:25 Year Wet | 1:25 Year Dry | 1:200 Year Dry |
| January | 49.4 | 74.3 | 66.5 | 33.2 | 28.2 |
| February | 35.8 | 54.0 | 48.3 | 24.1 | 20.5 |
| March | 29.7 | 44.7 | 40.0 | 20.0 | 16.9 |
| April | 44.7 | 67.3 | 60.2 | 30.1 | 25.5 |
| May | 49.9 | 75.2 | 67.2 | 33.6 | 28.5 |
| June | 70.8 | 107 | 95.4 | 47.7 | 40.4 |
| July | 63.6 | 95.8 | 85.7 | 42.9 | 36.3 |
| August | 50.6 | 76.2 | 68.1 | 34.1 | 28.8 |
| September | 52.3 | 78.8 | 70.5 | 35.2 | 29.9 |
| October | 58.1 | 87.5 | 78.2 | 39.1 | 33.1 |
| November | 49.8 | 75.0 | 67.1 | 33.5 | 28.4 |
| December | 57.6 | 86.8 | 77.7 | 38.8 | 32.9 |
| **Annual Total[2]** | **612** | **922** | **825** | **412** | **349** |

1) Wet and Dry Monthly values assumed to follow the same monthly distribution as the Average.

2) Annual total precipitation depths were rounded to the nearest mm for presentation purposes; therefore, it may appear the sum of the monthly values do not equal the annual total.

## 4.2 Rainfall

Annual maximum series for 24-hour precipitation from the derived historical data set was used to undertake a frequency analysis to provide rainfall design values. Results are shown in Table 10. The 24-hour, 3-day, and 10-day annual, spring, and summer probable maximum precipitation (PMP) depths were estimated using the Hershfield method (WMO 2009).

**Table 11: 24-hour Precipitation Depths for the Site (1974-2021)**

| Return Period (yr) | Depth (mm) [1, 2] |
|---|---|
| 2 | **33** |
| 10 | **47** |
| 25 | **54** |
| 100 | **64** |
| 200 | **69** |
| 1000 | **80** |

1) Log Pearson III distribution was selected based on the statistical distribution goodness-of-fit test.

2) Values rounded up to the nearest mm.

**Table 12: Annual, Spring, and Summer PMP Depths for the Site (1974-2021)**

| Period | Annual PMP[1] (mm) | Spring PMP[1, 2] (mm) | Summer PMP[1, 3] (mm) |
|---|---|---|---|
| 24-Hour | 224 | 192 | 191 |
| 3-Day[4] | 339 | 272 | 294 |
| 10-Day[5] | 562 | 295 | 486 |

1) The PMP does not have a return period.
2) Spring = March, April, May.
3) Summer = June, July, August.
4) Adjusted from fixed-time interval by a factor of 1.03 (Miller 1964).
5) Adjusted from fixed time interval by a factor of 1.01 (Miller 1964).

## 4.3 Air Temperature

Air temperature statistics for the Site were developed using historical data from the nearby ECCC climate station in Likely approximately 9 km northeast of the Site. The historical Likely data set was adjusted to the average elevation of the Mount Polley mine by applying the regional monthly lapse rate presented in Table 7. Data gaps were infilled using data from the four regional ECCC climate stations in a prioritized sequence and applying the monthly temperature lapse rate to adjust for elevation.

Monthly and annual air temperature statistics for the Site (1974-2021) are presented in Table 13 and Figure 16. The estimated mean annual temperature varies between 1.7°C and 6.3°C, with a long-term mean of 3.9°C. Mean monthly temperatures vary between –6.7°C in January and 15.1°C in July. The historical daily maximum and minimum air temperature from the derived long-term data set was 38.1°C in June 2021 (measured at the Site) and -39.8°C in December 1996, respectively. Mean monthly air temperatures generally turn positive in April and negative in November. The percentiles presented in Table 13 indicate the probability of the air temperature to be less than the calculated value for each period, i.e. the 25$^{th}$ percentile for the month of March indicates the monthly air temperature for March is 25% probable to be less than -2.2°C, or 75% probable to exceed -2.2°C. Larger variation between the 25$^{th}$ and 75$^{th}$ percentiles indicate greater variation in air temperature from the median during the month with the largest variations occurring in the winter months (December, January, and February).

**Table 13: Derived Air Temperature (°C) Statistics for Mount Polley Mine, 1974 to 2021**

| Month | Temperature (°C) | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25th Percentile | 50th Percentile | 75th Percentile | Daily Maximum | Daily Minimum |
| January | -16.0 | -6.7 | -0.3 | -8.7 | -6.3 | -4.0 | 11.2 | -39.4 |
| February | -13.0 | -4.8 | 0.7 | -7.7 | -4.3 | -2.1 | 13.6 | -35.4 |
| March | -6.7 | -1.0 | 3.2 | -2.2 | -0.8 | 0.5 | 18.4 | -32.7 |
| April | -0.7 | 3.7 | 12.0 | 2.8 | 3.7 | 4.3 | 27.5 | -16.7 |
| May | 5.2 | 8.5 | 13.1 | 7.5 | 8.3 | 9.6 | 33.1 | -7.9 |
| June | 8.6 | 12.2 | 15.5 | 11.1 | 12.2 | 13.2 | 38.1 | -4.9 |
| July | 11.8 | 15.1 | 21.2 | 13.3 | 14.8 | 16.4 | 36.0 | 0.6 |
| August | 11.0 | 14.6 | 17.1 | 13.6 | 14.8 | 15.7 | 33.0 | -4.1 |
| September | 6.8 | 10.0 | 14.2 | 8.7 | 9.6 | 11.2 | 36.3 | -7.1 |
| October | 0.8 | 4.1 | 8.7 | 3.4 | 4.1 | 4.7 | 31.1 | -26.4 |
| November | -13.7 | -2.4 | 2.6 | -3.8 | -2.1 | -0.4 | 17.3 | -36.9 |
| December | -13.7 | -6.6 | -1.2 | -9.5 | -5.5 | -3.9 | 11.3 | -39.8 |
| **Annual** | **1.7** | **3.9** | **6.3** | **3.2** | **3.9** | **4.5** | **38.1** | **-39.8** |

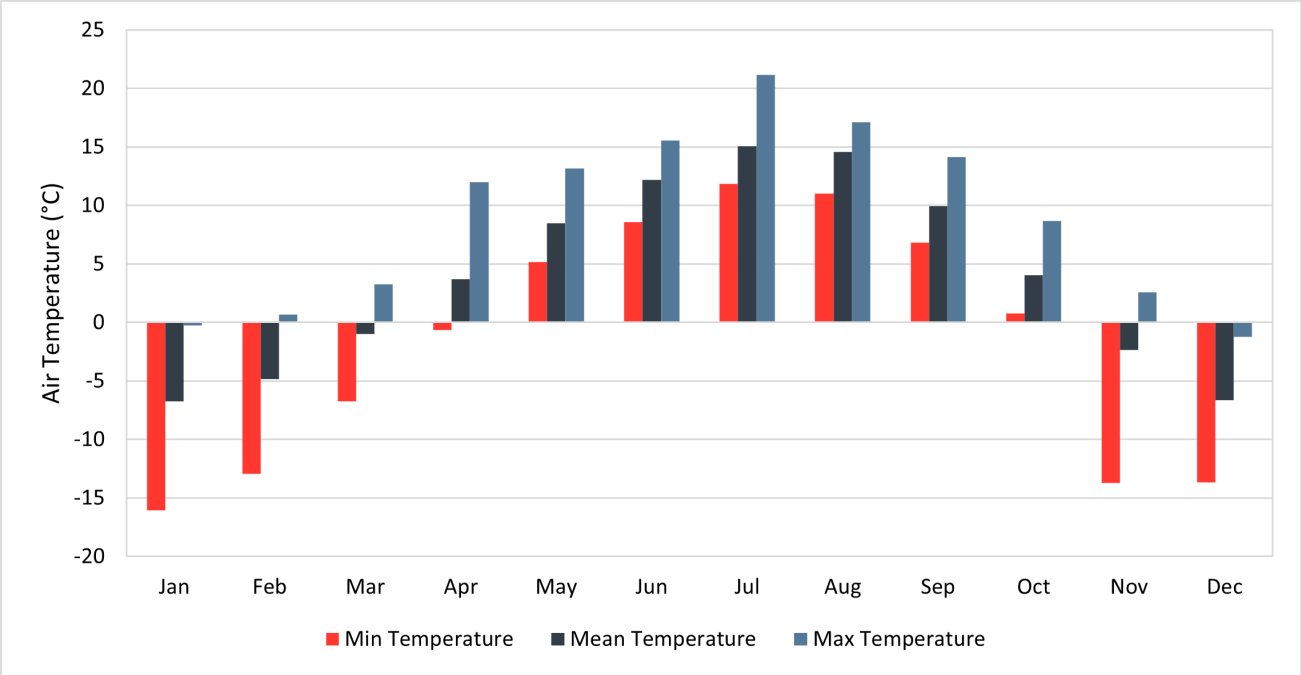

**Figure 16 : Derived Monthly Air Temperature Statistics for Mount Polley Mine (1974-2021)**

## 4.4 Relative Humidity

Statistics for relative humidity are presented in Table 14 and Figure 17. Mean annual relative humidity is 68.1%. Monthly mean values vary between 57.7% in April to 82.2% in December. The 25th and 75th percentiles for monthly relative humidity show little variation from the median indicating the Site experiences relatively constant relative humidity on a monthly basis from year to year.

**Table 14: Derived Monthly and Annual Relative Humidity Statistics for the Site (1974-2021)**

| Month | Relative Humidity (%) | | | | | |
|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25th Percentile | 50th Percentile | 75th Percentile |
| January | 69.2 | 81.3 | 90.1 | 78.9 | 81.7 | 84.0 |
| February | 65.5 | 75.0 | 84.8 | 72.0 | 75.6 | 77.8 |
| March | 55.4 | 64.9 | 76.2 | 61.0 | 64.0 | 68.3 |
| April | 47.9 | 57.7 | 69.4 | 54.9 | 57.4 | 60.5 |
| May | 45.6 | 58.1 | 70.3 | 54.1 | 57.8 | 61.5 |
| June | 44.2 | 60.4 | 72.4 | 54.4 | 60.2 | 67.7 |
| July | 42.2 | 59.0 | 72.9 | 52.6 | 58.6 | 65.9 |
| August | 48.4 | 60.2 | 81.2 | 55.0 | 58.8 | 63.6 |
| September | 47.5 | 66.4 | 79.1 | 61.3 | 66.1 | 71.3 |
| October | 54.3 | 72.3 | 86.7 | 69.7 | 72.0 | 76.1 |
| November | 61.4 | 80.1 | 87.8 | 77.6 | 80.4 | 83.5 |
| December | 70.8 | 82.2 | 89.3 | 78.9 | 82.6 | 85.0 |
| **Annual** | **54.4** | **68.1** | **80.0** | **64.2** | **67.9** | **72.1** |

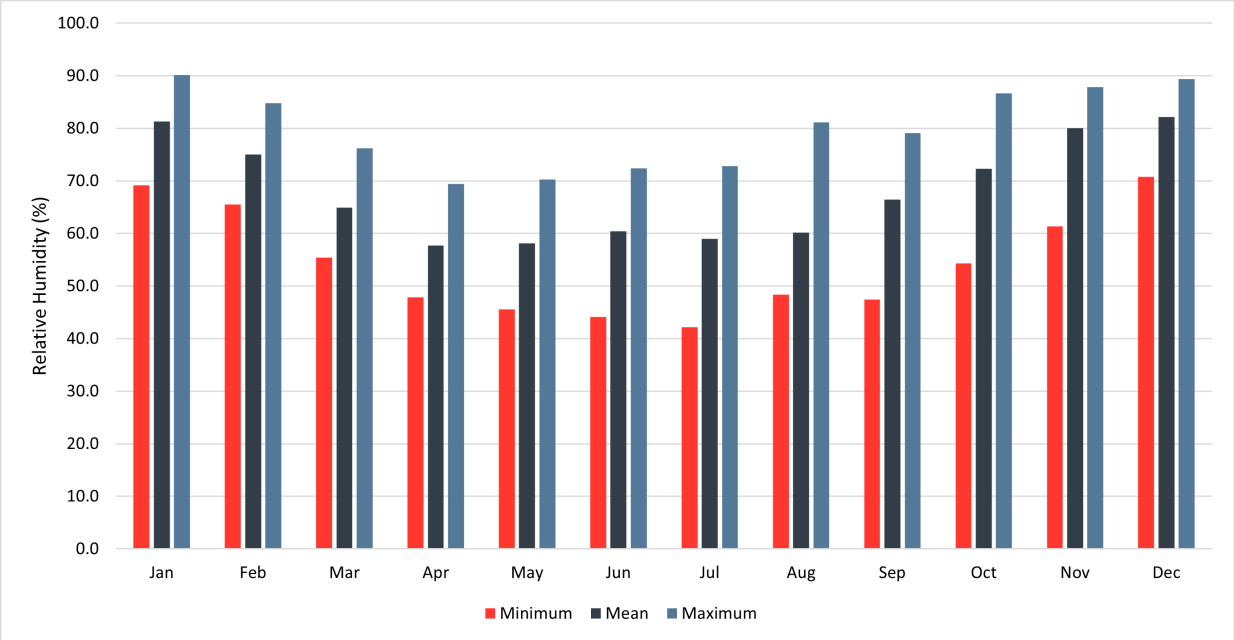

**Figure 17 : Derived Monthly Relative Humidity for the Site (1974-2021)**

## 4.5 Solar Radiation

Table 15 and Figure 16 present solar radiation statistics for the Site. Mean annual solar radiation is 135 W/m$^2$, with a minimum of 127 W/m$^2$ and maximum of 148 W/m$^2$. Mean monthly solar radiation varies between 20 W/m$^2$ in December to 257 W/m$^2$ in July following the same seasonal pattern for monthly air temperature. The 25$^{th}$ and 75$^{th}$ percentiles show greatest variation in solar radiation occurs in the summer months when solar radiation is greatest during the year, and less variation in winter months when solar radiation is lowest.

**Table 15: Estimated Solar Radiation Statistics for the Site (1974-2001)**

| Month | Solar Radiation (W/m$^2$) | | | | | |
|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25$^{th}$ Percentile | 50$^{th}$ Percentile | 75$^{th}$ Percentile |
| January | 16 | 27 | 40 | 23 | 27 | 32 |
| February | 37 | 60 | 86 | 54 | 61 | 67 |
| March | 85 | 114 | 152 | 108 | 113 | 123 |
| April | 143 | 180 | 215 | 161 | 179 | 201 |
| May | 196 | 230 | 275 | 214 | 227 | 250 |
| June | 192 | 246 | 302 | 228 | 244 | 267 |
| July | 211 | 257 | 318 | 234 | 258 | 276 |
| August | 158 | 225 | 261 | 211 | 228 | 248 |
| September | 99 | 152 | 188 | 139 | 149 | 168 |
| October | 55 | 79 | 103 | 71 | 79 | 86 |
| November | 23 | 33 | 50 | 28 | 32 | 37 |
| December | 12 | 20 | 27 | 18 | 20 | 23 |
| **Annual** | **127** | **135** | **148** | **132** | **135** | **140** |

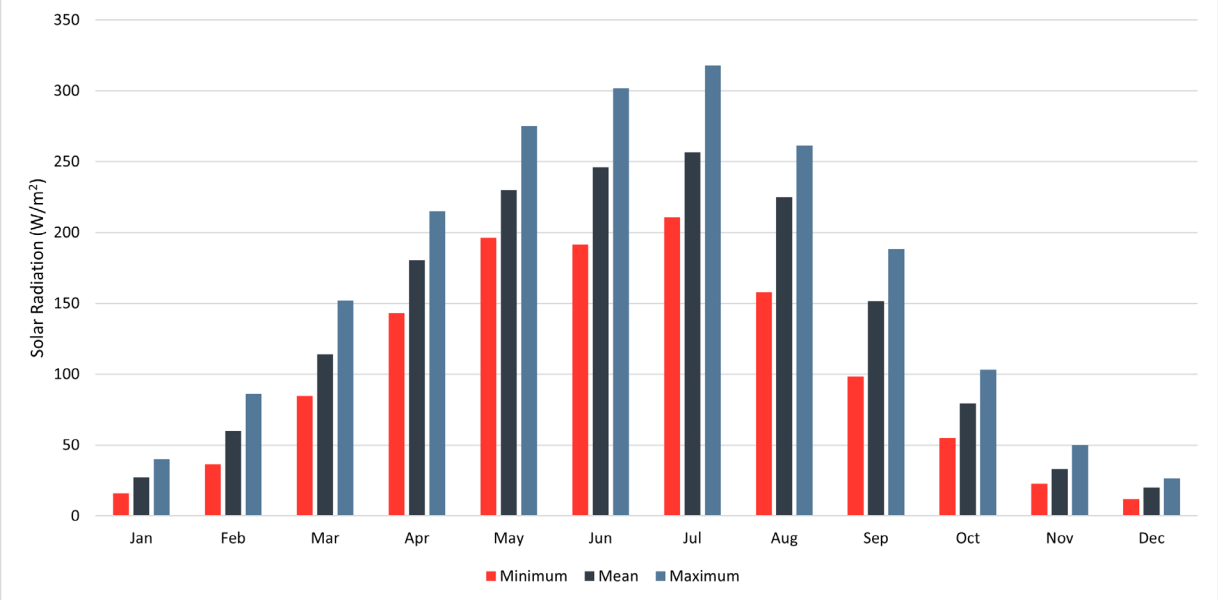

**Figure 18 : Estimated Monthly Solar Radiation for the Site (1974-2001)**

## 4.6 Evaporation and Evapotranspiration

The Morton model (Morton 1983) was applied to calculate monthly evaporation, potential evapotranspiration (PET), and actual evapotranspiration (AET) for the Site based on the air temperature, relative humidity, and solar radiation data presented in Sections 4.3, 4.4, and 4.5, respectively. The calculated evaporation rates are considered reflective of potential shallow lake evaporation rates; that is, there is no thermal impact of deeper water levels.

### 4.6.1 Shallow Lake Evaporation

Table 16 and Figure 19 present monthly statistics for shallow lake evaporation using the Morton Model. The mean annual evaporation rate is estimated to be 673 mm, varying between 606 mm and 762 mm. Mean monthly evaporation rates vary between 0 mm in December to 138 mm in July. The 25$^{th}$ and 75$^{th}$ percentiles indicate that greatest variation in monthly evaporation occurs in July when evaporation is greatest, and lowest variation occurs in January and December when evaporation is lowest.

**Table 16 : Estimated Monthly and Annual Shallow Lake Evaporation Statistics for the Site (1974-2001)**

| Month | Shallow Lake Evaporation (mm) | | | | | |
|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25$^{th}$ Percentile | 50$^{th}$ Percentile | 75$^{th}$ Percentile |
| January | 0 | 1 | 4 | 0 | 0 | 1 |
| February | 1 | 7 | 12 | 4 | 7 | 10 |
| March | 24 | 32 | 43 | 29 | 32 | 34 |
| April | 52 | 66 | 79 | 59 | 67 | 72 |
| May | 86 | 105 | 140 | 96 | 102 | 115 |
| June | 95 | 122 | 155 | 110 | 121 | 132 |
| July | 110 | 138 | 173 | 123 | 136 | 153 |
| August | 80 | 115 | 137 | 107 | 113 | 130 |
| September | 37 | 61 | 80 | 54 | 60 | 70 |
| October | 18 | 22 | 28 | 20 | 21 | 23 |
| November | 0 | 4 | 8 | 1 | 4 | 6 |
| December | 0 | 0 | 3 | 0 | 0 | 1 |
| **Annual** | **606** | **673** | **762** | **648** | **670** | **699** |

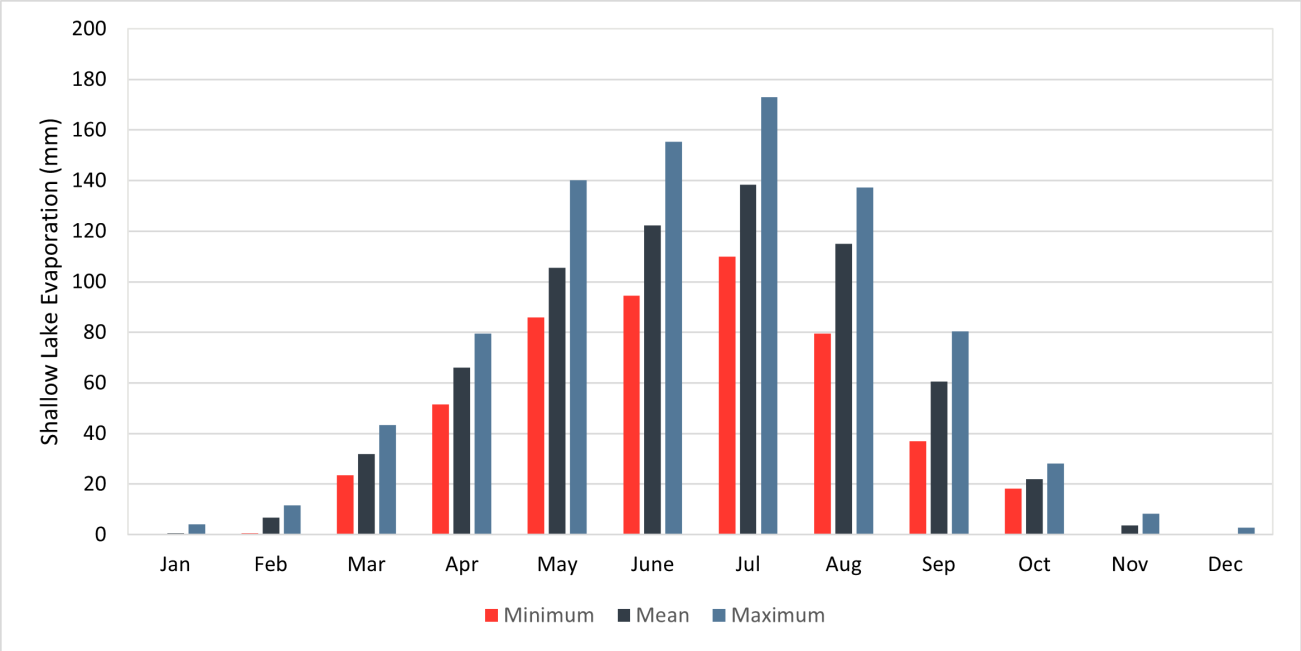

**Figure 19 : Estimated Shallow Lake Evaporation Statistics for the Site (1974-2001)**

### 4.6.2 Potential Evapotranspiration

Table 17 and Figure 20 present monthly statistics for PET using the Morton Model. The mean annual PET rate is estimated to be 863 mm, varying between 744 mm and 1022 mm. Mean monthly PET rates vary between 1 mm in December and January to 171 mm in July. The 25$^{th}$ and 75$^{th}$ percentiles indicate that greatest variation in monthly PET occurs in July when PET is greatest, and lowest variation occurs in January and December when PET is lowest. On an annual basis, PET rates are greater than shallow lake evaporation and AET since PET is not limited by the availability of water.

**Table 17 : Estimated Monthly and Annual Potential Evapotranspiration Statistics for the Site (1974-2001)**

| Month | Potential Evapotranspiration (mm) | | | | | |
|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25$^{th}$ Percentile | 50$^{th}$ Percentile | 75$^{th}$ Percentile |
| January | 0 | 1 | 5 | 0 | 0 | 2 |
| February | 1 | 7 | 11 | 4 | 7 | 10 |
| March | 24 | 41 | 59 | 34 | 42 | 45 |
| April | 68 | 92 | 112 | 83 | 93 | 102 |
| May | 103 | 134 | 178 | 120 | 131 | 149 |
| June | 113 | 150 | 195 | 125 | 155 | 174 |
| July | 124 | 171 | 240 | 151 | 166 | 191 |
| August | 84 | 151 | 199 | 135 | 152 | 174 |
| September | 54 | 89 | 117 | 71 | 89 | 108 |
| October | 17 | 24 | 40 | 20 | 23 | 26 |
| November | 0 | 4 | 9 | 1 | 4 | 6 |
| December | 0 | 1 | 4 | 0 | 0 | 1 |
| **Annual** | **744** | **863** | **1022** | **815** | **856** | **925** |

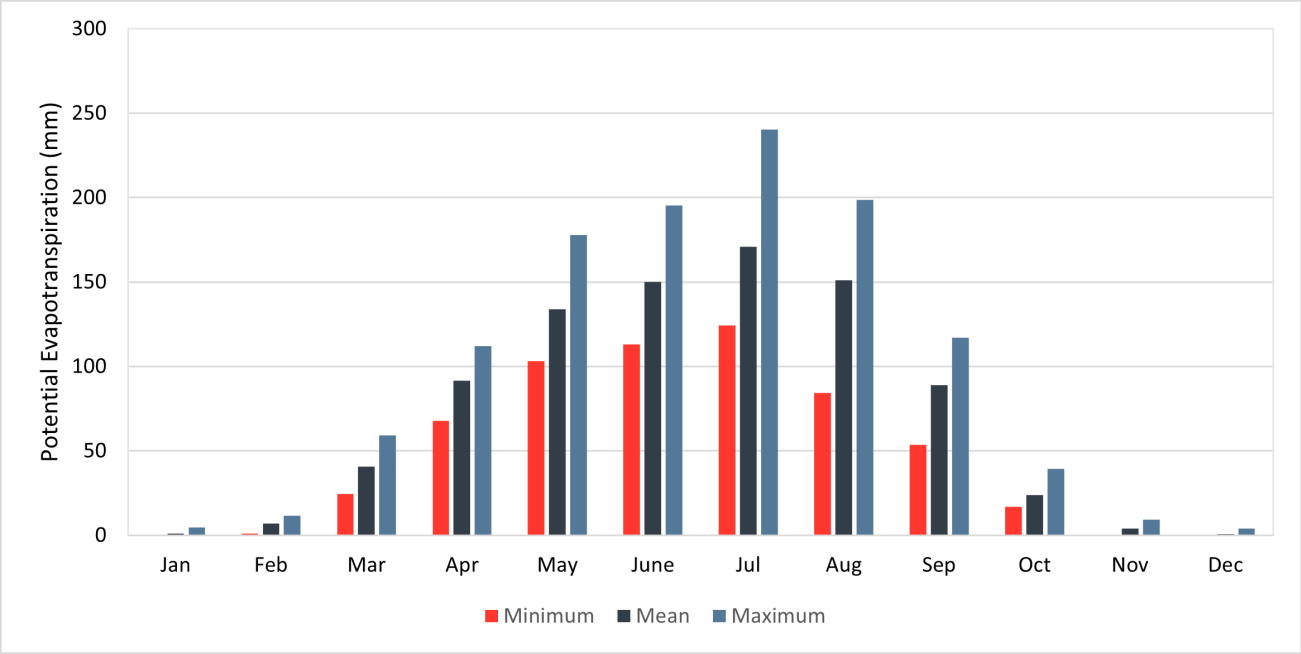

**Figure 20 : Estimated Potential Evapotranspiration Statistics for the Site (1974-2001)**

### 4.6.3 Actual Evapotranspiration

Table 18 and Figure 21 present monthly statistics for AET as calculated using the Morton Model. The mean annual AET rate is estimated to be 399 mm, varying between 319 mm and 449 mm. Mean monthly AET rates vary between 1 mm in December and January to 89 mm in July. The 25$^{th}$ and 75$^{th}$ percentiles indicate that greatest variation in monthly AET occurs in July when AET is greatest, and lowest variation occurs in January and December when AET is lowest. On an annual basis, AET at the Site is less than shallow lake evaporation and PET rates because AET is limited by the availability of water, particularly during the summer months when the air temperature is highest.

**Table 18 : Estimated Monthly and Annual Actual Evapotranspiration Statistics for the Site (1974-2001)**

| Month | Actual Evapotranspiration (mm) | | | | | |
|---|---|---|---|---|---|---|
| | Minimum | Mean | Maximum | 25$^{th}$ Percentile | 50$^{th}$ Percentile | 75$^{th}$ Percentile |
| January | 0 | 1 | 5 | 0 | 0 | 2 |
| February | 1 | 7 | 11 | 4 | 7 | 9 |
| March | 15 | 18 | 25 | 17 | 18 | 19 |
| April | 16 | 31 | 47 | 26 | 30 | 35 |
| May | 42 | 64 | 84 | 60 | 63 | 68 |
| June | 48 | 80 | 98 | 75 | 80 | 86 |
| July | 61 | 89 | 105 | 83 | 89 | 99 |
| August | 51 | 63 | 78 | 57 | 63 | 69 |
| September | 10 | 23 | 35 | 18 | 22 | 29 |

| November | 0 | 4 | 9 | 1 | 4 | 6 |
| December | 0 | 1 | 4 | 0 | 0 | 1 |
| **Annual** | **319** | **399** | **449** | **370** | **409** | **419** |

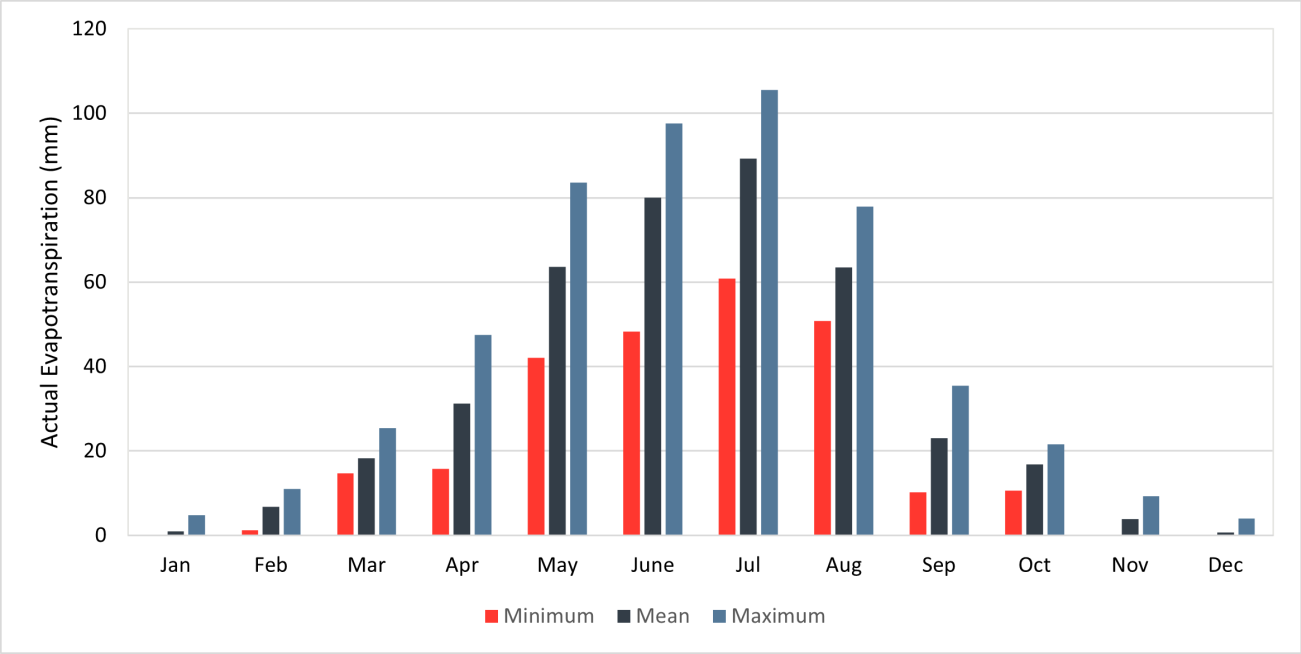

**Figure 21 : Estimated Actual Evapotranspiration Statistics for the Site (1974-2001)**

## 4.7 Wind Speed and Direction

A wind rose plot for the Site depicting the relative frequency of mean hourly wind speed and direction, and the seasonal distribution, between 29 August 1997 and 27 November 2003 is shown in Figure 22.

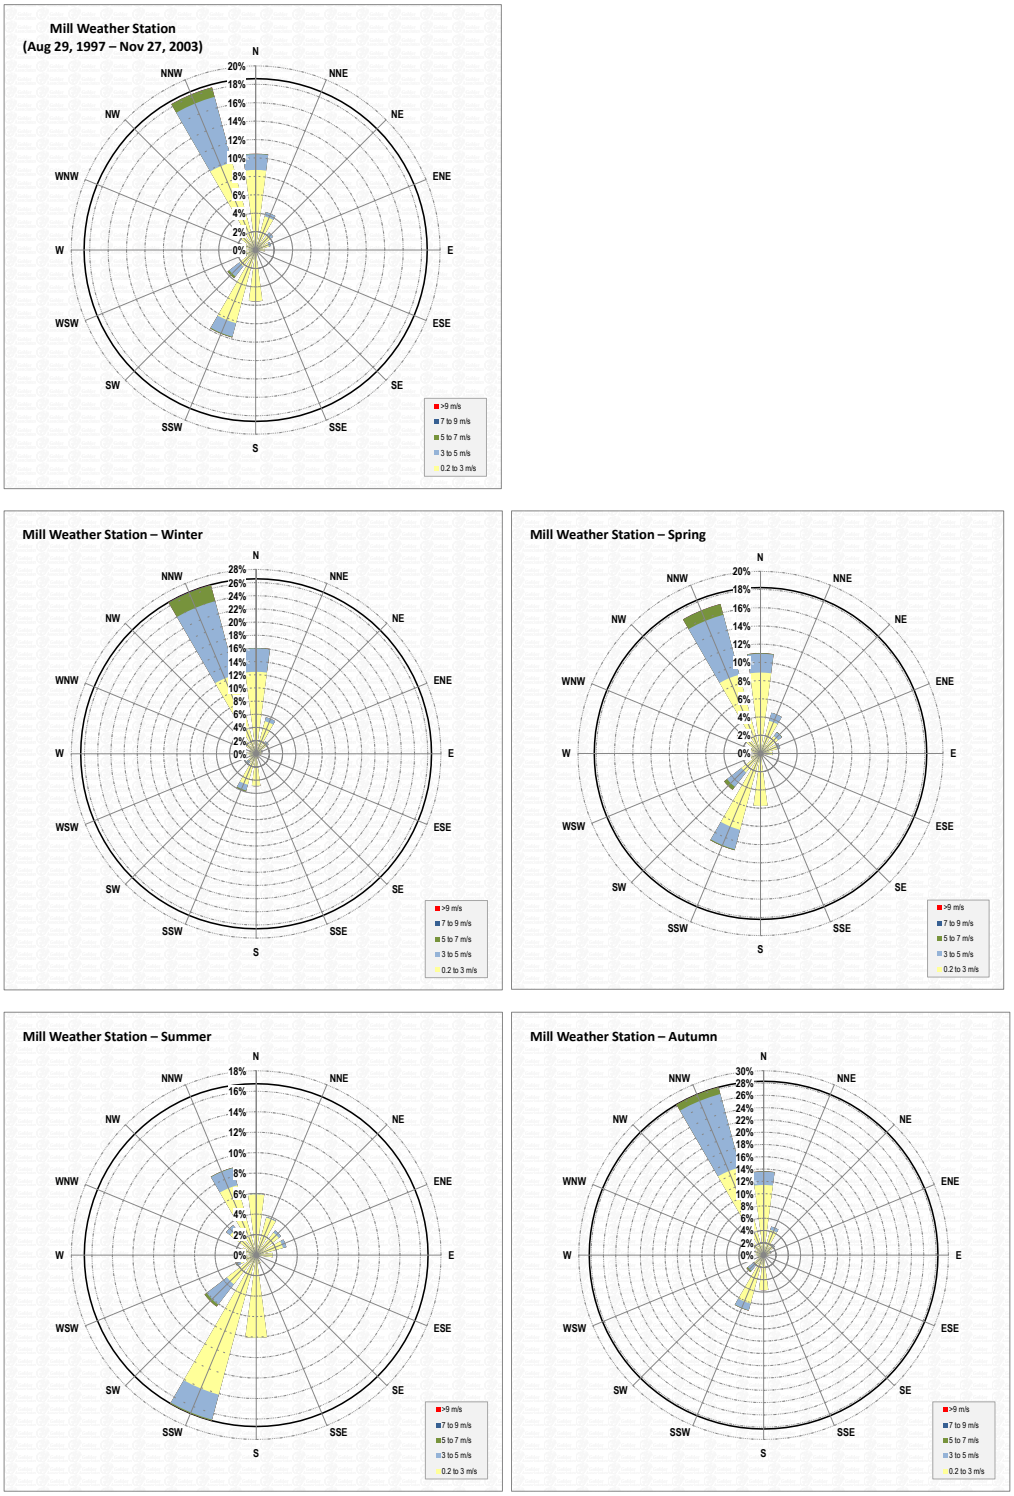

**Figure 22: MPMC Station Monitoring Period and Seasonal Wind Roses - 29 August 1997 to 27 November 2003**

Spring = March, April, May; Summer = June, July, August; Autumn = September, October, November; Winter = December, January, February.

Winds measured at the Site typically blew from the north-northwest, north, and south-southwest directions, with minimal winds from the east and the west. The spring, autumn, and winter seasonal wind roses were consistent with the wind rose pattern for the entire monitoring period; however, during the summer months, the majority of winds were from the south-southwest. Similarly, wind speeds in spring, autumn, and winter were generally consistent with the wind rose for the entire monitoring period, while wind speeds in summer were generally lower.

Wind speed measured and seasonal distributions at the Site from 2019 to 2021 were consistent with the relative frequency of wind speed magnitudes and the seasonal distributions recorded between 29 August 1997 and 27 November 2003 (Table 19 and Figure 23). A similar seasonal pattern in wind speed is identifiable with lower wind speeds in the summer months and higher wind speeds in the spring, autumn, and winter months (Table 20 and Figure 24). It is noted that the data from 2019 and 2021 are daily wind speed rather than hourly wind speed and only the relative frequency (%) of wind speed magnitude was compared.

**Table 19: Comparison of Relative Frequency of Wind Speed from Mill Weather Station and Weather Station 1 for the Site**

| Wind Speed (m/s) | Mill Weather Station 29 August 1997 to 27 November 2003[1] | Weather Station 1 1 January 2019 to 31 December 2021[2] |
|---|---|---|
| calm | 35% | 28% |
| 0.2 to 3 m/s | 50% | 56% |
| 3 to 5 m/s | 14% | 13% |
| 5 to 7 m/s | 2% | 3% |
| 7 to 9 m/s | 0% | 0% |
| >9 m/s | 0% | 0% |

1) Recorded as hourly wind speed.

2) Recorded as daily wind speed.

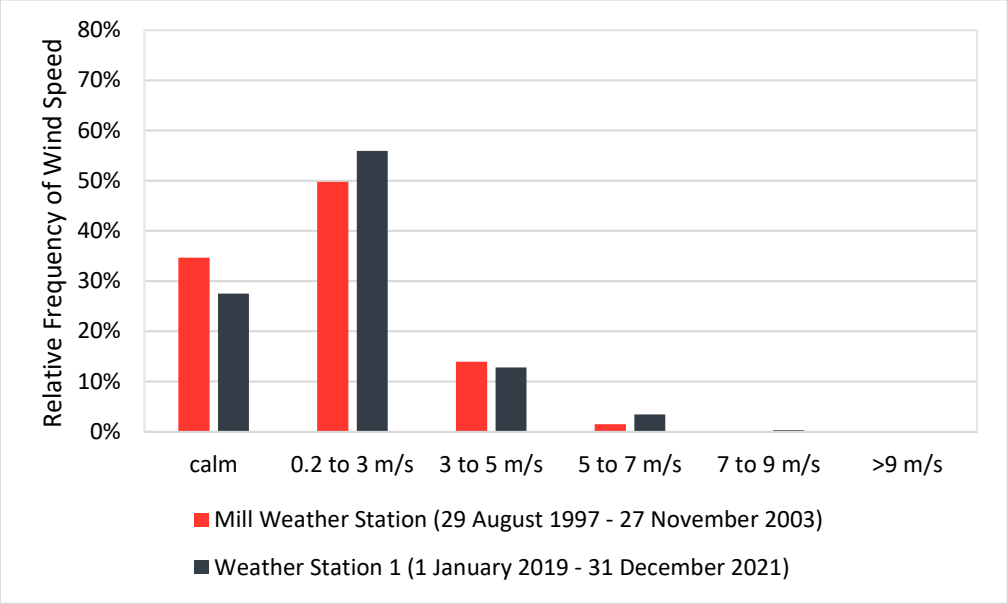

**Figure 23: Comparison of Relative Frequency of Wind Speed from Mill Weather Station and Weather Station 1 for the Site**

**Table 20: Comparison of Relative Frequency of Wind Speed Seasonal Distributions from Mill Weather Station and Weather Station 1 for the Site**

| Wind Speed (m/s) | Mill Weather Station 29 August 1997 to 27 November 2003[1] | | | | Weather Station 1 1 January 2019 to 31 December 2021[2] | | | |
|---|---|---|---|---|---|---|---|---|
| | Spring | Summer | Autumn | Winter | Spring | Summer | Autumn | Winter |
| calm | 31% | 32% | 22% | 27% | 23% | 18% | 31% | 37% |
| 0.2 to 3 m/s | 51% | 59% | 57% | 52% | 58% | 75% | 46% | 44% |
| 3 to 5 m/s | 16% | 9% | 19% | 19% | 13% | 7% | 17% | 15% |
| 5 to 7 m/s | 2% | 0% | 2% | 3% | 5% | 0% | 6% | 3% |
| 7 to 9 m/s | 0% | 0% | 0% | 0% | 1% | 0% | 0% | 1% |

1) Recorded as hourly wind speed.

2) Recorded as daily wind speed.

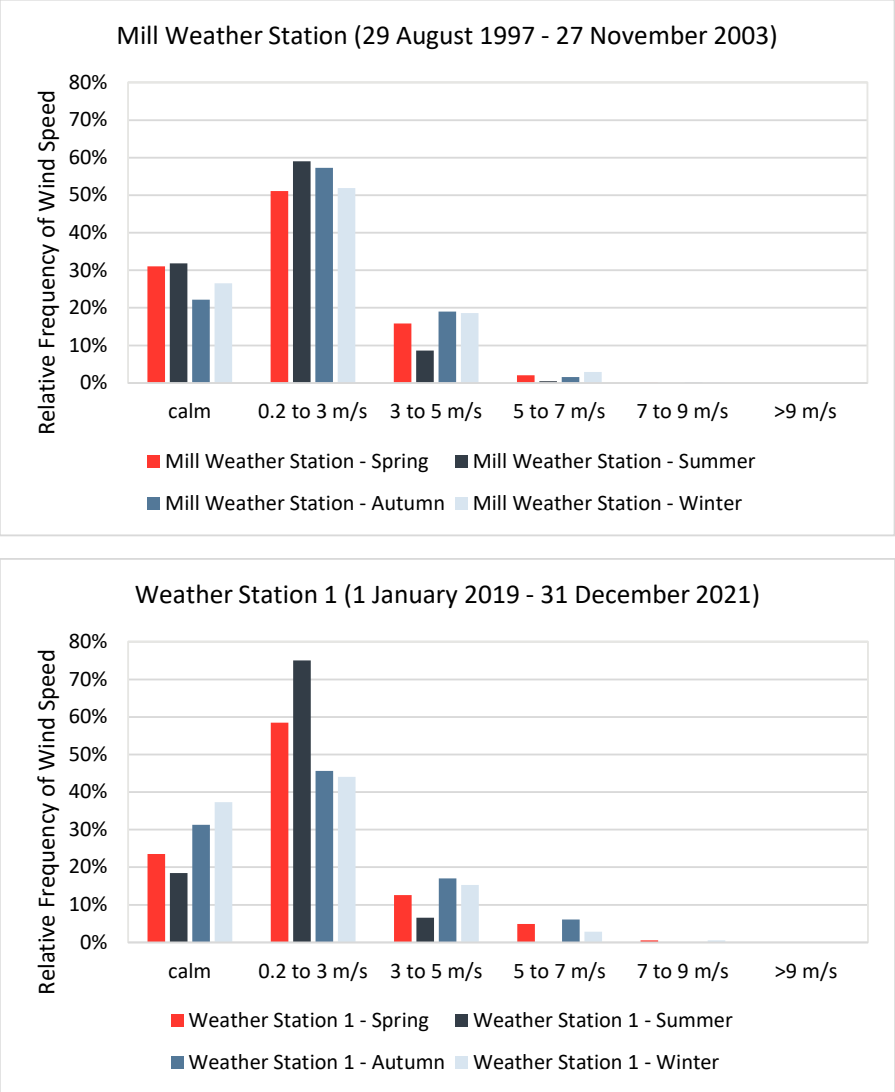

**Figure 24: Comparison of Relative Frequency of Wind Speed Seasonal Distribution from Mill Weather Station and Weather Station 1 for the Site**

## 4.8 Snow Cover Properties

Snow cover monthly statistics, reported as SWE, are presented in Table 21. At 50% exceedance, snow begins accumulating in November and achieves its maximum in March, reducing to 0 mm in April. The 5$^{th}$ and 95$^{th}$ percentiles and standard deviation values demonstrate the variability in the amount of SWE at the Site, with March having the greatest variability from year to year.

**Table 21: Snow Water Equivalent for the Site (1997-2021)**

| Month | Number of Measurements | Mean (mm) | Minimum (mm) | Percentile | | | | | Maximum (mm) | Standard Deviation (mm) |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | 5% | 25% | 50% | 75% | 95% | | |
| January | 22 | 147 | 76 | 88 | 120 | 139 | 164 | 327 | 339 | 56 |
| February | 22 | 182 | 99 | 104 | 131 | 193 | 222 | 338 | 344 | 61 |
| March | 22 | 185 | 0 | 6 | 97 | 198 | 257 | 403 | 411 | 108 |
| April | 21 | 33 | 0 | 0 | 0 | 0 | 81 | 177 | 177 | 58 |
| November | 22 | 17 | 0 | 0 | 0 | 9 | 37 | 72 | 72 | 25 |
| December | 22 | 102 | 32 | 50 | 77 | 101 | 122 | 193 | 196 | 44 |

# 5.0 CLIMATE CHANGE PROJECTIONS

Future climate projections are important for understanding how climate is projected to change at the Site from the climate baseline. Future climate projections come from publicly available statistical downscaled future climate projections on a daily scale. Recognizing the inherent uncertainty with projections, multiple projections from multiple models and scenarios were included in the analysis presented herein, and the future projections are presented in terms of percentiles or exceedance probabilities. Changes to climate may influence how representative the statistics estimated based on historical data are for future time periods.

## 5.1 Data Sources for Future Climate

The Intergovernmental Panel on Climate Change (IPCC) is generally considered to be the definitive source of information related to past and future climate change as well as climate science. As an international body, the IPCC provides a common source of information relating to emission scenarios, provides third party reviews of models, and recommends approaches to document future climate projections. Periodically, the IPCC issues assessment reports summarizing the current state of climate science. The Sixth Assessment Report (AR6) (IPCC 2021) represents the most currently available complete synthesis of information regarding climate change.

## 5.2 Global Climate Change Projections

Future climate is typically projected using global circulation models (GCMs) that involve the mathematical representation of global land, sea, and atmosphere interactions over a long period of time. These GCMs have been developed by various government agencies, but they share a number of common elements as described by the IPCC (2021). The IPCC does not run the models but acts as a clearinghouse for the distribution and sharing of the model forecasts.

Global climate models require extensive inputs to characterize the physical processes and social development paths that could alter climate in the future. To represent the wide range of the possible inputs to global climate models, the IPCC has established a series of Shared Socioeconomic Pathways (SSPs) that help define the future levels of radiative forcing terms. Future climate projection data are available from approximately 30 GCMs and four main SSPs (SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5) in AR6 (ECCC 2022c).

The primary differentiating aspect of each model are the SSPs developed by the IPCC and presented in AR6 to quantify potential emission output scenarios (ECCC 2022c). The SSPs were created with varying assumptions about human developments and are designed to work in combination with an updated version of the Representative Concentration Pathways (RCPs) from the previous IPCC Fifth Assessment Report (AR5) (ECCC 2022c). The SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5 scenarios are the four common greenhouse gas concentration profiles that are widely used; SSP5-8.5 represents the most extreme scenario with the highest volume of greenhouse gases emitted (ECCC 2022c).

## 5.3 Regional Climate Change Projections

The climate change projection data available from ClimateData.ca portal provided by ECCC uses GCMs with RCP pathways from IPCC AR5 rather than the latest SSPs from AR6. Therefore, the data used in this study will be obtained from ClimateBC.ca provided by the University of British Columbia (UBC). This tool downscales PRISM (Daly et al. 2008) 1971-2000 gridded monthly climate normal data (800 x 800 m) to scale-free point locations and uses the scale-free data as a baseline to downscale more than 200 future climate variables for individual years and periods between 1901 and 2100 (Wang et al. 2016).

The ClimateBC (UBC 2022) tool that is currently managed by UBC uses the same data management framework as Coupled Model Intercomparison Project Number 6 (CMIP6) where the SSP emission profiles are coupled with GCMs. ClimateBC selected a subset of eight GCMs from the models contributing to the CMIP6 ScenarioMIP project based on the following criteria (UBC 2022):

- Minimum of three historical runs available.
- Minimum temperature and maximum temperature available for all runs.
- At least one run for each of the four main SSP marker scenarios.
- One model per institution.
- No closely related models based on Figure 5 in *Reduced global warming from CMIP6 projections when weighting models by performance and independence* (Brunner et al. 2020).
- No large biases over BC.
- Are within IPCCs transient climate response "likely[1]" range and Earth's equilibrium climate sensitivity "very likely[2]" range.

The eight GCMs presented in this report are ACCESS-ESM1-5, BC-CSM2-MR, CNRM-ESM2-1, GFDL-ESM4, GISS-E2-1-G, MIROC6, MPI-ESM1-2-HR, and MRI-ESM2-0.

**Table 22: Inventory of Global Climate Models Referenced in this Study**

| Model | Source / Institution |
|---|---|
| ACCESS-ESM1-5 | Commonwealth Scientific and Industrial Research Organisation |
| BC-CSM2-MR | Beijing Climate Center |
| CNRM-ESM2-1 | CNRM (Centre National de Recherches Meteorologiques) and CERFACS (Centre Européen de Recherche et de Formation Avancée en Calcul Scientifique) |
| GFDL-ESM4 | National Oceanic and Atmospheric Administration, Geophysical Fluid Dynamics Laboratory |
| GISS-E2-1-G | Goddard Institute for Space Studies |
| MIROC6 | JAMSTEC (Japan Agency for Marine-Earth Science and Technology), AORI (Atmosphere and Ocean Research Institute), NIES (National Institute for Environmental Studies), and R-CCS (RIKEN Center for Computational Science) |
| MPI-ESM1-2-HR | Max Planck Institute for Meteorology |
| MRI-ESM2-0 | Meteorological Research Institute |

The Site coordinates and elevation were entered into ClimateBC to extract site-specific model outputs (i.e., projections) for precipitation, air temperature, solar radiation, relative humidity, and precipitation as snowfall.

[1] Transient climate response metric in the range 1.4 to 2.2°C (66% likelihood) deemed as "likely" in AR6 (Hausfather et al. 2022).

[2] Equilibrium climate sensitivity metric in the range 2 to 5°C deemed as "very likely" in AR6 (Hausfather et al. 2022).

## 5.4 Climate Change Projections Results

The following sections build on the current climate baseline by providing the projected changes under future climate conditions for two future time horizons (2041-2070; 2050s, and 2071-2100; 2080s). Time horizons used for the available projections are by periods. Section 5.4.1 provides a description of future projected conditions for temperature and precipitation. Sections 5.4.2 through 5.4.5 provide the projected changes in relative humidity, solar radiation, evaporation, and snow cover. In all sections, projections are provided in terms of exceedance probability measured over the 32-member multi-model ensemble (i.e., 8 models and 4 SSPs). The focus of the results discussion is on the 50$^{th}$ percentile (median), while additional exceedance probabilities are available in the tables presented, including the maximum and minimum. Using the median, or 50$^{th}$ percentile, provides an indication of the middle of the projected changes from the multi-model ensemble.

### 5.4.1 Future Temperature and Precipitation Projections

This section provides the projected future mean temperature and total precipitation for the Site. The future climate projections are benchmarked against a modelled baseline (e.g., ClimateBC output of the baseline information available for the 32-member multi-model ensemble for the normal period of 1991-2020) and are described in terms of “anomaly” or change from the baseline.

#### *Annual Temperature and Precipitation Projections*

Comparisons of the future climate projections of temperature and precipitation for the Site for the 2050s (2041-2070) and 2080s (2071-2100) projection periods are shown as a scatter plot in Figure 25. The plots illustrate the projected change in temperature (vertical axis) and precipitation (horizontal axis) from the current climate baseline (1991 through 2020 normal period) for each of the models and the four SSPs considered in the IPCC’s AR6 (IPCC 2021). For reference, the current climate is shown as a solid circle where the axes intersect. The model projections are generally in the upper right quadrant of the plots, suggesting a future climate that will likely be warmer and wetter. There is a larger spread of future projected precipitation, with a majority of model runs projecting a wetter future climate. Precipitation projections typically have larger uncertainty than temperature projections due to the challenge of capturing precipitation in the climate models (temperature is better understood) (Araya-Osses et al. 2020).

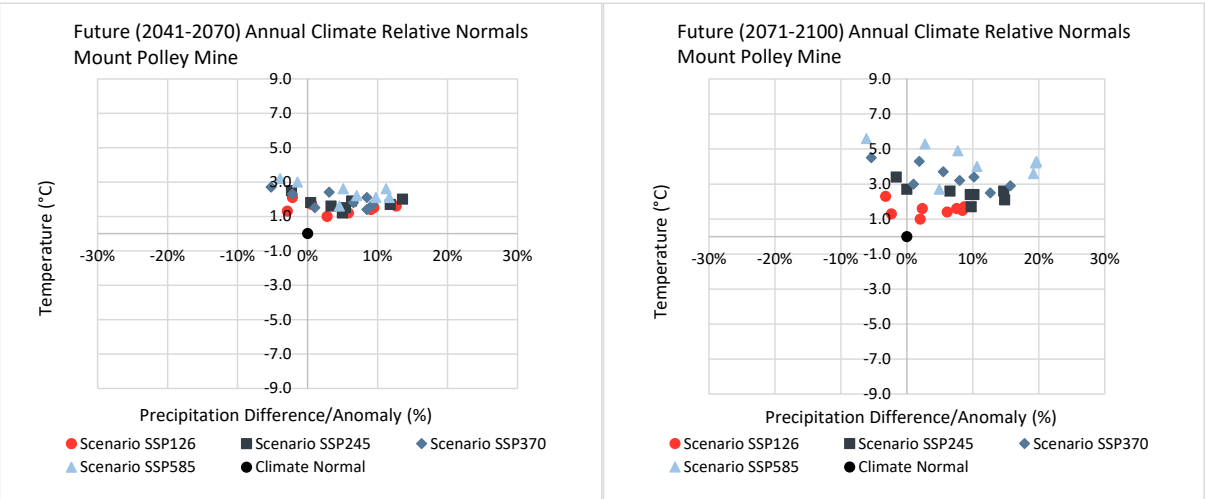

**Figure 25: Scatter Plots Presenting Annual Temperature and Precipitation Projections for the 2050s and the 2080s for the Mount Polley Mine Area**

## *Monthly Temperature and Precipitation Projections*

Figure 26 and Figure 27 depict the projected anomalies in monthly temperatures for the Site for the 2050s and 2080s, respectively. The figures also show a dashed line which represents the median of all the modelled projections. The dotted lines in the figures represents the spread between the 5th percentile and the 95th percentile of the ensemble. The figures show projected increases in temperature for all months for the 2050s and the 2080s. For the 2050s (Figure 26) the projected increase in the median temperature (dashed line) is less in winter months and greater in the summer months, with an annual average increase of 1.8ºC. The 5th and 95th percentiles of the 2050s ensembles range from an increase of 1.2ºC to around 2.9ºC. The 95th percentile shows a larger variation throughout the months of the year compared to the 5th percentile, and a seasonal pattern arises for the summer months, with larger projected increases of 4.3°C.

The projected increase in the median temperature for the 2080s (Figure 27) is less in winter months and greater in the summer months, with an annual average increase of 2.7ºC. The 5th and 95th percentiles of the 2080s ensemble range from an increase of approximately 1.4ºC to 5.1ºC on average. The 95th percentile shows a larger variation throughout the months of the year and greatest variation in the summer months, with projected increases of 7ºC.

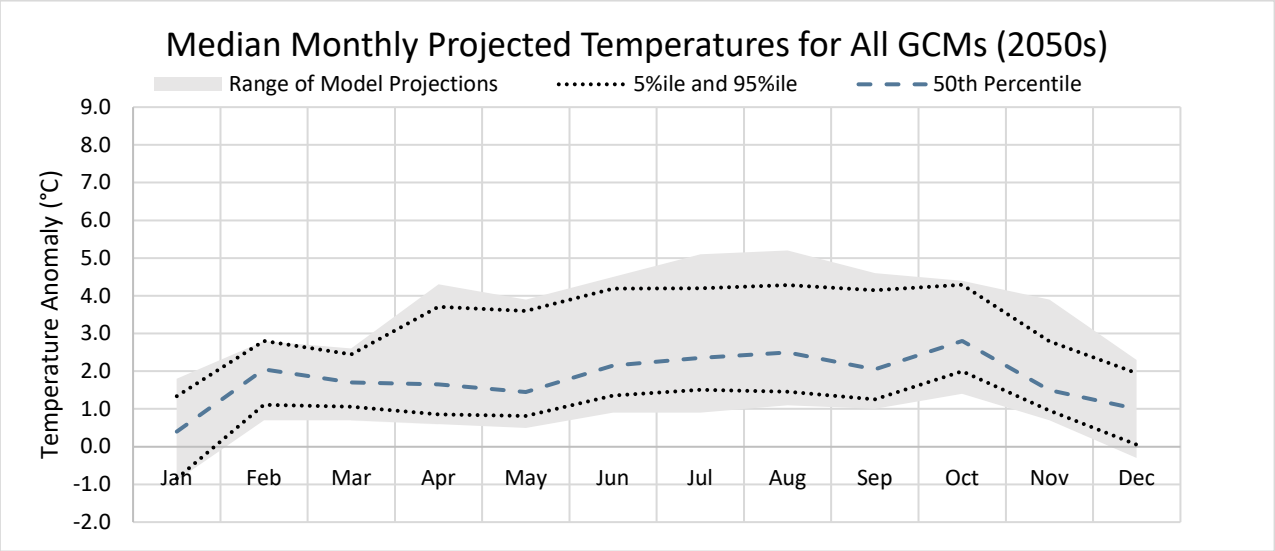

**Figure 26: Monthly Projected Temperature Anomalies for the Mount Polley Mine Area (2050s)**

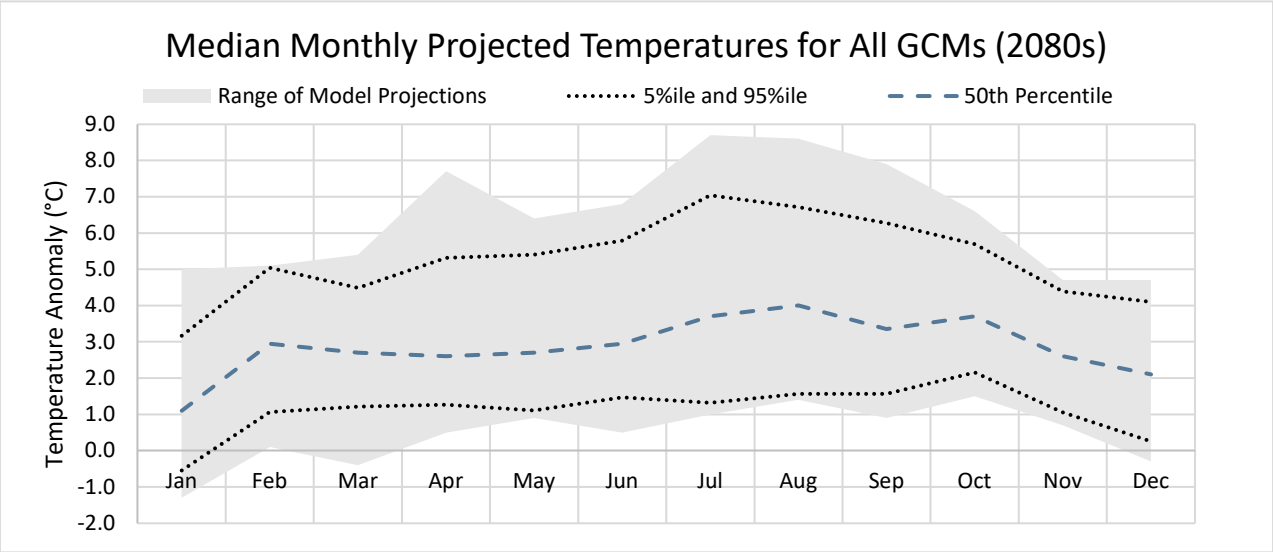

**Figure 27: Monthly Projected Temperature Anomalies for the Mount Polley Mine Area (2080s)**

Figure 28 and Figure 29 present the monthly projected precipitation anomalies for the Site for the 2050s and 2080s, respectively. For the 2050s (Figure 28) the projected median anomaly (dashed line) indicates changes in the seasonal distribution throughout the year, with an annual average increase of 5%, except for the summer where a slight decrease is projected for the months of June and July. The summer and fall months also present a larger spread in projections from the ensemble (shaded area on the graph), indicating less agreement between the projections. The 2080s (Figure 29) present similar behaviour to the 2050s except for an overall higher projected increase (around 8%), except for the months of June and July, where a decrease in precipitation is projected.

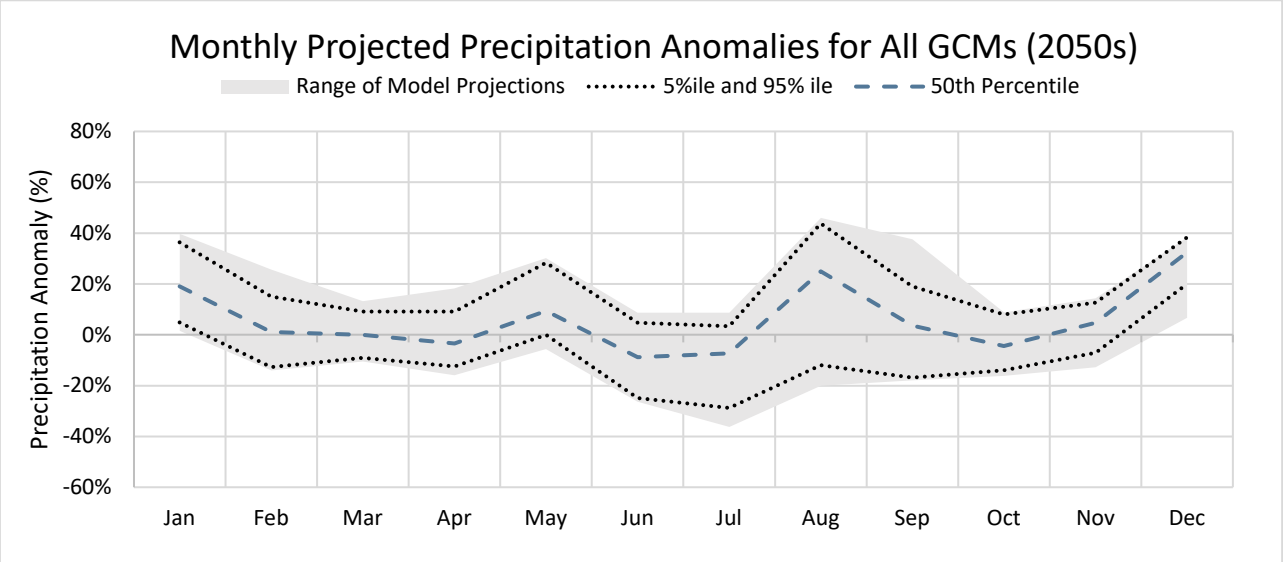

**Figure 28: Monthly Projected Precipitation Anomalies for the Mount Polley Mine Area (2050s)**

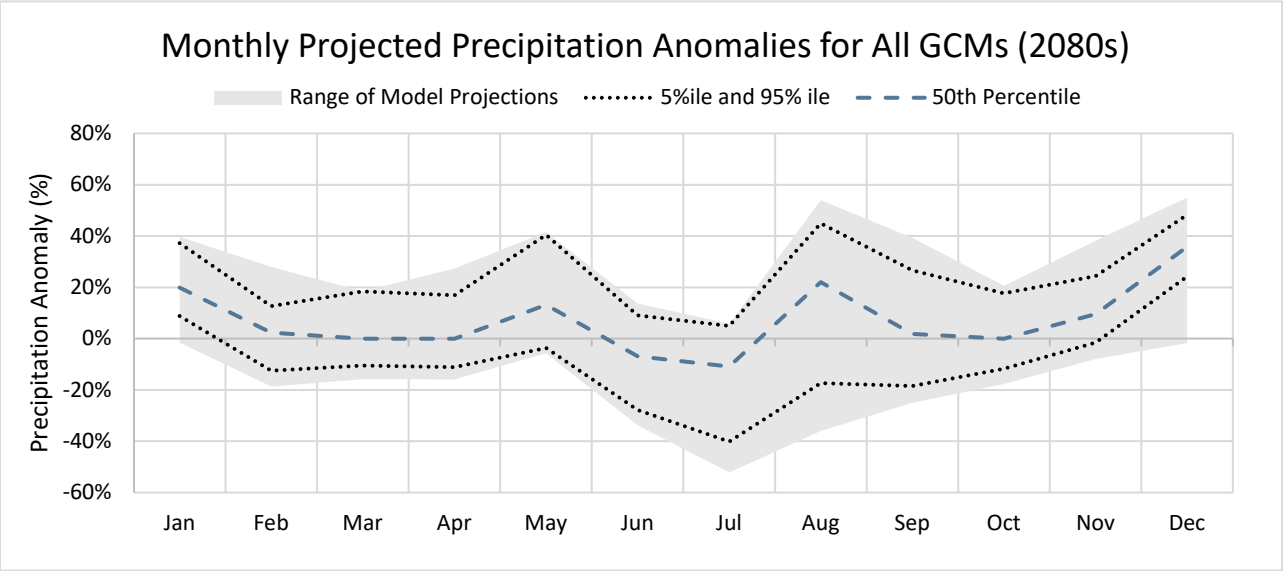

**Figure 29: Monthly Projected Precipitation Anomalies for the Mount Polley Mine Area (2080s)**

Overall, there is less variability and uncertainty (measured as the agreement within the ensemble or range of projected anomalies) during the 2050s. However, variability increases for both the precipitation and temperature anomalies during the 2080s.

## *Annual and Monthly Temperature and Precipitation Projections Summary*

The projected future changes in the 2050s and 2080s from the baseline period (1991 through 2020) in monthly and annual temperatures are summarized in Table 23 and Table 24. In the 2050s, at 50% exceedance probability, the annual temperature is projected to increase by 1.8°C, with the biggest monthly increase of 2.8°C in October, and smallest monthly increase of 0.4°C in January. In the 2080s, at 50% exceedance probability, the annual temperature is projected to increase by 2.7°C, with the biggest monthly increase of 4.0°C in August, and smallest monthly increase of 1.1°C in January.

**Table 23: Projected Anomalies in Monthly and Annual Temperature in the 2050s from Baseline**

| Month | Min | Percentiles | | | | | | | | Max | Mean | Std. Dev. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 5% | 10% | 25% | 50% | 75% | 90% | 95% | 99% | | | |
| January | -0.9 | -0.8 | -0.4 | 0.1 | 0.4 | 0.6 | 1.1 | 1.3 | 1.7 | 1.8 | 0.3 | 0.6 |

| November | 0.7 | 1.1 | 1.1 | 1.6 | 2.6 | 3.4 | 4.2 | 4.4 | 4.6 | 4.7 | 2.6 | 1.1 |
| December | -0.3 | 0.3 | 0.6 | 1.2 | 2.1 | 2.9 | 3.5 | 4.1 | 4.5 | 4.7 | 2.1 | 1.2 |
| Annual | 1.0 | 1.4 | 1.5 | 2.0 | 2.7 | 3.8 | 4.5 | 5.1 | 5.5 | 5.6 | 3.0 | 1.4 |

The projected future changes in the 2050s and 2080s from the baseline period (1991 through 2020) in monthly and annual precipitation are summarized in Table 25 and Table 26. The annual precipitation in the 2050s is projected to increase by 5% from the baseline at the 50% exceedance probability. The projected highest monthly increases in the 2050s occur in the winter and August while small and negative changes are expected in June and July. The 2080s annual precipitation is projected to increase by 8% from the baseline, with the largest increases occurring in winter and August, and a small decrease in the summer months of June and July.

**Table 25: Projected Anomalies in Monthly and Annual Precipitation in the 2050s from Baseline**

## *Comparison to Regional Projections*

Within Canada there are two major sources of regional projections available: the ClimateData.ca portal (ClimateData 2022) and Canada's Changing Climate Report (Bush and Lemmen 2019). The ClimataData.ca portal provides summarized information about selected locations within Canada using a multi-model ensemble across multiple emission scenarios following IPCC AR5 RCPs (IPCC 2013). Canada's Changing Climate Report (Bush and Lemmen 2019) looks at changing climate trends across Canada and how regional changes fit within the national and global context of climate change. Both resources are used to provide context for the analysis of projections presented in Section 5.4.1 above.

Under a high emissions scenario (RCP 8.5), the ClimateData.ca portal projects a mean annual average temperature increase of 1.6ºC for the 2021 to 2050 period at the Site, 3.6ºC for the 2051 to 2080 period, and 5.1ºC for the end of the century relative to the climate normal period from 1981 to 2010 (ClimateData.ca 2022). This is consistent with the ensemble projections presented above that show increases of 1.8ºC for the 2050s (2041-2070) and 2.7ºC for the 2080s (2071-2100) relative to the modelled climate normal period from 1991 to 2020. Similarly, average annual precipitation is projected by ClimateData.ca to increase by 5% for the 2021 to 2050 period, 12% for the 2051 to 2080 period, and by 15% for the end of the century relative to climate normal period from 1951 to 1980 (ClimateData.ca 2022). These projected changes are consistent with the projections presented above considering the difference in the projection and normal periods (i.e., projection of 5% increase for the 2041 to 2070 period above compared to the 7% increase for the 2051 to 2080 period relative to normal period from 1991 to 2020).

Bush and Lemmen (2019) (Canada's Change Climate Report) does not include trends specifically for the Mine area; however, projections indicate an increase in both mean annual temperature and precipitation, with northern Canada expected to experience larger increases. Under a low emissions scenario (RCP 2.6) temperature is projected to increase by 1.8°C and by more than 6°C under a high emissions scenario (RCP 8.5) by the end of the century. Annual mean precipitation is projected to increase by 7% under a low emissions scenario (RCP 2.6) and by 24% under a high emissions scenario (RCP 8.5) by the end of the century (Bush and Lemmen 2019).

### 5.4.2 Future Relative Humidity Projections

#### *Annual Projections*

Comparison of the future mean annual relative humidity projections from all GCMs for the Mine area and 2050s and 2080s projection periods are shown in Table 27 and Figure 30, and Table 28 and Figure 31, respectively. Projections for the 2050s period shows little variation compared to the baseline period (1991 to 2020) for all climate models and all SSPs with an anomaly range of -2% to 2%. Projections for the 2080s period shows similar pattern to the 2050s period (-1% to 2% anomaly range) for SSP1-2.6 and SSP2-4.5, and greater variation for higher emissions scenarios SSP3-7.0 and SSP5-8.5 (-2% to 5% anomaly range).

**Table 27: Projected Mean Annual Relative Humidity for all GCMs (2050s)**

| Climate Model | Relative Humidity Anomaly (%) | | | |
|---|---|---|---|---|
| | Scenario SSP1-2.6 | Scenario SSP2-4.5 | Scenario SSP3-7.0 | Scenario SSP5-8.5 |

| Baseline | 0.0 | 0.0 | 0.0 | 0.0 |
| Anomaly Range | -1 to 2 | -1 to 2 | -2 to 4 | -1 to 5 |

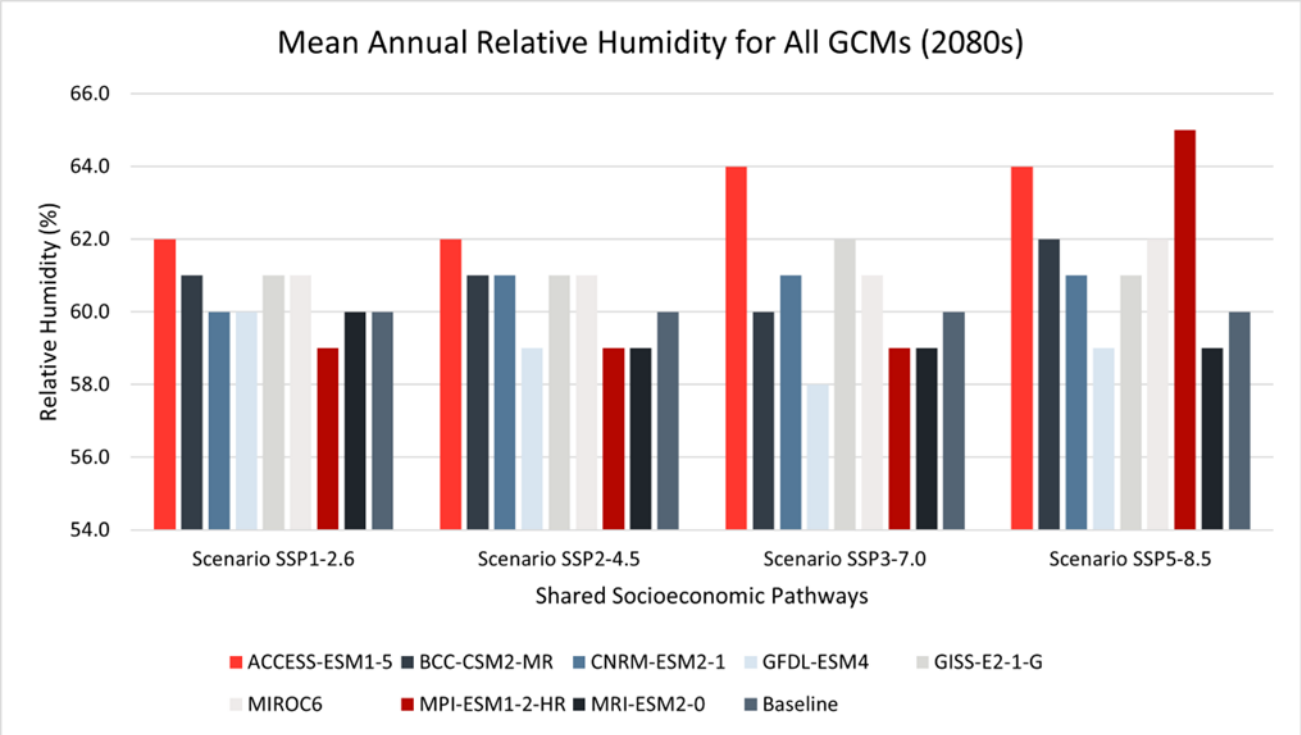

**Figure 31: Projected Mean Annual Relative Humidity for all GCMs (2080s)**

## *Monthly Projections*

Figure 32 and Figure 33 depict the projected anomalies in monthly median relative humidity at the Site for the 2050s and 2080s, respectively. The figures also show a dashed line which represents the median of all the modelled projections. The dotted lines in the figures represent the spread between the 5th percentile and the 95th percentile of the ensemble. The figures show the projected seasonal pattern with increases in relative humidity for spring and summer months and decreases in relative humidity for winter months, with no change to the annual average. The 5th and 95th percentiles of the 2050s ensembles range from a decrease of -1.0% to an increase of 2.2% on average. The 5th and 95th percentile variations follow the projected median throughout the months of the year, with no discernible seasonal pattern. The 5th and 95th percentiles of the 2080s ensemble, range from a decrease of -1.0% to an increase of 4.0% on average. The 5th and 95th percentile variations are similar throughout the winter months of the year with larger projected uncertainty in the spring and summer months.

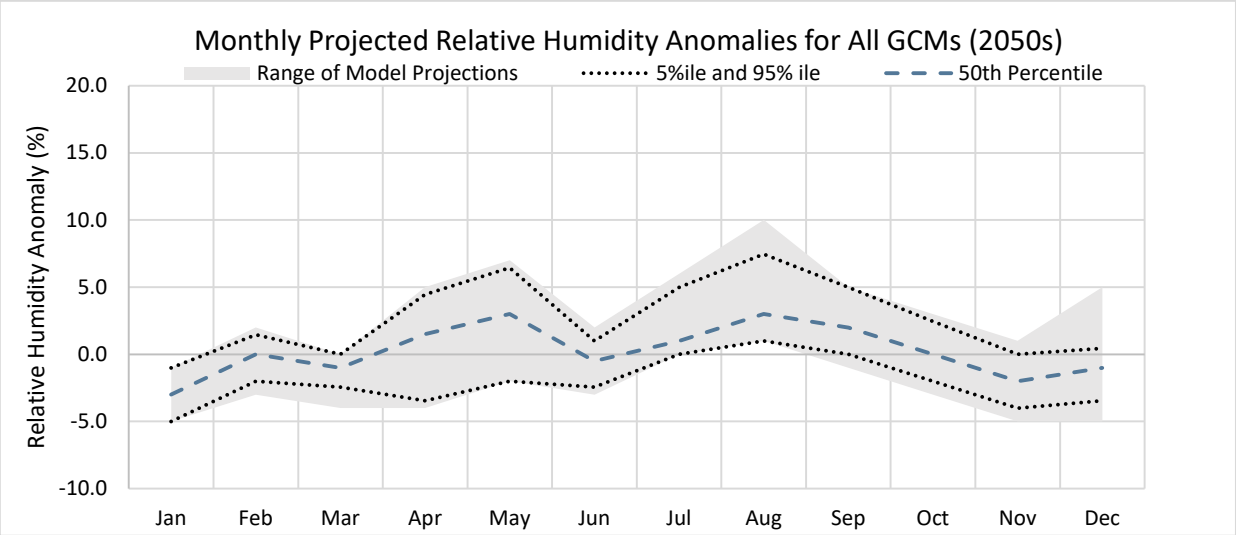

**Figure 32: Monthly Projected Relative Humidity Anomalies for Mount Polley Mine Area (2050s)**

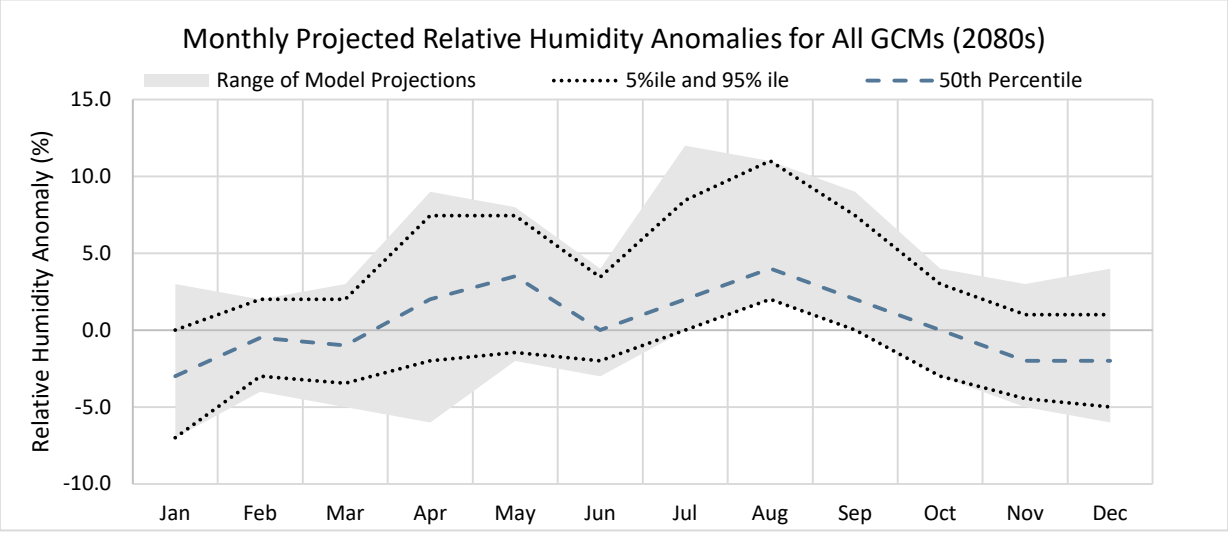

**Figure 33: Monthly Projected Relative Humidity Anomalies for Mount Polley Mine Area (2080s)**

## *Summary of Annual and Monthly Projections*

The projected future changes in the 2050s and 2080s from the baseline period (1991 through 2020) in monthly and annual relative humidity are summarized in Table 29 and Table 30. In the 2050s, at 50% exceedance probability, the annual relative humidity is projected to remain the same as baseline conditions with monthly relative humidity increasing in spring and summer months (up to 3% absolute increase in May and August) and decreasing in fall and winter months (up to -3% absolute decrease in January). In the 2080s, at 50% exceedance probability, the annual relative humidity is projected to remain the same as baseline conditions with monthly relative humidity increasing in spring and summer months (up to 4% absolute increase in August) and decreasing in fall and winter months (up to -3% in January). There is greater variability in the range of relative humidity in the summer months (Figure 33).

**Table 29: Projected Anomalies in Monthly and Annual Relative Humidity in the 2050s from Baseline**

| Month | Min | Percentiles | | | | | | | | Max | Mean | Std. Dev. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 5% | 10% | 25% | 50% | 75% | 90% | 95% | 99% | | | |
| January | -5% | -5% | -5% | -4% | -3% | -1% | -1% | -1% | -1% | -1% | -3% | 1% |

### 5.4.3 Future Solar Radiation Projections

#### *Annual Projections*

Comparison of the future mean annual solar radiation projections for the Mine area for the 2050s and 2080s projection periods are shown in Table 31 and Figure 34, and Table 32 and Figure 35, respectively. Baseline solar radiation for the Site is from ECCC Williams Lake climate station for the period from 1961 through 2001 as modelled baseline solar radiation for the Site is not available. Projections for the 2050s period shows a mean annual solar radiation increase of 4.3% from baseline, with a range of 2.1% to 11.3% increase from baseline across all climate models and SSPs. Projections for the 2080s period shows a mean annual solar radiation increase of 5% from baseline, with a range of 1.2% to 12.2% increase from baseline across all climate models and SSPs.

**Table 31: Projected Mean Annual Solar Radiation for all GCMs (2050s)**

| Climate Model | Solar Radiation Anomaly | | | |
|---|---|---|---|---|
| | Scenario SSP1-2.6 | Scenario SSP2-4.5 | Scenario SSP3-7.0 | Scenario SSP5-8.5 |
| ACCESS-ESM1-5 | 7.1% | 6.3% | 7.1% | 7.1% |
| BCC-CSM2-MR | 7.1% | 7.1% | 9.7% | 11.3% |
| CNRM-ESM2-1 | 3.7% | 3.7% | 2.9% | 2.9% |
| GFDL-ESM4 | 4.6% | 4.6% | 2.9% | 2.9% |
| GISS-E2-1-G | 4.6% | 2.1% | 2.1% | 2.1% |
| MIROC6 | 4.6% | 2.1% | 2.1% | 2.1% |
| MPI-ESM1-2-HR | 2.1% | 2.1% | 2.9% | 2.1% |
| MRI-ESM2-0 | 4.6% | 4.6% | 2.9% | 4.6% |
| Baseline[a] | 0% | 0% | 0% | 0% |
| Anomaly Range | 2.1% to 7.1% | 2.1% to 7.1% | 2.1% to 9.7% | 2.1% to 11.3% |

a) Baseline solar radiation for the Site is from ECCC Williams Lake climate station for a period from 1961 through 2001.

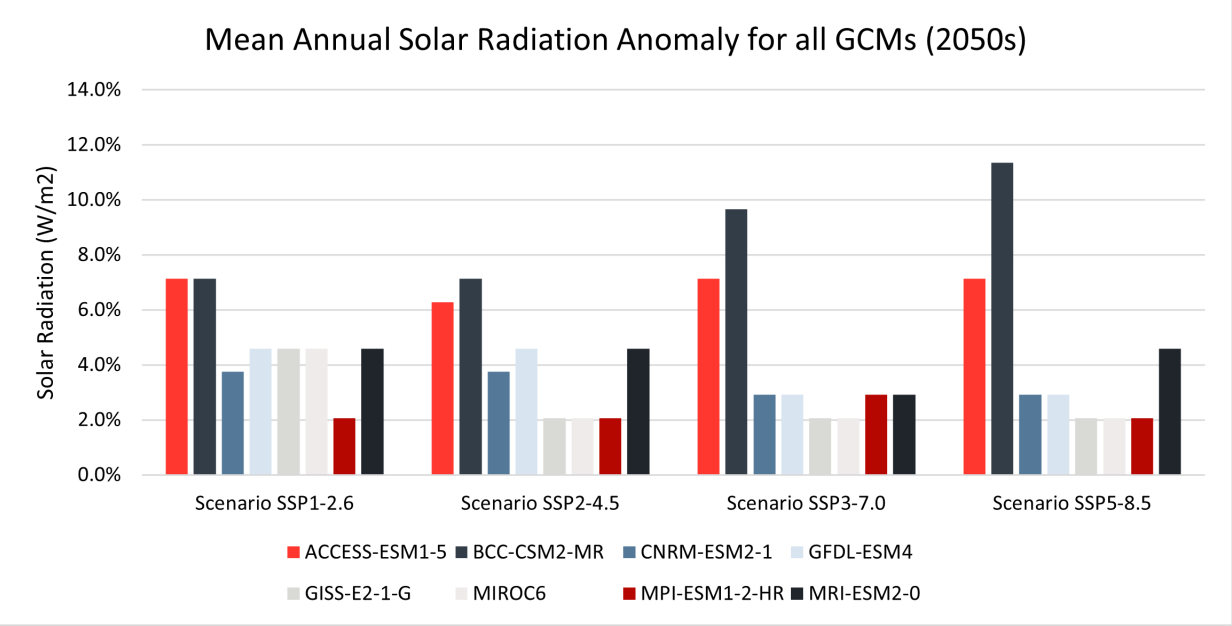

**Figure 34: Projected Mean Annual Solar Radiation Anomaly for all GCMs (2050s)**

**Table 32: Projected Mean Annual Solar Radiation for all GCMs (2080s)**

| Climate Model | Solar Radiation Anomaly | | | |
|---|---|---|---|---|
| | Scenario SSP1-2.6 | Scenario SSP2-4.5 | Scenario SSP3-7.0 | Scenario SSP5-8.5 |
| ACCESS-ESM1-5 | 7.1% | 7.1% | 8.0% | 8.0% |
| BCC-CSM2-MR | 9.7% | 10.5% | 13.9% | 12.2% |

| Baseline[a] | 0% | 0% | 0% | 0% |
| Anomaly Range | 2.9% to 9.7 | 1.2% to 10.5% | 2.1% to 13.9% | 0.4% to 12.2% |

a) Baseline solar radiation for the Site is from ECCC Williams Lake climate station for a period from 1961 through 2001.

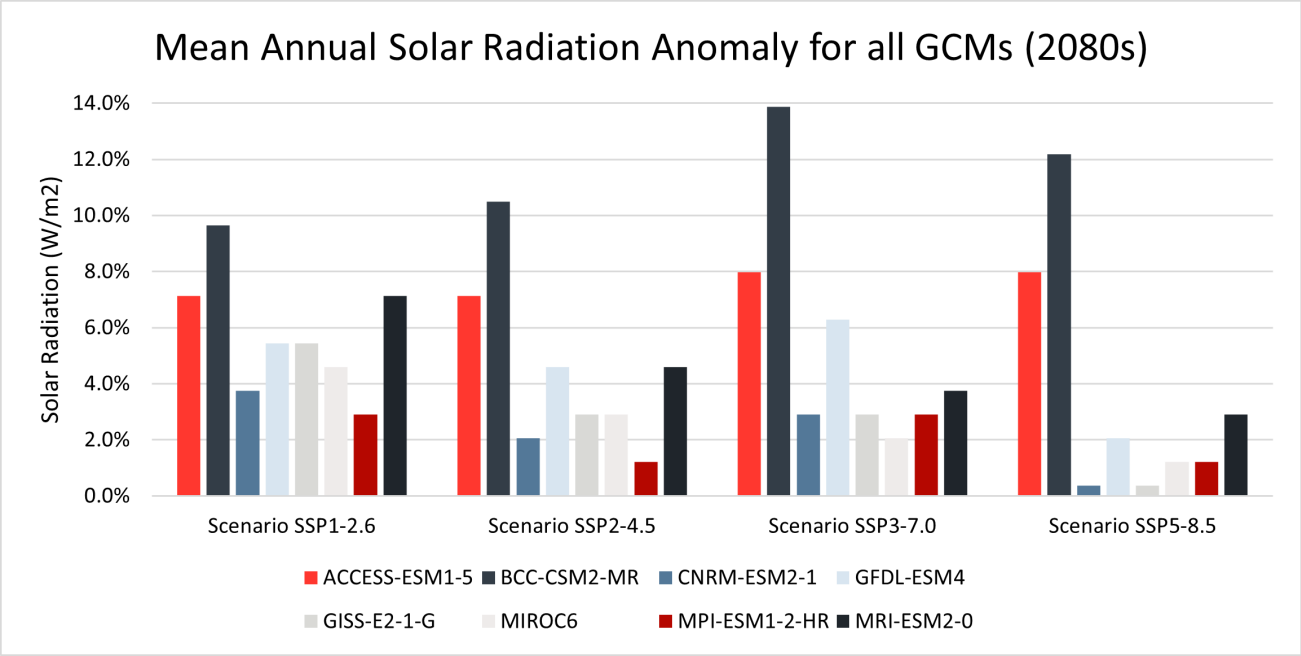

**Figure 35: Projected Mean Annual Solar Radiation Anomaly for all GCMs (2080s)**

## *Monthly Projections*

Figure 36 and Figure 37 depict the projected anomalies in monthly solar radiation at the Site for the 2050s and 2080s, respectively. The figures also show a dashed line which represents the median of all the modelled projections. The dotted lines in the figures represents the spread between the 5$^{th}$ percentile and 95$^{th}$ percentile of the ensemble. The figures show projected increases in solar radiation for all months for the 2050s and the 2080s except for April, May, and October. For the 2050s (Figure 36) the projected increase in the solar radiation (dashed line) is greater in winter months and less in the summer months, with an annual average increase of 5.1 W/m$^2$. The 5$^{th}$ and 95$^{th}$ percentiles of the 2050s ensembles range from 2.8 W/m$^2$ to 11.3 W/m$^2$ on average with the largest variation occurring in the summer months. The 95$^{th}$ percentile shows a larger variation during the summer months, with projected increases of nearly 21.7 W/m$^2$.

The projected increase in the mean solar radiation for the 2080s (Figure 37) show a similar pattern to the 2050s period. The projected increase (dotted line) is greater in winter months and less in summer months, with an average annual increase of 5.1 W/m$^2$. The 5$^{th}$ and 95$^{th}$ percentiles of the 2080s ensemble range from 1.2 W/m$^2$ to 15.4 W/m2 on average. The 95$^{th}$ percentile shows a larger variation throughout the summer months, with projected increases of nearly 41.2 W/m$^2$. There is greater uncertainty in the projected solar radiation in July and August.

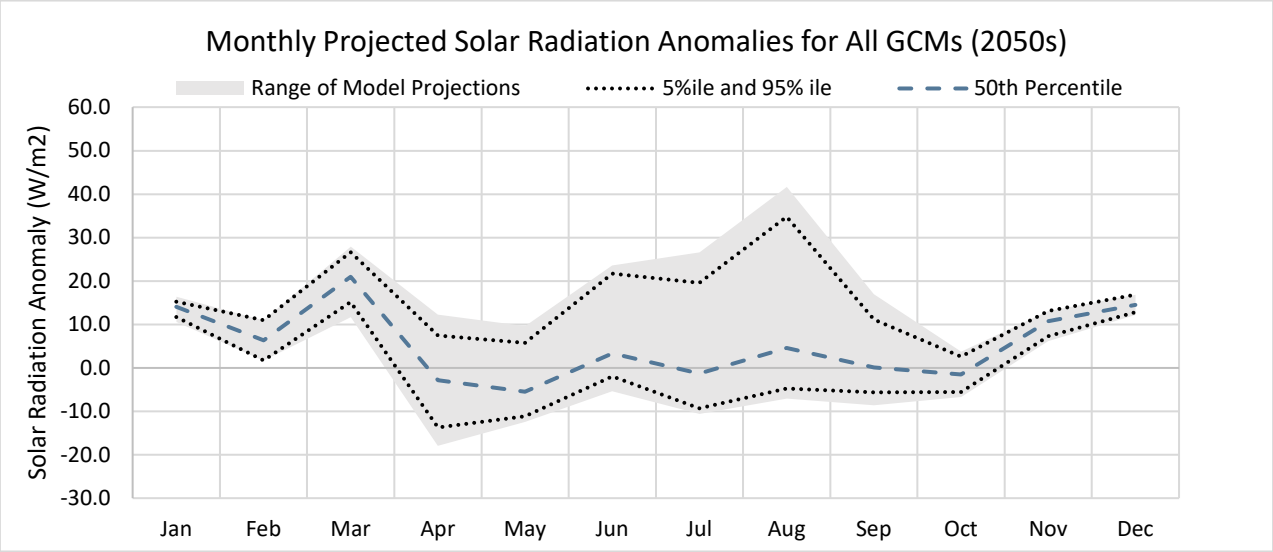

**Figure 36: Projected Monthly Solar Radiation Anomalies for Mount Polley Mine Area (2050s)**

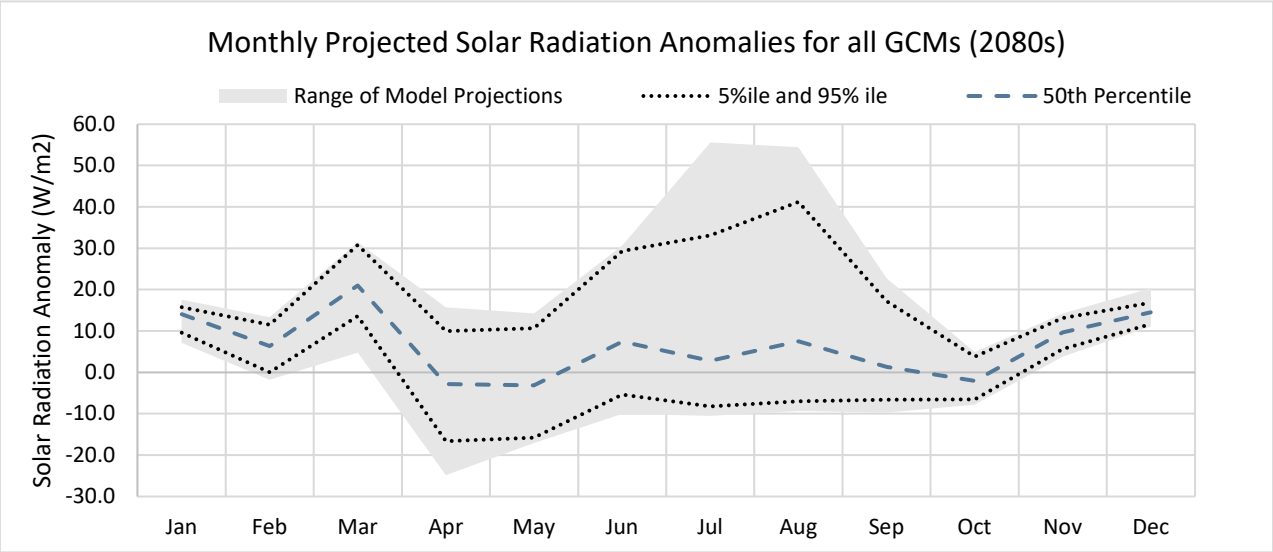

**Figure 37: Projected Monthly Solar Radiation Anomalies for Mount Polley Mine Area (2080s)**

## *Summary of Annual and Monthly Projections*

The projected future changes in the 2050s and 2080s from the baseline period (Williams Lake 1961 through 2001) in monthly and annual solar radiation are summarized in Table 33 and Table 34. In the 2050s and 2080s, at 50% exceedance probability, the median annual solar radiation is projected to increase by 5.1 W/m$^2$. Monthly solar radiation is projected to increase for all months except April, May, and October.

**Table 33: Projected Anomalies in Monthly and Annual Solar Radiation in the 2050s from Baseline**

| Month | Min | Percentiles | | | | | | | | Max | Mean | Std. Dev. |

| Annual | 0.5 | 1.2 | 1.7 | 3.7 | 5.1 | 9.8 | 13.0 | 15.4 | 18.3 | 19.0 | 6.6 | 4.7 |

### 5.4.4 Future Evaporation Projections

Evaporation and evapotranspiration projections are not available from ClimateBC or ClimateData.ca. However, evaporation and evapotranspiration are likely to change as dependent variables change, in particular air temperature. The extent of the change will depend on the climate change scenario.

### 5.4.5 Snow Cover Properties Projections

Potential changes in winter air temperature will likely lead to changes in snow cover properties and the annual SWE available for freshet. ClimateBC does not project snow cover and instead projects precipitation-as-snow (PAS) for future climate periods. PAS projections are indicative of the trends in total snow cover and SWE available to contribute to freshet flows, with less PAS resulting in less SWE. Table 35 summarizes ClimateBC projected PAS for future normal periods relative to the modelled baseline period (1991 through 2020) and indicates an overall decrease in PAS in the future. At 50% exceedance probability, the annual PAS is projected to decrease by 30 mm and 59 mm on average for the 2050s and 2080s, respectively.

Climate change model data published for the province of BC by ECCC (2019) project snow depth reduction relative to the 1986 to 2005 reference normal period using CMIP5 RCP (Table 36). At 50% exceedance, the snow cover depth is projected to decrease by 83 mm and 117 mm on average for the 2046-2065 and 2081-2100 normal periods, respectively.

**Table 35: Projected Annual Precipitation-As-Snow Anomaly for the Mount Polley Mine Area**

| Shared Socioeconomic Pathway | Normal Period | Precipitation-as-Snow Anomaly Percentiles (mm) | | |
|---|---|---|---|---|
| | | 25% | 50% | 75% |
| SSP1-2.6 | 2011-2040 | -7 | -4 | 2 |
| | 2041-2070 | -23 | -17 | -13 |
| | 2071-2100 | -25 | -21 | -18 |
| SSP2-4.5 | 2011-2040 | -11 | -5 | 2 |
| | 2041-2070 | -32 | -27 | -18 |
| | 2071-2100 | -50 | -47 | -38 |
| SSP3-7.0 | 2011-2040 | -5 | -2 | 2 |
| | 2041-2070 | -41 | -33 | -16 |
| | 2071-2100 | -78 | -72 | -55 |
| SSP5-8.5 | 2011-2040 | -6 | -1 | 3 |
| | 2041-2070 | -50 | -43 | -29 |
| | 2071-2100 | -110 | -95 | -80 |
| Average | 2011-2040 | -7 | -3 | 2 |
| | 2041-2070 | -36 | -30 | -19 |
| | 2071-2100 | -66 | -59 | -48 |

**Table 36: Snow Depth Change Relative to 1986 to 2005 Predictions for British Columbia (ECCC 2019)**

| Representative concentration Pathway | Normal Period | Snow Depth Change (mm) | | |
|---|---|---|---|---|
| | | 25% | 50% | 75% |
| RCP2.6 | 2016-2035 | -46.5 | -41.4 | -12.7 |
| | 2046-2065 | -67.5 | -61.3 | -17.4 |
| | 2081-2100 | -72.6 | -68.4 | -21.3 |
| RCP4.5 | 2016-2035 | -43.8 | -39 | -10 |
| | 2046-2065 | -80.4 | -80.5 | -33.4 |
| | 2081-2100 | -109.1 | -105.4 | -37 |
| RCP8.5 | 2016-2035 | -52.8 | -50.1 | -14.1 |
| | 2046-2065 | -101 | -105.7 | -35.4 |
| | 2081-2100 | -159.4 | -176.4 | -58.9 |

# 6.0 CONCLUSION AND RECOMMENDATIONS

This report provides the five-year update of climate baseline at Mount Polley Mine Site as per Requirement 2.1 of the Global Industry Standards on Tailings Management (GISTM). The purpose of the update is to extend the existing long-term climate data for the Site using local and regional data collected in the last five years. The last climate baseline update was carried out by WSP Golder in 2016.

This report provides an updated climate baseline for precipitation, air temperature, relative humidity, solar radiation, evaporation, wind speed and direction, and snow depths, and includes updated climate change projections for the Site. Overall, trends in these climate parameters at Mount Polley are similar to those at Environment and Climate Change Canada (ECCC) regional stations. Future climate projections for Mount Polley show that the future climate at the Site would likely be warmer and wetter, with larger variations throughout the months. The greatest variation would likely be in summer months with a projected summer temperature increase of 7°C and less summer precipitation by the year 2100. Annual temperature is projected to increase by 2.7°C and annual precipitation is projected to increase by 8% from the baseline by 2100.

The updated climate parameters and extended long-term climate dataset are deemed to be representative of the climate at the Site and are suitable for support of design and modelling activities. It is recommended that MPMC continue to monitor and record climate data, and that the climate parameters be updated a minimum of every five years to encompass local and regional data collected, and to reflect uncertainties due to climate change.

# Predictions of Hydrogeological Conditions near the Springer and Cariboo Pits

# TECHNICAL MEMORANDUM

**DATE** 17 October 2016 **REFERENCE No.** 1411734-151-TM-Rev0-16000

**TO** Dale Reimer, General Manager
Mount Polley Mining Corporation

**FROM** Willy Zawadzki and Don Chorley **EMAIL** Willy_Zawadzki@golder.com; Don_Chorley@golder.com

**PREDICTIONS OF HYDROGEOLOGICAL CONDITIONS NEAR THE SPRINGER AND CARIBOO PITS – TECHNICAL ASSESSMENT REPORT – MOUNT POLLEY MINE**

## 1.0 INTRODUCTION

This technical memorandum presents seepage predictions for the Springer Pit and Cariboo Pit at the Mount Polley Mine, which is operated by Mount Polley Mining Corporation (MPMC). These predictions consider the mine plan that is incorporated into the Technical Assessment Report (TAR) being prepared for the mine by Golder Associates Ltd. (Golder). The predictions are based on the hydrogeological model (Figure 1) that was previously developed for the area adjacent to these open pits (Golder 2010, 2014) and that has been recently updated (Golder 2016) to include the results of the field program that was completed in the spring of 2015 (Golder 2015) and subsequent monitoring. The reader is referred to these documents for details of model development, the underlying assumptions, and the approach adopted to simulate open pit seepage.

This memorandum documents predictions of groundwater seepage near the Springer Pit and Cariboo Pit for the TAR. It is understood that the pit lake hydrology and the pit lake water quality and resulting seepage quality are assessed by concurrent studies conducted by MPMC and Golder.

## 2.0 MINE PLAN

MPMC provided the ultimate pit shells for the Springer and Cariboo pits that represent final configuration of the mine workings after four years of mining (Figure 2). From the perspective of seepage assessment, the key assumptions in the mine plan for these open pits are as follows:

- The Springer Pit and Cariboo Pit will be mined to the ultimate depths of approximately 878 m and 938 m elevation, respectively.
- The ground elevation along the pit wall separating the Springer Pit and Cariboo Pit will be approximately 1,028 m.
- Potentially acid generating materials will be placed in the Springer Pit and Cariboo Pit for subaqueous disposal up to an elevation of approximately 1,004 m.
- Tailings will not be deposited in the Springer Pit and Cariboo Pit (i.e., tailings currently deposited in the Springer Pit will be removed and transported to the Tailings Storage Facility).

## 3.0 SEEPAGE PREDICTIONS

The hydrogeological model was used to simulate groundwater conditions near the Springer Pit and Cariboo Pit for the scenario representing the fully dewatered conditions, scenarios representing rising pit lake levels up to the spillway elevation of 1,050 m, and fully developed pit lake with lake surface at 1,050 m elevation. In these model simulations, it was assumed that the potentially acid generating materials that will be placed in the Springer Pit have hydraulic conductivity significantly higher than the surrounding rockmass, and thus offer no resistance to seepage entering or exiting the pit lake.

For comparison purposes, Figure 3 and Figure 4 present hydrogeological conditions predicted by the calibrated model for the existing Springer Pit in mid-2014, when this pit was fully dewatered, and for July 2015, when the pit lake level was at an elevation of approximately 1,017.2 m. Figure 5 and Figure 6 present predictions for the fully dewatered Springer Pit at its ultimate configuration (Figure 5, panel A) and at increased pit lake levels up to the spillway elevation of 1,050 m (Figure 6, panel C). The corresponding seepage quantities predicted by the model are summarized in Table 1.

**Table 1: Predicted Seepage Quantities for the Ultimate Configuration of the Springer Pit and Cariboo Pit**

| | Springer Pit | | Cariboo Pit | |
|---|---|---|---|---|
| **Pit Lake Elevation (m)** | **Groundwater Flow ($m^3/d$)** | | **Groundwater Flow ($m^3/d$)** | |
| | **Into the Lake** | **Out of the Lake** | **Into the Lake** | **Out of the Lake** |
| **Base Case** | | | | |
| 880 (dewatered pit) | 520 | 0 | 600[a] | 0[a] |
| 940 | 510 | 0 | 610 | 0 |
| 960 | 490 | 0 | 610 | 0 |
| 980 | 460 | 0 | 590 | 0 |
| 1,000 | 420 | 0 | 540 | 0 |
| 1,020 | 320 | 10 | 460 | 0 |
| 1,030 | 300 | 100 | 420 | 0 |
| 1,040 | 280 | 250 | 380 | 0 |
| 1,050 (spillover elevation) | 270 | 400 | 320 | 20 |
| **Upper Bound** | | | | |
| 1,050 (spillover elevation) | 440 | 880 | 500 | 90 |
| **Lower Bound** | | | | |
| 1,050 (spillover elevation) | 190 | 220 | 250 | 0 |

a) These values represent conditions when the Cariboo Pit is fully dewatered (i.e. the base of the Cariboo Pit is at ~938 m elevation).

Model results indicated that when the Springer Pit and Cariboo Pit are at the ultimate configuration and are fully dewatered, the respective groundwater inflow to these pits would be approximately 520 $m^3/d$ and 600 $m^3/d$, respectively. When fully dewatered, both pits would act as strong groundwater sinks that would reverse groundwater flow between Bootjack Lake and the pit such that the seepage from Bootjack Lake to the underlying bedrock would occur. As the pit lake level is raised, the groundwater seepage into the pit lake was predicted to gradually decrease to approximately 270 $m^3/d$ in the Springer Pit and 320 $m^3/d$ in the Cariboo Pit once the spillway elevation of 1,050 m is reached.

In addition, as the pit lake level increases between 1,020 m and 1,030 m elevation, seepage in the range of 10 $m^3/d$ to 100 $m^3/d$ from the Springer Pit lake into the subsurface was predicted to occur. This seepage was found to gradually increase to approximately 400 $m^3/d$ when the pit lake reaches the spillover elevation of 1,050 m. In the Cariboo Pit, seepage towards Bootjack Lake of approximately 20 $m^3/d$ was predicted to occur only when the pit lake level approaches 1,050 m elevation. At this elevation, the pit lake was predicted to act as a "flow-through" lake with groundwater recharge occurring from the uplands located northeast from both pits and recharge to groundwater occurring towards the southwest.

Seepage pathways predicted for the conditions representing the pit lake at the spillway elevation are presented in Figure 7. Uncertainty in the predicted seepage rates, as presented in Table 1, was quantified using the same approach as the one that was adopted in previous analyses (e.g., Golder 2014).

## 4.0 CLOSURE

We trust that the above information is sufficient for your needs at this time. Should you have any questions or require clarification, please do not hesitate contact the undersigned at 604-296-4200.

# Study Limitations

This document has been prepared for the exclusive use of Mount Polley. The factual information, descriptions, interpretations, and comments contained herein are specific to the project described in this document and do not apply to any other project or site. Under no circumstances may this information be used for any other purposes than those specified in the scope of work unless explicitly stipulated in the text of this document or formally authorized by Golder. This document must be read in its entirety as some sections could be falsely interpreted when taken individually or out-of-context. As well, the final version of this document and its content supersedes any other text, opinion or preliminary version produced by Golder.

Golder shall not be held responsible for damages resulting from unpredictable or unknown underground conditions, from erroneous information provided by and/or obtained from other sources than Golder, and from ulterior changes in the site conditions unless Golder has been notified by Mount Polley of any occurrence, activity, information or discovery, past or future, susceptible of modifying the underground conditions described herein, and have had the opportunity of revising its interpretations, comments and recommendations. Furthermore, Golder shall not be held responsible for damages resulting from any future modification to the applicable regulations, standards and criteria, for any use of this document and its content by a third party, and/or for its use for other purposes than those intended. Golder shall not be held responsible for any decrease, real or perceived, of a property's value or any failure to complete a transaction, as a consequence of this document.

Hydrogeologic/hydrologic investigations and groundwater modelling are dynamic and inexact sciences. They are dynamic in the sense that the state of any hydrological system is changing with time, and in the sense that the science is continually developing new techniques to evaluate these systems. They are inexact in the sense that groundwater systems are complicated beyond human capability to evaluate them comprehensively in detail, and we invariably do not have sufficient data to do so. A groundwater model uses the laws of science and mathematics to draw together the available data into a mathematical or computer-based representation of the essential features of an existing hydrogeologic system. While the model itself obviously lacks the detailed reality of the existing hydrogeologic system, the behaviour of a valid groundwater model reasonably approximates that of the real system. The validity and accuracy of the model depends on the amount of data available relative to the degree of complexity of the geologic formations, the site geochemistry, the fate and transport of the dissolved compounds, and on the quality and degree of accuracy of the data entered. Therefore, every groundwater model is a simplification of a reality and the models described herein are not an exception.

The professional groundwater modelling services performed as described in this document were conducted in a manner consistent with that level of care and skill normally exercised by other members of the engineering and science professions currently practising under similar conditions, subject to the quantity and quality of available data, the time limits and financial and physical constraints applicable to the services. Unless otherwise specified, the results of previous or simultaneous work provided by sources other than Golder and quoted and/or used herein are considered as having been obtained according to recognised and accepted professional rules and practices, and therefore deemed valid. This model provides a predictive scientific tool to evaluate the impacts on a real groundwater system of specified hydrological stresses and/or to compare various scenarios in a decision-making process. However and despite the professional care taken during the construction of the model and in conducting the simulations, its accuracy is bound to the normal uncertainty associated to groundwater modelling and no warranty, expressed or implied, is made.

Mount Polley Mining Corporation

**FROM** Jesse Maddaloni and Darryl Howard **EMAIL Jesse.Maddaloni@wsp.com; Darryl.Howard@wsp.com**

**WATER TREATMENT UPDATE TO MINE PLAN AND RECLAMATION PROGRAM UPDATE 2022 – MOUNT POLLEY MINE**

## 1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) has developed a Mine Plan and Reclamation Program Update 2022 (herein referred to as the 2022 MRP) that is being submitted to the Ministry of Energy, Mines, and Low Carbon Innovation (EMLI) in compliance with the conditions outlined in the amendment to *Mines Act* Permit M-200. As required in the *Mines Act* Permit M-200 amendment, the 2022 MRP is being provided to EMLI as an update to the 2017 MRP. This technical memorandum provides an update on water treatment activities and progression since the 2017 MRP and discusses water treatment for the remaining operating phase of the mine as well as water treatment during closure/post-closure. The 2022 MRP incorporates the planned disturbance and corresponding reclamation requirements associated with continued mining until September 2024.

This water treatment update memorandum provides:

- A brief overview of the water management and treatment components that currently exist at the mine.
- Predicted and observed water quantity and quality design criteria for water treatment during operations and closure/post-closure.
- A summary the Best Achievable Technology (BAT) assessment previously completed for the mine and the associated technologies that are currently used for operations and considered for closure/post-closure.
- An update on work completed to investigate and advance various treatment technologies.
- An update on anticipated future work to support water treatment during closure/post-closure.

# 2.0 MINE WATER MANAGEMENT SUMMARY

A network of channels, ponds, and pumping systems is operated by MPMC for managing surface water at the mine. Contact and non-contact water systems are managed with the objective of avoiding the mixing of these waters.

The non-contact water system includes channels to divert runoff from undisturbed catchments away from mine infrastructure. Contact water from within the mine site is actively managed using on-site water management infrastructure and conveyed to the Tailings Storage Facility (TSF) or to the Perimeter Embankment Till Borrow Pond (PETBP) for re-use as part of mine operations or for treatment through the Water Treatment Plant (WTP) and subsequent discharge through a pipeline to Quesnel Lake. The ability to cycle water through the mine mill and back to the TSF or PETBP allows mill components to provide lime pre-treatment for precipitation of metals (copper) when required.

The mine has a positive water balance, with discharge required during mine operations to prevent year-on-year accumulation of water. The only currently permitted discharge of treated contact water from site occurs through the existing WTP and the Quesnel Lake pipe and diffusers. Water management during operations will continue per the current water management infrastructure. The existing WTP (Actiflo patented high-rate ballasted coagulation and flocculation process, with lime pre-treatment as required) is considered the BAT for treatment and discharge through assumed future operations (Golder 2015).

The design capacity of the existing WTP is 0.23 $m^3/s$. Additional temporary treatment capacity of 0.05 $m^3/s$ has been recently added in 2022 to assist in treating and discharging surplus contact water currently on-site (rental system of the same Actiflo technology). The allowable maximum annual discharge volume from site is currently 10.59 $Mm^3$/year (average of 0.33 $m^3/s$), as per Environmental Management Act (EMA) Permit 11678. The design capacity of the WTP effluent pipeline and diffusers is 0.6 $m^3/s$ (equivalent to the permitted maximum daily instantaneous rate).

The mine's water management plan assumes minimal storage of contact water on site, although during freshet (April through June) and extreme storm events, the volume of mine water runoff will exceed the discharge and treatment capacity, and temporary retention will be necessary to store water prior to discharge. Temporary water accumulation will occur in the TSF or in available pit volume(s). Temporary stored water will be discharged to the environment through the WTP following the freshet period or the storm event.

As the mine moves into closure and post-closure, the objectives of water management are to return the impacted land to pre-mining land functions. As the mine is constructed across a watershed divide, it is desired that during the post-closure period, drainages will be distributed back to their natural watersheds (i.e., to Bootjack Lake, Polley Lake, and Hazeltine Creek), provided that this can be achieved in an environmentally appropriate and permittable manner. MPMC has been proceeding with a program of evaluating and developing passive, semi-passive, and active water treatment technologies for their possible use during mine closure to support the goal of distributing discharge back into the pre-mining configuration. Two treatment options are considered the BAT for treatment during closure and post-closure: Option A – distributed passive/semi-passive treatment systems (applied to select sources), and Option B – pit-lake treatment followed by the centralized Actiflo plant (Golder 2016a). Option B is the current assumption for water treatment during closure/post-closure, but MPMC has also been progressing technology evaluations to support Option A.

# 3.0 WATER TREATMENT DESIGN BASIS

A Site-Wide Water Balance and Water Quality Model (SWWBM) was used to predict flow rates and water quality for mine contact water requiring treatment during operations, closure, and post-closure (Golder 2022a, Golder 2022b). The SWWBM uses a stochastic function to estimate the level of modeled precipitation. Out of 1,000 realizations, 90$^{th}$ percentile results represent the highest 10% of precipitation. The 90$^{th}$ percentile scenario was modeled for the remaining duration of the operational period, and the analysis showed that the existing WTP capacity provides sufficient treatment capacity for this period (Golder 2022a). For closure and post-closure, the model was again used to predict 90$^{th}$ percentile treatment flow rates for the period of 2025 to 2124. For the closure period of 2025 to 2034, results showed that an average treatment capacity of 0.19 $m^3/s$ would be sufficient for the 90$^{th}$ percentile precipitation amount (Golder 2022a). For the post-closure period of 2035 to 2124, results showed than an average treatment capacity of 0.08 $m^3/s$ would be sufficient for the 90$^{th}$ percentile precipitation amount (Golder 2022a).

## 3.1 Operations Water Quality

The SWWBM was used to predict water quality at the PETBP during operations (the current influent source to the WTP). Table 1 provides a list of constituents of interest determined following review of modeled water quality predictions during operations (Golder 2022b). Table 1 compares the current EMA Permit 11678 WTP discharge limits with the predicted 95$^{th}$ percentile parameter concentrations in the PETBP.

**Table 1: WTP Influent Water Quality During Operations**

| Parameter | Unit | EMA Permit 11678 WTP Discharge Limit | PETBP 95$^{th}$ Percentile Predicted Concentrations |
|---|---|---|---|
| **Major Ions** | | | |
| Total Sulphate | mg/L | 1,100 | 705 |
| **Nutrients** | | | |
| Total Ammonia | mg/L (as N) | 1.3 | 0.24 |
| Total Nitrate | mg/L (as N) | 34 | 21 |
| Total Phosphorus | mg/L | 0.09 | 0.04 |
| **Total Metals** | | | |
| Arsenic | mg/L | 0.028 | 0.002 |
| Chromium | mg/L | 0.004 | 0.001 |
| Copper | mg/L | 0.033 | **0.273** |
| Iron | mg/L | 1.0 | 0.62 |
| Manganese | mg/L | 3.4 | 0.70 |
| Molybdenum | mg/L | 0.36 | 0.19 |
| Selenium | mg/L | 0.075 | **0.105** |
| Zinc | mg/L | 0.059 | 0.019 |

Notes:

1) **Bold and underlined** values exceed permitted discharge limits. These EMA Permit 11678 discharge limits apply to the effluent of the WTP, and not to be PETBP (WTP influent). PETBP water quality predictions are shown to demonstrate the requirement for treatment of a water quality parameter.
2) The SWWBM was developed to predict water quality conservatively; where uncertainty exists in the model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected.

Table 1 shows that total copper and total selenium are predicted to require treatment during operations. Total Suspended Solids (TSS), not listed in Table 1, is also required for treatment during operations. The existing WTP has been shown to effectively treat both TSS and total copper for the majority of operating conditions (discussed in more detail in Golder 2022c). WTP influent and effluent quality were assessed over six years between 2016 and 2021, showing effluent TSS consistently below permit limit and effluent total copper only occasionally above permit limit, with high influent copper instances managed through temporary WTP recirculation without discharge and a Trigger Response Plan (Golder 2022c).

Total selenium is modeled to require treatment during operations, as predicted by the 95$^{th}$ percentile PETBP concentration shown in Table 1. Even though predictions show that PETBP total selenium concentration could be above the permit limit, monitoring data has shown actual total selenium in the PETBP consistently below the permit limit (Golder 2022c). The water treatment system during operations has not required selenium treatment and it is not anticipated to require selenium treatment for the remainder of operations.

## 3.2 Closure/Post-Closure Water Quality

The SWWBM was used to predict water quality at the PETBP during closure/post-closure. The PETBP may not collect all treatment influent water in the final post-closure water treatment configuration (particularly if distributed treatment and discharge can be permitted), but collection to this location has been assumed for the purposes of the 2022 MRP as it represents the currently permitted system configuration. Table 2 provides a list of constituents of interest and the 95$^{th}$ percentile predicted concentrations in the PETBP during closure and post-closure (Golder 2022b). Table 2 also compares predicted PETBP water quality to MPMC's current EMA Permit 11678 WTP discharge limits. These WTP discharge limits have been assumed for closure/post-closure as they represent the currently permitted treatment requirements. Distributed treatment during closure/post-closure may discharge to different receiving environments with different discharge limits than the existing EMA Permit, but the current limits have been assumed for closure/post-closure for the purposes of the 2022 MRP.

**Table 2: WTP Influent Water Quality During Closure/Post-Closure**

| Parameter | Unit | EMA Permit 11678 WTP Discharge Limit | PETBP 95th Percentile Predicted Concentrations – Closure | PETBP 95th Percentile Predicted Concentrations – Post-Closure |
|---|---|---|---|---|
| **Major Ions** | | | | |
| Total Sulphate | mg/L | 1,100 | 654 | 282 |
| **Nutrients** | | | | |
| Total Ammonia | mg/L (as N) | 1.3 | 0.24 | 0.027 |
| Total Nitrate | mg/L (as N) | 34 | 19 | 5.2 |
| Total Phosphorus | mg/L | 0.09 | 0.036 | 0.036 |
| **Total Metals** | | | | |
| Arsenic | mg/L | 0.028 | 0.0018 | 0.0019 |
| Chromium | mg/L | 0.004 | 0.0014 | 0.0018 |
| Copper | mg/L | 0.033 | **0.3** | **0.17** |
| Iron | mg/L | 1.0 | 0.68 | 0.23 |
| Manganese | mg/L | 3.4 | 0.75 | 0.23 |
| Molybdenum | mg/L | 0.36 | 0.17 | 0.074 |
| Selenium | mg/L | 0.075 | **0.078** | 0.033 |
| Zinc | mg/L | 0.059 | 0.014 | 0.0067 |

Notes:

1) **Bold and underlined** values exceed permitted discharge limits. These EMA Permit 11678 discharge limits apply to the effluent of the WTP, and not to be PETBP (WTP influent). PETBP water quality predictions are shown to demonstrate the requirement for treatment of a water quality parameter.
2) The SWWBM was developed to predict water quality conservatively; where uncertainty exists in the model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected.

Table 2 shows that total copper and total selenium are predicted to require treatment during closure, with only total copper requiring treatment during post-closure. TSS, not listed in Table 2, is also required for treatment during closure/post-closure.

The assumed treatment system during closure/post-closure is pit-lake treatment followed by the centralized Actiflo plant (existing WTP), with the possibility of distributed passive/semi-passive treatment if systems are environmentally appropriate and permittable. TSS treatment is assumed to be required through closure and post-closure and will be achieved with the Actiflo plant. Total copper treatment is predicted to be required through closure and post-closure and will be achieved with a combination of the Actiflo plant (total copper removal through TSS removal), and future trimercapto-striazine trisodium salt (TMT) pre-treatment, if required (for dissolved copper precipitation).

Total selenium treatment is predicted to be required during closure, but not during post-closure. If required, the assumed method of selenium treatment is semi-passive pit-lake pre-treatment (active dosing of carbon source to pit-lake), followed by treatment by the Actiflo plant. It is not currently known whether selenium treatment will be required during the closure/post-closure phases, as existing monitoring data has consistently shown total selenium in site contact water to be below discharge limits. If selenium treatment is required, MPMC has been progressing the development of multiple treatment technologies that target selenium.

Details on modeled water quality concentrations for all parameters and various site locations (in addition to the PETBP) can be found in Golder 2022b.

# 4.0 WATER TREATMENT TECHNOLOGY DEVELOPMENT

MPMC has been progressing and evaluating multiple technologies to support the treatment of identified constituents of concern (COCs) and to support potential decentralized treatment and discharge during closure/post-closure. Various studies have been completed since 2017 to support these efforts as an important component of closure refinement. An inventory of treatment technologies and a summary of their development is presented in Table 3.

Good engineering practice typically requires a project to follow a standardized engineering design process for the selection and progressive refinement of the final project concept. A project progresses from a pre-concept phase for the identification of multiple treatment options, through concept, pre-feasibility, and feasibility phases to project execution. Generally, the engineering studies performed for each of these project phases are supported by test work that progresses from proof-of-concept and detailed bench-scale testing to pilot-scale and demonstration-scale test work. Some of the treatment technologies tested may not progress to the next stage of development. For example, a treatment technology may be eliminated if its treatment capacity is insufficient to treat the forecast volumes. This framework takes a staged approach, such that input assumptions, design, and cost for the total system can be refined as each stage is completed and the information that the plan relies on becomes more certain. This allows input assumptions to be less conservative as they become more accurate with accumulated knowledge. The technology development stages presented in Table 3 align with this approach. Additional details regarding this project development framework and how it aligns with the BC Ministry of Environment and Climate Change Strategy's BAT policy is provided in Golder 2020a.

This water treatment update technical memorandum assumes that the reader is familiar with the technologies in Table 3 and only provides updates on work completed by MPMC since 2017 to support the development of these technologies. Detailed descriptions of the technologies and associated process flow schematics can be found in Golder 2020a.

**Table 3: Treatment Technology Inventory and Stage of Development**

| Technology / Stage of Development | Targeted COCs | Proof-of-Concept Bench-Scale Testing | Detailed Bench-Scale Testing | Pilot-Scale Testing | Demo-Scale Testing | Full-Scale Execution | Work Completed |
|---|---|---|---|---|---|---|---|
| Actiflo | TSS, total copper | | | | | → | Bench and full-scale testing. |
| Lime Treatment | Dissolved copper | | | | | → | N/A |
| TMT Treatment | Dissolved copper | → | → | → | → | | Bench and full-scale testing. Toxicity evaluation. |
| Pit-Lake Treatment | Selenium, nitrate | → | → | → | | | Preliminary concept design and proof-of-concept bench-scale testing. Pilot-scale testing workplan. |
| Saturated Rock Fill (SRF) | Selenium, nitrate | → | → | | | | Concept design, proof-of-concept bench-scale testing, detailed bench-scale testing workplan (in progress), and long-term substrate leach testing. Wight Pit SRF assessments. |
| Packed Bed Reactor (PBR) | Selenium, nitrate | → | → | | | | Concept design, proof-of-concept bench-scale testing, and detailed bench scale testing workplan (in progress). |
| Biochemical Reactor (BCR) | Selenium, nitrate | — | — | | | | Concept design and proof-of-concept bench-scale testing. |
| Submerged Sand Reactor (SSR) | Selenium, nitrate | — | | | | | Screening analysis. |
| Constructed Wetland Treatment (CWT) | Selenium, nitrate | → | → | → | | | Concept design, bench-scale testing, and on-site pilot scale testing (by others). |

Implemented → Under Consideration → Eliminated/Paused —

## 4.1 Actiflo

Actiflo, the tradename of a technology supplied by Veolia, is the technology currently in use as the site's WTP and is considered the BAT for TSS removal during operations and closure/post-closure. The main targeted COC of this technology is TSS, with total copper removal also occurring via TSS removal. Polyaluminum chloride (PAC) is dosed into the influent water in the Actiflo process, which produces aluminum hydroxide precipitates that adsorb to copper complexes, thus removing copper during the solids-liquids separation step of the process. The Actiflo technology is currently implemented at full-scale on-site, as indicated in Table 3.

Concept design, bench-scale, and full-scale testing have been completed for the Actiflo technology, including assessment and optimization of PAC and various chelating agent dosages (including TMT) to assist copper removal (Golder 2016b, Golder 2017a, Golder 2018a, Golder 2019a, Golder 2019b, Golder 2020b).

Actiflo treatment is currently operating as the core component of the treatment system during operations and is currently assumed as the core component of treatment during closure/post-closure.

## 4.2 Lime Treatment

Active treatment with lime is currently in use at the site, where existing process plant infrastructure is used to raise contact water pH, resulting in the precipitation of metal hydroxides, particularly dissolved copper. The main targeted COC of this technology is dissolved copper. Lime treatment is currently implemented on-site, as indicated in Table 3, and used as a pre-treatment step of the Actiflo water treatment system to target dissolved copper removal. Use of this technology is well known to industry and technology development to support this has not been required.

Lime treatment, when required, is currently a component of the water treatment system during operations.

## 4.3 TMT Treatment

TMT is a chelating agent that aids with dissolved copper precipitation that allows copper treatment through TSS removal. The main targeted COC of this technology is dissolved copper.

Bench-scale test work completed showed that TMT is able to effectively precipitate dissolved copper (Golder 2016b, Golder 2017a, Golder 2018a) and the full-scale trials completed showed that the existing Actiflo treatment system was able to remove the copper bound with TMT to below the permit limit (Golder 2019a, Golder 2019b, Golder 2020b). Full-scale trials also showed that copper removal to lower concentrations (total copper <0.012 mg/L) was challenging for Actiflo with TMT treatment, not due to limitations in dissolved copper precipitation but due to limitations in TSS removal. TMT was effective in precipitating dissolved copper, but the Actiflo system was not effective in subsequently removing the precipitate to result in low effluent copper concentrations. The toxicity of TMT has also been evaluated and showed that its use would not result in an acutely lethal effluent (Golder 2018b).

TMT treatment is still being considered for full-scale implementation.

## 4.4 Pit-Lake Treatment

Pit-lake treatment targeting COCs of selenium and nitrate is an in-situ technology that requires nutrient and carbon source dosing to create conditions for biological treatment within the pit-lake.

A conceptual assessment of full-scale pit-lake selenium treatment was completed (Golder 2017b) and the technology was deemed a cost-effective approach to managing selenium and was recommended for further bench and pilot-scale testing. Proof-of-concept bench-scale testing for pit-lake selenium treatment was also completed and showed effective removal of selenium and nitrate, with further pilot-scale testing recommended (Golder 2019c). A pilot-scale study for pit-lake treatment was designed for Cariboo Pit (Golder 2020c), but the pit is being dewatered to support future mining activities and this work has not yet been completed.

Pit-lake treatment targeting selenium and nitrate is still being considered for full-scale implementation and is currently assumed as part of the treatment system during closure/post-closure if required.

## 4.5 Saturated Rock Fill (SRF)

SRF treatment is a fixed-film anaerobic system targeting the treatment of selenium and nitrate and ideally utilizes a mined-out open pit as a bioreactor operated in a horizontal flow configuration.

A concept study for SRF treatment was completed (Golder 2020d) and SRF was recommended for further bench-scale and pilot-scale testing. Proof-of-concept bench-scale testing for SRF was also completed (Golder 2021), which showed effective removal of selenium and nitrate, but also indicated metal leaching. Detailed bench-scale testing and waste rock SRF substrate metal leach testing was recommended following completion of the proof-of-concept work. Bench-scale leach testing using anticipated SRF substrate waste rock from site was completed (Golder 2022d – draft RevA), which monitored leached metals over a long-term test period of 52 weeks. Results showed that metal leaching varies over time and differs between metals and must be considered during the start-up phase of SRF implementation (and may lead to additional required polishing treatment steps downstream of the SRF). Detailed bench-scale testing for SRF has been proposed for 2023 and a test plan has been submitted in draft to MPMC (Golder 2022e – draft RevA). Geotechnical and geochemical substrate characterization for SRF media waste rock is currently ongoing and anticipated for completion in 2023. It is anticipated that geochemical substrate characterization will be conducted by MPMC's geochemical consultant SRK.

SRF treatment is still being evaluated for full-scale implementation and is currently considered a technology option for semi-passive treatment of selenium and nitrate during closure/post-closure if required.

## 4.6 Packed Bed Reactor (PBR)

PBR treatment is another fixed-film anaerobic system targeting the treatment of selenium and nitrate. PBR treatment differs from SRF treatment through the use of a vertical flow (top to bottom) reactor.

Proof-of-concept bench-scale testing was completed (Golder 2019d) and PBR treatment was shown to be effective in reducing selenium and nitrate. Further detailed bench-scale and pilot-scale testing was recommended following completion of the initial testing. Detailed bench-scale testing for PBR has been proposed for 2023 and a test plan has been submitted in draft to MPMC (Golder 2022f – draft RevA).

PBR treatment is still being evaluated for full-scale implementation and is currently considered a technology option for semi-passive distributed treatment of selenium and nitrate during closure/post-closure if required.

## 4.7 Biochemical Reactor (BCR)

BCR treatment is another fixed-film anaerobic treatment technology that consists of a lined pond filled with a submerged organic substrate media mix. The main targeted COCs of this technology are selenium and nitrate. BCR treatment is passive and does not involve continuous dosing of a carbon source to the media bed.

Proof-of-concept bench-scale testing was completed (Golder 2019d) and BCR treatment was shown to be effective in reducing selenium and nitrate, but redox sensitive metals were present in the BCR effluent.

Upon review of the BCR technology in comparison to other passive and semi-passive technologies, MPMC decided to not proceed with further development of this technology (MPMC 2021) for the following reasons:

- Limited lifespan of BCR passive treatment systems based on the availability of a carbon source that is encapsulated in the system during construction – this needs to be replaced periodically at significant cost.
- Emission of elevated levels of biochemical oxygen demand (BOD) from the system during commissioning and start-up of operation that exceed standards for discharge to the environment.
- Persistent emission of phosphorus from the BCR during operation that will likely exceed plausible standards for discharge to the environment.

BCR treatment is no longer being developed as a passive treatment technology option during closure/post-closure.

## 4.8 Submerged Sand Reactor (SSR)

SSR is similar to other anaerobic reactor technologies, with the use of the existing tailings as media for the bioreactor. The main targeted COCs of this technology are selenium and nitrate.

A concept study was completed for SSR (Golder 2020d), as well as proof-of-concept bench-scale testing (Golder 2019d). Use of MPMC tailings as SSR bioreactor media or use of the site's TSF as an in-situ SSR was not recommended for further investigation. Bench-scale testing resulting in metal release in the reactor effluent when using site tailings as the reactor media. The concept study also concluded that further investigation of SSR was not warranted, based on a review of literature, an evaluation of historical water quality monitoring data, and an evaluation of the feasibility of utilizing the TSF from a hydrogeological and permitting perspective.

SSR treatment is no longer being developed as a treatment technology option during closure/post-closure.

## 4.9 Constructed Wetland Treatment (CWT)

MPMC retained Ensero Solutions Inc. (Ensero), formerly known as Contango Strategies Ltd., to conduct a detailed assessment and evaluation of the feasibility of a CWT system for passive/semi-passive treatment during closure/post-closure. The main targeted COCs of this technology are selenium and nitrate.

Pilot-scale design, sizing, and testing for CWT was completed by Ensero (Ensero 2020), and the technology demonstrated promising results for treatment of targeted COCs; however other passive/semi-passive technologies have indicated improved treatment capability in comparison. MPMC may choose to proceed with demonstration-scale on-site testing of CWT once the pilot-scale results have been fully understood and if the performance of competing technologies (SRF and others) indicates an advantage for CWT.

CWT is still being evaluated for full-scale implementation and is currently considered a technology option for passive/semi-passive and distributed treatment of selenium and nitrate during closure/post-closure if required.

# 5.0 ANTICIPATED FUTURE WORK

The existing and assumed water treatment systems for operations, closure, and post-closure have been outlined in this memorandum; however, changes may still be implemented during all phases of the mine as knowledge and needs evolve. The water treatment system for closure/post-closure will continue to develop in more detail as MPMC better understands technology capabilities and refines their final approach to water treatment for the closure period.

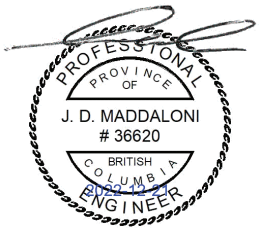

Table 3 provides a summary of the development stage of the treatment technologies implemented or being considered for operations, closure, and post-closure. Future work is anticipated for any technology still under consideration that has not achieved full-scale implementation. The following items describe the priority treatment work anticipated over approximately the next three years, but do not exhaustively describe all potential remaining work for technologies still under consideration:

- Actiflo technology is a component of the operations and closure/post-closure BAT and a main component of the existing treatment system during operations and assumed treatment system during closure/post-closure. Further development of the technology is anticipated with respect to PAC and TMT usage, as well improving the solid-liquid separation in the process to address potential high-copper instances. Several recommendations for future system improvements have been outlined in Golder 2020b, including supporting bench-scale and field trials. Recommendations are mainly focused on improving removal of particulate copper from the WTP effluent and improving the effectiveness of PAC and TMT use.
- Pit-lake treatment is currently assumed as a component of the closure/post-closure treatment system. Pilot-scale pit-lake work was anticipated for Cariboo pit, but recent mine operational changes have resulted in the draining of both Springer and Cariboo pits and pit-lake treatment trials are no longer feasible at these locations. Operational changes have also resulted in Wight pit being filled. The previous pilot-scale study designed for Cariboo pit (Golder 2020c) could be redesigned for Wight pit if operational conditions in the near future are deemed appropriate, further advancing the development of this technology.
- Two options exist as the BAT for treatment during closure/post-closure: distributed passive/semi-passive treatment systems, and pit-lake treatment followed by the centralized Actiflo plant. Golder has proposed to undertake a treatment option life cycle cost comparison study between the two options, informed by the knowledge gained during recent technology development, to assess pros/cons and capital and operating costs between the options and inform future treatment program development decisions.
- SRF and PBR detailed bench scale testing have been proposed to MPMC and this work is expected for completion in the near future to continue the development of these technologies.

## 6.0 CLOSURE

The reader is referred to the Study Limitations section, which precedes the text and forms an integral part of this memorandum. We trust that the information provided herein is sufficient for your needs at this time. If you have any questions or need additional information, please do not hesitate to contact us.

**MOUNT POLLEY MINE WATER BALANCE MODEL – RECLAMATION AND CLOSURE**

## 1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) retained Golder Associates Ltd., a member of WSP (WSP Golder) to update the Site Wide Water Balance Model (SWWBM) to support the water management information requirements for the Five Year Mine Reclamation and Closure Plan. This exercise is a requirement outlined in MPMC's Ministry of Energy, Mines and Low Carbon Innovation (EMLI) Mines Act Permit M-200 (amended 10 December 2020).

The SWWBM was developed using GoldSim™, a highly graphical software for carrying out dynamic, probabilistic simulations to support decision-making (GoldSim 2018). GoldSim™ is frequently used to evaluate water management alternatives, perform sensitivity analyses, and conduct mass balance simulations.

The SWWBM was developed as part of the Mount Polley Mine Resumed Operations and Closure Water Management Plan Permit Amendment Application and Technical Assessment Report (Golder 2016a) to model water management across the site. The details of the SWWBM are described in the Mount Polley Mine Water Balance Report (Golder 2016b). The SWWBM was updated in the Water Management Plan that addresses water management through future operations (Golder 2020).

The SWWBM in this exercise was updated to include the closure and post-closure phases for the period of 1 September 2024 to 1 September 2124. The updated SWWBM simulates the site water circuitry (the logic driving water transfers, discharges, and flows on site) during the closure and post-closure phases. The closure phase is planned to commence on 1 September 2024 and will include closure and reclamation activities as identified in the Mine Reclamation and Closure Plan Update. The post-closure phase is assumed to commence on 1 September 2034 and extends, for the purposes of this analysis, to 2124.

This technical memorandum presents the updates made to the SWWBM for consistency with the remaining currently permitted mine plan and the proposed closure configuration. Included herein is a summary of the model updates, the assumptions made for the five year mine and reclamation plan, the model inputs, and a discussion of the model results.

# 2.0 MODEL UPDATE

This section describes the implementation of updates to reflect the currently approved mine plan and the closure configuration, and the model inputs for the SWWBM during the closure and post-closure phases.

## 2.1 Summary of Model Updates

An update to the existing SWWBM was carried out using GoldSim™ (Version 14.0). The SWWBM was originally developed for the TAR to support the effects predictions in the Mount Polley Mine Long Term Water Management Plan (Golder 2016a) for the mine and has since been calibrated on an annual basis (refer to Golder 2022 for 2021 annual calibration). The SWWBM was updated to include the closure and post-closure phases for the period of 1 September 2024 to 1 September 2124. The model updates were as follows:

- Included a closure phase extending from 1 September 2024 to 31 August 2034.
- Included a post-closure phase commencing on 1 September 2034 and extending, for the purposes of this analysis, to 2124.
- Updated the SWWBM with the currently approved mine plan.
- Updated flows for the closure configuration, including discharges to the environment and the transfer flows.
- Added the combined Springer-Cariboo Pit (Springer Pit and Cariboo Pit will combine into one pit in the closure phase), including updated stage storage curve and updated direct precipitation, runoff and groundwater inflows from 1 September 2024 based on the Springer-Cariboo Pit closure design surface provided by MPMC.
- Added configuration of the TSF to reflect a 970 m dam crest elevation for the purpose of closure phase modelling.
- Updated climate inputs according to the Climate Baseline Update Report (Golder 2022).
- Added climate change scenarios.

## 2.2 Model Scope and Flow Diagram

The scope and structure of the SWWBM is outlined in the conceptual flow diagrams for assumed closure phase and post closure phase in Figure 1 and Figure 2, respectively. The flow diagrams illustrate the water circuit system at the Mine, including the storage and conveyance of water. A description of the model flows is provided in Attachment A. The water management infrastructure within the SWWBM for the closure and post-closure phases are summarized in Table 1. The flow types that are programmed into the SWWBM are outlined in Table 2.

## 2.3 Key Input Parameter Values and Assumptions

Key initial parameter values and assumptions for the closure phase model simulations are presented in Table 3.

**Table 3: Key Initial Parameter Values and Assumptions for Closure Phase**

| Parameter | Value | Notes |
|---|---|---|
| Spillway Invert Elevation | 965.7 masl | Deposition of tailings in the TSF is assumed to be complete. |
| Initial Springer-Cariboo Pit Water Volume | 0 $m^3$ | Combined Springer-Cariboo Pit assumed to be empty at the start of the closure phase. |
| PAG Waste Rock Void Ratio | 0.33 | PAG waste rock is stacked uniformly to an elevation of 1,004 masl in the base of the Springer-Cariboo Pit, and no water is stored within the pit. |
| Initial TSF Volume | 264,102 $m^3$ | Assumes that at the end of the operations, the TSF pond is drained to the spillway invert elevation. |
| Initial Boundary Pit Water Volume | 1,601 $m^3$ | Arbitrarily assumed. There is no plan to dewater this pit. |
| Initial Wight Pit Water Volume | 0 $m^3$ | Pit is assumed to be empty at the start of the closure phase. |
| Initial 9K Sump Water Volume | 100 $m^3$ | Arbitrarily assumed. |
| Initial NW Sump Water Volume | 100 $m^3$ | Arbitrarily assumed. |
| Initial South Seepage Pond Water Volume | 100 $m^3$ | Arbitrarily assumed. |
| Snowpack | Stochastically generated | The summation of precipitation depths for December, January, and February (3 months). |

# 3.0 MODEL INPUTS

## 3.1 Climate Inputs

Climate datasets are used in the SWWBM to run various deterministic and stochastic scenarios. The climate datasets were derived from local and site-based climate stations as described in Mount Polley Mine Climate Baseline Update (Golder 2022).

### 3.1.1 Deterministic Climate Inputs

The model features a deterministic simulation mode, where two climate scenarios have been predefined, based on long-term Environment and Climate Change Canada and local data:

- Average annual precipitation data: The associated annual precipitation is repeated for each year of the simulation period. Annual average lake evaporation is assumed, and snowpack is accumulated within the model based on the assumption that snow accumulates from December to February, with 5%, 90%, and 5% of the accumulated snowpack melting in March, April, and May, respectively.

- Climate change: An ensemble of monthly temperature and precipitation projections were obtained from ClimateBC consisting of 9 climate models and 2 emissions scenarios (SSP2-4.5 and SSP5-8.5) covering mid to high emissions from the Sixth Intergovernmental Panel on Climate Change Assessment Report (IPCC 2021). A stochastic approach (outside the Goldsim model) was used to extend these projections from the year 2100 to 2200 by resampling monthly data from 2071 to 2100 projections and relating projected changes in temperature and precipitation climate variables to a set of extended greenhouse gas concentration pathways beyond the year 2100 (van Vuuren et al. 2011). The range of projected temperature and precipitation values for each month was summarized across the ensemble of climate models and emission scenarios using a range of values. The mean and upper bound results have been included in the deterministic simulation mode of SWWBM to analyze the potential effects of climate change. Lake evaporation, snow accumulation and snowmelt are calculated in the same way as for the average climate scenario.

### 3.1.2 Stochastic Climate Inputs

GoldSim™ has stochastic elements, allowing uncertainty to be represented in model input data. GoldSim™ uses the Monte Carlo method to sample stochastic elements for probabilistic simulations. A stochastic generator is included in the model to probabilistically simulate natural climatic variation at the mine. The stochastic generator operates on a monthly basis and generates random sequences of monthly precipitation over the simulation period; one such random sequence over the simulation period is called a “realization”. Stochastic climate input is used to model a wide range of precipitation inputs and acts as a sensitivity analysis that can be easily viewed as results in the form of percentile values.

To simulate stochastic conditions, monthly precipitation data were fitted to a log-normal probability distribution. A probability distribution is a mathematical representation of the relative likelihood of an uncertain variable having specific values; all distribution types use a set of arguments to specify the relative likelihood for each possible value. The arguments for log-normal distribution are the dataset’s mean and standard deviation. The mean and standard deviation for the monthly precipitation values are shown in Table 4.

**Table 4: Stochastic Climate Generator Log-Normal Distribution Input Arguments**

| Month | Mean of the Monthly Precipitation Depths (mm) | Standard Deviation of the Monthly Precipitation Depths (mm) |
|---|---|---|
| January | 49.4 | 30.9 |
| February | 35.8 | 24.2 |
| March | 29.7 | 13.9 |
| April | 44.7 | 43.6 |
| May | 49.9 | 20.2 |
| June | 70.8 | 32.9 |
| July | 63.6 | 55.1 |
| August | 50.6 | 31.2 |
| September | 52.3 | 30.1 |
| October | 58.1 | 27.9 |
| November | 49.8 | 28.9 |
| December | 57.6 | 32.7 |

The derived monthly means and standard deviations of the precipitation values, defined in the model as stochastic elements, were used to generate random values based on the normal distribution of the dataset. The stochastic generator was set to perform 1000 realizations to create a sample size that was sufficiently large to account for a range of conceivable monthly climatic precipitation scenarios for the study period. The probabilistic results from each realization were compiled to generate percentile values, the value below which a certain percentage of the realizations occur. For example, the 90$^{th}$ percentile is the value for which 90% of the realizations are equal to or less than. Conversely, 10% of the realizations are greater than this value.

## 3.2 Hydrology Inputs

The following sections describe the hydrologic processes and inputs used in the closure and post-closure phases.

### 3.2.1 Runoff Parameters

Runoff for closure and post-closure phases in the SWWBM is estimated using seasonal runoff coefficients. Runoff coefficients represent the proportion of rainfall that reports as runoff or seepage, accounting for losses due to evaporation, storage, and infiltration. The runoff coefficients account for the following two seasonal climate periods:

- **General (July to February)** – mid-range coefficients to reflect soil moisture contents for intermittent runoff events.
- **Freshet (March to June)** – highest runoff coefficients to represent expected higher soil moisture content, and therefore greater runoff.

The seasonal runoff coefficients defined for the catchment types considered in the SWWBM are presented in Table 5.

**Table 5: Seasonal Runoff Coefficients**

| Catchment Type | General | Freshet |
|---|---|---|
| Exposed tailings | 0.6 | 0.9 |
| Disturbed areas | 0.3 | 0.9 |
| Rock disposal site areas | 0.1 | 0.6 |
| Open pits | 0.75 | 0.9 |
| Undisturbed catchments | 0.4 | 0.42 |
| Haul roads and access roads | 0.15 | 0.9 |
| Mill site area | 0.1 | 0.1 |

Source: Golder 2020.

### 3.2.2 Catchment Areas

The catchment areas for each storage element included within the SWWBM are unchanged from the TAR (Golder 2016a) and are shown in Table 6.

**Table 6: Catchment Areas for SWWBM Storage/Conveyance Elements for Closure and Post-closure**

| Storage or Conveyance Element | Total Reporting Area ($m^2$) |
|---|---|
| South Seepage Pond | 385 |
| Main Embankment Seepage Pond | 376,900 |
| TSF upstream catchment (external) | 622,800 |
| TSF impoundment catchment (internal) | 2,269,700 |
| PETBP | 524,300 |
| CCS | 438,600 |
| Bootjack Creek Sump | 175,200 |
| SERDS Ditch | 1,537,600 |
| Mill Site Sump | 1,630 |
| Mine Drainage Creek Sump | 1,115,900 |
| Long Ditch | 2,494,000 |
| Springer-Cariboo Pit | 1,974,000 |
| NW Sump | 330,200 |
| 9K Sump | 698,800 |
| Wight Pit | 413,900 |
| Boundary Pit | 23,400 |
| **Total Reporting Area** | **12,997,315** |

Source: Golder 2016a

## 3.3 Storage Capacities

Free water volumes in storage ponds, sumps, and tailings facilities depend on a balance between inflows and outflows. The stage (water elevation) can be directly correlated to a specific storage volume using site bathymetric (sub-aqueous surface) and topographic (land surface) data. These relationships are referred to as stage storage curves.

Stage storage curves were used for the following major storage elements:

- Combined Springer-Cariboo Pit (closure design surface from MPMC).
- TSF (step 15 of 2% slope tailings deposition plan from 2017 Closure and Reclamation Mount Polley Mine Water Balance Model [Golder 2017]).
- Wight Pit (13 January 2022 bathymetric survey).

Dynamic storage facilities such as the TSF (tailings deposition changes the available storage) require regular survey updates to confirm whether existing stage storage curves are appropriate for projecting free water volumes. An updated stage storage curve for the TSF up to a dam crest elevation of 970 m for the closure and post-closure phases was not available at the time of writing of this technical memorandum; therefore, the start of closure stage storage curve estimated in the 2017 Closure and Reclamation Mount Polley Mine Water Balance Model (Golder 2017) was used in this analysis.

The estimated volume capacities for the facilities listed above are presented in Table 7.

**Table 7: Maximum Capacities for Major Storage Facilities**

| Storage Facility | Estimated Capacity ($M\text{-}m^3$) |
|---|---|
| Springer-Cariboo Pit Final Mine-Out (Phase 4 – M-200 Permitted Mine Plan) | 30.3 |
| TSF – Final Layout | 0.26 |
| Wight Pit | 3.8 |

## 3.4 Discharge Locations

During the closure phase, Springer-Cariboo Pit and Wight Pit are allowed to discharge surface water flows directly to the environment. Outside of the TSF, surface water flows will either flow or be pumped to SERDS/Long Ditch, which flows to Central Collection Sump (CCS). Water from CCS reports by gravity to Perimeter Embankment Till Borrow Pond (PETBP) where it will be treated and discharged. Water from TSF will be pumped to CCS for treatment prior to discharge. Water from South Seepage Pond and Main Embankment Seepage Pond will be pumped to PETBP for treatment before discharge to the environment.

During the post-closure phase, surface water flows outside of the TSF will directly flow to the environment. Water from South Seepage Pond and Main Embankment Seepage Pond will continue be pumped to PETBP for the first 10 years of the post-closure phase, South Seepage Pond and Main Embankment Seepage Pond will be allowed to discharge to the environment directly starting from 10 years after the post-closure phase. Water treatment and discharge at the mine is decentralized with flows discharging to the environment during the post-closure phase as listed in Table 8.

**Table 8: Discharge Locations during Post-closure Phase**

| Water Management Infrastructure | Discharge Destination |
|---|---|
| Wight Pit | Polley Lake |
| SERDS/ Long Ditch | |
| Perimeter Embankment Till Borrow Pond | Hazeltine Creek |
| Main Embankment Seepage Pond | Edney Creek |
| South Seepage Pond | |
| 9K Sump | Bootjack Lake |
| NW Sump | |
| Springer-Cariboo Pit | |
| Mine Drainage Creek Sump | |

# 4.0 MODEL SCENARIOS AND SUMMARY OF RESULTS

Two SWWBM modules were developed to evaluate the simulated water storage time-series for TSF and the pit lakes, and flow time-series from the individual mine catchments during the closure and the post-closure phases.

- **Base case module** – reflects the closure and post-closure plan for the Project with stochastically generated mean monthly precipitation depths. The base case module was run stochastically for 1000 realizations to present the model results for the mean, the 90$^{th}$, and the 99.5$^{th}$ percentiles. The probabilistic results can be considered equivalent to extreme climate scenarios: 90$^{th}$ percentile equivalent to 1:10-year (10% probability of exceedance) and 99.5$^{th}$ equivalent to 1:200-year (0.5% probability of exceedance) climate scenarios, respectively.
- **Climate change module** – deterministic module (Section 3.1.1), using the mean and the upper bound of precipitation inputs from 9 climate models and 2 emissions scenarios (SSP2-4.5 and SSP5-8.5).

The following sections present the model results from the base case and climate change modules.

## 4.1 Base Case Results

### 4.1.1 TSF

At the end of operations, a spillway will be constructed at the north abutment (Corner 5) of the TSF at an elevation of 965.7 masl, which is 4.3 m below the TSF embankment crest at 970 masl. Water will discharge from the TSF and flow to the PETBP for treatment, if necessary, prior to discharge to Hazeltine Creek. During the closure and post-closure phases, the TSF pond volume will vary seasonally, limited by the spillway invert to a maximum of approximately 260,000 m$^3$ (Figure 3).

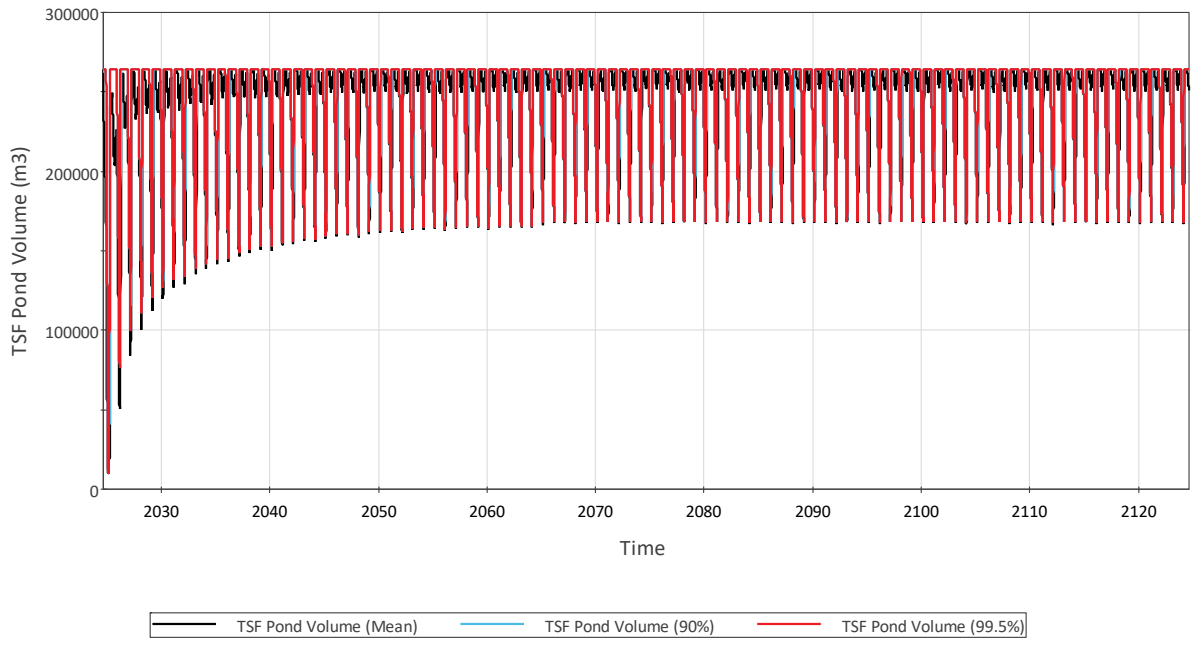

**Figure 3: TSF Pond Volume during Closure and Post-closure**

### 4.1.2 Pit Lakes

The formation of pit lakes in the combined Springer-Cariboo Pit, the Boundary Pit, and the Wight Pit were also assessed during closure and post-closure. The simulations consider direct rainfall and runoff, groundwater seepage in and out of the pits, and evaporation losses.

#### *4.1.2.1 Springer-Cariboo Pit Lake*

A result comparison between different climate conditions for Springer-Cariboo Pit Lake volume during closure and post-closure is provided in Figure 4. Results of the simulations indicate that water levels within the pit will cover the PAG material placed in pit by approximately 2028 under each of the climate conditions simulated. Under the mean condition, the combined Springer-Cariboo Pit Lake is estimated to start overflowing in 2054, while under the 90$^{th}$ percentile condition it is estimated to start overflowing in 2050, and in 2049 under the 99.5$^{th}$ percentile condition.

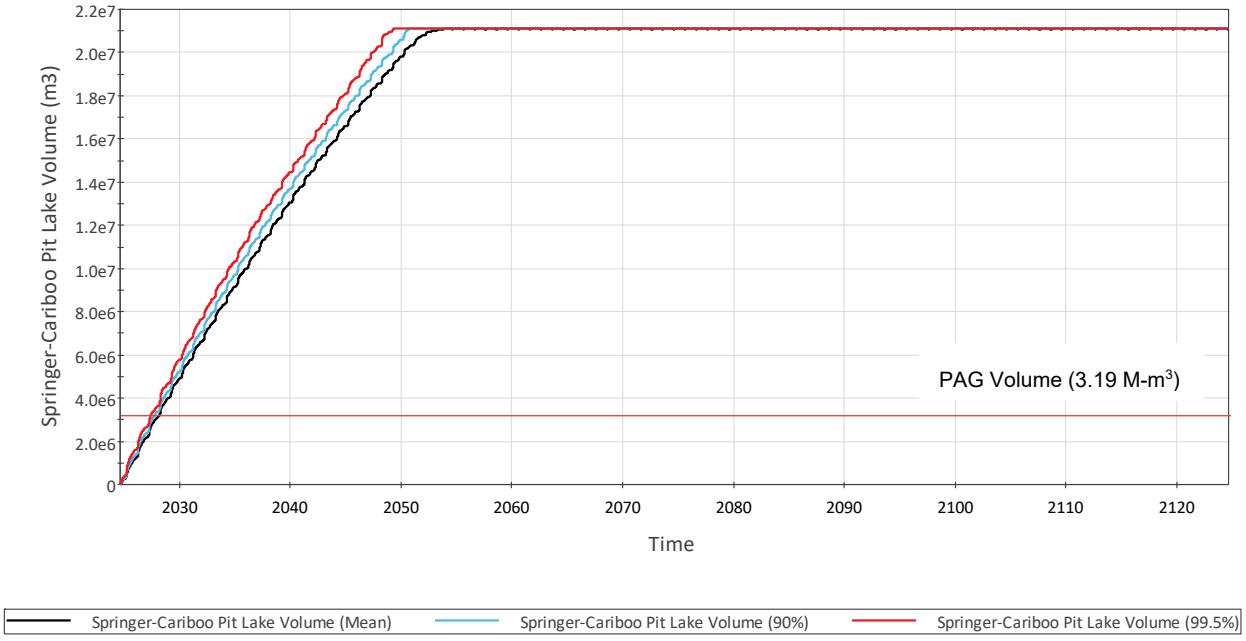

**Figure 4: Combined Springer-Cariboo Pit Lake Volume during Closure and Post-closure**

#### *4.1.2.2 Wight Pit Lake*

The Wight Pit Lake is projected to start overflowing in 2028 under the mean, 90$^{th}$ percentile, and 99.5$^{th}$ percentile climate conditions (Figure 5). Overflow from the Wight Pit Lake will discharge to Polley Lake.

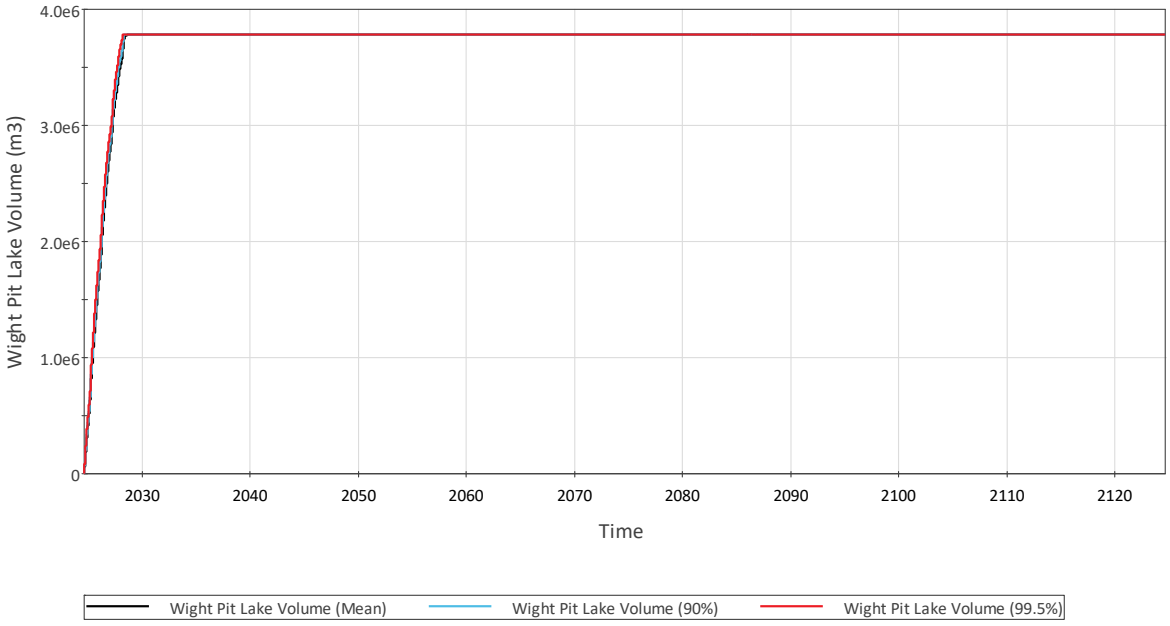

**Figure 5: Wight Pit Lake Volume during Closure and Post-closure**

### *4.1.2.3 Boundary Pit Lake*

A seasonal pond is expected to develop in the Boundary Pit during closure and post-closure and is not projected to overflow during the simulation period (1 September 2024 to 1 September 2124) (Figure 6).

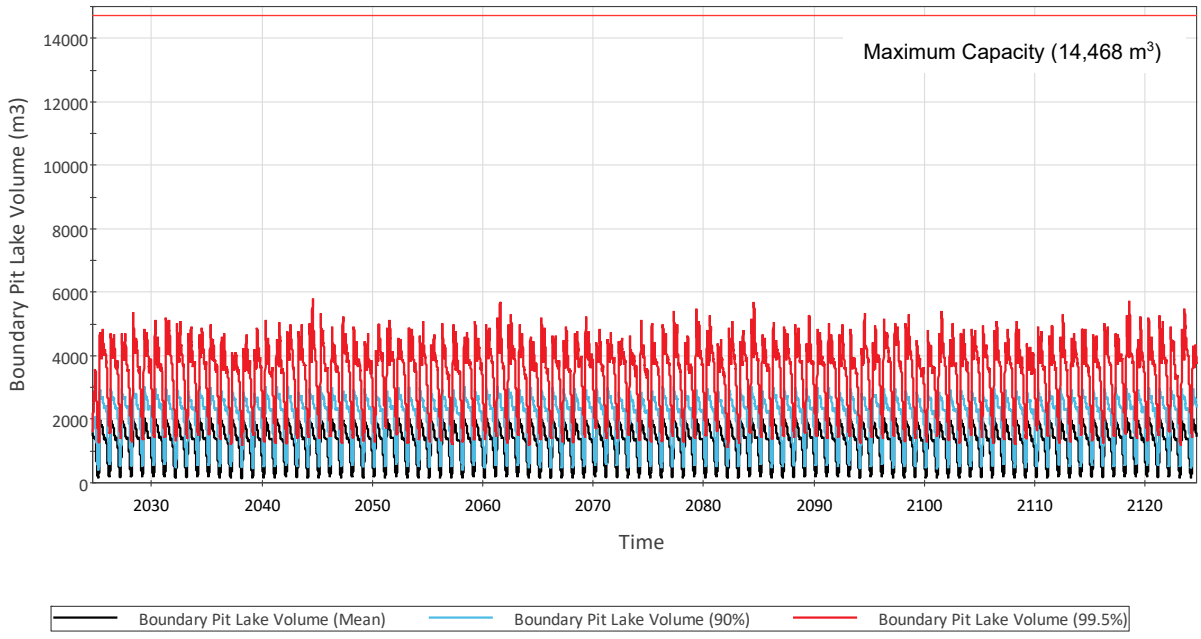

**Figure 6: Boundary Pit Lake Volume during Closure and Post-closure**

### 4.1.3 Mine Catchment Results

Discharge results from the individual mine catchments during closure and post-closure are summarized in this section for following discharge destinations (Table 8):

- Polley Lake
- Hazeltine Creek
- Edney Creek
- Bootjack Lake

For each of the 9 decentralised discharge locations, daily discharges ($m^3/d$) are presented graphically for the average, and the 90$^{th}$ and 99.5$^{th}$ percentiles for years 2024 to 2124, and a summary of annual discharge volumes are presented for selected years.

#### *4.1.3.1 Polley Lake*

The mine catchments discharging to Polley Lake during closure and post-closure are:

- Wight Pit Lake
- Long Ditch/SERDS Ditch

##### *Wight Pit*

Estimated daily discharge rates from Wight Pit during the closure and post-closure phases are presented in Figure 7, and annual discharge volumes are provided in Table 9. Wight Pit Lake is projected to reach its overflow elevation by about 2027, and the annual discharge volume to Polley Lake is expected to remain relatively constant from 2029 through 2124.

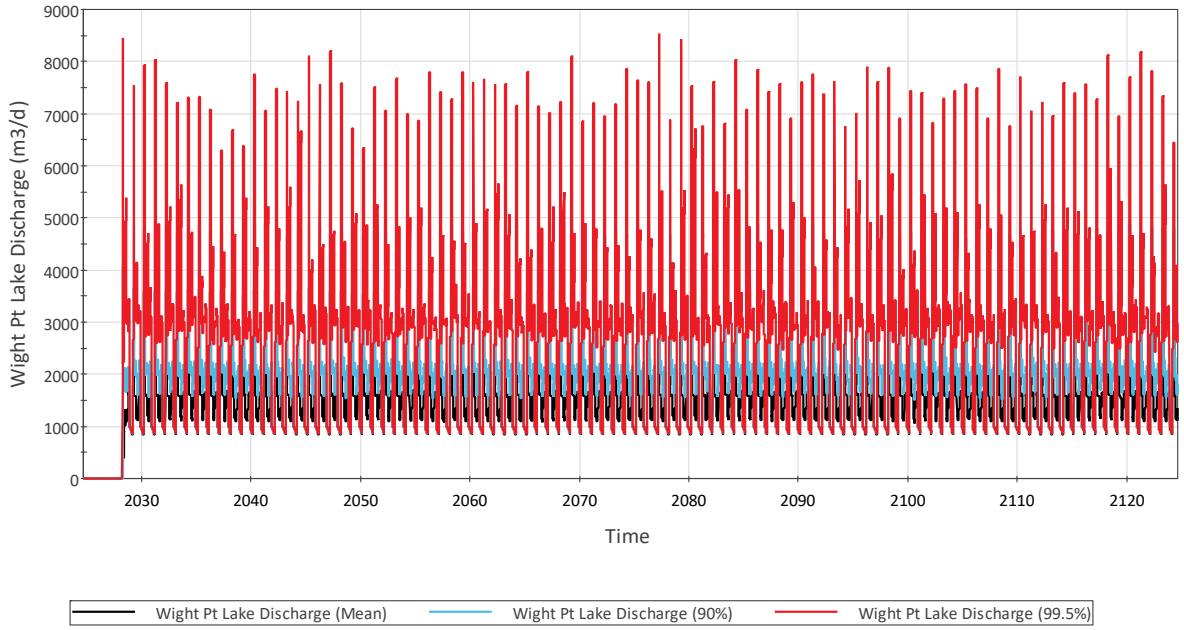

**Figure 7: Wight Pit Lake Discharge to Polley Lake during Closure and Post-closure ($m^3/d$)**

**Table 9: Annual Discharge Quantity from Wight Pit Lake during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 0 | 0 | 0 |
| 2035 | 553,581 | 620,777 | 722,972 |
| 2045 | 553,651 | 616,848 | 734,620 |
| 2085 | 550,155 | 612,999 | 706,107 |
| 2115 | 553,220 | 618,910 | 705,562 |

## *Long Ditch / SERDS Ditch*

Estimated annual discharge volumes from Long Ditch during the closure and post-closure phases are presented in Table 10, and Figure 8 illustrates daily discharge rates. Discharge from Long Ditch is projected to start in 2034 and remain relatively constant from 2035 through 2124.

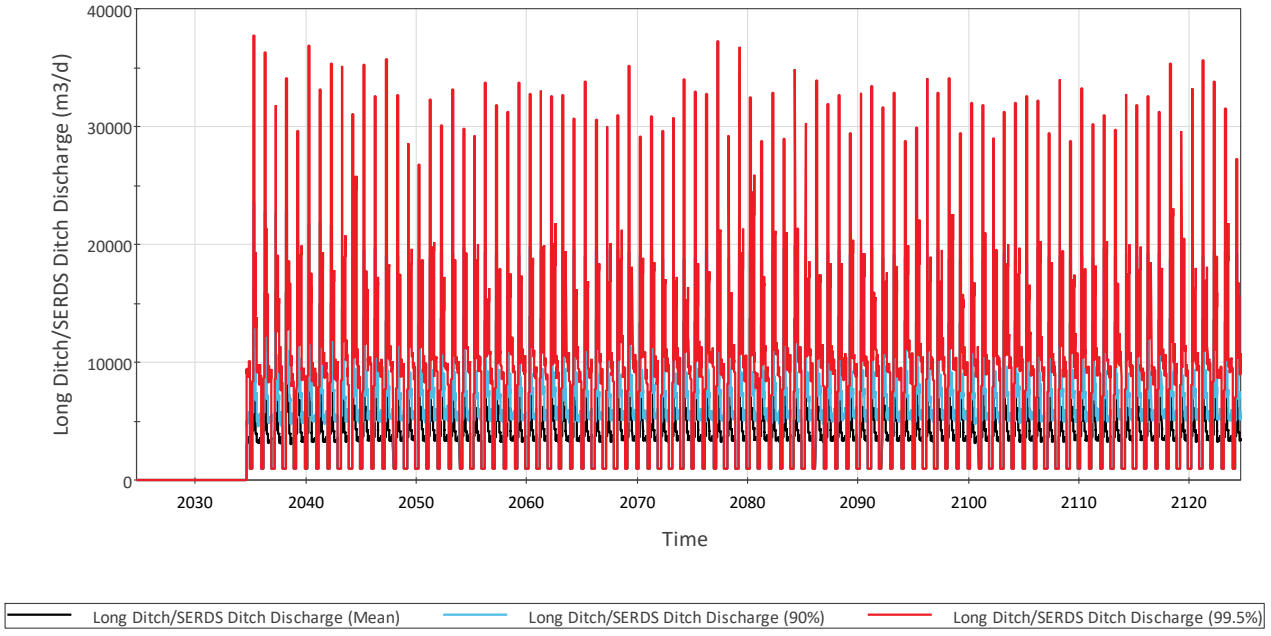

**Figure 8: Long Ditch/SERDS Ditch Discharge to Polley Lake during Closure and Post-closure ($m^3/d$)**

**Table 10: Annual Discharge Quantity from Long Ditch/SERDS Ditch during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 0 | 0 | 0 |
| 2035 | 1,627,200 | 1,948,600 | 2,453,800 |
| 2045 | 1,504,300 | 1,783,900 | 2,339,500 |
| 2085 | 1,488,100 | 1,763,100 | 2,129,200 |
| 2115 | 1,502,000 | 1,792,700 | 2,164,300 |

#### 4.1.3.2 Hazeltine Creek

The mine catchments discharging to Hazeltine Creek during closure and post-closure are:

- Perimeter Embankment Till Borrow Pond

##### Perimeter Embankment Till Borrow Pond

Estimated annual untreated discharge volumes from the Perimeter Embankment Till Borrow Pond (PETBP) during the closure and post-closure phases are presented in Table 11, and Figure 9 illustrates daily untreated discharge rates. Annual discharge volumes from the PETBP are simulated to decrease from 2027 through 2034, and then remain relatively constant from 2035 through 2124.

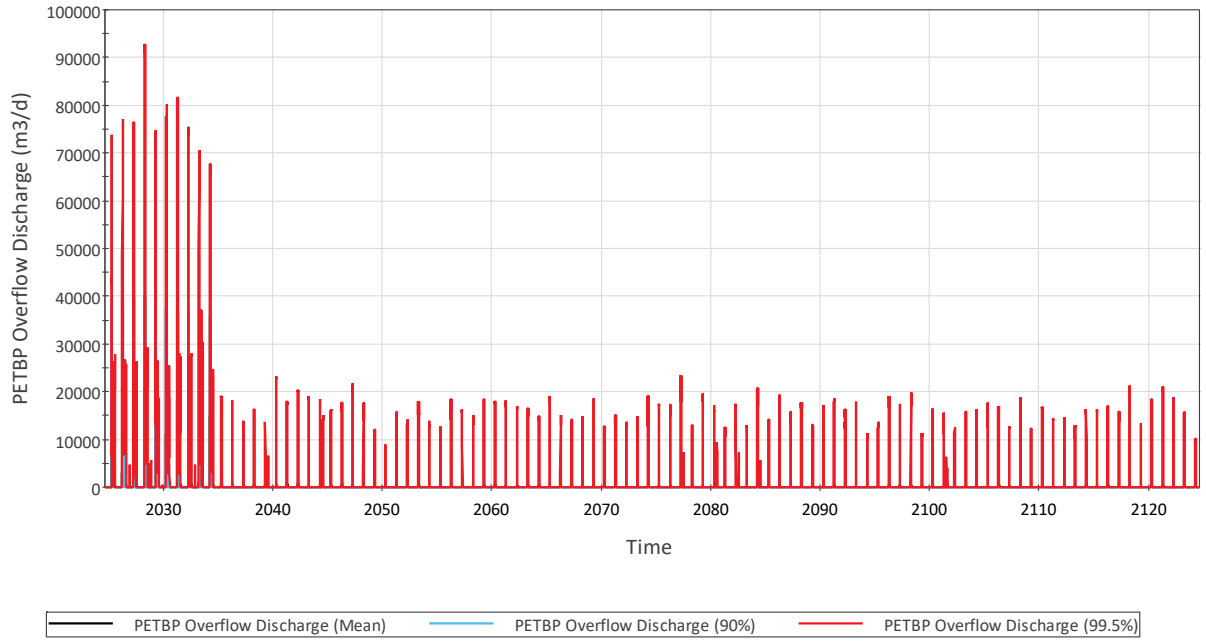

**Figure 9: PETBP Untreated Discharge to Hazeltine Creek during Closure and Post-closure ($m^3$/d)**

**Table 11: Annual Untreated Discharge Quantity from the PETBP during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 341,889 | 884,065 | 2,252,200 |
| 2035 | 12,875 | 0 | 423,672 |
| 2045 | 9,789 | 0 | 361,134 |
| 2085 | 5,709 | 0 | 305,570 |
| 2115 | 8,716 | 0 | 454,162 |

Estimated annual treated discharge volumes from the PETBP during the closure and post-closure phases are presented in Table 12, and Figure 10 illustrates daily treated discharge rates.

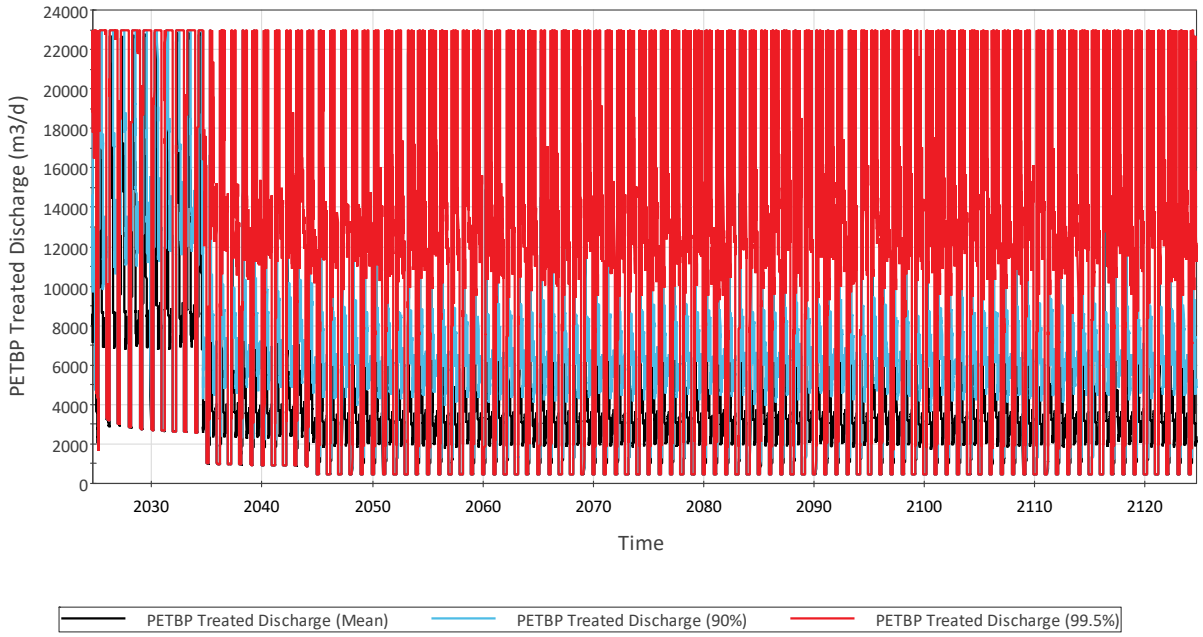

**Figure 10: PETBP Treated Discharge to Hazeltine Creek during Closure and Post-closure ($m^3/d$)**

**Table 12: Annual Treated Discharge Quantity from the PETBP during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 3,427,000 | 4,000,900 | 4,770,300 |
| 2035 | 1,397,400 | 1,833,600 | 2,405,800 |
| 2045 | 1,140,700 | 1,534,500 | 2,066,400 |
| 2085 | 1,152,200 | 1,544,400 | 1,971,800 |
| 2115 | 1,169,000 | 1,565,900 | 1,943,500 |

#### *4.1.3.3 Edney Creek*

The mine catchments discharging to Edney Creek during closure and post-closure are:

- South Seepage Pond
- Main Embankment Seepage Pond

## South Seepage Pond

Estimated annual discharge volumes from the South Seepage Pond during the closure and post-closure phases are presented in Table 13, and Figure 11 illustrates daily discharge rates. The South Seepage Pond is simulated to reach its overflow elevation in 2044, and the annual discharge volume to Edney Creek is expected to remain relatively constant from 2066 through 2124.

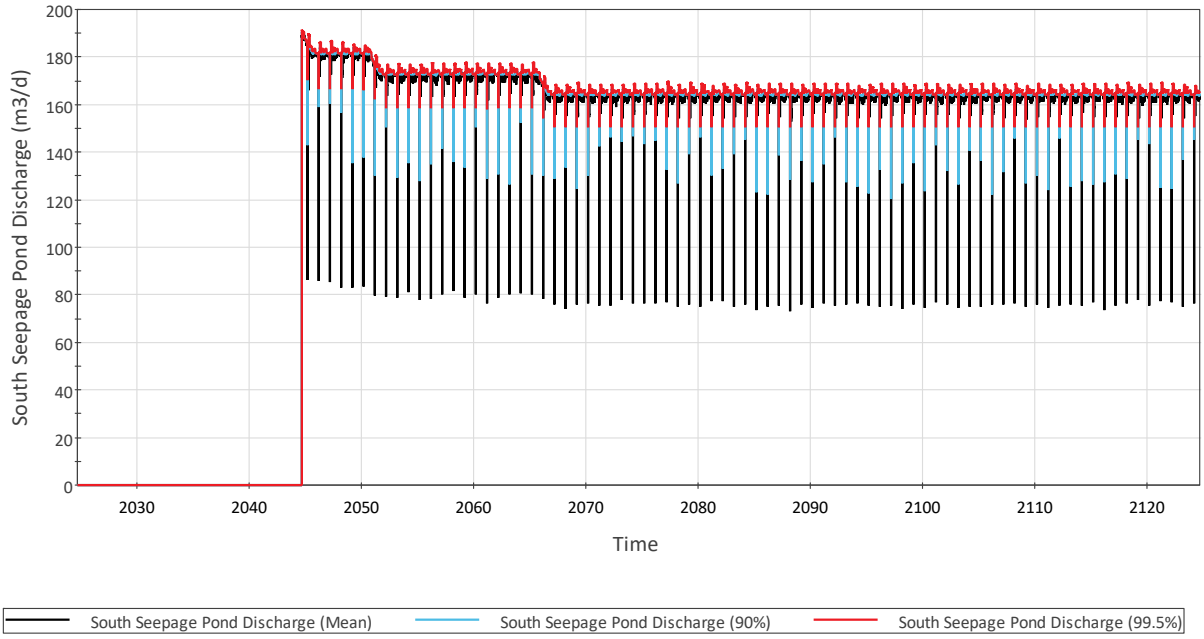

**Figure 11: South Seepage Pond Discharge to Edney Creek during Closure and Post-closure ($m^3/d$)**

**Table 13: Annual Discharge Quantity from South Seepage Pond during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 56 | 245 | 593 |
| 2035 | 0 | 0 | 0 |
| 2045 | 66,721 | 66,776 | 66,879 |
| 2085 | 59,732 | 59,784 | 59,866 |
| 2115 | 59,734 | 59,789 | 59,860 |

## Main Embankment Seepage Pond

Estimated annual discharge volumes from the Main Embankment Seepage Pond during the closure and post-closure phases are presented in Table 14, and Figure 12 illustrates daily discharge rates. The Main Embankment Seepage Pond is simulated to reach its overflow elevation in 2045, and the peak daily discharge and annual discharge volume to Edney Creek is expected to remain relatively constant from 2045 through 2124.

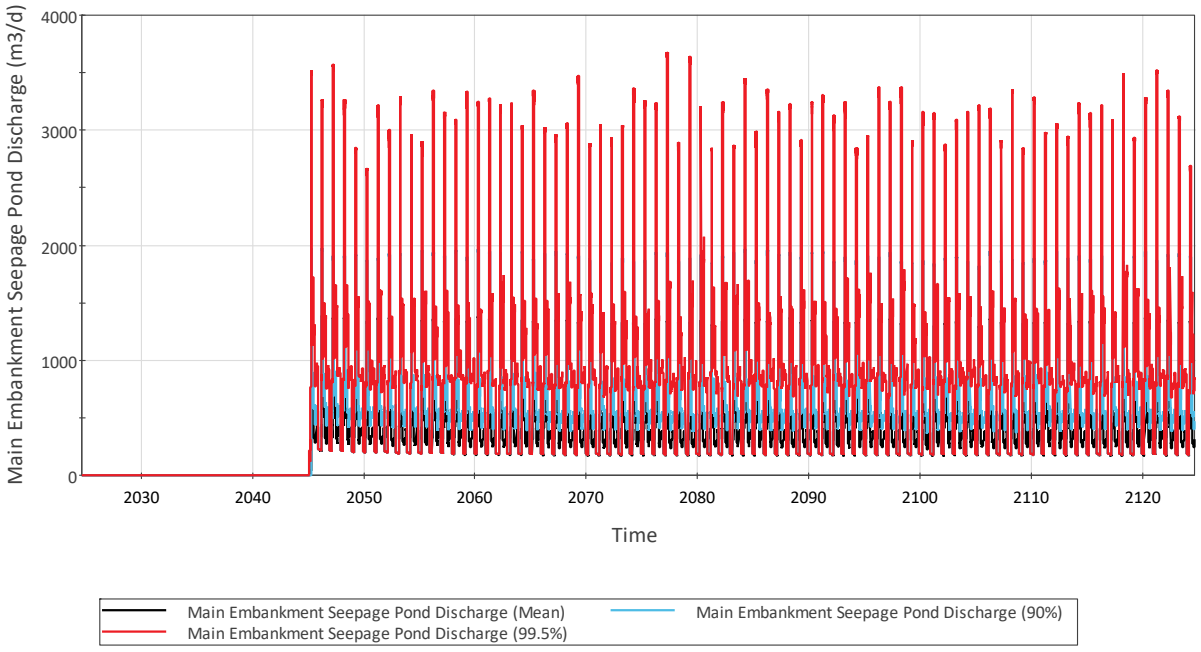

**Figure 12: Main Embankment Seepage Pond to Edney Creek during Closure and Post-closure ($m^3/d$)**

**Table 14: Annual Discharge Quantity from Main Embankment Seepage Pond during Closure and Post- closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 0 | 0 | 0 |
| 2035 | 0 | 0 | 0 |
| 2045 | 127,606 | 155,078 | 215,272 |
| 2085 | 147,446 | 172,634 | 208,607 |
| 2115 | 148,688 | 175,921 | 214,352 |

#### *4.1.3.4 Bootjack Lake*

The mine catchments discharging to Bootjack Lake during closure and post-closure are:

- 9K Sump
- NW Sump
- Springer-Cariboo Pit Lake
- Mine Drainage Creek Sump

### 9K Sump

Estimated annual discharge volumes from 9K Sump during the closure and post-closure phases are presented in Table 15, and Figure 13 illustrates daily discharge rates. The 9K Sump is simulated to reach its overflow elevation by about 2034, and the annual discharge volume to Bootjack Lake is expected to remain constant from 2035 through 2124.

**Figure 13: 9K Sump Daily Discharge to Bootjack Lake during Closure and Post-closure ($m^3$/d)**

**Table 15: Annual Discharge Quantity from 9K Sump during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 0 | 0 | 0 |
| 2035 | 314,761 | 360,387 | 434,492 |
| 2045 | 311,197 | 353,197 | 457,335 |
| 2085 | 308,547 | 351,324 | 410,887 |
| 2115 | 310,559 | 356,203 | 421,621 |

### NW Sump

Estimated annual discharge volumes from the NW Sump during the closure and post-closure phases are presented in Table 16, and Figure 14 illustrates daily discharge rates. The NW Sump is simulated to reach its overflow elevation in 2025, and the annual discharge volume to Bootjack Lake is expected to remain relatively constant from 2035 through 2124.

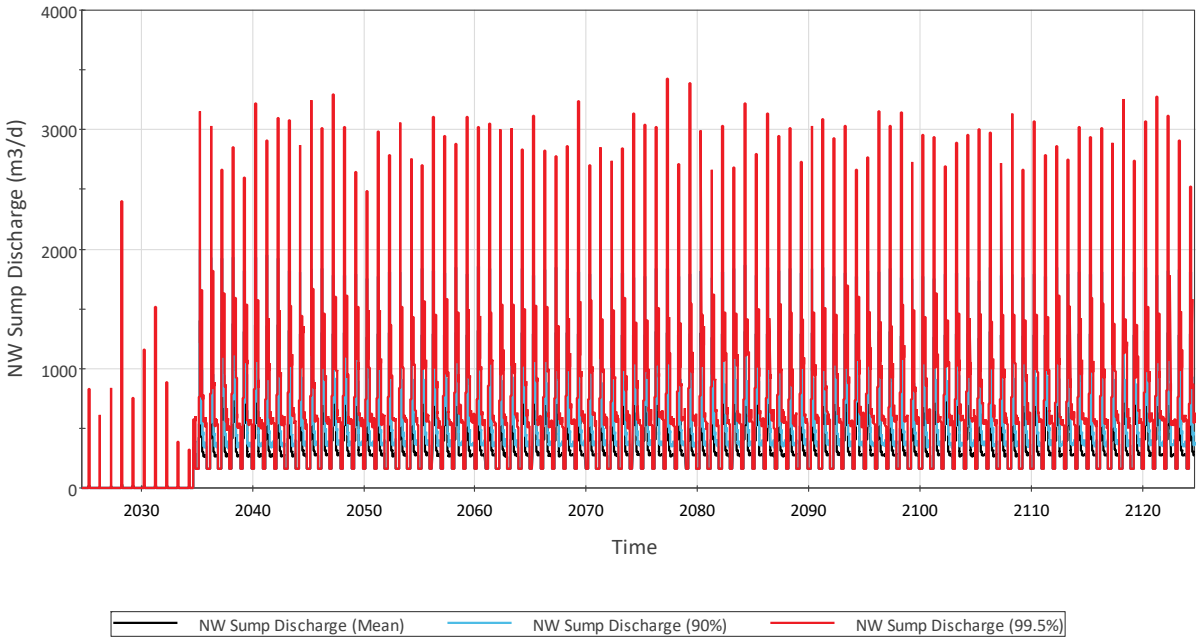

**Figure 14: NW Sump Daily Discharge to Bootjack Lake during Closure and Post-closure ($m^3$/d)**

**Table 16: Annual Discharge Quantity from NW Sump during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 460 | 0 | 24,742 |
| 2035 | 148,675 | 172,613 | 211,955 |
| 2045 | 144,080 | 165,940 | 221,189 |
| 2085 | 142,719 | 164,676 | 194,788 |
| 2115 | 143,716 | 166,292 | 201,693 |

## *Springer-Cariboo Pit*

Estimated annual discharge volumes from the Springer-Cariboo Pit during the closure and post-closure phases are presented in Table 17, and Figure 15 illustrates daily discharge rates. Springer-Cariboo Pit is projected to reach its overflow elevation by about 2048, and the peak daily discharge and annual discharge volume to Bootjack Lake is expected to remain constant from 2051 to 2124.

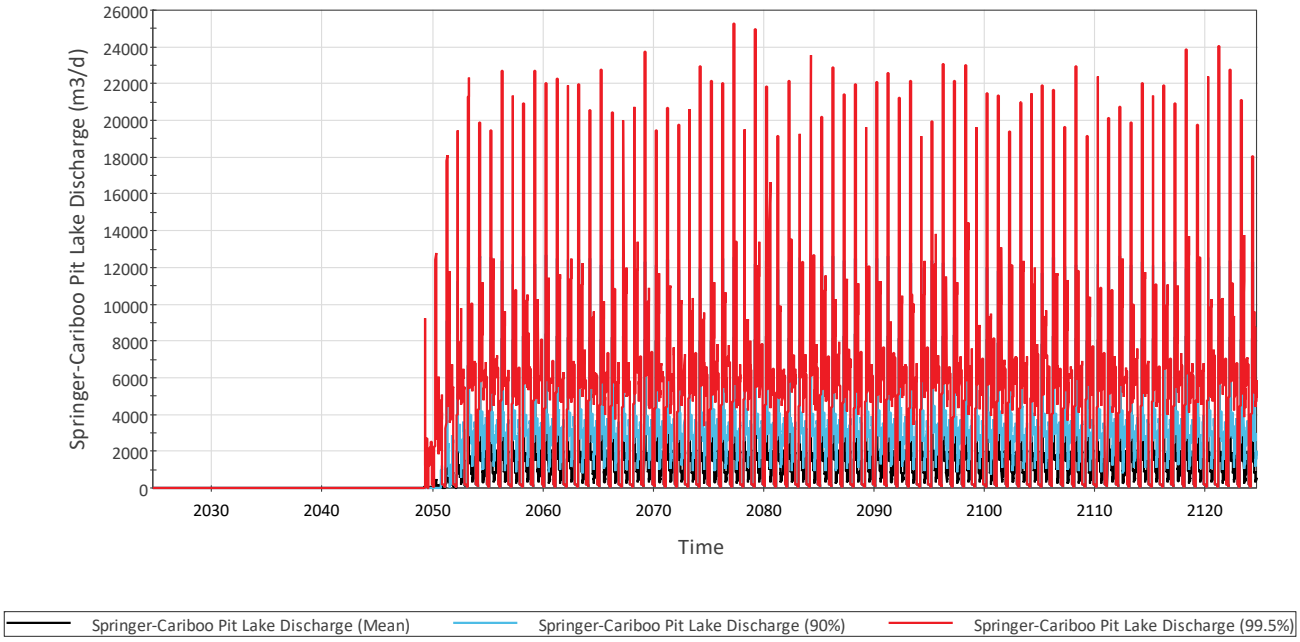

**Figure 15: Springer-Cariboo Pit Lake Daily Discharge to Bootjack Lake during Closure and Post-closure ($m^3/d$)**

**Table 17: Annual Discharge Quantity from Springer-Cariboo Pit Lake during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 0 | 0 | 0 |
| 2035 | 0 | 0 | 0 |
| 2045 | 0 | 0 | 0 |
| 2085 | 579,882 | 782,137 | 1,056,900 |
| 2115 | 589,823 | 797,252 | 1,100,100 |

## *Mine Drainage Creek Sump*

Estimated annual discharge volumes from the Mine Drainage Creek Sump during closure and post-closure are presented in Table 18, and Figure 16 illustrates daily discharge rates. Discharge from the Mine Drainage Creek Sump is simulated to decrease from 2028 through 2034, and then remain relatively constant through the post-closure phase to 2124.

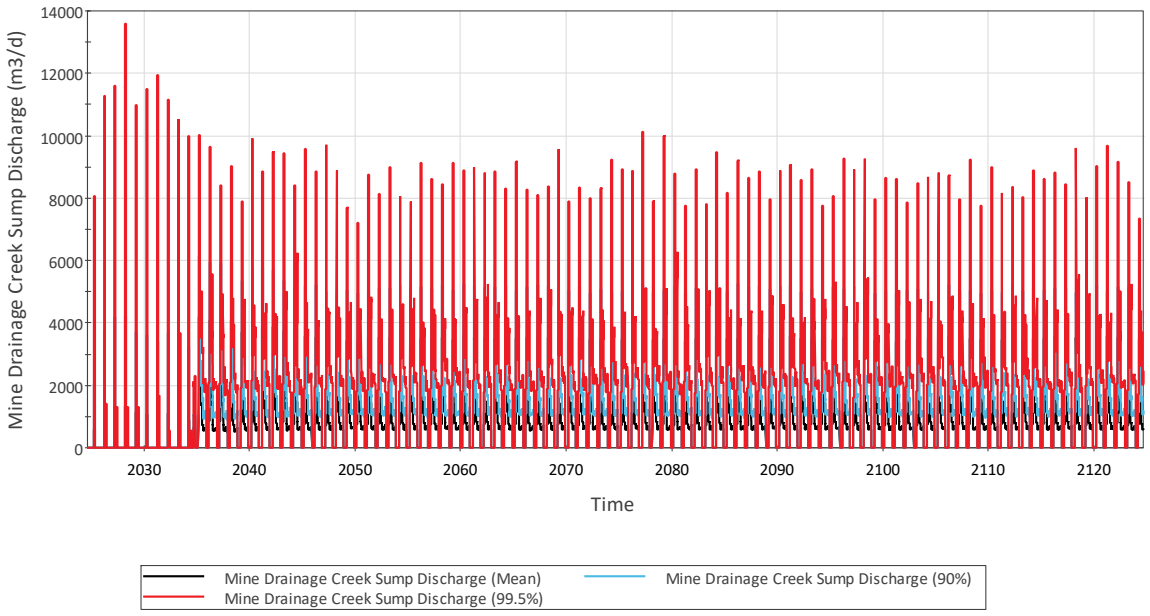

**Figure 16: Mine Drainage Creek Sump Daily Discharge to Bootjack Lake during Closure and Post-closure ($m^3/d$)**

**Table 18: Annual Discharge Quantity from Mine Drainage Creek Sump during Closure and Post-closure**

| Year | Annual Discharge Quantity ($m^3$) | | |
|---|---|---|---|
| | Average (mean) | 1:10-year ($90^{th}$ percentile) | 1:200-year ($99.5^{th}$ percentile) |
| 2025 | 17,216 | 61,257 | 240,564 |
| 2035 | 338,252 | 424,805 | 560,075 |
| 2045 | 308,851 | 383,050 | 543,058 |
| 2085 | 304,379 | 378,285 | 477,521 |
| 2115 | 308,093 | 387,792 | 493,379 |

## 4.2 Climate Change Results

The climate change module results are provided in Attachment B. A comparison between the climate change results and base case results is provided in the following:

- In general, climate change results follow similar patterns to the base case results.
- The mean results of the climate change projections during the closure and the post-closure phases are approximately 15% higher than the mean results of the base case, while the upper bound of the climate change results are approximately 10% lower than the base case $90^{th}$ percentile results.
- The pit filling times with climate change projections are similar to the base case $90^{th}$ and $99.5^{th}$ percentile results.

# 5.0 SUMMARY

The SWWBM was updated to incorporate the closure and post-closure phases for the Mount Polley Mine using GoldSim™ (Version 14.0). The SWWBM is being used to support water management planning and the assessment of water quality and associated water treatment and discharge options for the closure and post- closure phases of the mine.

The base case module was run stochastically for 1000 realizations to present mean, 90$^{th}$, and 99.5$^{th}$ percentile model results. The climate change module was run using a range of projected precipitation inputs to derive mean and the upper bound deterministic results.

The main conclusions for the modelling are as follows:

- The Wight Pit is expected to initiate spilling in 2028 under both the base case and climate change.
- The Boundary Pit is not expected to spill during the modelling period from 1 September 2024 to 1 September 2124 under both the base case and climate change.
- The combined Springer-Cariboo Pit Lake is estimated to start overflowing between 2049 and 2054 under the base case, and between 2048 and 2049 under climate change.
- PAG material placed in the combined Springer-Cariboo Pit is estimated to be inundated and covered by the pit lake in approximately 2028 under the base case, and by 2027 under climate change.

## 6.0 CLOSURE

This technical memorandum summarizes the update of the SWWBM to support the water management information requirements for the Five Year Mine and Reclamation Plan. The reader is referred to the Study Limitations section, which follows the text and forms an integral part of this memorandum.

We trust this technical memorandum satisfies your current requirements. Please contact the undersigned should you have any questions.

## APPENDICES

**APPENDIX A**
Site-Wide Water Quality Model Calibration Results

# 1.0 INTRODUCTION

Mount Polley Mining Corporation (MPMC) retained WSP Golder to update the Site Wide Water Quality Model (SWWQM) to support the water management requirements for the Five Year Mine and Reclamation Plan (RCP). This exercise is a requirement outlined in MPMC's Ministry of Energy, Mines and Low Carbon Innovation (EMLI) Mines Act Permit M-200 (amended 10 December 2020).

The SWWQM was developed as part of the Mount Polley Mine (Mine) Resumed Operations and Closure Water Management Plan Permit Amendment Application and Technical Assessment Report (Golder 2016a) to model water quality across the site. The SWWQM was updated in 2020 as part of the Water Management Plan that addressed the water management through future operations (Golder 2020).

The SWWQM was updated as part of the RCP to include the closure and post-closure phases for the period of 1 September 2024 to 1 September 2124. The closure phase will commence on 1 September 2024, and will include closure and reclamation activities as identified in the Mine Reclamation and Closure Plan Update. The post-closure phase will commence on 1 September 2034 and extends to 2124.

This report presents the updates made to the SWWQM for consistency with the remaining currently permitted mine plan and the proposed closure configuration. Included herein is a summary of the model, the assumptions made for the RCP, and the model inputs and results.

# 2.0 MODEL APPROACH

A reclamation and closure site wide surface water balance model (SWWBM) was developed to predict flow at the Mine and potential discharges to the receiving environment, and comprises the underlying framework for evaluating mass transfers in the SWWQM (Appendix H of the RCP). The SWWQM is directly linked to the reclamation and closure SWWBM and includes mass transfers for each flow.

The SWWQM model does not include treatment of drainage or mixing in the receiving environment. Rather, water quality was simulated in Mine facilities so that treatment technologies can be selected and applied, as described in the Closure Water Treatment memorandum that was prepared along with this report (Appendix G of the RCP).

## 2.1 Model Platform

The model was developed using GoldSim Version 14.0 (GoldSim 2021). GoldSim is a graphical, object-oriented mathematical modelling program where all input parameters and functions are defined by the user and are built as individual objects or elements linked together by mathematical expressions. The object-based nature of the program is designed to facilitate an understanding of the various factors that control an engineered or natural system and to predict potential changes in the system.

GoldSim was selected for the current assessment for the following reasons:

- It facilitates probabilistic simulations, allowing descriptive statistics and probabilities to be assigned to the model outputs.
- The model framework can be easily adjusted to account for changing/future conditions on a mine site, allowing the model to be used as a planning tool.
- Water quantity and water quality models can be directly linked, allowing both models to be updated simultaneously when conducting sensitivity scenarios for alternate water management strategies.

## 2.2 Model Periods

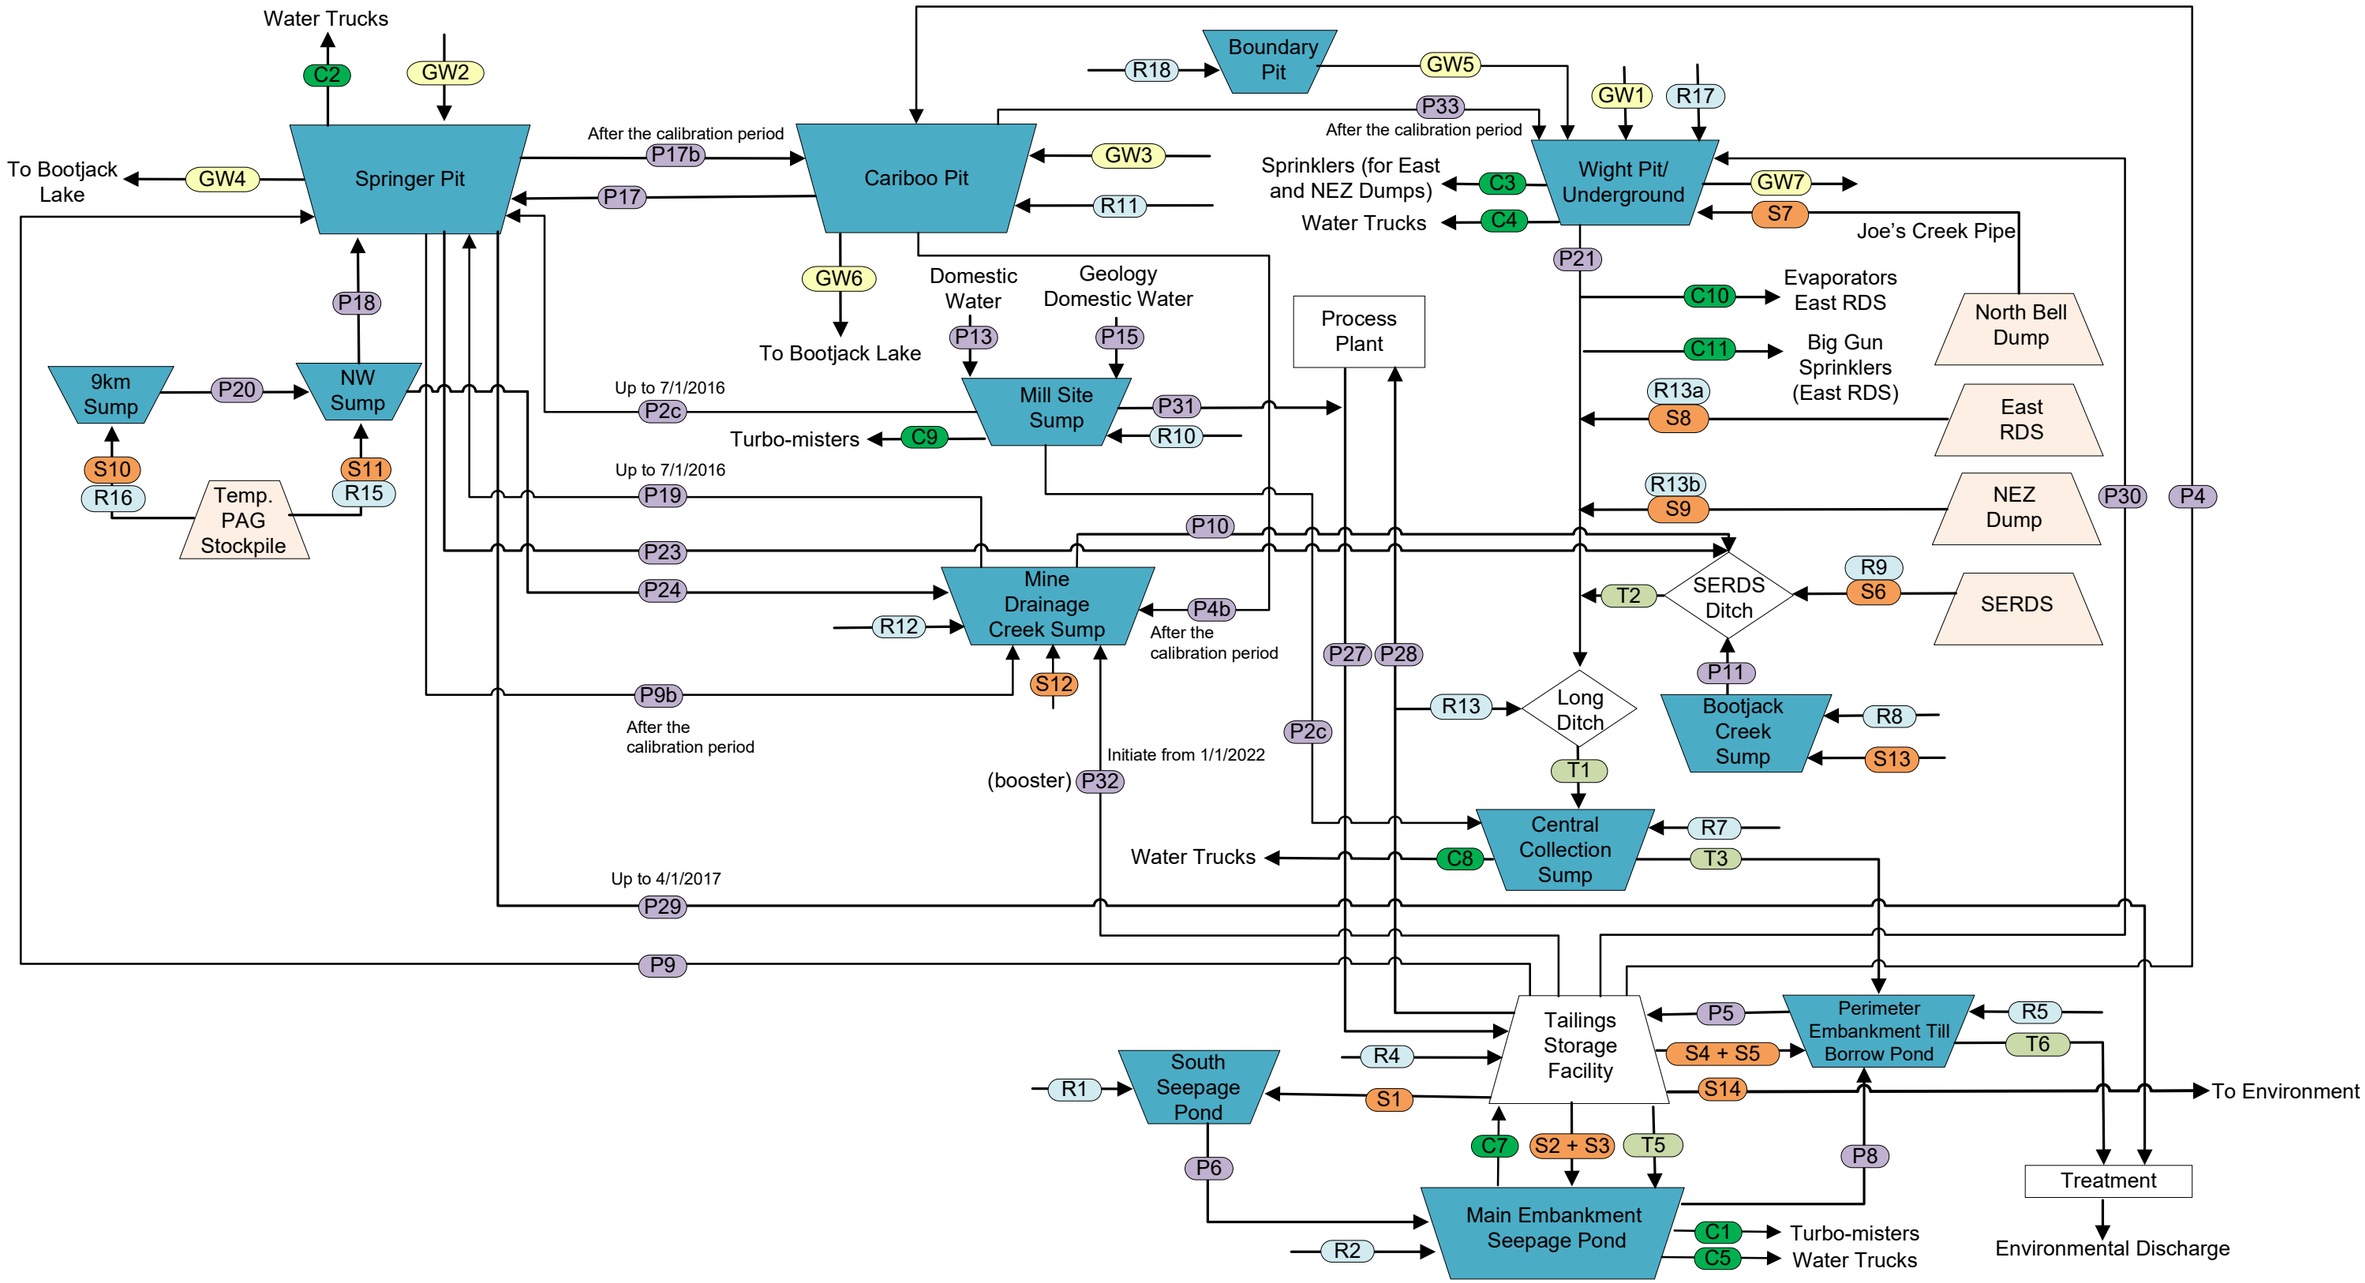
The model simulations included four time periods:

- **Calibration** (1 January 2017 to 31 December 2021) – the calibration period includes care and maintenance of the Mine site. During this period, water in the Perimeter Embankment Till Borrow Pond (PETBP) is treated at the water treatment plant and discharged to Quesnel Lake.
- **Operations** (1 January 2023 to 31 August 2024) – the resumed operations period when, similar to the calibration period, water in the PETBP is treated at the water treatment plant and discharged to Quesnel Lake.
- **Closure** (1 September 2024 to 31 August 2034) – a ten-year active closure period is assumed, during which potentially acid generating (PAG) stockpile material from the Temporary Northwest (NW) PAG stockpile is deposited into the Springer-Cariboo Pit and other facilities are reclaimed. The closure phase will include reclamation activities as identified in the RCP. Details on the closure and post-closure management of mine facilities is provided in Section 8 of the RCP, and the SWWBM Report (Appendix H of the RCP).

- **Post-closure** (1 September 2034 to 31 August 2124) – this period includes filling of pits, discharge, and establishment of steady-state conditions for the drainage from mine facilities. Results are presented for two periods within post-closure:
  - Early post-closure (1 September 2034 to 31 August 2044) – Represents the first ten years of post-closure during which drainage from Mine facilities is assumed to progressively return to undisturbed water quality.
  - Long-term post-closure (1 September 2044 to 1 August 2124) – this time period has been selected to represent steady-state conditions after all closure and post-closure changes have taken place.

Uncertainty exists regarding the exact timing of these transitions. The time periods are intended to show, at a conceptual level, the difference in site drainage quality as the site progresses through the post-closure period; it is not intended to imply that the transitions will occur on precisely those dates.

## 2.3 Facilities



The SWWQM includes the following facilities (grouped into five categories):

- **Open Pits**: Springer-Cariboo Pit, Wight Pit, and Boundary Pit.
- **Sumps**: NW Sump, 9K Sump, Mine Drainage Creek Sump (MDCS), Bootjack Creek Sump (BCS), Central Collection Sump (CCS), Perimeter Embankment Till Borrow Pond (PETBP), South Embankment Seepage Collection Pond (SESCP), and Main Embankment Seepage Collection Pond (MESCP).
- **Ditches/Drains**: Long Ditch and Southeast Rock Disposal Site (SERDS) Ditch.
- **Rock Disposal Sites (RDSs)**: East RDS, SERDS, Northeast Zone (NEZ) RDS, North Bell RDS, and Boundary RDS.
- **Other Facilities**: Tailings Storage Facility (TSF), TSF Quarry, Temporary NW PAG Stockpile, and haul roads.

## 2.4 Mine Site Flows

The SWWBM accounts for mine waste and water management plans, which are described in detail in Section 2.4 of the RCP. During the calibration and operations periods, the Mine facilities are used to manage water within the Mine site and the only Mine discharge to the receiving environment is from the water treatment plant (Table 1 and Figure 1). During closure, water will continue to be managed within the Mine facilities and the combined Springer-Cariboo Pit will be allowed to fill before discharging to Bootjack Lake (Table 2 and Figures 2 and 3). To the extent possible, flows from the Mine site will be returned to pre-disturbance watershed flows as the facilities are reclaimed during closure (Table 3).

During post-closure, most site catchment areas are expected to drain directly to their pre-disturbance watersheds; this applies to 9K Sump, NW Sump, Springer-Cariboo Pit, Mine Drainage Creek, Wight Pit, Joe's Creek, SESCP, and the MESCP. Some sumps, ponds, and ditches are expected to flow together and to be discharged as a combined flow to their pre-disturbance watersheds; Long Ditch discharge will include flow from SERDS Ditch and Bootjack Creek Sump, and PETBP discharge will include overflows from the TSF and CCS (Table 3).

**Table 1: Facility Flows during Calibration and Operations**

| Facility | Inflows to the Facility | Discharge Destinations |
|---|---|---|
| 9K Sump | Runoff and seepage from the Temporary NW PAG Stockpile, North Bell RDS, disturbed, and undisturbed watershed areas | NW Sump |
| NW Sump | Pumping from 9K Sump; Runoff and seepage from the Temporary NW PAG Stockpile, disturbed, and undisturbed watershed areas | Springer Pit |
| Springer Pit | Pumping from NW Sump; pit wall runoff, groundwater inflow, disturbed, and undisturbed watershed areas | Cariboo Pit and TSF |
| Cariboo Pit | Pumping from Springer Pit; pit wall runoff, groundwater inflow, disturbed, and undisturbed watershed areas | Wight Pit and TSF |
| MDCS | Pumping from TSF, Springer Pit, and Cariboo Pit; runoff and seepage from haul roads, disturbed, undisturbed and RDS areas | SERDS Ditch |
| Wight Pit Lake | Seepage from Boundary Pit; pit wall runoff, groundwater inflow, and runoff and seepage from haul roads, undisturbed, disturbed area, and RDS areas | SERDS Ditch |
| Long Ditch | SERDS Ditch overflow and runoff and seepage from the East RDS, NEZ RDS, SERDS RDS, haul roads, disturbed and undisturbed watershed areas | CCS |
| SESCP | TSF seepage and minimal runoff from undisturbed watershed areas | MESCP |
| MESCP | Pumping from SESCP; TSF seepage, runoff from the TSF embankment, and runoff and seepage from undisturbed watershed areas | PETBP |
| PETBP | TSF pond overflow (via CCS), TSF seepage, runoff from TSF impoundment, and runoff and seepage from haul roads, disturbed, and undisturbed watershed area | Influent to the water treatment plant |

Note: NW Sump = Northwest Sump; MDCS = Mine Drainage Creek Sump; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond; PAG = potentially acid-generating; NAG = Non-potentially acid-generating; RDS = Rock Disposal Site; TSF = Tailings Storage Facility; Central Collection Sump = CCS; SERDS = Southeast Rock Disposal Site.

**Table 2: Facility Flows during Closure**

| Facility | Inflows to the Facility | Discharge Destinations |
|---|---|---|
| 9K Sump | Runoff and seepage from the Temporary NW PAG Stockpile, North Bell RDS, disturbed, and undisturbed watershed areas | NW Sump |
| NW Sump | Pumping from 9K Sump; Runoff and seepage from the Temporary NW PAG Stockpile, disturbed, and undisturbed watershed areas | Springer Pit |
| Springer-Cariboo Pit | Pit wall runoff, groundwater inflow, disturbed, and undisturbed watershed areas | Bootjack Lake |
| MDCS | Pumping from TSF, Springer Pit, and Cariboo Pit; runoff and seepage from haul roads, disturbed, undisturbed and RDS areas | SERDS Ditch |
| Wight Pit Lake | Seepage from Boundary Pit; pit wall runoff, groundwater inflow, and runoff and seepage from haul roads, undisturbed, disturbed area, and RDS areas | SERDS Ditch |
| Long Ditch | SERDS Ditch overflow and runoff and seepage from the East RDS, NEZ RDS, SERDS RDS, haul roads, disturbed and undisturbed watershed areas | CCS |
| SESCP | TSF seepage and minimal runoff from undisturbed watershed areas | MESCP |
| MESCP | Pumping from SESCP; TSF seepage, runoff from the TSF embankment, and runoff and seepage from undisturbed watershed areas | PETBP |
| PETBP | TSF pond overflow (via CCS), TSF seepage, runoff from TSF impoundment, and runoff and seepage from haul roads, disturbed, and undisturbed watershed area | Influent to the water treatment plant and Hazeltine Creek |

Note: NW Sump = Northwest Sump; MDCS = Mine Drainage Creek Sump; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond; PAG = potentially acid-generating; NAG = Non-potentially acid-generating; RDS = Rock Disposal Site; TSF = Tailings Storage Facility; Central Collection Sump = CCS; SERDS = Southeast Rock Disposal Site.

**Table 3: Facility Flows during Post-closure**

| Facility | Inflows to the Facility | Discharge Destinations |
|---|---|---|
| 9K Sump | Runoff and seepage from the Temporary NW PAG Stockpile, North Bell RDS, disturbed, and undisturbed watershed areas | Bootjack Lake |
| NW Sump | Runoff and seepage from the Temporary NW PAG Stockpile, disturbed, and undisturbed watershed areas | |
| Springer-Cariboo Pit Lake | Pit wall runoff, groundwater inflow, disturbed, and undisturbed watershed areas | |
| MDCS | Runoff and seepage from haul roads, disturbed, undisturbed and RDS areas | |
| Wight Pit Lake | Pit wall runoff, groundwater inflow, and runoff and seepage from haul roads, undisturbed, disturbed area, and RDS areas | Polley Lake |
| Long Ditch | SERDS Ditch overflow and runoff and seepage from the East RDS, NEZ RDS, SERDS RDS, haul roads, disturbed and undisturbed watershed areas | |
| SESCP | TSF seepage and minimal runoff from undisturbed watershed areas | Edney Creek |
| MESCP | TSF seepage, runoff from the TSF embankment, and runoff and seepage from undisturbed watershed areas | |
| PETBP | TSF pond overflow (via CCS), TSF seepage, runoff from TSF impoundment, and runoff and seepage from haul roads, disturbed, and undisturbed watershed area | Influent to the water treatment plant and Hazeltine Creek |

Note: NW Sump = Northwest Sump; MDCS = Mine Drainage Creek Sump; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond; PAG = potentially acid-generating; NAG = Non-potentially acid-generating; RDS = Rock Disposal Site; TSF = Tailings Storage Facility; Central Collection Sump = CCS; SERDS = Southeast Rock Disposal Site.

## 2.5 Scenarios

Two SWWBM scenarios (outlined in Appendix H of the RCP) were modelled for the closure and post-closure periods.

- A climate change scenario – deterministic SWWBM simulation, using the mean and the upper bound of precipitation inputs from 9 climate models and 2 emissions scenarios. The water quality inputs are sampled stochastically (1000 realizations) in this scenario.
- A base case scenario – reflects the closure and post-closure plan for the Mine with stochastically generated mean monthly precipitation depths. The SWWBM and SWWQM were run stochastically for 1000 realizations.

These scenarios only apply to the closure and post-closure periods of the SWWQM. The calibration period uses historical data for the climate inputs and the operations period uses an average annual climate input.

## 2.6 Model Setup

The model simulated concentrations on a daily time step from January 2017 to December 2021 (calibration period), January 2023 to September 2024 (operations) and from September 2024 to September 2124 (closure and post-closure). As described above, the SWWQM was run stochastically for 1000 realizations for both the climate change and base case scenarios. For each realization, a unique concentration for each parameter was selected based on randomly sampled values from within a statistical probability distribution function that was derived for each input.

To interpret the results, median and 95th percentile concentrations were calculated for each Mine facility. To put the results in context, a 95th percentile prediction indicates the maximum concentration that is likely to be reached over the duration of the simulation, with a 95% likelihood that concentrations will be at or below that concentration (it does not suggest that concentrations will exceed this value 5% of the time).

### 2.6.1 Modelled Parameters and Particulate Addition

The parameters in the SWWQM include physical parameters, major ions, nutrients, and dissolved metals and metalloids (Table 4). The dissolved fractions of metals and metalloids are used in all mixing calculations in the model. The total concentrations of metals and metalloids are calculated by adding particulate fractions to the dissolved concentrations as described below.

**Table 4: Parameters in the Site Wide Water Quality Model**

| Category | Parameters |
|---|---|
| Physical parameters | Total dissolved solids (calculated), hardness (calculated) |
| Major ions | Calcium, chloride, fluoride, magnesium, potassium, sodium, sulphate |
| Nutrients | Nitrate, nitrite, total ammonia, total phosphorus |
| Dissolved metals and metalloids | Aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, titanium, uranium, vanadium, zinc |

Total metal predictions were calculated using dissolved metal predictions and empirical particulate metal concentrations. Monitoring data for the SERDS Ditch and Long Ditch were used to establish the empirical particulate metal concentrations because these facilities are expected to represent the majority of particulate load to site discharges. The model assumes that TSS will be settled to 15 mg/L (i.e., the current average authorized discharge concentrations) prior to discharge.

Monitored data for total and dissolved metals were used to calculate observed particulate metal concentrations in the SERDS Ditch and Long Ditch. The strength of correlation of measured particulate metal concentrations to TSS concentrations was calculated using linear regressions. An empirical particulate metal concentration for each parameter was established by grouping each parameter into the following categories:

- Correlated parameters ($R^2 \geq 0.75$)—a particulate concentration corresponding to 15 mg/L TSS was calculated using the regression equation, and this concentration was added to both the maximum median and 95th percentile dissolved metal predictions to calculate a total metal concentration.

- Poorly-correlated parameters ($0.25 < R^2 < 0.75$)—median and 95th percentile particulate concentrations were calculated based on observed data for samples with a TSS below 15 mg/L, and these concentrations were added to the maximum median and 95th percentile dissolved metal concentrations, respectively.
- Non-correlated parameters ($R^2 \leq 0.25$)—median and 95th percentile particulate concentrations were calculated based on all observed data, and these concentrations were added to the maximum median and 95th percentile dissolved metal concentrations, respectively.

A summary of the correlated and non-correlated parameters and the particulate concentrations used in the model are presented in Table 5.

**Table 5: Particulate Metal Concentrations**

| Parameter | Coefficient of Determination ($R^2$) | Category | Median Particulate Concentration (mg/L) | 95th Percentile Particulate Concentration (mg/L) |
|---|---|---|---|---|
| Aluminum | 0.82 | Correlated | 0.41 | 0.41 |
| Antimony | 0.022 | Non-correlated | 0.000020 | 0.00014 |
| Arsenic | 0.87 | Correlated | 0.00019 | 0.00019 |

| Lithium | 0.51 | Poorly-correlated | 0.00020 | 0.0010 |
| Manganese | 0.79 | Correlated | 0.014 | 0.014 |
| Mercury | 0.017 | Non-correlated | - | - |
| Molybdenum | 0.0073 | Non-correlated | 0.00010 | 0.011 |
| Nickel | 0.83 | Correlated | 0.00047 | 0.00047 |
| Selenium | 0.0061 | Non-correlated | - | 0.0056 |
| Silver | 0.63 | Poorly-correlated | - | 0.0000051 |
| Strontium | 0.0035 | Non-correlated | 0.017 | 0.34 |
| Thallium | 0.41 | Poorly-correlated | - | 0.000000050 |
| Tin | 0.22 | Non-correlated | - | 0.000080 |
| Titanium | 0.8 | Correlated | 0.022 | 0.022 |
| Uranium | 0.0071 | Non-correlated | 0.000023 | 0.00031 |
| Vanadium | 0.84 | Correlated | 0.0012 | 0.0012 |
| Zinc | 0.76 | Correlated | 0.0014 | 0.0014 |

### 2.6.2 Water Quality Prediction Calculations

In the SWWQM, Mine facilities were grouped into four categories: open pits, water management ponds sumps and ditches, RDSs, and TSF. The concentrations of parameters at each Mine facility were estimated as described below.

#### *2.6.2.1 Pits, Ponds and Ditches*

Conveyance facilities on site (Long Ditch and SERDS Ditch) that are flow-through systems (i.e. they do not retain volumes of water for more than a single timestep) were modelled by assigning a water quality to each inflow and calculating a mixed water quality based on the proportions of each inflow (Equation 1). For pits, sumps, and ponds where water can be stored (9K Sump, NW Sump, Springer-Cariboo Pit, MDCS, Wight Pit, SESCP, MESCP and the PETBP), the concentration and volume retained from the previous time step is included in the calculation (Equation 2).

$$C_{pond} = \frac{\sum C_i Q_i}{\sum Q_i}$$ Equation 1

Where:

$C_{pond}$ = concentration in facility
$C_i$ = concentration in inflow *i*
$Q_i$ = flow rate of inflow *i*

$$C_{pond} = \frac{C_x V_x + \sum C_i Q_i - \sum C_x Q_o}{V_x + \sum Q_i - \sum Q_o}$$ Equation 2

Where:

$C_{pond}$ = concentration in facility
$C_i$ = concentration in inflow *i*
$Q_i$ = flow rate of inflow *i*
$C_x$ = concentration in facility in previous timestep *x*
$V_x$ = volume of water in facility in previous timestep *x*
$Q_o$ = flow rate of outflow *o*

Evaporation from water surfaces was included as a decrease in total volume ($V_i$); in other words, evaporation was a water quantity reduction only and did not remove mass of modelled parameters from the system.

#### *2.6.2.2 Rock Disposal Sites and Tailings Storage Facility*

Runoff and seepage volumes from RDS and the TSF were predicted by the SWWBM and input water quality was assigned to these flows based on site monitoring data. Concentrations at these Mine facilities were calculated using Equation 1.

### 2.6.3 Model Inputs

Water quality inputs in the SWWQM were derived from site water quality monitoring data. A summary of the water quality inputs assigned to each flow in the SWWQM is presented in Table 6 and described below. Site water quality monitoring data from 2006 to 2022 (depending on the input) were used to develop water quality inputs in the SWWQM. For each parameter, water quality inputs were represented in the model by probability distribution functions. The development of the distribution inputs is described in Section 2.6.3.1, and a summary of the distributions selected, the maximum, 95$^{th}$ percentile, and mean values used for each parameter, and the number of samples for each water quality input are presented in Table 7.

As areas in the mine site are reclaimed, the assigned water quality inputs are adjusted in the SWWQM (Table 6):

- Before reclamation of the RDS facilities, the water quality of runoff is assigned either PAG, non-potentially acid-generating (NAG), Boundary Dump (in the Boundary Pit RDS runoff), or Joe' s Creek Pipe (in the Wight Pit RDS runoff) water quality depending on the RDS location. The water quality of runoff is assumed to be equal to disturbed runoff while the facilities are being reclaimed, and then gradually return to undisturbed watershed runoff.
- Seepage from the RDS facilities is conservatively assumed to remain as contact water in perpetuity.
- For Wight Pit and Boundary Pit, the pit wall runoff is assigned the same water quality input during the calibration, operations, closure and post-closure periods. The water quality input assigned to runoff from each of the pit walls is calculated using monitoring data from the corresponding pit (for example, the water quality distribution assigned to pit wall runoff into Wight Pit is calculated using monitoring data from Wight Pit).
- Pit wall runoff into the Springer-Cariboo Pit during closure and post-closure is assigned water quality from two source terms:
  - For pit walls of the former Springer Pit, the source term is calculated based on observed data from Springer Pit. This assumes no acid generation or change in pit wall runoff water quality over time.
  - For pit walls of the former Cariboo Pit, the source term is calculated based on observed data from Cariboo Pit. This assumes no acid generation or change in pit wall runoff water quality over time.
- During the calibration, operations, closure and post-closure periods, disturbed areas are assigned a water quality input calculated using monitoring data from the North Dump Creek and Bootjack Creek (Stations W4 and W5).
- During the calibration, operations, closure and post-closure periods, undisturbed areas are assigned a water quality input calculated using monitoring data from undisturbed runoff (Stations W8 and W8z).
- During the calibration, operations and closure periods, runoff from the TSF beach, impoundment and embankment is assigned a water quality input calculated using monitoring data from the TSF supernatant (Stations E1 and E1a). The water quality of TSF beach, impoundment and embankment runoff is assumed to be equal to undisturbed runoff once the area has been reclaimed in post-closure.
- The proportion of seepage from saturated and unsaturated tailings in the TSF during closure and post-closure are based on hydrogeologic modelling of seepage from the facility (Appendix F). Seepage from unsaturated tailings is assigned the water quality input calculated using monitoring data from the MESCP (Stations E4 and E5). Seepage from the saturated tailings is assigned predicted water quality from the TSF.

- Runoff from the Haul Road is assigned NAG water quality until it is reclaimed in post-closure. Once the Haul Road is reclaimed, runoff from this area is assigned the undisturbed water quality input.
- During the calibration, operations, closure and post-closure periods, groundwater inflow into the combined Springer-Cariboo Pit is assigned a water quality input calculated using monitoring data from Springer Pit Wells (Stations GW12-1/2 and GW15-1/2).

**Table 6: Site-Wide Water Quality Model Inputs**

| Category | Description | Model Input | | |
|---|---|---|---|---|
| | | Calibration Period and Operations | Closure | Post-closure |
| Rock Disposal Site Contact Water | RDS Runoff to Boundary Pit | Boundary Dump Seep water quality data (n = 70, June 2013 - October 2021) | Disturbed Runoff: W4 and W5 site monitored data (n = 225, January 2014 to January 2022) | Undisturbed Runoff: W8 and W8z site monitored water quality (n = 219, January 2006 to January 2022) |
| | RDS Seepage to Boundary Pit | Boundary Dump Seep water quality data (n = 70, June 2013 - October 2021) | | |
| | RDS Runoff to Wight Pit | Joe's Creek Pipe (from North Bell Dump) water quality (n = 62, August 2014 to March 2022) | Disturbed Runoff: W4 and W5 site monitored data (n = 225, January 2014 to January 2022) | Undisturbed Runoff: W8 and W8z site monitored water quality (n = 219, January 2006 to January 2022) |
| | RDS Seepage to Wight Pit | Joe's Creek Pipe (from North Bell Dump) water quality (n = 62, August 2014 to March 2022) | | |
| | NAG Waste Rock Runoff | East Rock Disposal Site, Northeast Zone Dump, SERDS Seep water quality (n = 510, May 2013 to March 2022) | Disturbed Runoff: W4 and W5 site monitored data (n = 225, January 2014 to January 2022) | Undisturbed Runoff: W8 and W8z site monitored water quality (n = 219, January 2006 to January 2022) |
| | NAG Waste Rock Seepage | East Rock Disposal Site, Northeast Zone Dump, SERDS Seep water quality (n = 510, May 2013 to March 2022) | | |
| | Temporary NW PAG Stockpile Runoff | PAG Dump Seep water quality (n = 88, May 2013 - March 2022) | Disturbed Runoff: W4 and W5 site monitored data (n = 225, January 2014 to January 2022) | Undisturbed Runoff: W8 and W8z site monitored water quality (n = 219, January 2006 to January 2022) |
| | Temporary NW PAG Stockpile Seepage | PAG Dump Seep water quality (n = 88, May 2013 - March 2022) | NAG Waste Rock: East Rock Disposal Site, Northeast Zone Dump, SERDS Seep water quality (n = 510, May 2013 to March 2022) | |
| Pit Wall Runoff | Boundary Pit Wall Runoff | Boundary Pit water quality (n = 14, February 2016 - October 2021) | | |
| | Wight Pit Wall Runoff | Wight Pit water quality (n = 50, January 2016 - July 2022) | | |
| | Springer Pit Wall Runoff | Springer Pit water quality (n = 45, January 2016 - January 2022) | | |
| | Cariboo Pit Wall Runoff | Cariboo Pit water quality (n = 16, January 2016 - December 2021) | | |
| Tailings Storage Facility | TSF Beach, Impoundment, and Embankment Runoff | TSF supernatant water quality (n = 70, May 2011 to January 2022) | | Undisturbed Runoff: W8 and W8z site monitored water quality (n = 219, January 2006 to January 2022) |
| | Unsaturated TSF Seepage | TSF Main Embankment Seepage Collection Pond (n = 129, January 2006 - October 2021) | | |
| | Saturated TSF Seepage | Predicted concentration in the TSF | | |
| Other | Haul Road Runoff | NAG Waste Rock: East Rock Disposal Site, Northeast Zone Dump, SERDS Seep water quality (n = 510, May 2013 to October 2022) | | Undisturbed Runoff: W8 and W8z site monitored water quality (n = 219, January 2006 to January 2022) |
| | Disturbed Runoff | W4 and W5 site monitored data (n = 225, January 2014 to January 2022) | | |
| | Undisturbed Runoff | W8 and W8z site monitored water quality (n = 219, January 2006 to January 2022) | | |
| | Groundwater Inflow to Springer-Cariboo Pit | GW12-1/2, GW15-1/2 site monitored data (n = 244, June 2013 to February 2022) | | |

Note: NW Sump = Northwest Sump; MDCS = Mine Drainage Creek Sump; SESCP = South Embankment Seepage Collection Pond; MESCP = Main Embankment Seepage Collection Pond; PETBP = Perimeter Embankment Till Borrow Pond; PAG = potentially acid-generating; NAG = Non-potentially acid-generating; RDS = Rock Disposal Site; TSF = Tailings Storage Facility; SERDS = Southeast Rock Disposal Site.

**Table 7. Summary of Stochastic Water Quality Inputs**

| Parameter | Units | Boundary Pit Waste Rock Contact Water | | | | | Wight Pit Waste Rock Contact Water/Joe's Creek Pipe | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Distribution Selected | Mean | Standard Deviation | Maximum | Number of Samples | Distribution Selected | Mean | Standard Deviation | Maximum | Number of Samples |
| **Physical Parameters** | | | | | | | | | | | |
| Total Dissolved Solids | mg/L | Normal | 760 | 267 | 1,190 | 70 | Lognormal | 1,558 | 1.1 | 2,050 | 62 |
| **Major Ions** | | | | | | | | | | | |

#### 2.6.3.1 Development of Water Quality Inputs

The following standardized process was used to develop a statistical distribution for each parameter (Table 7):

- Step 1: Determine if data are available and if values are less than the method detection limit (MDL). Except for special cases listed below under Step 5, values below the MDL were set equal to half of the MDL.
- Step 2: Examine time-series of available data to select the most representative range of data to use for input:
  - The following general rules were used to select the data used for input to the model:
    - Where no trend was apparent in the monitored data over time, the whole data set was used as input to the model.
    - Where a decreasing trend was observed in the monitored data, the whole data set was used, including the earlier, higher values, thereby adding conservatism and representing a potential return to conditions that led to higher concentrations (without specifying what those conditions were).
    - Where an increasing trend was observed in the monitored data, input data were limited to the range of data most representative of current or recent conditions.
- Step 3: Remove outliers from selected data:
  - Three statistical tests were used to identify outliers. These included the three times standard deviation (3σ) rule, the Hampel identifier, and combined Rosner-Dixon test. A data point was considered an outlier only if it was flagged by all three tests. By using multiple tests, the possibility of misdiagnoses was reduced (Beckman and Cook 1983; Jain 1981; Kottegoda 1984; Pearson 2001).
- Step 4: Fit suitable statistical distributions to the resulting data:
  - The probability distributions considered for the water quality data were normal, lognormal, or delta-lognormal, as these are typical distributions for water quality data (AEP 1995; US EPA 1991). To identify which distribution best described a constituent, all three distributions were initially fitted to the available data. Statistical goodness of fit tests, consisting of the Chi-squared test, the Kolmogorov-Smirnov test and the squared correlation coefficient (Sokal and Rohlf 1981) were used to determine which distribution was most appropriate.
- Step 5: Process data with a single value:
  - Where all data were at a single value a constant input was used equal to this value.
  - Where all data were below detection limits, a constant input was used at half the detection limit.
  - Where dissolved mercury data were not available for a location, a constant input was used equal to half the lowest detection limit measured on site, consistent with other locations.
- Step 6: Determine the minimum and maximum bounds to define a reasonable range for the selected distribution:
  - When possible, the maximum observed value was used as the maximum bound of all distributions. In cases where the maximum observed value was too low to result in a fitted distribution, the lowest maximum value acceptable for a fitted distribution was used as the maximum bound. The maximum is considered reasonable because there is a large dataset of mine water chemistry and parameter concentrations in drainage water are not expected to increase significantly from the period of observed data to closure.

- The minimum value of a distribution was set to zero for the normal distribution, a value very close to zero (e.g., 0.00000001) for the lognormal distribution, or half the detection limit for the delta-lognormal distribution.

### 2.6.4 Initial Water Quality

Concentrations in ponds, sumps, and pits at the beginning of the calibration period are based on monitoring data in 2017. Concentrations in ponds, sumps, and pits at the beginning of the operations period are based on monitoring data in 2022. For closure, stochastic initial concentrations were based on a triangular distribution using the median, the 5th percentile, and 95th percentile predicted concentrations from operations in September 2024 as the lower and upper bounds on the distribution.

## 2.7 Model Assumptions

The key assumptions that have been made in the SWWQM are:

- The input water qualities used in the SWWQM are representative of their respective input sources and will continue to be representative over the modelled timeframe. Water quality data for model inputs were selected from available lab testing and field monitoring, augmented by professional judgement where necessary.
- Concentrations of parameters from monitoring data that were lower than the analytical detection limit were set equal to half the detection limit.
- Concentrations of parameters in direct precipitation onto the water surface of water management facilities were assumed to be zero.
- All open pits, ponds, and sumps are fully mixed systems. No stratification is considered over the modelled timeframe. All inputs are mixed with existing water volumes to calculate concentrations of parameters.
- All parameters are assumed to behave conservatively. That is, they are assumed to not settle, precipitate, sorb, degrade, or undergo any other process that would reduce concentrations. This assumption is likely to have negligible effects on major ion predictions but may lead to over-estimation of some nutrients and metals.
- All PAG waste rock will be disposed sub-aqueously in the Springer-Cariboo Pit at closure to mitigate onset of acid generation. Acid generation is not expected to occur prior to subaqueous disposal, and disposal in the Springer-Cariboo Pit Lake will prevent acid onset in the future by limiting oxidation in the waste rock. Geochemical characterization studies estimate the time to the onset of acid generation varies between decades and 100 years (MPMC 2015).
- The combined Springer-Cariboo Pit is assumed to be empty at the start of closure.
- Rock disposal sites are assumed to be reclaimed in post-closure following the reclamation schedule described in Section 2.3. Following revegetation, the runoff from these facilities is assumed to return to undisturbed runoff quality over the course of ten years.
- Diffusive flux from the submerged PAG waste rock into the Springer-Cariboo Pit Lake water cap was not modelled.
- Accumulation and flushing of oxidation products from weathered PAG material prior to subaqueous disposal was not modelled.
- No mass was removed or added to modelled systems through evaporation or direct precipitation. These processes affected water quantity only and did not affect mass of modelled parameters in the system.

# 3.0 MODEL CALIBRATION

The SWWQM was set up to hindcast concentrations from 1 January 2017 to 31 December 2021 at six locations:

- Springer Pit
- Wight Pit
- CCS
- PETBP
- TSF
- NW Sump

Where discrepancies between model results and monitoring data existed, the model was adjusted to better reflect monitoring data. The same adjustments, made during calibration of the SWWQM in the 2020 Water Management Plan (Golder 2020), were maintained in this update to achieve calibration with monitoring data:

- Adjusting the proportion of Wight Pit runoff and groundwater inflows assumed to be waste rock contact water based on storage of waste rock in the pit.
- Adjusting the proportion of runoff from waste rock that is assigned an undisturbed water quality input.
- In the TSF, applying calibration factors greater than 1.0 to improve the model calibration for chloride, fluoride, potassium, sodium, nitrite, antimony, arsenic, barium, lithium, molybdenum, and vanadium.

## 3.1 Calibration Results

Model calibration results are shown compared to monitoring data in Figures 4 to 9 (model calibration results for all parameters and locations are provided in Appendix A). Monitoring data were generally between the projected 5th and 95th percentile model calibration results for all parameters.

Where monitoring data fell within the 5th and 95th percentile model calibration results, the model was considered to be in good agreement with monitoring data. The good agreement indicates that model inputs were well characterized and that these parameters had low sensitivity to assumptions or model conditions not matching site conditions.

Where monitoring data were consistently below the 5th percentile predictions, the model was considered to be over predicting concentrations. Possible reasons why the model may be over-predicting concentrations are:

- The model was developed to predict water quality conservatively; where uncertainty exists in model inputs, the inputs are selected such that under-prediction would be minimized. Thus, over-prediction is generally expected. For example, seepage from RDS was assigned a NAG water quality for the entire model simulation period, which is a conservative assumption.
- Metal concentrations that are far below detection limits may be skewed upward by model inputs where half-detection limits were applied.
- Settling of particulate material is not accounted for in the model.

- Geochemical processes, such as precipitation and adsorption, are not accounted for in the model.

Although these factors may lead to over-prediction of concentrations, the model is considered valid for the purpose of predicting concentrations of parameters on the mine site and in the influent to the WTP because deviations in model predictions from monitoring data in this category tend toward additional environmental protection.

# 4.0 MODEL RESULTS

After the model calibration was completed, model simulations were performed for the following periods:

- Operations (1 January 2023 to 8 September 2024, Section 4.1)
- Closure (9 September 2024 to 8 September 2034, Section 4.2)
- Post-closure (9 September 2034 to 9 September 2124, Section 4.3)

Maximum predicted concentrations and time series results for these time periods are presented below.

## 4.1 Operations Model Results

The PETBP is the influent water to the water treatment plant, which discharges to Quesnel Lake. Maximum of the daily median and maximum of the daily 95$^{th}$ percentile concentrations in the PETBP are presented in Table 8. Predictions are shown assuming no treatment (with the exception of removal of TSS to a maximum monthly average of 15 mg/L), so that water treatment can be added or modified if necessary. Time series for predicted concentrations in the PETBP are presented for key parameters (i.e., parameters with permit limits) in Figures 10 to 15. In general, concentrations in the PETBP are predicted to remain relatively consistent during operations. This consistency is due to the assumption that the entire surface area of the RDS are accounted for at the beginning of the model simulation. Therefore, the runoff and seepage volumes from the RDS do not change. Changes in predicted concentrations in the PETBP (for example, from 600 mg/l to 300 mg/L for sulphate several times within a year [Figure 10]) are due to:

- Variable pumping from the TSF to the MDCS during operations. During periods when the TSF is pumped to the MDCS (P100 booster pumping in Figure 1), concentrations of most parameters increase in the MDCS. Concentrations decrease in the MDCS when there is no pumping from the TSF. Changes in MDSC water quality reach the PETBP through the pathway connecting the MDCS to the PETBP:
  - TSF → MDCS → SERDS Ditch → Long Ditch → CCS → PETBP
- Surface runoff at the mine site causes fluctuations in concentrations depending on the proportions of the catchment areas flowing into the facilities (e.g., RDS areas, disturbed areas, undisturbed areas). Parameter concentrations reach steady-state during the winter months (e.g., between November 2023 and February 2023) because surface runoff is low.

**Table 8. Predicted Maximum Concentrations in the Perimeter Embankment Till Borrow Pond – Operations**

| Parameter | Units | Predicted Maximum of Median Concentrations | Predicted Maximum of 95th Percentile Concentrations |

## 4.2 Closure and Post-closure Model Results

The following sections present predicted discharge water quality for each of the nine discharge locations in closure and post-closure (Section 2.4):

- 9 km Sump
- NW Sump
- Springer-Cariboo Pit Sump
- Mine Drainage Creek Sump
- Wight Pit
- Long Ditch
- South Embankment Seepage Collection Pond (SESCP)
- Main Embankment Seepage Collection Pond (MESCP)
- Perimeter Embankment Till Borrow Pond (PETBP)

Predicted concentrations for both the climate change and the base case water balance scenarios are presented. Trends in water quality predictions are similar in each of the water balance scenarios.

Maximum of median and 95$^{th}$ percentile predicted concentrations are presented for all modelled parameters. Time series for predicted discharge water qualities are presented for key parameters (i.e. parameters with permit limits). Time series predictions are also compared to historical observed data for each facility in the model as a quality control check.

### 4.2.1 9 km Sump and Northwest Sump

The 9K Sump and the NW Sump receive drainage from undisturbed and disturbed areas in their catchment areas, as well as runoff and seepage from the Temporary NW PAG Stockpile and East RDS. Discharge from the 9K Sump and NW Sump is assumed to be directed to Bootjack Lake.

Time series plots for key parameters in the 9K Sump for closure and post-closure are shown in Figures 16 to 18 for the climate change module results and in Figures 19 to 21 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 9 and 10 for the climate change and base case modules, respectively. Time series plots for key parameters in the Northwest Sump for closure and post-closure are shown in Figures 22 to 24 for the climate change module results and in Figures 25 to 27 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 11 and 12 for the climate change and base case modules, respectively.

Peak concentrations for most key parameters in the 9K Sump and NW Sump occur in the first two years of closure (2024 – 2025). During this period, the stockpiled PAG waste material is re-handled and placed in the Springer-Cariboo Pit. During re-handling, runoff and seepage from the Temporary NW PAG Stockpile is assigned a PAG waste rock water quality, hence the higher predicted concentrations.

Trends for all key parameters reach steady state conditions in the 9K Sump and NW Sump by approximately 2037, or ten years after the Temporary NW PAG Stockpile is assumed to be reclaimed (Figures 16 to 21 for the 9K Sump; Figures 22 to 27 for the NW Sump). Concentrations of most parameters gradually decrease as runoff water qualities from all facilities reporting to the 9K Sump are predicted to return to background water (Table 6). After the PAG material has been removed from the 9K Sump catchment area, runoff from the Temporary NW PAG Stockpile is assigned the disturbed runoff water quality and progressively returns to undisturbed over ten years, which causes concentrations of most parameters to decrease.

Seasonal concentration peaks during winter are associated with continued seepage through the reclaimed Temporary NW PAG Stockpile. During winter months, the relative flow contribution of seepage from the Temporary NW PAG Stockpile is high compared to runoff because snowfall is assumed to accumulate on the stockpile and not melt until spring. Seepage from the Temporary NW PAG Stockpile is assigned a PAG water quality input during reclamation and then a NAG water quality input in perpetuity once reclamation is complete. The NAG and PAG water quality in the seepage flows during the winter results in the seasonal winter peaks in concentrations.

The only parameters with predicted maximum concentrations greater in post-closure than closure are aluminum, arsenic, chromium, iron, lead, silver and silicon. These parameters have higher concentrations in the statistical distributions assigned for undisturbed runoff water quality than the statistical distributions assigned for PAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more flows on the Mine site, which results in predicted concentrations of aluminum, arsenic, chromium, iron, lead, silver and silicon to be higher in post-closure than closure.

**Table 9. Predicted Maximum Concentrations in the 9K Sump during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |
|---|---|---|---|---|---|---|---|

### 4.2.2 Springer-Cariboo Pit

At closure, the PAG material from the Temporary NW PAG Stockpile will be placed in the Springer-Cariboo Pit, and a pit lake will form. The pit will fill passively with groundwater and surface runoff from the pit catchment area. The groundwater inflow to the pit is assumed to flow into the stored PAG material in closure and post-closure. The surface runoff includes runoff and seepage from North Bell RDS, East RDS, and the haul roads. These facilities will be reclaimed in closure according to the schedule presented in Section 2.3. The pit lake is predicted to fill by 2048, at which point, overflow from the pit will discharge to Bootjack Lake.

Time series plots for key parameters in the Springer-Cariboo Pit for closure and post-closure are shown in Figures 28 to 30 for the climate change module results and in Figures 31 to 33 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 13 and 14 for the climate change and base case modules, respectively. It is anticipated that particulate metals such as aluminum and copper will be lower in pit lake waters compared to model predictions, as has been observed in operational monitoring (Golder 2016b).

Peak concentrations are predicted to occur before the post-closure period, around 2026 (Figures 28 to 33) because:

- The PAG material in the Springer-Cariboo Pit contains pore water with a PAG Dump Seep water quality (Table 6).
- The groundwater inflow to the pit, which has a groundwater water quality (Table 6), is assumed to flow into the PAG material and displace the pore water upwards into the forming pit lake.
- The displacement of pore water from the PAG material into the pit lake causes pit lake concentrations to peak in closure.

The only parameters with predicted maximum concentrations greater in post-closure than closure are potassium, aluminum, antimony, arsenic, chromium, copper, iron, lead, silver and silicon. Potassium, antimony and copper concentrations are higher in the statistical distributions assigned to the Cariboo and Springer pit wall runoff than the statistical distributions for the NAG waste rock water quality. Aluminum, antimony, chromium, iron, lead, silver and silicon have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to PAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to a greater proportion of the total inflows to the Springer-Cariboo pit.

**Table 13. Predicted Maximum Concentrations in the Springer-Cariboo Pit during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |

### 4.2.3 Mine Drainage Creek Sump

The Mine Drainage Creek Sump receives drainage from undisturbed and disturbed areas, haul roads, and RDSs in its catchment area. Discharge from the Mine Drainage Creek Sump is planned to be directed to Bootjack Lake.

Time series plots for key parameters in the Mine Drainage Creek Sump for closure and post-closure are shown in Figures 34 to 36 for the climate change module results and in Figures 37 to 39 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 15 and 16 for the climate change and base case modules, respectively.

For most parameters, predicted peak concentrations in the Mine Drainage Creek Sump occur at the beginning of closure, and then decrease as disturbed areas, haul roads, and RDS areas are reclaimed (Figures 34 to 39). Concentrations are highest at the beginning of closure for most parameters because RDS and haul road runoff is assigned the NAG water quality input until reclamation, which will occur throughout closure (Section 2.3). Water qualities from these facilities are predicted to return to background water quality (Table 6). Predicted water quality reaches steady state conditions by 2044, after all watershed areas have been reclaimed.

Seasonal peak concentrations during winter are driven by seepage from the East RDS. During winter months, when precipitation occurs as snowfall, East RDS seepage represents a high proportion of the total flow to the Mine Drainage Creek Sump and causes concentrations of parameters to peak.

Some parameters are predicted to have higher concentrations in post-closure than closure. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows to the Mine Drainage Creek Sump, which causes concentrations of parameters, such as aluminum, to increase from closure to post-closure.

**Table 15. Predicted Maximum Concentrations in the Mine Drainage Creek Sump during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |

### 4.2.4 Wight Pit

A pit lake will form in Wight Pit during closure as the mined-out pit refills passively with groundwater, seepage from Boundary Pit, surface runoff from pit walls, disturbed areas, and haul roads in the Wight Pit catchment. The pit lake is predicted to fill approximately five years into closure (2028), at which point overflow will be directed to Polley Lake. Reclamation of the disturbed areas and haul roads is assumed to occur throughout closure (see Section 2.1). Runoff water quality from these facilities is predicted to return to background water quality as presented in Table 6.

Time series plots for key parameters in Wight Pit for closure and post-closure are shown in Figures 40 to 42 for the climate change module results and in Figures 43 to 45 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 17 and 18 for the climate change and base case modules, respectively.

Predicted concentrations of key parameters in Wight Pit are generally stable in post-closure by 2050 (Figures 40 to 45). Concentrations of key parameters decrease slightly through early post-closure after the pit has filled and is flushed with runoff from reclaimed disturbed areas and haul roads in the Wight Pit catchment area.

Some parameters are predicted to have higher concentrations in post-closure than closure. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows into Wight Pit.

**Table 17. Predicted Maximum Concentrations in the Wight Pit during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |

### 4.2.5 Long Ditch

In closure, the Long Ditch continues to receive flow from the SERDS Ditch and overflow from Bootjack Creek Sump (via SERDS Ditch). Discharge from the Long Ditch will be directed to Polley Lake. The combined catchment area for the Long Ditch, the SERDS Ditch, and Bootjack Creek includes the SERDS RDS, NEZ RDS, and East RDS along with haul roads, disturbed areas, and undisturbed catchment area.

Time series plots for key parameters in Long Ditch for closure and post-closure are shown in Figures 46 to 48 for the climate change module results and in Figures 49 to 51 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 19 and 20 for the climate change and base case modules, respectively.

Peak concentrations in the Long Ditch are predicted to occur early in closure, representing runoff and seepage from un-reclaimed RDS areas within the combined catchment area for the Long Ditch, the SERDS Ditch, and Bootjack Creek (Figures 46 to 51). These facilities are reclaimed throughout closure, at which point runoff is assigned undisturbed water quality (Table 6). Parameter concentrations in the Long Ditch are predicted to decrease through closure, reaching steady state conditions in early post-closure, around 2044.

Seasonal peak concentrations in winter are driven by seepage from the RDS area within the watershed which is assigned the NAG water quality in perpetuity. During winter months, when precipitation occurs as snowfall, RDS seepage represents a higher proportion of the total flow to the Long Ditch and causes concentrations to peak.

Some parameters are predicted to have higher concentrations in post-closure than closure. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows into Bootjack Creek Sump, SERDS Ditch, and Long Ditch which causes concentrations of some parameters, such as aluminum, to increase.

**Table 19. Predicted Maximum Concentrations in the Long Ditch during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |

### 4.2.6 South Embankment Seepage Collection Pond

The SWWBM assumes that the SESCP has a small catchment area, and receives mostly TSF seepage in closure. Time series plots for key parameters in SESCP for closure and post-closure are shown in Figures 52 to 54 for the climate change module results and in Figures 55 to 57 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 21 and 22 for the climate change and base case modules, respectively.

Predicted peak concentrations in the SESCP occur at the beginning of closure, and then decrease as TSF beach and impoundment areas are reclaimed. Water quality is predicted to reach steady-state conditions by 2044, after the TSF surface has been reclaimed. Because the saturated TSF seepage is assumed to be the same water quality as the TSF beach, impoundment, and embankment areas, the decrease in SESCP concentrations is coincident with the decrease in parameter concentrations in the TSF beach and impoundment. The assigned TSF beach, impoundment and embankment water quality changes progressively from the TSF supernatant input to undisturbed water quality during the closure period causing the decrease in concentration in the TSF. As TSF concentrations decrease, concentrations in the SESCP decrease due to saturated seepage from the TSF. The increase in concentrations from 2034 to 2074 is due to a proportion of the seepage from the TSF to the SESCP that maintains an unsaturated water quality based on hydrogeologic modelling of seepage from the facility (Appendix F). While the range in predicted concentrations is considered reasonable, the timing of this transition is uncertain because the amount of time it may take to flush process water from the tailings is unknown.

**Table 21. Predicted Maximum Concentrations in the South Embankment Seepage Collection Pond during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |

### 4.2.7 Main Embankment Seepage Collection Pond

The SWWBM assumes that the MESCP has minimal surface catchment area from TSF area and undisturbed catchment area and receives mostly TSF seepage in closure. Discharge from the MESCP will be directed to upper Edney Creek. Time series plots for key parameters in MESCP for closure and post-closure are shown in Figures 58 to 59 for the climate change module results and in Figures 60 to 62 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 23 and 24 for the climate change and base case modules, respectively.

Peak concentrations in the MESCP occur at the beginning of closure, and then are predicted to decrease as TSF beach and impoundment areas are reclaimed (Figures 58 to 62). Reclaimed areas of the TSF beach and impoundment are assigned an undisturbed water quality. Predicted water quality reaches steady state conditions by 2044, after all watershed areas have been reclaimed. The increase in concentration from 2034 to 2044 for most parameters in the MESCP is caused by increased pumping rates from the SESCP. Pumping from the SESCP to the MESCP ends in 2044. Similar to the SESCP, the range in predicted concentrations is considered reasonable. However, the timing is uncertain because the amount of time it might take to flush process water from the tailings is unknown.

**Table 23. Predicted Maximum Concentrations in the Main Embankment Seepage Collection Pond during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |

### 4.2.8 Perimeter Embankment Till Borrow Pond

Discharge from the PETBP will be directed to Hazeltine Creek in closure. This discharge includes overflow and seepage from the TSF, as well as runoff from catchment areas of the PETBP, TSF, and CCS. Time series plots for key parameters in PETBP for closure and post-closure are shown in Figures 64 to 66 for the climate change module results and in Figures 67 to 69 for the base case module results. Maximum of median and 95th percentile predictions are presented in Tables 25 and 26 for the climate change and base case modules, respectively.

Predicted peak concentrations in the PETBP occur at the beginning of closure, and then decrease as TSF beach and impoundment areas are reclaimed (Figures 61 to 66). Reclaimed areas of the TSF beach and impoundment are assigned an undisturbed water quality (Table 6). The increase in concentrations of most parameters in the PETBP from 2034 to 2044 is caused by the increase in concentrations in the MESCP. Predicted water quality reaches steady state conditions by 2044, after all watershed areas have been reclaimed.

Some parameters are predicted to have higher concentrations in post-closure than closure. These parameters have higher concentrations in the statistical distributions assigned to undisturbed runoff water quality than the statistical distributions assigned to NAG waste rock water quality. As more areas are reclaimed on the Mine site, undisturbed runoff water quality is assigned to more inflows to the PETBP

**Table 25. Predicted Maximum Concentrations in the Perimeter Embankment Till Borrow Pond Pond during Closure and Post-closure - Climate Change Module**

| Parameter | Units | Closure (September 2024 to August 2034) | | Post-closure - First Ten Years (September 2034 to August 2044) | | Post-closure - Long Term/Steady State (September 2044 to August 2124) | |
|---|---|---|---|---|---|---|---|

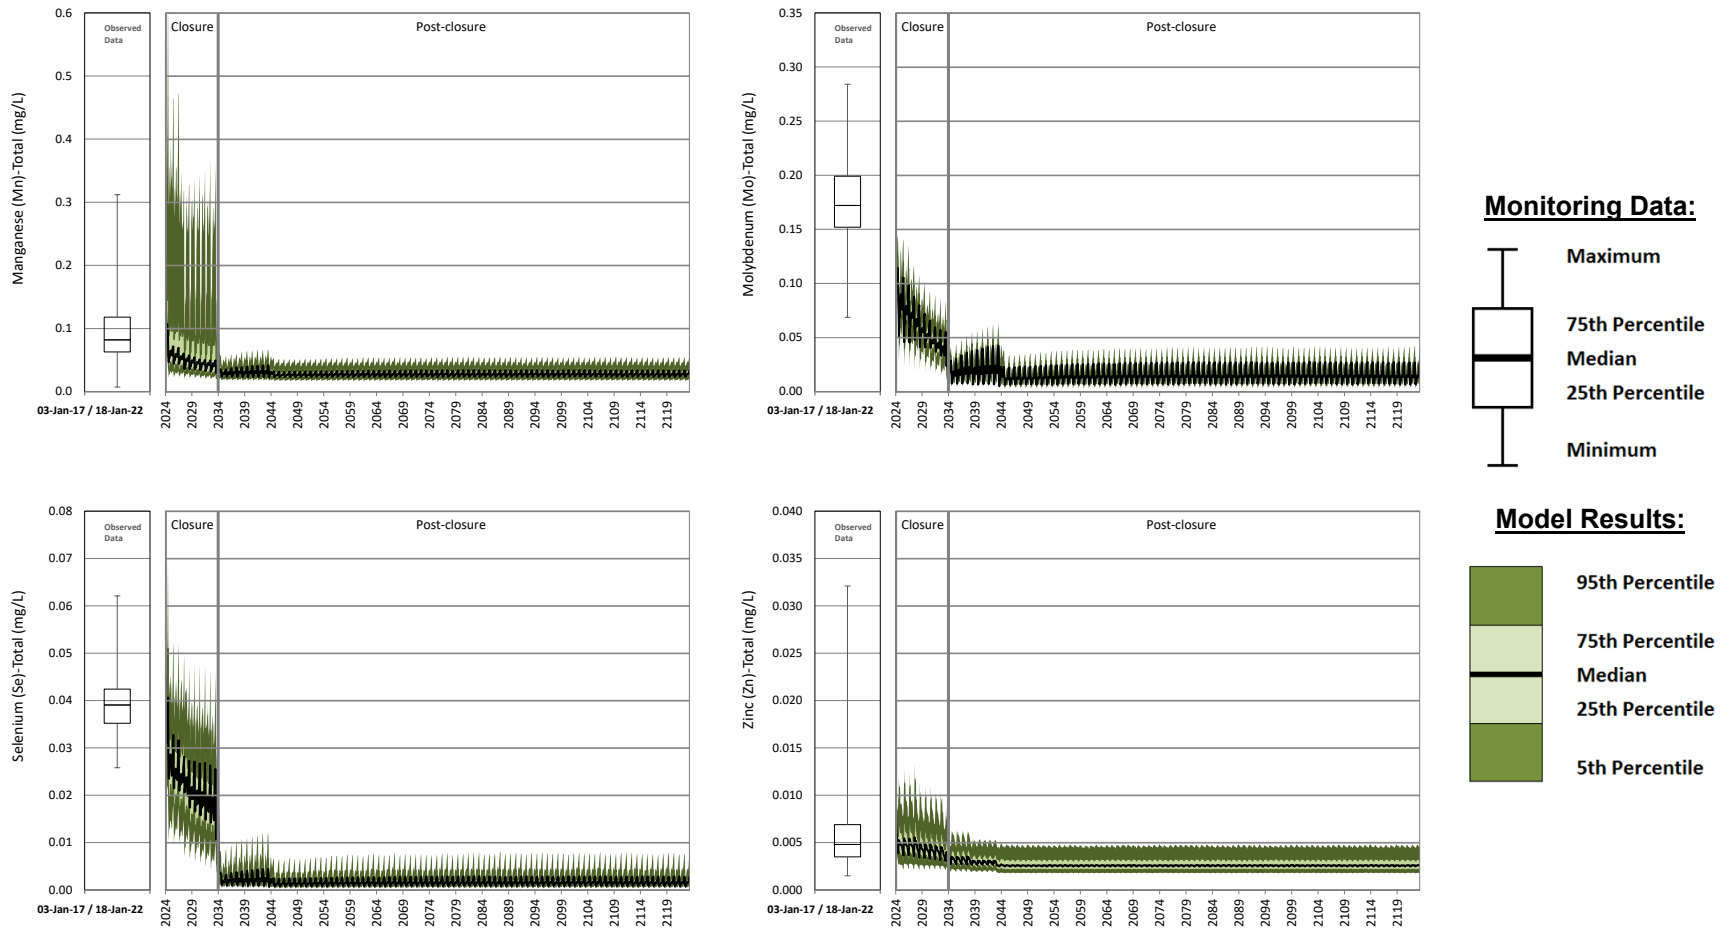

**Figure 69: Predicted Total Manganese, Molybdenum, Selenium and Zinc Concentrations in the Perimeter Embankment Till Borrow Pond during Closure and Post-closure – Base Case Module**

# 5.0 SUMMARY

The GoldSim model that was developed for the 2017 RCP to predict discharge water quality at the mine during closure and post-closure was updated with the latest RCP and water balance (base case and climate change scenarios) to reflect the closure and post-closure conditions on the mine site from 2024 to 2124. The model was also updated with additional monitoring data for assigned water quality inputs to refine the distribution inputs into the model. The updated model was calibrated against monitoring data from the mine site. During closure and post-closure, discharges from the mine will preferably be returned to their undisturbed watersheds, to the extent possible. Specifically, nine potential mine discharge locations are expected to drain to Polley Lake, Bootjack Lake, Edney Creek, and Hazeltine Creek.

Model results were generated for each potential discharge to inform treatment planning for closure and post-closure (Appendix G). In general, the model predicted higher concentrations in the closure period, relative to the post-closure period for most parameters with the exception of parameters that are predicted to be higher in the assigned undisturbed runoff water quality than in the assigned disturbed, NAG or PAG waste rock water quality.

# 6.0 CLOSURE

This report summarizes the reclamation and closure update of the SWWQM.

We trust this report satisfies your current requirements. Please contact the undersigned should you have any questions.

## 2016 Underground Stability Memo

**Mount Polley Mining Corporation**
**IMPERIAL METALS CORPORATION**

30 November 2016

Doina Priscu M.Eng, P.Eng
Golder Associates Ltd.

This letter evaluates the risk of surface subsidence following the closure of the underground mining operation at Mount Polley Mine.

The current situation in the mine is reflected in the following attached figures:

Figure 1 shows an oblique view of the underground workings beneath the Wight Pit. The Portal and Alimak Raise are both shown on the drawing as well as the active exploration site from which the Martel Zone is being diamond drilled. There are three completely extracted mining zones in the current mine:

- The Zuke Zone has very little void space, as the caved backs have nearly completely filled the stope voids with swelled muck. The prospect of caving to surface was presented as highly event unlikely in a report entitled “An Assessment of the Zuke Zone Back Caving”, prepared for MEM on 15 January 2016 by Asterisk Mining Services Ltd.
- The Boundary Zone is partially filled. The entire back of the Boundary Zone was cablebolted, and the system appears to be very effective, as no caving is evidenced anywhere in the back of the stope. The maximum void space is estimated to be 75,000 $m^3$, comprising 100% of the light blue (“D” stopes) and red (“C” stopes) shapes plus half of the dark blue (“B” stopes) shape in Figure 1. The white zone (“A” Stopes) were completely filled. It has exhibited stable walls and back at every stage of the mining process and minimal dilution was generated during mining. It is currently set up as a loose waste receiver, with the rock generated by the Martel exploration development drives placed in the stope without cement.
- The Halo Zone is completely open with a 26m x 26m open back and a void space of approximately 10,000 $m^3$. Unlike the Boundary Zone, no cable bolts were installed in the back. The ground of the Halo Zone was found to be the strongest and most competent unit in the mine and is still standing without any evidence of back or wall failure. The brow is still open.

Figure 2 shows a plan view of the underground workings with the surface projected over it, demonstrating the relative locations of the underground workings relative to the Wight Pit.

Figure 3 shows that the closest mining zone to surface is the 25m x 25m Halo Zone, with a rock covering of 185 m.

Figure 3 also shows the larger and deeper Boundary Zone, with a maximum open span of 67 m (25 m of which is reasonably tightly filled). The average width is 22 m, as demonstrated on Figure 4. The Boundary Zone is covered by a minimum of 217 m of rock.

Mine Management considers the risk of subsidence to surface to be minimal for four reasons:

1. The backs and walls of all open stopes exhibit no signs of failure.
2. There will be no future mining in the current zones to expand the current voids beyond their current dimensions.
3. The largest void, in the Boundary Zone, is already past its “worst case” scenario with a maximum open void of 75,000 $m^3$. It is actively being filled as part of ongoing operations with development muck, reducing this void on a daily basis.
4. Were any of the existing stope backs to fail, the open voids would be completely filled by muck due to the swell factor of the rock, estimated to be 30%. This would completely confine any back failure before it was able to propagate to surface. This phenomenon has been exhibited in the Zuke Zone back failures, which continue to be monitored and appear to have stopped. The Halo Zone would be anticipated to be confined after a failure of 33,000 $m^3$, representing a vertical distance of 53m above the stope (29% of the distance to surface). The Boundary Zone would be completely confined after a failure of 250,000 $m^3$, representing a failure distance of 170 m above the stope (78% of the distance to surface).

I trust that this memorandum addresses your concerns. Please let me know if additional information is required.

Regards,

R. Goodwin

Richard Goodwin, P.Eng

# 1 INTRODUCTION

Erosion results in the loss of soil particles, mineral nutrients and organic matter that support vegetation, and in turn, wildlife. In addition, eroded materials entering adjacent watercourses may adversely affect water quality, fish and fish habitat. This "Sediment and Erosion Control Plan" (the Plan) is a tool to provide direction for the management of surface erosion at Mount Polley Mine. The Plan addresses existing and potential surface erosion impacts associated with mine expansion (construction activities), operation, and decommissioning phases, and applies to all Mount Polley personnel and contractors. The main objective of this Plan is to minimize erosion and intercept potential sediments as close to the source as possible. Erosion and sediment control measures and best management practices (BMPs) are incorporated in the Plan as approaches to prevent erosion and the introduction of sediment into natural water bodies and watercourses. Guidelines for monitoring the efficacy of measures in this Plan are also outlined. This Plan is a "live" document that is to be routinely updated to reflect changes in site conditions and operations, as well as industry BMPs.

## *1.1 Legislation and Best Management Practices*

The following lists the federal and provincial regulatory requirements with regards to surface erosion prevention and sediment control. The guidance in the subsequent sections is designed to help works proceed in accordance with these regulations:

- BC *Water Act*
- BC *Environmental Management Act*
- Canada *Fisheries Act*

The following are examples of BMPs and guidelines applicable to surface erosion prevention and sediment control. These documents may be used as resource when developing project specific environmental management plans (EMPs). This Plan is designed to incorporate BMPs from these resources:

- "Environmental Best Management Practices for Urban and Rural Land Development in British Columbia" (Draft) (MWLAP, 2004)
- "Best Management Practices Guide for Storm water: Appendix H Construction Site Erosion and Sediment Control Guide" (Dayton and Knight, 1999)
- "Standards and Best Practices for Instream Works" (MWLAP, 2004)
- "Developing a Mining Erosion and Sediment Control Plan Version 1.0" (BC Ministry of Environment [MoE], 2015)
- "Land Development Guidelines for the Protection of Aquatic Habitat" (DFO, 1993).

### *1.2 Environmental Protection and Mitigation*

The general approach applied in this document is to reduce sediment sources and minimize contact between sediment sources and water. Where avoidance is not possible, mitigation measures are adopted to reduce erosion. Sediment and erosion control measures are, and will continue to be, used during construction, operation, and decommissioning activities at the Mount Polley Mine site. Such activities may include clearing vegetation and stripping topsoil, stockpiling topsoil, and constructing roads, infrastructure, tailings and water management structures. Potential hazards from these activities, in the absence of planned mitigation measures, include increased surface erosion from disturbed areas, increased sediment load to downstream receiving environments, and siltation or erosion of downstream watercourses or water bodies.

The subsequent sections discuss short- and long-term procedures for sediment retention and erosion control measures for work with potential for land surface disturbance..

## 2 SURFACE DEVELOPMENT/CONSTRUCTION PROJECTS

This section provides general guidelines to be followed for future construction projects and/or surface development on the mine site.

### *2.1 Pre-Project Planning*

The guidance documents referenced in Section 1.1 and, when necessary, qualified consulting professionals, are available to support planning of a specific project. Prior to starting any new construction work, the following should be considered:

- Design of projects to minimize the amount of ground cleared and disturbed.
- Design of projects to minimize disturbance adjacent to receiving environment watercourses and water bodies.
- Planning of works such that areas adjacent to waterways and drainage lines remain undisturbed or protected from erosion for as long as practicable.
- Planning of work to minimize the use of heavy equipment and have equipment conduct work as efficiently as possible.
- Planning of interim water and runoff management strategies to reduce erosion and identify available mitigation techniques in the event that sediment is mobilized.
- Planning of long-term erosion control measures to be implemented after project completion.
- Identification of monitoring and inspection requirements for during and after the project.
- Design of project criteria, construction plans, and mitigation for stream and other watercourse crossings to meet or exceed all standards and codes established by relevant authorities for the project.
- Obtaining the appropriate approvals prior to conducting works in and around watercourses and water bodies, and ensure works are being conducted in accordance with the regulated in stream work windows, or as otherwise agreed with relevant agencies. Permitting, notification, and reporting requirements for projects will vary based on their location and proximity to natural water bodies and water courses. These permits and notifications may include:
    - DFO Project Review;
    - Section 9 approval (*Water Act*);
    - MoE approval; and
    - Ministry of Energy and Mines (MEM) approval.

If the project has potential to impact natural watercourses or water bodies (i.e., if the work is outside site contact water collection systems and/or is adjacent to natural waterways), a site-specific EMP for project work should be developed. The EMP should include, at minimum:

- A summary of how information requirements in the bullets above have or are being implemented.
- Details of drainage patterns over the area, both clean water and potential construction runoff.
- Locations of adjacent environmentally sensitive areas that could be impacted.
- Details of existing or planned erosion and sedimentation control methods to filter or collect construction runoff.
- The locations of spill kits and extra sediment and erosion control materials.
- The location of any existing or planned drainage diversions.
- A general outline of the planned work.
- The location of any existing or planned required pumping or sediment ponds.
- An inspection and monitoring schedule.
- A revision number and date.

For projects requiring an EMP, appropriate training and awareness to involved supervisors, workers (employees and contractors) regarding their legal responsibilities of complying with general water quality related legislation should be conducted. Workers are to be made aware of the required mitigation measures for a task, in addition to any requirements contained in any public or private approvals and agreement documents.

The following subsections outline potential sediment and erosion control techniques that may be incorporated into planning, either as preventative or contingency measures.

### 2.1.1 Stabilization and Treatment Methods

Sediment control measures are to be planned and, if required, installed prior to any clearing or earthwork activities. Stabilization measures are put in place to prevent or reduce the mobilization of sediment by stabilizing the source (e.g., exposed soils). Typical interim measures that may be used to stabilize areas that have the potential to be sources of sediment to water bodies or watercourses include:

- Non-vegetative cover (e.g., gravel and straw);
- Rip-rap placement;
- Slope modification to reduce erosive energy (e.g., flattening or benching);
- Surface ripping and roughening to promote infiltration;
- Diversion berms and drains (in particular to intercept upstream runoff);
- Chute construction;
- Sandbags;
- Buffer zones; and
- Erosion blankets.

While pro-active stabilization measures are used to avoid the presence of sediment laden water, treatment measures may be necessary when it is not possible to completely prevent the mobilization of sediment. Typical treatment measures that may be used to manage sediment in contact water include the following:

- Check dams or weir drop structures;

- Outlet protection;
- Sediment retention ponds, sediment traps and sediment basins;
- Silt fence or similar barrier, such as straw; and
- Swales.

#### 2.1.2 Runoff Collection Ditches

Runoff collection ditches may be either temporary or permanent structures. Permanent surface runoff control works should be sized to convey runoff from a 1 in 10 year 24-hour flood flow and to withstand a 1 in 200 year 24 hour event without significant damage as per MoE Permit 11678.

The design of sections of ditch may depend on topography, excavation material (till or bedrock) and design discharge. Different material gradations or design approaches may be used for armoring depending on site-specific conditions and material availability. Any convergences with other ditches or streams should be armored.

Some initial flushing, erosion and self-armoring are expected following construction, and appropriate measures should be taken for ditches discharging into the receiving environment. For example, small ponds with rock overflow weirs can be constructed or this water can temporarily be collected in mine contact water systems until it is of appropriate quality to discharge. With aging, erosion and sediment runoff will be controlled to be comparable to natural conditions; however, inspections and monitoring (refer to Section 5) are required to confirm appropriate sediment control.

#### 2.1.3 Sediment Control Ponds

A sediment control pond is used to detain runoff from a disturbed area so that sediment can settle out of the water column. Sediment control ponds should be designed according to the “Guidelines for the Design, Size, and Operation of Sedimentation Ponds used in Mining” (MoE, 2002), where applicable.

### *2.2 Construction*

Construction should comply with the plans developed in the pre-construction phase (Section 2.1) so that work is conducted in a manner that avoids or minimizes erosion and the discharge of silt, sediment or other deleterious substances into any watercourse. Changes to the construction plan are to be reviewed by the appropriate Environmental Department and Engineering Department staff prior to implementation to allow sediment and erosion control plans to be revised accordingly.

Monitoring is to be carried out as per Section 5 of this document. Actions and maintenance that may be required based on monitoring observations include:

- Correcting deficiencies of the erosion and sediment control measures as soon as they are observed.
- Removal of any sediment and debris accumulation that compromises the effectiveness of the erosion and sediment control measures.
- Implementation of additional stabilization and treatment measures listed in Section 2.2.

Additional measures recommended for all stages of construction include:

- Monitor weather forecasts for upcoming rainfall or other climatic conditions that may affect the construction works and surrounding environment.

- Suspend work in areas adjacent to natural water bodies or watercourses during heavy precipitation or runoff conditions.
- Follow the project EMP (especially for pumping, diversion, or relocation of water undertaken) and revise it if the project work plan changes.
- Refer to the site Emergency Response Plan in the event of a major incident.

#### 2.2.1 Soil Salvage

Under MPMC's *Mines Act* Permit M-200, surficial soils are required to be stripped from the areas to be disturbed in advance of construction of works including waste rock dumps, waste or ore stockpiles, and roads. Stockpiles are often required to store salvaged soils for later use in reclamation, and further erosion control considerations apply, in addition to the earthworks project considerations discussed above. Stockpile locations should have minimal exposure to wind, southwest sun, and runoff pathways. Stockpiles should be promptly seeded with a native seed mixture containing grasses and/or forbes. If stockpiles have the potential to impact natural watercourses or water bodies, temporary erosion and control measures should be installed and maintained until a vegetative cover is established. Refer to the MPMC Soil Management Plan for additional details on the site protocol for soil salvage.

### *2.3 Post-Construction*

When a project is completed, long-term sediment retention and erosion control measures should be implemented. These measures may include elements of the stabilization and treatment options in Section 2.1.1, as well as:

- Restricting access to areas being rehabilitated.
- Establishing a vegetative cover.
- Armoring areas receiving surface runoff.
- Slope modification to reduce erosive energy, such as flattening or benching.
- Surface ripping and roughening to promote infiltration.
- Diversion berms and drains (in particular to intercept upstream runoff).

Any interim measures should remain in place until long-term controls are established. When monitoring and inspections (as described in Section 5) find long-term measures are sufficient, interim or temporary erosion and sediment control features may be reclaimed.

# 3 MINE OPERATIONS

Sediment and erosion control practices for new disturbances at the mine site are to follow the procedures outlined in Sections 2.1 to 2.3, but measures are also to be implemented and maintained on a site-wide scale.

### 3.1.1 Collection of Mine Contact Water

Collection of runoff from disturbed areas on site that may impact water quality in the receiving environment is to be carried out across the mine site. Thus, runoff from disturbed areas that potentially contains sediments is not directly released to the environment. Water from these collection systems is stored on site, and is not permitted to be discharged to the environment unless specific regulatory requirements are met. These requirements include maximum allowable total suspended solids and turbidity levels, necessitating removal of suspended sediments through active or passive treatment prior to discharge.

To minimize the volume of contact water collected and stored at the site, upstream ditches to divert non-site contact water may be constructed. As water from these works enters the receiving environment, for construction of new diversion ditches, an EMP should be developed and followed for construction, and the guidelines in Sections 2.1 to 2.3 followed.

Inspection and monitoring requirements for site water collection systems and diversion ditches are outlined in Section 5.

### 3.1.2 Emergency Release of Water

If emergency release of water from the site water collection system should occur, sediment and erosion control materials are to be installed, as required, to avoid the displacement of sediment as water moves over land. These materials are stored in the Environmental C-Can located beside the Leach Pad, and the Environmental Department staff is available to guide proper installation. The Mount Polley Emergency Response Plan and Water Management Inspection Manual outline in more detail response protocol for such events, and Section 5 outlines event-based monitoring procedures.

### 3.1.3 Adaptive Management

This Plan is designed to be updated as sediment and erosion control science and BMPs develop over time. It is also designed to be adapted for operational changes and water management needs at the mine site. Continuous improvements that may be carried out include (but are not limited to):

- Changes to the design of works to eliminate deficiencies that are noted during inspections and require regular maintenance.
- Implementation of mitigation measures in response to water quality trends noted in the receiving environment.
- Implementation of measures that reduce treatment needs prior to discharging water.
- Implementation of measures to reduce maintenance costs.
- Implementation of measures to reduce environmental risk.

Measures in place to identify areas where maintenance or mitigative measures are required are (or opportunities for improvements exist) are described in Section 5.

# 4 DECOMMISSIONING AND RECLAMATION

At closure, MPMC is responsible for leaving the mine site in compliance with all regulations, including site runoff water quality and revegetation to meet end land use and land capability objectives. The following steps should be implemented during reclamation works to reduce erosion:

- Grade and contour any disturbed areas to promote drainage and conform to adjacent topography.
- Apply soil in a rough manner to create microtopography.
- Apply coarse woody debris, as available, to the reclamation site if it is not already incorporated into the soil.
- Seed and/or plant disturbed areas with a suitable mixture of grass, legume and woody species to establish ground cover and provide stabilization in a timely manner.
- On disturbed areas with potential to impact natural water bodies or watercourses, maintain temporary stabilization measures, such as geotextile or mulch until a vegetative cover is established.

Detailed soil application and revegetation plans that include methods for reducing erosion are included in the site Reclamation and Closure Plan. Monitoring and inspections requirements for reclaimed sites are included in Section 5.

# 5 MONITORING AND INSPECTIONS

Site monitoring and inspections of sediment and erosion control systems are based on associated risk to the environment. Figure 1 identifies environmentally sensitive areas (i.e., receiving environment waterways) adjacent to the Mount Polley Mine footprint that could potentially be impacted by sedimentation. It also shows the location of contact water conveyance structures, areas undergoing progressive reclamation and soil stockpile locations, which are potential sources of sediment. Table 1 relates potential sediment sources to these sensitive areas and assigns a level of risk based on sensitivity of the receiving environment (receiver size, fish bearing status, etc.) and erosion potential. Note that Hazeltine Creek and adjacent areas impacted by the August 4, 2014 TSF breach are outside of the scope of this document.

Based on the risk matrix and site conditions, water management works appear to be the largest risk to receiving environment systems, because:

- Reclamation areas and soil stockpiles on site (with the exception of localized active stripping and stockpile locations) have all been seeded or inspected to confirm natural revegetation is underway. Site-specific observations from routine reclamation inspections and annual soil stockpile surveys indicate that minimal erosion is occurring at these sites.
- Mine site hydrology systems are snowmelt dominated, and periods of high flow are experienced annually during freshet, meaning that:
    - There is higher potential for in-ditch erosion;
    - There is higher potential for erosion by surface runoff that reports to collection ditches; and
    - Risk of an emergency release of water is elevated.
- Collection ditches are located downstream of disturbed areas on site, and collect and convey any turbid water that is generated from disturbed areas on site.

Thus, water management inspections are the primary focus of the monitoring program. In the following subsections, monitoring and inspection requirements, roles and responsibilities, and reporting protocol are outlined. Protocol is broken into the following areas:

1. Water Monitoring;
2. Reclamation areas (soil stockpiles and progressive reclamation sites); and
3. Construction projects.

Note that these monitoring programs are reflective of current conditions (operations phase of the mine life). At closure, they revisions for post-closure conditions will be made to this document and it will be incorporated into the site Closure Management Manual.

**Table 1.** Mount Polley Sediment and Erosion Control Risk Matrix

| Receiving Environment Area | Area Sensitivity | Primary Potential Source(s) | Secondary Potential Sources(s)[1] | Erosion Potential Considerations[2] | Risk[3] |
|---|---|---|---|---|---|
| **6km Creek** | - Not fish bearing in upper reaches<br>- Variable forest buffer | - Access Road<br>- Junction Zone Ditch or 9km Sump | - NW PAG Stockpile soil stockpiles<br>- NW PAG Stockpile/Junction Zone Ditch access roads<br>- NW Sump | - Established gravel ditch bottom<br>- Upstream area mostly covered with waste rock<br>- Soil stockpiles revegetating<br>- Two high traffic road crossings | Medium |
| **Mine Drainage Creek** | - Not fish bearing<br>- Connected to Bootjack Lake | - Mine Drainage Creek Sump<br>- West Ditch | - Waste Haul Road<br>- Helipad reclamation parcel<br>- Crusher Access Road<br>- Ore Switchback Road<br>- Cariboo Stockpile and soil stockpiles<br>- Pipeline from Springer Pit to water treatment plant | - Some unarmoured ditch sections<br>- Some till placed on outer slope of Waste Haul Road<br>- Active haul traffic on roads (can develop sediment-laden puddles)<br>- Cariboo Stockpile soil stockpiles new<br>- Helipad reclamation parcel revegetating<br>- Majority of runoff into ditch (including from reclamation and soil stockpile areas) filters through rock haul road<br>- Water in pipeline to treatment plant contains low total suspended solids | Medium |
| **W20 Creek** | - Fish bearing (very low productivity)<br>- Variable forest buffer | - West Ditch<br>- West Ditch Access Road | - Light Vehicle Tailings Road<br>- Waste Haul Road<br>- Above Waste Haul Road reclamation parcel<br>- Pipeline from Springer Pit to water treatment plant | - Ditch armoured<br>- Reclamation parcel revegetating; upstream of Waste Haul Road<br>- Active haul traffic on roads (can develop sediment-laden puddles)<br>- Water in pipeline to treatment plant contains low total suspended solids<br>- Majority of runoff into ditch filters through rock haul road | Medium |
| **Bootjack Lake** | - Fish bearing,<br>- Medium sized receiver<br>- Variable forest buffer | - NW Sump<br>- NW Ditch<br>- Mine Drainage Creek Sump<br>- West Ditch<br>- West Ditch Access Road<br>- Mine Drainage Creek<br>- W20 Creek | - Waste Haul Road<br>- Helipad reclamation parcel<br>- Crusher Access Road<br>- Ore Switchback Road<br>- Cariboo Stockpile and soil stockpiles<br>- Light Vehicle Tailings Road<br>- Waste Haul Road<br>- Above Waste Haul Road reclamation parcel<br>- Pipeline from Springer Pit to water treatment plant | - Some unarmoured ditch sections<br>- Some till placed on outer slope of Waste Haul Road<br>- Active haul traffic on roads (can develop sediment-laden puddles)<br>- Cariboo Stockpile soil stockpiles new<br>- Reclamation parcels revegetating<br>- Water in pipeline to treatment plant contains low total suspended solids<br>- Majority of runoff into ditch filters through rock dumps and rock haul road | Medium |
| **North Dump Creek** | - Not fish bearing in upper reaches<br>- Variable forest buffer | - Joe's Creek Coffer Dam<br>- Joe's Creek Pipeline<br>- Gavin's Ditch (clean water diversion)<br>- Wight Pit Ditch (clean water diversion)<br>- Wight Pit Haul Road | - North Bell Dump reclamation areas and soil stockpiles<br>- Access Road<br>- East Dump reclamation areas and soil stockpiles | -Joe's Creek Coffer Dam/Pipeline water very low turbidity/suspended solids<br>- Ditches armoured or have established low-erodibility substrates except some potentially erodible sections in Wight Pit Ditch<br>- East Dump reclamation area in early stages of revegetation<br>- Varying levels of soil stockpile revegetation (some new)<br>- Two moderate use road crossings | Medium |
| **Bootjack Creek** | - Not fish bearing<br>- Connected to Polley Lake | - Bootjack Creek Sump<br>- Tailings Access Road Ditch<br>- SERDS Ditch | - Tailings Access Road<br>- Tailings Access Road soil stockpiles<br>- SERDS access roads<br>- Southeast Zone soil stockpiles | - Some erodible ditch sections<br>- Portion of runoff into ditches filters through waste rock roads/dumps<br>- Three high use road crossings | Medium |
| **Polley Lake** | - Fish bearing,<br>- Large sized receiver<br>- Forest buffer | - Wight Pit Ditch (clean water diversion)<br>- Long Ditch<br>- North Dump Creek<br>- Bootjack Creek | - North Bell Dump reclamation areas and soil stockpiles<br>- Access Road<br>- NEZ Dump reclamation area and soil stockpiles<br>- East Dump reclamation areas and soil stockpiles<br>- Tailings Access Road<br>- Tailings Access Road soil stockpiles<br>- SERDS access roads<br>- Southeast Zone/SERDS soil stockpiles | - Varying levels of revegetation of upstream reclamation areas and soil stockpiles<br>- Ditches armoured or have established low-erodibility substrates except some potentially erodible sections in Wight Pit Ditch | Low |
| **Hazeltine Creek**[4] | - Not fish bearing<br>- Undergoing rehabilitation<br>- Sedimentation ponds constructed at outflow | - Polley Lake<br>- Long/SERDS Ditch (combined)<br>- Central Collection Sump<br>- Perimeter Till Borrow Pit and ditch from Central Collection Sump<br>- Pipeline from Springer Pit to water treatment plant<br>- Edney Creek | - TSF and associated infrastructure<br>- TSF Perimeter Embankment and PAR soil stockpiles<br>- TSF Ditch (clean water diversion)<br>- TSF South Seepage Pond<br>- TSF South Toe Drain Ditch<br>- TSF Main Seepage Pond<br>- ABR/Main Seepage Pond Ditch | - High volume water transfers<br>- Water has time to settle in the TSF and Perimeter Embankment Till Borrow Pit<br>- Water in pipeline to treatment plant contains low total suspended solids<br>- Soil stockpiles varying levels of revegetated<br>- South Till Borrow area revegetation is advanced<br>- Active TSF construction upstream | Medium (risk will increase when the creek returns to fish-bearing status) |
| **Edney Creek** | - Fish bearing<br>- Forest/wetland buffer | - TSF Ditch (clean water diversion)<br>- TSF South Seepage Pond<br>- TSF South Toe Drain Ditch<br>- TSF Main Seepage Pond<br>- ABR/Main Seepage Pond Ditch<br>- South Till Borrow reclamation area | - TSF and associated infrastructure<br>- South and Main Embankment soil stockpiles | - Few erodible ditch sections<br>- Low water volumes managed<br>- Water seepage ponds contain low turbidity/suspended solids<br>-New soil stockpiles (early stages of revegetation)<br>- Active TSF construction upstream<br>- South Till Borrow area revegetation is progressing | Low |

**Notes:**

1) Secondary sources are potential sources of sediment that are upstream of (i.e., potentially contribute to) primary sources

2) Historic turbidity and total suspended data in relevant water collection infrastructure were considered when assessing erosion potential; water management contingency measures in place across water management system

3) Based on combination of area sensitivity and erosion potential

4) Sediment and erosion control in Hazeltine Creek beyond the mine footprint related to the Tailings Storage Facility embankment breach is managed under a separate program

### *5.1 Water Monitoring (Site Infrastructure and Receiving Environment)*

#### 5.1.1 Inspections

Daily inspections of site water containment infrastructure are completed as per the Water Management Inspection Manual to verify the collection system is working as designed. As per this document, inspections are completed at least once on day shift and night shift during high risk periods (i.e. freshet). The inspection form template is included as Appendix A. Completed forms are provided to the Environmental Department for review and filing at the end of each seven (7) day set. Note that protocol and triggers are in place for immediate notifications to occur if deficiencies are observed. Daily inspections are the responsibility of Mill Maintenance, and the Environmental and Engineering Departments are responsible for updating the Water Management Inspection Manual, which is a component of the site Operation Maintenance and Surveillance (OMS) Manual.

Thorough inspections of all site water management infrastructure (sumps, ditches, culverts, etc.) are completed in spring after freshet and in fall prior to freeze up, as per *Environmental Management Act* Permit 11678. This is the responsibility of the Environmental Department. Results are documented in the inspection form (refer to the template provided as Appendix B) and filed internally. Inspection results are used to inform upgrades of water management structures. Noted deficiencies, including areas of sedimentation or erosion, are compiled and prioritized in a project list which is provided to the Engineering Department to address, based on the identified levels of urgency.

As per the Water Management Inspection Manual, supplemental inspections are to be completed by Mill Maintenance, Mine Operations, and the Environmental Department during high risk periods (i.e., precipitation and/or snowmelt runoff events), with support from the Engineering Department. Aside from the frequency changes, the inspection procedure is consistent with the one previously described. Inspection reports from high flow periods provide feedback on the functioning of site water collection systems under conditions when erosion potential is higher. Noted deficiencies are incorporated into project planning for continuous improvements along with findings from routine inspections as described above.

#### 5.1.2 Contact Water Monitoring

Routine monitoring of mine site contact water conveyed through various infrastructure components is conducted as per *Mines Act* Permit M-200. This sampling program, including sample locations, frequencies, and QA/QC procedures, is detailed in the site OMS Manual, which is regularly updated to account for operational changes at the mine site. All routine samples collected on site are analysed for physical parameters (including total suspended solids and turbidity), anions, nutrients, and total and dissolved metals. Monitoring locations and frequencies (at the time of this update) are shown in Figure 1.

These sample results are included in the Annual Environmental and Reclamation Report to MoE and the MEM, which is written and submitted by the Environmental Department.

Results from these samples are used, along with inspection results, to identify potential upgrade opportunities for site water conveyance structures as described in Section 5.1.1

### 5.1.3 Receiving Environment Monitoring
