Executive Summary

Golder Associated Ltd. (Golder) was retained by Mount Polley Mining Corporation (MPMC) to conduct a human health risk assessment (HHRA) of the tailings spilled following the Tailings Storage Facility (TSF) embankment breach at the Mount Polley Mine (herein referred to as "the Mine") on 4 August 2014. The HHRA outlined in this report focuses on the evaluation of potential long term impacts of the TSF embankment breach to people who may be present on the off-site impacted area downgradient of the TSF. The HHRA is one of several technical deliverables related to the assessment of impacts related to the TSF embankment breach. An ecological risk assessment that includes a terrestrial and aquatic component will be completed under separate cover.

The HHRA was conducted following the guidance as directed by Technical Guidance 7, which is consistent with Health Canada (2010a, 2012) and generally with international risk assessment guidance such as the United States Environmental Protection Agency (US EPA) Risk Assessment Guidance for Superfund.

Currently, the Hazeltine Channel receiving environment is within provincial crown land designated as a mixture of wildlands and backcountry recreational areas, with a small section of land designed within an Agricultural Land Reserve along lower Hazeltine Channel. The area designated as an Agricultural Land Reserve is forested. For the purpose of the HHRA, the overall land use of the remediation areas is considered to be wildland, with people accessing the area for recreational and subsistence land uses.

Subsistence use includes hunting, collecting plants and fishing. Although specific data regarding local consumption rates for different traditional foods was not available to the study team, community liaison members have reported that the land was, and still is, used for harvesting of food. Therefore, the HHRA included a First Nation subsistence and traditional land user receptor who was assumed to harvest food from the land. The subsistence and traditional land user is considered to be the most sensitive receptor, due to the assumptions made regarding reliance on traditional foods.

Current uses of Polley Lake, Quesnel Lake and Quesnel River include commercial, recreational and aboriginal fisheries, and recreational uses such as swimming, boating, kayaking, canoeing and waterskiing, and in the winter, snowmobiling and ice fishing when ice conditions allow. Quesnel Lake is also used as a source of drinking and residential water for domestic purposes[1].

The following receptors were evaluated in the HHRA:

- Subsistence and Traditional Land User
- Hiker/Camper
- ATV/Snowmobile User
- Boater/Kayaker
- Sport Fisher

[1] Domestic purposes as defined in the BC Water Act means the use of water for household requirements, sanitation and fire prevention, the watering of domestic animals and poultry and the irrigation of a garden not exceeding 1012 m^2 adjoining and occupied with a dwelling house.

- Hunter/Trapper
- Quesnel Lake Resident
- Logger
- Mine/Rehabilitation Worker

The DSI Update (Appendix A) identified contaminants in soil, groundwater, sediment and surface water. The contaminants in these media were evaluated in the HHRA. Aluminum was also evaluated at the request of the project reviewers. The following COPCs were identified for the HHRA:

- **Soil**: no CSR exceedances; aluminum added at the request of project reviewers
- **Groundwater**: no access to groundwater along Hazeltine Corridor
- **Sediment**: vanadium exceeded CSR PL standard; aluminum added at the request of project reviewers
- **Surface water**: none; no exceedances of drinking water standards
- **Air**: none; all potential contaminants met screening criteria
- **Vegetation**: copper and vanadium; aluminum added at the request of project reviewers
- **Fish**: aluminum, copper and vanadium; screening criteria not available, COPCs were identified based on the media listed above

Risks to the subsistence and traditional land user, hiker/camper, ATV/snowmobile user, boater/kayaker, sport fisher, hunter/trapper, Quesnel Lake resident, logger and mine/rehabilitation worker from exposure to aluminum, copper and vanadium were evaluated in the HHRA. Specifically, the following exposure pathways were evaluated:

- **Subsistence and traditional land user**: incidental sediment and soil ingestion, dermal contact with sediment, soil and surface water, inhalation of soil particulates, ingestion of surface water and ingestion of berries, traditional plants, deer meat, deer liver, moose meat, moose liver, fish and grouse
- **Hiker/Camper**: incidental sediment and soil ingestion, dermal contact with sediment, soil and surface water, inhalation of soil particulates, ingestion of surface water and ingestion of berries
- **ATV User**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of berries
- **Boater/Kayaker**: incidental sediment ingestion, dermal contact with sediment, ingestion of surface water and ingestion of fish
- **Sport Fisher**: ingestion of surface water and ingestion of fish
- **Hunter/Trapper**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of deer, moose, fish and grouse

- **Quesnel Lake Resident**: incidental sediment ingestion, dermal contact with sediment and surface water, ingestion of surface water and ingestion of berries, deer, moose, fish, grouse and cattle
- **Logger**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of fish
- **Mine/Rehabilitation Worker**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of berries and fish

Even with the conservative assumptions applied in the HHRA, the results indicate that risks are low for the subsistence and traditional land user, hiker/camper, ATV/snowmobile user, boater/kayaker, sport fisher, hunter/trapper, Quesnel Lake resident, logger and mine/rehabilitation worker exposed to aluminum, copper and vanadium in sediment, soil, surface water and dietary items (i.e., berries, plants, deer meat, deer liver, moose meat, moose liver, grouse, fish and cattle). The calculated hazard indices were below the threshold of 1 for each of the exposure pathways.

The estimated risks for the above receptors were considered acceptable because the hazard indices were below the threshold of 1.0. The majority of hazard indices were less than 1. Therefore, human health risks associated with the TSF embankment breach are considered to be very low.

The only risk control for the human health risk assessment is that groundwater in the Hazeltine Corridor should not be used for drinking water purposes unless found acceptable by a qualified professional. The rationale behind this risk control includes:

i) Based on the investigations of the tailings impacted groundwater, the following metals exceeded the drinking water standards: iron, manganese, arsenic, molybdenum, sulfate.

ii) Test wells were installed within the tailings deposition overlying the native till. The tailings thickness at the test well locations was generally 1-1.5 metres in the areas where the test wells were installed.

iii) Currently, there are no groundwater supply wells in the Hazeltine Corridor and no exposure pathway to groundwater.

iv) If groundwater supply wells are installed along the Hazeltine Corridor in the future, installation and evaluation of groundwater quality should be conducted under the supervision of a qualified professional.

This HHRA was conducted according to Technical Guidance 7, Supplemental Guidance for Risk Assessment. Risks to human health were quantified and found to be less than 1.0. Therefore, in accordance with the CSR **18**(3)(b), risks to human health are acceptable under current and future conditions.

1.0 INTRODUCTION

Golder Associated Ltd. (Golder) was retained by Mount Polley Mining Corporation (MPMC) to conduct a human health risk assessment (HHRA) of the tailings spilled following the Tailings Storage Facility (TSF) embankment breach at the Mount Polley Mine (herein referred to as "the Mine") on 4 August 2014. Note that in this report, "spilled tailings" refer to a mixture of tailings, construction materials and scoured natural soils and sediments.

Immediately following the TSF embankment breach, the Mine implemented a Rehabilitation and Remediation Strategy (R&RS) as outlined in the Figure 1. Phase I of the R&RS focused on control of the tailings release and site safety measures. Phase II of the R&RS involved an evaluation of the impacts of the TSF embankment breach immediately following the release. The HHRA outlined in this report is included in Phase III of the R&RS and focuses on the evaluation of potential long term impacts of the TSF embankment breach to people who may be present on the off-site impacted area downgradient of the TSF.

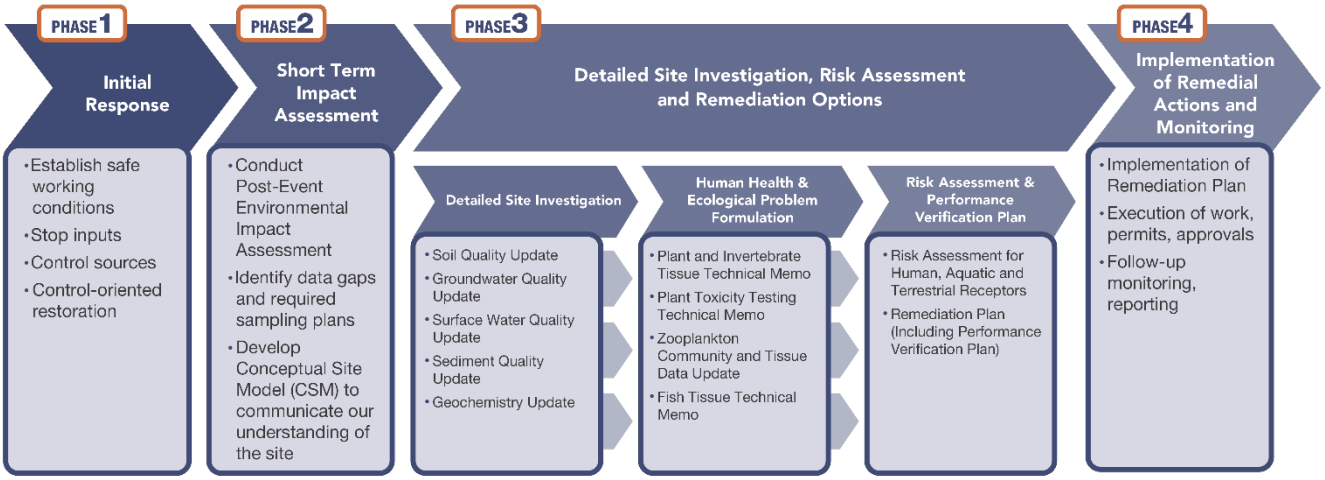

Figure 1: Rehabilitation and Remediation Strategy

The spatial areas of the zone of potential impact were identified early in the R&RS process and are outlined as areas of potential environmental concern (APECs) in Figure 2. These APECs collectively make up the area of investigation and are referred to as the "Study Area". Several investigations have been conducted of the physical, chemical and biological changes to these APECs as part of Phase II of the R&RS (MPMC 2015a). The findings of these reports have been used and referred to in this assessment.

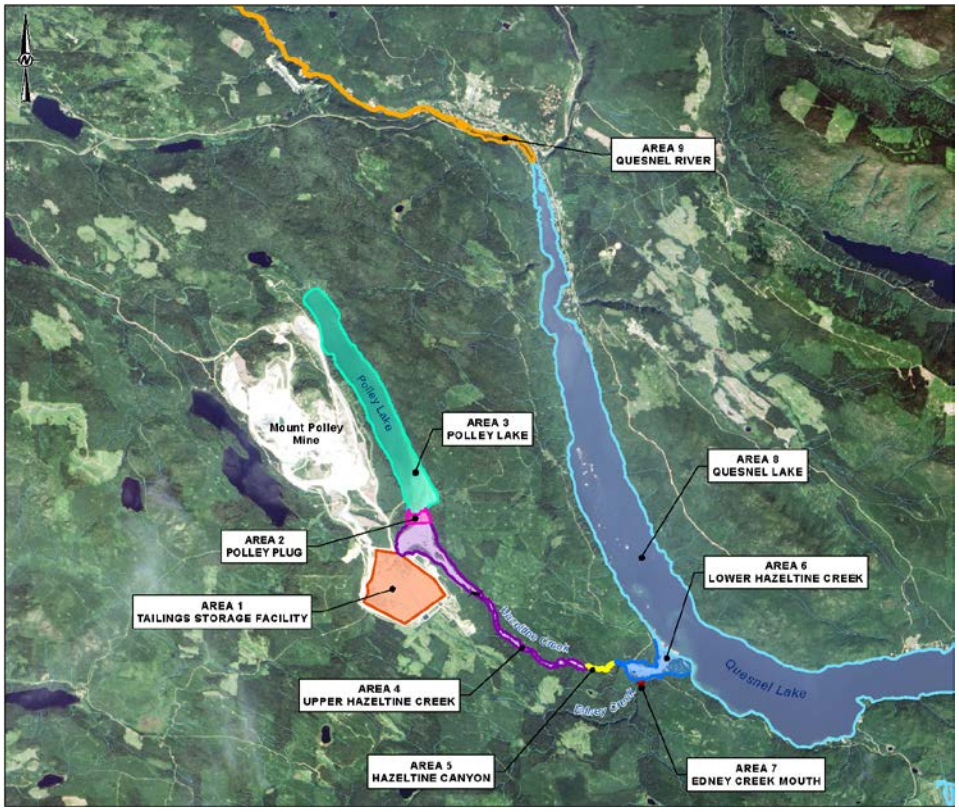

Figure 2: Mount Polley Mine TSF Embankment Breach Remediation Areas

1.1 Regulatory Context

In British Columbia (BC), environmental matters pertaining to the investigation and remediation of contaminated sites fall under the jurisdiction of the BC Ministry of Environment (MoE), pursuant to the Environmental Management Act (EMA; SBC 2003, Chapter 53 assessed 23 October 2003, including BC Reg. 179/2016 amendments effective 19 July 2016). Exceptions include federal lands and waters with migratory fish that fall under the jurisdiction of Environment Canada. The two key regulations under the EMA relating to the assessment and remediation of contaminated sites are the Contaminated Sites Regulation (CSR; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 184/2016, effective 19 July 2016), and the Hazardous Waste Regulation (BC Reg. 63/88, O.C. 268/88 including amendments up to BC Reg. 179/2016 App 1 amendments effective 19 July 2016).

The areas impacted by the tailings from the TSF embankment breach are under a Pollution Abatement Order (PAO; #107461) issued pursuant to Section 83 (1c) of the EMA. Section 83 outlines the actions to be taken to satisfy the Act, including a requirement to "undertake investigations, tests, surveys and any other action the director considers necessary to determine the extent and effects of the pollution and to report the results to the director" (Section 83[2b]). Pollution, in the context of the EMA, refers to substances or contaminants that substantially alter or impair the usefulness of the environment (Section 1[1]). The CSR 11(1) defines contaminants as those parameters that exceed the applicable CSR standard for the site.

The HHRA outlined in this report fulfills the requirement of the PAO Amendment to conduct a HHRA under the EMA. An ecological risk assessment that includes a terrestrial and aquatic component will be completed under separate cover. The separation of these two risk assessment reports is being done at the request of project reviewers.

The EMA, the CSR and its associated Protocols and Technical Guidance directly address the central question of determining whether contaminants associated with the release of tailings have the potential to constitute pollution that impairs the environment. Ultimately, the purpose of the HHRA is to determine if health risks associated with the tailings are acceptable for human health or if remediation works are needed for compliance with the CSR and EMA.

1.2 Technical Approach for Risk Assessment

In BC, preferences and policy decisions applicable to contaminated site HHRAs are contained in Technical Guidance 7 (BC MoE 2015a). Technical Guidance 7 provides “guidance related to the performance of human health and ecological risk assessments for contaminated sites in British Columbia [to] supplement existing provisions in protocols under the Environmental Management Act”. The guidance identifies the preferred sources for model parameterization and toxicity reference values (TRVs) for HHRAs.

The HHRA was conducted following the guidance as directed by Technical Guidance 7, which is consistent with Health Canada (2010a, 2012) and generally with international risk assessment guidance such as the United States Environmental Protection Agency (US EPA) Risk Assessment Guidance for Superfund. Key decisions that reflect specific information from Technical Guidance 7 include:

- Problem Formulation elements such as the evaluation of potential exposure pathways, human ‘receptors’, contaminants of potential concern (COPCs) and scenario assumptions followed Health Canada (2010a, 2012). If a particular exposure parameter, equation or scenario was not available in applicable Health Canada guidance, US EPA guidance was used.
- The purpose of the Problem Formulation step is to focus the quantitative steps of the risk assessment on those potentially significant exposure pathways that warrant further assessment and to identify those pathways that are not significant and do not require further assessment.
- Toxicological equations followed Health Canada (2010a, 2012).
- Classification of substances as carcinogenic followed the preferred hierarchy of data sources (Health Canada, US EPA Integrated Risk Information System [IRIS], International Agency for Research on Cancer [IARC]).
- TRVs (e.g., acceptable daily intakes, reference doses, cancer slope factors) were adopted from the US EPA IRIS. If a TRV was not available from the US EPA, then other sources (e.g., Health Canada) were consulted.

1.3 Report Organization and Relationship to Other Documents

The HHRA is one of several technical deliverables related to the assessment of impacts related to the TSF embankment breach. Findings from previous technical reports (Section 1.3.2) were used as they were applicable to this study.

1.3.1 Report Organization

This current document is organized as follows:

- Section 1—Introduction. This section provides regulatory and project context, describes the overall approach used in the risk assessment, and presents the qualifications of the authors.
- Section 2—Summary of Site Investigations. This section provides an overview of the results of the site investigations completed to date, which sets the stage for the HHRA.
- Section 3—Problem Formulation. The problem formulation provides a brief overview of the available data, and:
  - identifies the relevant stressors and COPCs, and presents a conceptual model of how those stressors and COPCs can impact human receptors
  - discusses key uncertainties or data gaps in the available information
  - describes how the available data will be interpreted and integrated in the context of a site-specific HHRA
- Sections 4, 5 and 6—Risk Assessment. Risks to human receptors are evaluated for those pathways, stressors and receptor combinations which were retained for quantitative risk assessment at the completion of the problem formulation.
- Section 7—Risk Conclusions. This section summarizes the overall risk conclusions. A discussion about the implications of the risk conclusions for site management planning is provided, with emphasis on how the risk assessment can be used to guide decisions regarding remediation and long term monitoring. Opportunities for refinement in risk conclusions in the context of the overall uncertainty are also discussed.

1.3.2 Previous Technical Deliverables

The HHRA was completed using data from pre-breach baseline reports, the Post-Event Environmental Impact Assessment Reports (PEEIAR), the detailed site investigation (DSI) report and other post-TSF embankment breach monitoring information, as detailed below. Relevant data for the risk assessment were available from the following previous technical deliverables:

- Golder completed a PEEIAR on behalf of MPMC in June 2015 (MPMC 2015b), which MPMC submitted to the BC MoE. The PEEIAR provided an assessment of the physical, chemical and biological impacts in the first six to eight months following the TSF embankment breach. The PEEIAR included the following relevant technical appendices for the HHRA:
  - geochemical characterization of the spilled tailings

- soil quality assessment
- sediment quality assessment
- surface water quality assessment

- Golder completed a DSI in January 2016 in accordance with the PAO amendment Order 107461 to characterize and delineate contamination in abiotic media associated with the release of tailings in the different remediation areas (Golder 2016a). Under the CSR Site Investigation and Remediation Process, the purpose of the DSI is to:

  v) identify COPC based on site history

  vi) characterize contamination at the site based on comparison of the chemistry of site samples to environmental quality standards

  vii) delineate the extent of contamination and estimate volumes

  Site sample chemistry data were compared to the applicable numerical standards prescribed by the CSR. The DSI included the following technical appendices:

  - Update to the soil quality assessment
  - Update to the geochemical characterization of the spilled tailings
  - Groundwater assessment
  - Update to the surface water quality assessment
  - Update to the sediment quality assessment

- Golder prepared an update to the PEEIAR in June 2016 (Golder 2016b). The update report continued to expand on the available information regarding the distribution of contaminants in surface water, groundwater, soil and sediment provided in the PEEIAR and DSI reports, and included the following additional technical appendices:

  - Groundwater quality
  - Sediment toxicology and benthic invertebrate tissue assessment
  - Lake productivity and lower trophic level tissue assessment
  - Fish tissue assessment
  - Terrestrial ecosystem assessment
  - Terrestrial plant and soil invertebrate tissue analysis
  - Evaluation of mercury for biomagnification potential

- Golder completed a DSI Update in February 2017 (Appendix A). The DSI Update report is a continuation of site investigation work previously completed at the Mine, and forms part of the on-going remediation and rehabilitation works at the Mine. The DSI Update presents the findings of investigation and monitoring works conducted at the Mine between August 2015 and August 2016, and incorporates the findings of the previous DSI report for the Mine as well as the PEEIAR update that was completed in June 2016 (Golder 2016b). The overall objective of the DSI Update was to confirm soil, groundwater and surface water quality to support the completion of a HHRA and an Ecological Risk Assessment for the Mine.
- MPMC submitted a comprehensive environmental monitoring plan (CEMP) to the BC MoE in June 2016 (MPMC 2016). This document outlined how existing and proposed monitoring programs would be executed for the next three to five years, and was generally built around the same data collection elements (abiotic and biotic chemistry, toxicity testing, and monitoring of biological communities) that comprised the PEEIAR. The CEMP includes provisions for monitoring updates based on the outcomes of the HHRA.

In many instances, these previous reports contained technical appendices where data were interpreted in light of the specific objectives. Several other investigations have been completed to date, some of them specifically for the HHRA. For transparency, Golder has opted to include the entirety of these reports as appendices, which are compiled in the Appendix Book, to convey a full understanding of the methods and data. The body of this report provides a summary of methods, but analysis and interpretation of those data emphasized a risk assessment context.

The following technical reports that are relevant to the HHRA are provided in the Appendix Book:

Appendix[1]	Appendix Title
APPENDIX A	**Detailed Site Investigation Update**
A-1	Background Soil Quality Technical Memorandum
A-2	SRK Laboratory Kinetic Tests on Spilled Tailings
A-3	SRK Polley Flats Geochemical Conceptual Model
A-4	Groundwater Quality Update Technical Memorandum
A-5	Physical Hydrogeological Assessment and Conceptual Site Model Technical Memorandum
A-6.1	Surface Water Quality Impact Assessment Update, March to August 2015
A-6.2	Addendum to Surface Water Quality Impact Assessment Update Technical Memorandum
A-7.1	Minnow Sediment Quality Data Report - August 2015 Collections
A-7.2	Minnow Sediment and Sediment Porewater Quality Data Update Memorandum
A-8	2016 Co-located Soil Samples – Laboratory Certificates of Analysis
APPENDIX B	**Human Health Risk Assessment Supporting Information**
B-1	Data Screening for the Human Health Risk Assessment
B-2	Berry and Fish Ingestion Rates
B-3	Food Chain Model Inputs and Outputs for Estimating Tissue Concentrations
B-4	Human Health Risk Assessment Model Outputs
B-5	Sample Calculation
B-6	Toxicity Information
B-7	Physiologically Based Extraction Test Results
APPENDIX C	**Air Quality**
C-1	Air Quality Prediction Methods Memo
C-2	Continuous Particulate Monitoring at Mount Polley 17 to 29 September 2015: Summary of Particulate Monitoring 7 July to 29 September 2015
APPENDIX D	**Fish Tissue Chemistry**
D-1	Summary of Available Fish Tissue Chemistry Data (2014–2015) for Assessment of Potential Changes in Concentrations Related to the Mount Polley Tailings Dam Failure
D-2[2]	Sentinel Fish Tissue Quality in the Vicinity of Mount Polley Mine, 2015-2016
APPENDIX E	**Terrestrial Plant and Invertebrate Tissue Chemistry**
E-1.1	Tissue Data Report for Plants Collected Along Hazeltine Channel
E-1.2	Addendum to Tissue Data Report for Plants Collected Along Hazeltine Channel
E-2	Tissue Data Report for Soil Invertebrates Collected Along Hazeltine Channel

1) Additional appendices relevant to the ecological and aquatic health risk assessments will be included in the Appendix Book.

2) Appendix D-2 will be issued with the ecological and aquatic health risk assessments Appendix Book.

1.4 Professional Statement

Protocol 6 (BC MoE 2015b) specifically outlines that qualified Approved Professionals may make recommendations to a Director that an application for a contaminated sites legal instrument be approved. This HHRA was completed by a team of risk assessment specialists with significant experience in applying the HHRA framework used as part of the CSR and other relevant guidance manuals. This team worked under the supervision of Trish Miller, MSc, RPBio, CSAP (Risk), who was assisted by Dr. Reidar Zapf-Gilje, PEng, CSAP (Standards, Risk). A summary of qualifications for each risk assessment practitioner involved in the HHRA is provided below.

1.4.1 Professional Statement and Signature of Risk Assessor Completing the Risk Assessment Report

Professional statement and signature:

1) In accordance with Section 63 of the Contaminated Sites Regulation, I confirm that I have demonstrable experience in conducting human health and/or ecological risk assessment pertinent to the purposes of the Contaminated Sites Regulation.

2) I also confirm that:

   a) the risk assessment performed by me, and reported herein, has been performed to the best of my ability in accordance with Ministry approved protocols, guidance, procedures, policies, methods and standards of professional practice, and

   b) the information used in the performance of the risk assessment and the conclusions of the risk assessment reported herein are true and accurate based on my current knowledge as of the date completed.

Print Name	Signature	Date Completed

1.4.2 Qualifications of Lead Authors

Trish Miller, MSc, RPBio, CSAP

Trish Miller, MSc, RPBio, CSAP, is a senior environmental scientist and Principal with Golder Associates Ltd. with more than 25 years' experience in human health and ecological risk assessment. Ms. Miller is active in all aspects of contaminated sites risk assessment and remediation, including oversight of the development of sampling plans, integrating objectives and data requirements of a risk assessment into work plans and site investigations, designing toxicology testing programs for ecological assessments, coordinating data analysis, developing site-specific remediation standards, liaising with clients, and reporting. Ms. Miller has developed provincial matrix standards and water quality guidelines, and derived numerous site-specific risk-based soil, groundwater and surface water standards. She works with a variety of First Nations on both large and small scale projects ranging for investigation and remediation of large scale diesel contamination to risk assessments of risk-based closure of remote dump sites. Ms. Miller works with Health Canada to develop guidance including how to conduct site investigations to support risk assessments in remote northern communities, guidance for sediment quality guidelines for human health and guidance for risk assessments in federal environmental impact assessments. She conducts workshops for professional development of managers and consultants on the advantages of risk assessment for contaminated site remediation and on general principles and procedures involved in the conduct of risk assessments. Ms. Miller was appointed by the Province to the BC Contaminated Sites Approved Professionals (CSAP) in Risk Assessment. She regularly reviews reports and makes recommendations related to remediation of contaminated land in BC on behalf of the Provincial Ministry of the Environment. Also, as an Approved Professional, Ms. Miller has served on the Technical Review Committee, currently serves on the Performance Assessment Committee, conducts peer Performance Assessments and was a member of the Board of Directors from 2011–2013. Confirmation of CSAP membership can be made by visiting the MOE website: http://www.csapsociety.bc.ca/member_database.htm.

Ms. Miller was responsible for technical direction and oversight of the risk assessment work.

Reidar Zapf-Gilje, PhD, PEng, CSAP

Dr. Reidar Zapf-Gilje, PhD, PEng, CSAP, has been providing contaminated site consulting and professional development services for 35 years. He is the Founder and Principal of GeoEnviroLogic. His experience includes development of management plans for contaminated soil, groundwater, and sediment from initial investigations stages, risk assessment and to implementation of remediation and/or risk management solutions. His experience includes work on remote and First Nations communities dealing with hydrocarbon and metals contaminated sites, as well with closure of former landfills and mines. He has also been involved with developing contaminated site framework and guidance documents for the Province of BC, Health Canada, Canadian Council of Ministers of the Environment, Fisheries and Oceans Canada, Public Works Canada and Environment Canada.

Dr. Zapf-Gilje also organizes and teaches professional development seminars on contaminated sites topics and has taught graduate and undergraduate courses on a part-time basis as Adjunct Professor in the departments of Civil Engineering and Earth and Ocean Sciences at UBC. He has been involved with development of new courses and programs for contaminated site education and training at the British Columbia Institute of Technology and Kwantlen University College. He was the Chair of the former Roster of Contaminated Site Experts (now replaced by the CSAP Society), and in that role he led the development of the new CSAP Society. He is an Approved Professional in BC for both numerical standard-based and risk-based submissions.

Dr. Zapf-Gilje was a technical advisor on the human health risk assessment and was technical director for the DSI.

Victoria Hart, MSc, BIT

Victoria Hart, MSc, BIT, is an environmental scientist with over five years' experience in human health risk assessment. She has worked on several contaminated sites risk assessments across Canada, primarily in BC and Ontario. Ms. Hart has also worked on multiple environmental assessments both nationally and internationally for the mining sector (e.g., metals, coal, diamond), primarily focusing on human health effects. She has also provided technical support for human and ecological health risk assessments for federal contaminated sites.

Ms. Hart co-authored the human health risk assessment, working under the direction of Ms. Miller.

Cristina Quinn, PhD, PChem

Cristina Quinn is an environmental scientist with 8 years of experience in human health risk assessment. Her project experience includes risk assessments of contaminated sites, environmental assessments of mining and wastewater treatment facilities, and the development of federal pesticide guidance documents. Dr. Quinn has a PhD in environmental chemistry. Her doctoral research on the bioaccumulation of persistent organic pollutants in terrestrial organisms, aquatic organisms, and humans was awarded the IPA/DGUV Award for Young Exposure Scientists in 2013 by the International Society of Exposure Science. Dr. Quinn is a member of the Association of the Chemical Profession of British Columbia as a professional chemist.

Dr. Quinn provided technical support to the human health risk assessment.

2.0 SUMMARY OF SITE INVESTIGATIONS

2.1 Detailed Site Investigation and Detailed Site Investigation Update

Golder (2016a and Appendix A) completed a DSI to characterize and delineate contamination associated with the TSF embankment breach for eight of the nine remediation areas that were identified in the PEEIAR. Area 1, the TSF, was excluded from the scope of the DSI as it is part of the operating mine. The eight areas were grouped into four receiving environments, as follows:

- Polley Lake: Area 3
- Hazeltine Creek: includes Area 2–Polley Flats, Area 4–Upper Hazeltine Creek, Area 5–Hazeltine Canyon, Area 6–Lower Hazeltine Creek, and Area 7–Edney Creek Mouth
- Quesnel Lake: Area 8
- Quesnel River: Area 9

Additional data have been collected since the completion of the DSI to support the HHRA. The following is a brief summary of the work reported in the DSI Update (Appendix A):

- Soil: Local background soil samples were collected in order to supplement the existing background soil concentrations for the Study Area. The local background soil results are presented in APPENDIX A-1 of the DSI Update. The 2014 and 2015 soil results were screened against the CSR soil standards for agricultural land use based on the identification of land dedicated under the Agricultural Land Reserve.
- Groundwater: Golder installed and sampled an additional 14 monitoring wells in 2016. Three additional background monitoring wells were also completed to evaluate background groundwater quality. The groundwater results are presented in APPENDIX A-4 of the DSI Update.
- Sediment: Minnow Environmental Inc. (Minnow) completed a 2016 sediment sampling program to i) characterize sediment and porewater quality at locations sampled in 2014 and/or 2015 and provide temporal comparisons of sediment quality from year to year, and ii) provide sediment quality data from previously unsampled locations to augment the existing spatial extent characterization. The 2016 sediment results are presented in APPENDIX A-7 of the DSI Update.
- Surface water: Since the TSF embankment breach, the surface water monitoring program has evolved, in consideration of factors that included, but were not limited to: monitoring results, safety and logistical constraints, recommendations from BC MoE and seasonal conditions (e.g., lake turnover, onset of winter). The DSI Update report included a summary of surface water quality data collected between August 2015 and December 2015 that is related to the TSF embankment breach, and that is relevant to the Study Area investigation works. The surface water quality results for this time period are presented in APPENDIX A-6 of the DSI Update.

The field observations and analytical results were used to update the conceptual site model.

The TSF embankment breach resulted in:

- Transportation and scouring of tailings, construction materials and natural sediments, and deposition of "spilled tailings" in Polley Lake and the Polley Flats, and
- Transportation, scouring and deposition of a mixture of tailings, construction and natural materials in the Hazeltine Creek corridor.

The impacted physical environment around Polley Lake, Edney Creek and Hazeltine Creek included approximately 136 hectares (ha; 1.36 square kilometres) where topsoil was removed and an additional area of approximately 100 ha (1 square kilometre) where tailings were deposited overlying intact topsoil.

In some areas, the tailings settled out in two distinct layers: a grey fine silt and a black-orange sand. The two layers settled out according to particle size and density, generally with the finer material overlying the coarser sand. As the debris flow moved down the Hazeltine Creek valley, it picked up and mixed with native till. Approximately 20 million cubic metres of tailings, native soil, water and debris were deposited into Quesnel Lake where a turbidity plume formed 20 to 30 metres below surface. The plume included a significant amount of fine-grained natural lake sediment that became suspended by the debris flow from Hazeltine Creek. Turbidity in Quesnel Lake persisted into December 2014, but cleared over the winter. Some turbidity was measured in Hazeltine Creek and in Quesnel Lake near Hazeltine Creek in 2015; however, the source of this turbidity has been accounted for in creek channel rehabilitation work, as well as other remediation work.

Together, the soil, sediment, groundwater and surface water results all confirm that while some tailings-related metals are present in these media above CSR standards, the leachability and migration potential of the dissolved phase are low. These results are significant, as it is the dissolved phase that is associated with uptake and toxicity in biota. Therefore, the results of the DSI Update support the preliminary findings of the PEEIAR and the DSI report submitted in January 2016, that the impacts related to the breach have been largely due to physical effects.

A summary of the remediation areas and human health contaminants of concern identified in the DSI Update are provided in Table 1. The DSI Update report is included in APPENDIX A. Section 7.0 of the DSI Update satisfies the requirements of the PAO; namely:

- Identification of areas of potential environmental concern
- Determination of the potential contaminants of concern based on the applicable CSR standards
- Delineation of the horizontal and vertical extent of contamination
- Confirmation that the contamination at the site is stable or decreasing in concentration and extent over time

Table 1: Contaminants of Concern Identified in the DSI Update

Remediation Area	Contaminant	Medium	CSR Schedule
Area 2 – Polley Plug/Polley Flats and Area 4, 5, and 6 – Hazeltine Channel	Copper	Soil	5 – Toxicity to soil invertebrates and plants
	Vanadium	Soil	4 – Parkland and Agricultural
	Sulfur	Soil	4 – Agricultural
	Molybdenum	Soil	4 – Agricultural
	Iron	Groundwater	6 – Irrigation
			6 – Drinking Water
	Manganese	Groundwater	6 – Irrigation
			6 – Drinking Water
	Arsenic	Groundwater	6 – Drinking Water
			6 – Livestock
	Molybdenum	Groundwater	6 – Irrigation
			6 – Livestock
	Sulfate	Groundwater	6 – Drinking Water
	Total and dissolved copper	Surface Water	BC Water Quality Guideline – Aquatic Life
	Copper	Sediment	9 – Typical
Area 3 – Polley Lake	Arsenic	Sediment	9 – Sensitive
	Copper	Sediment	9 – Sensitive
			9 – Typical
Area 7 – Edney Creek Mouth	Total and dissolved copper	Surface Water	BC Water Quality Guideline – Aquatic Life
Area 8 – Quesnel Lake	Copper	Sediment – Littoral and Profundal	9 – Sensitive
			9 – Typical
	Arsenic	Sediment – Littoral and Profundal	9 – Sensitive

CSR = Contaminated Sites Regulation.

2.2 Post DSI/DSI Update Soil Remediation Works

MPMC has been implementing a rehabilitation and remediation strategy throughout the Hazeltine corridor. Rehabilitation works have included excavation and removal of tailings, intermixing tailings with native soils, and re-grading and re-sloping of the slopes of the Hazeltine corridor. The rehabilitation works have been ongoing in parallel to field investigations for the preliminary soil quality impact assessment (MPMC 2015) and the DSI/DSI Update (Golder 2016a and Appendix A). Those reports provided information on the area, depth and degree of soil contamination in the Hazeltine corridor. However, because rehabilitation works were and are continue to be ongoing, the soil conditions and topography within the Hazeltine corridor are continuously changing. As such, the soil quality described in the DSI/DSI Update (Golder 2016a and Appendix A) is not representative of areas of the Hazeltine corridor that have undergone rehabilitation works. The remediation works have not changed the COPCs under investigation in this risk assessment, but they have changed the soil exposure concentrations. The impact of the remediation work on soil quality will be described under separate cover.

3.0 PROBLEM FORMULATION

3.1 Management Goal

The goal for the HHRA is to evaluate health risks to people from exposure to the spilled tailings on the Study Area. Specifically, as per the CSR (BC MoE 2016a; Part 6 Section 18.1 [4]), the management goal has been met if:

a) the calculated incremental lifetime cancer risk (ILCR) is less than or equal to 1 in 100,000 (1×10^{-5})

b) the hazard index is less than or equal to 1

3.2 Identification of Receptors of Potential Concern

The selection of human receptors was based on information available regarding the current use of the remediation areas (Figure 2), which was provided by MPMC staff and Golder employees who have visited the Study Area. On 7 August 2013, MPMC hosted a tour of reclamation sites at the Mine for a group of Elders and interested individuals from the T'exelc First Nations. Members of the T'exelc First Nations in attendance were interested in following plant species: balsam fir (*Abies balsamea*), blueberry (low, mid and high bush; *vaccinium* sp.), paper birch (*Betula papyrifera*), cedar, chamomile, common juniper (*Juniperus communis*), Devil's club (*Oplopanax horridus*), kinnikinnick (*Arctostaphylos* sp.), mosses, mullen, soapberry (*Shepherdia Canadensis*) and yarrow (*Achillea millefolium*).

Currently, the Hazeltine Channel receiving environment is within provincial crown land designated as a mixture of wildlands and backcountry recreational areas, with a small section of land designed within an Agricultural Land Reserve along lower Hazeltine Channel. The area designated as an Agricultural Land Reserve is forested. For the purpose of the HHRA, the overall land use of the remediation areas is considered to be wildland, with people accessing the area for recreational and subsistence land uses.

Subsistence use includes hunting, collecting plants and fishing. Although specific data regarding local consumption rates for different traditional foods was not available to the study team, community liaison members have reported that the land was, and still is, used for harvesting of food. Therefore, the HHRA included a First Nation subsistence and traditional land user receptor who was assumed to harvest food from the land. The subsistence and traditional land user is considered to be the most sensitive receptor, due to the assumptions made regarding reliance on traditional foods.

The Hazeltine Channel area is accessible via the Horsefly-Likely FSR to the public, hikers, all-terrain-vehicle (ATV) users and others who wish to use the area. Use of the FSR is highest in the summer, and to some extent in the early fall. It is plowed from Horsefly to Mitchell Bay in the winter. Mine workers will also plow access from the Mine down to lower Hazeltine Channel, but this segment will not connect up with the publicly accessible portion[2], so winter access will only be possible for mine-facilitated traffic and, potentially, ATV users (i.e., snowmobilers). Due to rehabilitation activities, this area has been officially closed to the public due to hazards such as opening or closing of the sluice gate at the Polley Lake weir. There is signage in place that indicates the area is closed. Despite the signage, hunting, trapping, logging and collection of plants for nourishment and medicinal purposes may take place in the Hazeltine Channel area. Therefore, people were assumed to access the area. Groundwater within the Hazeltine Channel area is not currently used for drinking water, nor is it anticipated to be used for this purpose in the future.

[2] This section of the Gavin Lake FSR used to be open to the public and may be at some point again in the future.

Current uses of Polley Lake, Quesnel Lake and Quesnel River include commercial, recreational and aboriginal fisheries, and recreational uses such as swimming, boating, kayaking, canoeing and waterskiing, and in the winter, snowmobiling and ice fishing when ice conditions allow. Quesnel Lake is also used as a source of drinking and residential water for domestic purposes[3]. It was assumed that receptors may consume drinking water from Quesnel Lake while they are in the Study Area.

Based on this information, the following scenarios were evaluated:

- **Subsistence and Traditional Land User**—A subsistence and traditional land user was considered to be the most sensitive receptor for this assessment based on the understanding that there is the potential for hunting, trapping, fishing and consumption of plants for nourishment and medicinal purposes. This scenario assumed that a person could be hunting game and collecting traditional plants found within the remediation areas for consumption throughout the year. The subsistence and traditional land user could come into contact with surrounding soils and surface water and sediment in Hazeltine Channel, Polley Lake, Quesnel Lake or Quesnel River, and consume berries, plants, game or fish. It was assumed that berries, traditional plants, game and fish could be brought home and frozen for consumption throughout the year. Sediment and surface water contact may occur during recreational activities such as swimming, playing in the shoreline and fishing during the warmer months (i.e., May through October). Soil contact may occur during the snow-free months. The subsistence and traditional land user was assumed to be people of any age (including toddlers).
- **Backcountry Recreation User (Hiker/Camper)**—Areas of Hazeltine Channel, Polley Lake, Quesnel Lake and Quesnel River are publicly accessible and are known to be used by the general public. Therefore, a scenario that assumed recreational hikers/campers could come to these areas to hike, camp, collect berries, fish and engage in activities along the lake shoreline (e.g., wading and swimming) was included. The hiker/camper was assumed to access the area three days per week during the warmer months (i.e., May through October). While visiting the area, the hiker/camper could come into contact with surrounding soils and surface water and sediment in Hazeltine Channel, Polley Lake, Quesnel Lake or Quesnel River, and consume berries or fish. Berry consumption would only occur when berries are ripe (i.e., July through September). It was assumed that fish would be consumed once per week while they are in the Study Area. The hiker/camper was assumed to be people of any age (including toddlers), given the easy access routes provided to some areas.
- **Backcountry Recreation User (ATV/Snowmobile User)**—Areas of Hazeltine Channel, Polley Lake, Quesnel Lake and Quesnel River are publicly accessible and are known to be used by the general public. Therefore, a scenario that assumed recreational ATV/snowmobile users could be present at any of the remediation areas was included. The ATV/snowmobile user would be present during the day throughout the year, but would not stay overnight. The ATV/snowmobile user could come into contact with surrounding soils and consume berries. Soil contact would only occur during the snow-free months and berry consumption would only occur when berries are ripe (i.e., July through September). The ATV/snowmobile user was assumed to be limited to teens and adults.

[3] Domestic purposes as defined in the BC Water Act means the use of water for household requirements, sanitation and fire prevention, the watering of domestic animals and poultry and the irrigation of a garden not exceeding 1012 m^2 adjoining and occupied with a dwelling house.

- **Boater/Kayaker**—Polley Lake, Quesnel Lake and Quesnel River are publicly accessible and are known to be used for recreational boating/kayaking activities. Therefore, a scenario that assumed people could go to these water bodies to participate in recreational activities (e.g., power boating, kayaking, canoeing and rafting) was included. The boater/kayaker would be on the water during the day over the warmer months (i.e., May through October) and could come into contact with sediment and surface water from Polley Lake, Quesnel Lake or Quesnel River and consume fish. The boater/kayaker was assumed to be people of any age (including toddlers).

- **Sport Fisher**—Polley Lake, Quesnel Lake and Quesnel River are publicly accessible and are known to be used for sport fishing. Therefore, a scenario that assumed people could go to these water bodies to participate in sport fishing was included. It was assumed that fish could be brought home, frozen and eaten throughout the year. It was also assumed that the sport fisher would be fishing during the day throughout the year as ice fishing may occur in the winter. The sport fisher was assumed to be people of any age (including toddlers).

- **Hunter/Trapper (Non-subsistence)**—The Hazeltine Channel area is located within the Cariboo Region 5 (management unit 5-2). Hunting and trapping licenses are available for some species in the region including: white-tailed deer, bighorn mountain sheep and sharp-tailed grouse (BC MoE 2016b). Therefore, a scenario that assumed non-subsistence hunters/trappers come up to the Hazeltine Channel area to hunt and set traps was included. The hunter/trapper could come into contact with the surrounding soils and consume game and fish. It was assumed that game meat and fish could be brought home, frozen and consumed throughout the year. Contact with soil was assumed to occur during the snow/ice-free months. The hunter/trapper was assumed to be limited to adults, but an additional scenario was considered where the game was consumed throughout the year by people of any age, including toddlers.

- **Quesnel Lake Resident**—Residential properties border Quesnel Lake. It was assumed the resident could be fishing, hunting and trapping, using surface water from Quesnel Lake as drinking water and consuming cattle (i.e., beef) that graze in the remediation areas throughout the year. Residents could come into contact with surface water and sediment in Hazeltine Channel, Polley Lake, Quesnel Lake or Quesnel River, and consume berries, game or fish. Sediment and surface water contact may occur during recreational activities such as swimming and playing in the shoreline during the warmer months (i.e., May through October). It was assumed that game meat, fish and berries could be brought home, frozen and consumed throughout the year. The resident was assumed to be people of any age (including toddlers).

- **Logger**—Logging currently occurs in the region and close to the Hazeltine Channel area; however, since the TSF embankment breach, logging has not occurred within the boundaries of the area impacted by the TSF embankment breach. The logger was conservatively retained because logging activity could occur in the area in the future. It was assumed that the logger would be present during the day during throughout the year. The logger could come into contact with the surrounding soils, surface water in Hazeltine Channel and consume berries. Contact with soil and surface water was assumed to occur during the snow/ice-free months. Berry consumption would only occur when berries are ripe (i.e., July through September). An adult would be the primary receptor for the logger scenario.

- **Mine/Rehabilitation Worker**—A mine/rehabilitation worker was considered as rehabilitation works are currently underway and could potentially occur in the future within the remediation areas. It was assumed that the mine/rehabilitation worker would be present during the day during the snow-free months. The mine/rehabilitation worker may come into contact with the surrounding soils, surface water, consume berries and catch fish while working within the remediation areas. Berry consumption would only occur when berries are ripe (i.e., July through September). An adult would be the primary receptor for the mine/rehabilitation worker scenario.

3.3 Identification of Contaminants of Potential Concern

3.3.1 Data Quality Review

Technical Bulletin 2 (BC MoE 2015c) emphasizes the importance for risk assessment professionals to seek confirmation from the Standards Approved Professional that site characterization data has been done adequately and that the data are representative of current site conditions. The risk assessor also needs to determine that each COPC has been adequately delineated to meet the needs of the risk assessment. This broader data quality review is particularly relevant to the current HHRA given that the assessment is based on a diverse data set collected during the initial emergency response and the subsequent assessment and rehabilitation activities.

Golder completed a data quality evaluation for media relevant to human health (i.e., soil, sediment, surface water, air, vegetation [berries and plants], fish and wild game) to determine the adequacy of the data to support the HHRA (Golder 2016c). The data quality evaluation resulted in one of three categories:

- **Category 1**: There is sufficient data and the uncertainty is low
- **Category 2**: There is some data and uncertainty is moderate to high
- **Category 3**: There is limited data and the future conditions are uncertain

The results of the data quality evaluation are provided in Golder (2016c). Groundwater was not included in the evaluation because it was not considered to be an operable exposure pathway for human health receptors. The results of the data quality evaluation are provided below in Table 2. Additional berry and plant data were collected to support the risk assessment in the summer of 2016. Golder considers there to be sufficient data to complete the HHRA. Wild game and cattle tissue samples were not collected for the HHRA. Concentrations of COPCs in wild game and cattle tissues were modelled for COPCs retained for evaluation in other media.

Table 2: Data Quality Evaluation of Media Included in the Human Health Risk Assessment

Media	Sufficient Number of Samples?	Additional Sampling Scheduled?	Category
Soil	Yes	Yes	1
Sediment	Yes	Yes	1
Surface Water	Yes	Yes	1
Air	Yes	No	1
Vegetation (Berries and Plants)	Yes	Yes	1
Fish	Yes	Yes	2

Additional soil, groundwater and vegetation (berry and plant) samples were collected in August 2016 to support the HHRA. Additional sediment and surface water samples were collected in 2016 as part of on-going monitoring. There is sufficient data and low uncertainty with the groundwater data collected within the remediation areas; however, additional background sampling is required to adequately characterize the local background reference concentrations. There is sufficient data and low uncertainty with the vegetation data to adequately support the HHRA. The measured vegetation tissue concentrations were lower in 2016 compared to 2015 (APPENDIX E-1), and it is, therefore, unlikely that vegetation concentrations have been underestimated. Additional plant samples will be collected as part of the CEMP.

The available fish tissue data are considered to be preliminary at this time. However, based on consultation with project reviewers, exposure to fish tissue using this preliminary data was included in the risk assessment for completeness. Concentrations of metals in fish tissue will continue to be monitored as part of the CEMP and evaluated to determine if a TSF embankment breach-related impact occurs over the longer term (see APPENDIX D-1 for further details). The preliminary data indicate that a TSF embankment breach-related impact to fish tissue is not anticipated in the future.

3.3.2 Approach for Further Evaluation of Contaminants of Potential Concern for Human Health

The starting point for identifying contaminants on a Study Area is the DSI. In the DSI, possible contaminants are investigated in relevant environmental media based on their physical/chemical properties and fate when introduced to the environment. Contaminants identified in the DSI (Table 1) were passed along to the risk assessment to determine the significance of the concentrations measured in the environment. In the problem formulation step of the HHRA, contaminants are evaluated in terms of their hazard with respect to human health. The CSR standards for the protection of human health were used as the primary screening criteria for determining if COPCs require assessment in the HHRA in each of the media. Note that under the CSR, only those parameters that exceed a CSR standard are required to be further evaluated in the risk assessment.

The CSR standards are the first line of assessment in a CSR risk assessment. For many potential contaminants, there are different standards for human health protection and environmental protection. The screening process in the risk assessment sorts the contaminants identified in the DSI into those that are a potential concern for humans, those that are a potential concern for the environment and those that may be a concern for both humans and the environment.

The CSR standards are intended to be protective of all situations for both human and ecological receptors, and incorporate multiple conservative assumptions such as safety factors and conservative exposure conditions. Therefore, comparison to standards represents a conservative evaluation of the potential for the contaminant concentrations to cause adverse effects. Comparison to background concentrations was also included in the screening process for substances. Since the Study Area is located in a highly mineralized area with rich ore deposits, this was considered a reasonable approach to identify and retain the substances that are present at concentrations exceeding what is normal for this area of BC.

The following general approach was used to identify COPCs for human health in soil, groundwater, sediment and surface water for the HHRA:

- **Step 1** – Compare the maximum concentrations to the applicable human health-based screening criteria. If the maximum concentration of a parameter exceeds the screening criterion, the substance was retained for further evaluation. A substance was concluded to be present in non-hazardous concentrations and eliminated from further evaluation if the maximum observed concentration was lower than the human health-based screening criteria or the 95th percentile regional background concentration.
- **Step 2** – For the substances retained at the completion of Step 1, calculate the 95% upper confidence limit of the mean (UCLM) concentration as an upper bound estimate of mean exposure and compare to the human health-based screening criteria. A substance was retained for further evaluation in the HHRA if the 95% UCLM was greater than the screening criteria.

No substances that are regulated under the CSR were excluded from further assessment on the basis of a comparison to local background concentrations. Substances that exceeded a CSR standard also exceed local background.

3.3.3 Contaminants of Potential Concern

The DSI Update (Appendix A) identified contaminants in soil, groundwater, sediment and surface water (Table 1). The contaminants in these media were then evaluated in the HHRA using the approach described in the previous section. Aluminum was also evaluated at the request of the project reviewers. The detailed results of the COPC screening process, including the data and screening criteria are described in more detail in APPENDIX B-1. The following COPCs were identified for the HHRA:

- **Soil**: no CSR exceedances; aluminum added at the request of project reviewers
- **Groundwater**: no access to groundwater along Hazeltine Corridor
- **Sediment**: vanadium exceeded CSR PL standard; aluminum added at the request of project reviewers
- **Surface water**: none; no exceedances of drinking water standards
- **Air**: none; all potential contaminants met screening criteria
- **Vegetation**: copper and vanadium; aluminum added at the request of project reviewers
- **Fish**: aluminum, copper and vanadium; screening criteria not available, COPCs were identified based on the media listed above

Wild Game and Cattle Tissue

Wild game and cattle tissue samples were not collected as part of the HHRA. The soil to plant bioaccumulation factors (BAFs) for aluminum, copper and vanadium were below one (APPENDIX E-1); therefore, the uptake of these COPCs into higher trophic levels (i.e., into mammals and birds) is not expected. However, exposure to aluminum, copper and vanadium in wild game and cattle tissues were included in the calculation of risk estimates as part of a multi-media assessment. Deer, moose and grouse, including deer and moose liver, were considered representative wild game species and organs potentially consumed by people. The concentrations of aluminum, copper and vanadium in game and cattle tissues were estimated using uptake models.

3.4 Identification of Exposure Pathways

Concentrations of potential contaminants in soil and tailings related to the breach were found to exceed the standards for the protection of soil invertebrates and plants, but are less than the standards for the protection of human health. Notwithstanding the fact that concentrations of COPCs in soil and tailings were acceptable for human health, exposures for these COPCs were calculated for humans exposed to sediment, soil, surface water, berries, traditional plants, fish, wild game and cattle at the request of project reviewers. Exposure pathways for human receptors are routes by which people could potentially be exposed to chemicals in each environmental media. Based on the current and likely future uses by humans, the receptors and exposure pathways that were included in the HHRA are presented in Table 3 and Figure 3. The exposure pathways were determined based on the potential receptors and their associated activities while on the Study Area, which are outlined above in Section 3.2.

Table 3: Exposure Pathways for Human Receptors

Receptor of Potential Concern	Soil			Groundwater[1]		Sediment		Surface Water		Dietary Items				
	Incidental Ingestion	Dermal Absorption	Particulate Inhalation	Ingestion	Dermal Contact	Incidental ingestion	Dermal Absorption	Ingestion	Dermal Absorption	Traditional Plants	Berries	Fish	Wild Game	Cattle
Subsistence and Traditional Land User	✓	✓	✓	×	×	✓	✓	✓	✓	✓	✓	✓	✓	×
Hiker/Camper	✓	✓	✓	×	×	✓	✓	✓	✓	×	✓	✓	×	×
ATV/Snowmobile User	✓	✓	✓	×	×	×	×	✓	×	×	✓	×	×	×
Boater/Kayaker	×	×	×	×	×	✓	✓	✓	×	×	×	✓	×	×
Sport Fisher	×	×	×	×	×	×	×	✓	×	×	×	✓	×	×
Hunter/Trapper	✓	✓	✓	×	×	×	×	✓	×	×	×	✓	✓	×
Quesnel Lake Resident	×	×	×	×	×	✓	✓	✓	✓	×	✓	✓	✓	✓
Logger	✓	✓	✓	×	×	×	×	✓	×	×	✓	×	×	×
Mine/Rehabilitation Worker	✓	✓	✓	×	×	×	×	✓	×	×	✓	✓	×	×

✓ = operable exposure pathway; × = inoperable exposure pathway.

1) There is no access to groundwater along Hazeltine Corridor groundwater is not currently used for drinking water, nor is it anticipated to be used for this purpose in the future.

The following exposure pathways were evaluated in the HHRA:

- Exposure to COPCs in soil/tailings (incidental ingestion, dermal contact and inhalation of soil particulates). While there were no CSR exceedances in soil/tailings for human health, incremental exposure to aluminum, copper and vanadium from soil was added to the assessment (Section 3.3.3). The subsistence and traditional land user, hiker/camper, ATV/snowmobiler, hunter/trapper, logger and mine/rehabilitation worker may be exposed to soil/tailings while accessing the Study Area.
- Exposure to COPCs in sediment (incidental ingestion and dermal contact). The subsistence and traditional land user, hiker/camper, boater/kayaker and Quesnel Lake resident may contact sediment during recreational activities (e.g., fishing from the shore, toddlers playing along the lake shoreline). Exposure to aluminum, copper and vanadium in sediment was evaluated further for these receptors of concern as concentrations in sediment exceeded the generic (Schedule 4) CSR soil standard in Quesnel Lake near the Hazeltine Channel. For the purpose of the HHRA, it was assumed that people exposed to sediment are exposed only to Quesnel Lake sediments. This was considered conservative since people may also use Polley Lake and Hazeltine Channel for recreational activities and no COPCs were identified in these sediments.
- Exposure to COPCs in surface water (ingestion as drinking water and dermal contact while swimming). Surface water quality meets drinking water standards for all water bodies in the study area. Incremental exposure to COPCs in surface water was added to the assessment at the request of project reviewers. Quesnel Lake is a source of drinking and residential water for domestic purposes. All receptors were assumed to obtain drinking water from Quesnel Lake while accessing the Study Area. The subsistence and traditional land user, hiker/camper and Quesnel Lake resident may contact surface water during recreational swimming. While the boater/kayaker and sport fisher may also be in contact with surface water (e.g., while fishing or launching boats), this pathway was considered negligible due to the relative surface area is small compared to a swimmer. If risks are predicted for the dermal contact with surface water during swimming pathway, a closer look at dermal contact with surface water for the boater/kayaker and sport fisher will be completed.
- Ingestion of COPCs in vegetation (i.e., edible berries and plants). The subsistence and traditional land user may consume vegetation collected from the remediation areas. Exposure to aluminum, copper and vanadium in both berries and plants was evaluated further for the subsistence and traditional land user. The hiker/camper, ATV/snowmobile user, Quesnel Lake resident, logger and mine/rehabilitation worker may consume berries collected from the remediation areas. Exposure to aluminum, copper and vanadium in berries was evaluated further for these receptors of concern.
- Ingestion of COPCs in wild game (i.e., deer, moose and grouse). The subsistence and traditional land user, hunter/trapper and Quesnel Lake resident may hunt wild game in the Study Area. Exposure to aluminum, copper and vanadium in deer, moose and grouse was evaluated further for these receptors of concern.
- Ingestion of COPCs in fish muscle tissue. The subsistence and traditional land user, hiker/camper, boater/kayaker, sport fisher, hunter/trapper, Quesnel Lake resident and mine/rehabilitation worker may consume fish from Polley Lake, Quesnel Lake or Quesnel River. Exposure to aluminum, copper and vanadium in fish tissue was evaluated further for these receptors of concern.
- Ingestion of COPCs in cattle muscle tissue. The Quesnel Lake resident may consume beef cattle that have been grazing in the remediation areas. Exposure to aluminum, copper and vanadium in cattle was evaluated for the Quesnel Lake resident.

The following were considered to be inoperable exposure pathways:

- There are no drinking water groundwater wells located on the Study Area or in the vicinity. Therefore, exposure to groundwater from ingestion and dermal contact were not retained as operable pathways for the receptors of concern.
- Ingestion of small mammals was not evaluated in the HHRA. Small mammals (e.g., rabbit, beaver and groundhog) were not among the top ten food items reportedly consumed by First Nations in the area. In addition, the small mammal ingestion rates were considerably lower than ingestions rates for the wild game included in this risk assessment.

A conceptual exposure model for the HHRA is presented in Figure 3.

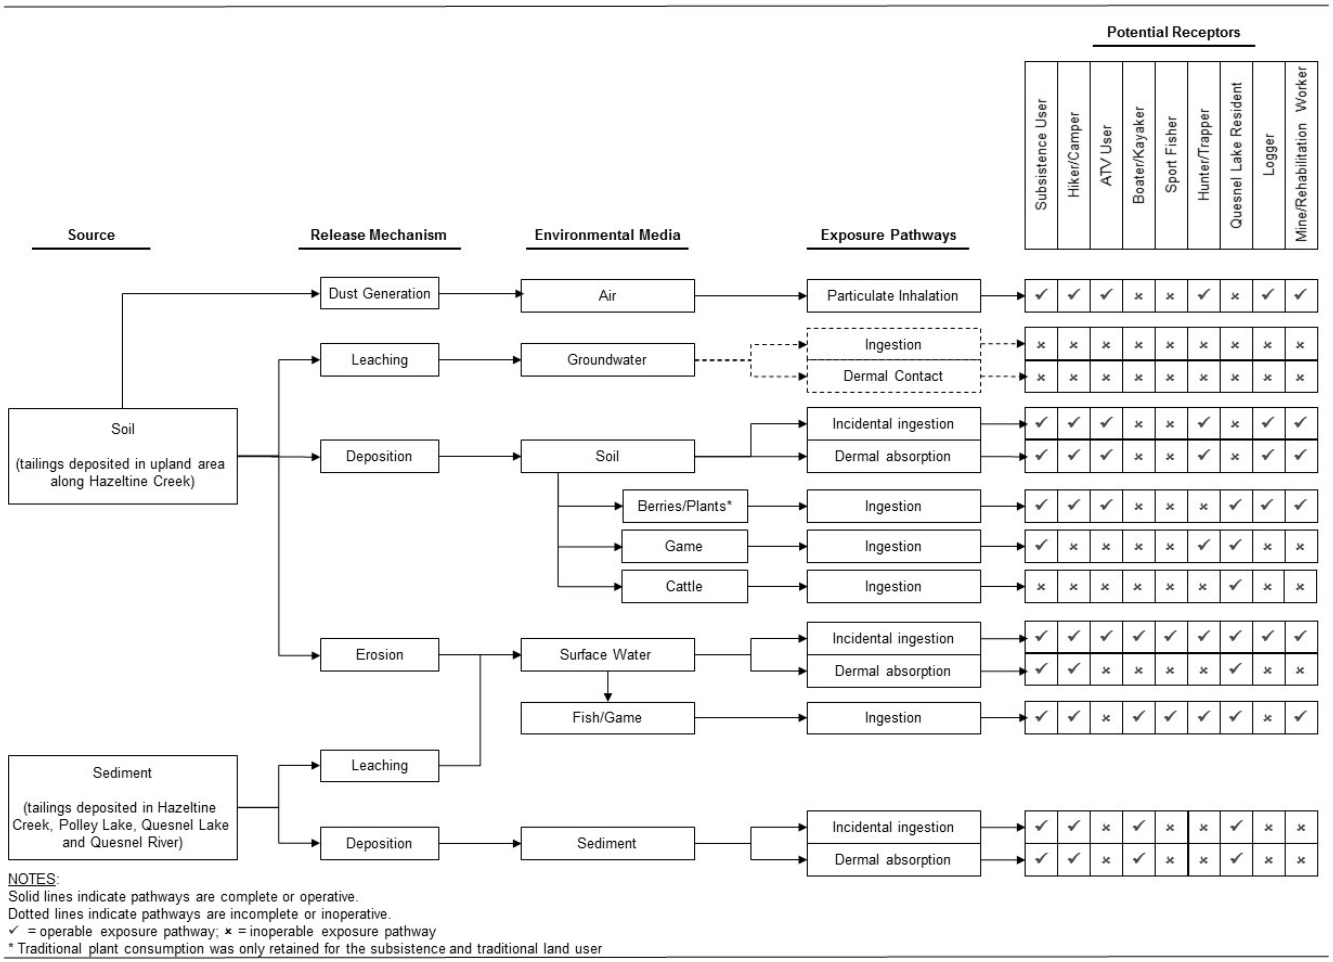

Figure 3: Conceptual Exposure Model for the Human Health Risk Assessment

4.0 EXPOSURE ASSESSMENT

Exposures and risks were calculated for the most sensitive receptor for the relevant exposure pathways. The infant life stage has the highest relative berry and traditional plant ingestion rates per unit body weight in comparison to other life stages. The toddler life stage has the highest relative sediment, soil, game, fish and cattle ingestion rates per unit body weight in comparison to other life stages. A teen was considered the most sensitive life stage for the ATV/snowmobile user. Non-carcinogenic exposure and risks were also calculated for the adult life stage for information purposes. Aluminum, copper and vanadium are not considered by regulatory agencies as carcinogenic COPCs (Section 5.2); therefore, carcinogenic exposures and risks were not calculated.

4.1 Receptor Characteristics

To evaluate the food consumption pathway, the receptors of concern were divided into two groups, First Nations Consumer (i.e., subsistence and traditional land user) and non-First Nations Consumer (i.e., hiker/camper, ATV/snowmobile user, boater/kayaker, sport fisher, hunter/trapper, Quesnel Lake resident, logger and mine/rehabilitation). Food ingestion rates were not available for the T'exelc First Nation (Williams Lake Indian Band) or Xatśūll First Nation (Soda Creek Indian Band). Therefore, the First Nations Food, Nutrition and Environment Study (FNFNES; Chan et al. 2011) was used to determine appropriate food consumption rates for the subsistence and traditional land user. The remaining human receptors were not considered to rely on traditional foods to the same extent as the subsistence and traditional land user. It was conservatively assumed that 100% of the country foods consumed by First Nations is obtained from the Hazeltine Channel corridor.

Receptor parameterization was conducted using Health Canada (2012) receptor characteristics for the Canadian population. Parameters that are not specifically addressed by Health Canada were adopted from other sources. Receptor characteristics used to evaluate potential exposure in the HHRA are presented in Table 4.

Table 4: Receptor Characteristics

Receptor Characteristic	Units	Infant	Toddler	Teen	Adult	Source
Age	-	0 to 6 months	7 months to 4 years	12 to 19 years	≥20 years	Health Canada (2012)
Body weight	kg	8.2	16.5	59.7	70.7	Health Canada (2012)

1) Inoperable exposure pathway; game, fish and cattle ingestion were not considered applicable for the infant.

2) Inoperable exposure pathway; sediment, vegetation, game, fish and cattle ingestion exposure pathways were not applicable for the ATV/snowmobile user.

3) The sediment loading rate for lower legs reported by Shoaf et al. (2005a) was assumed to be applicable for lower and upper legs.

"-" = not applicable; ≥ = greater than or equal to; cm^2 = square centimetre; g/cm2/event = grams per square centimetre per event; kg = kilogram; kg/day = kilograms per day; n/a = not applicable.

The mine rehabilitation worker wears some level of personal protective equipment while performing work in the remediation areas (e.g., footwear, long pants). It was assumed that hands and forearms may be exposed to soil.

Health Canada (2012) does not provide incidental sediment ingestion rates, sediment loading rates, skin surface areas of feet or cattle (i.e., beef) ingestion rates. The incidental sediment ingestion rates were taken from Intrinsik (2011), who completed a review on sediment exposure parameters for Health Canada. The sediment ingestion rates for a high contact recreational exposure scenario, which were assumed to be the same as the soil ingestion rates recommended by Health Canada (2012), were used in the HHRA.

The sediment loading rates were obtained from a Shoaf et al. (2005a) study, which estimated sediment loading rates for children (aged 7 to 12 years) playing in tidal flats without shoes on in medium to coarse sand. In another study by Shoaf et al. (2005b), sediment dermal loading rates were reported for adults digging in tidal flats in very fine to fine sand sediment. Sediment loading rates from Shoaf et al. (2005a) were considered more appropriate for the HHRA because impacted sediment that people may be exposed to in Quesnel Lake is predominantly sand (89.2% at near-field stations and 61.6% at far-field stations; APPENDIX A-7). The high sand content of substrate from near-field stations was visually evident during sample collection in both 2015 and 2016, and is likely a result of continued washing of fine substrates from these shallow sampling locations. The child sediment loading rates were applied for the infant, toddler and adult as there is no indication that rates would differ between the life stages. The skin surface area of feet was obtained from Richardson (2013). This was considered appropriate because the skin surface areas were based on the Canadian population and are more current than the skin surface areas presented in Richardson (1997). The skin surface area of forearms was obtained from Intrinsik (2011) and was assumed to be equal to 50% of the upper and lower arm skin surface area provided by Health Canada (2012). It was assumed that hands, forearms, legs (lower and upper) and feet were available for sediment contact.

The beef ingestion rates were obtained from US EPA (2011), which provides average per capita intake rates for various meats, dairy products and fats. The average intake rate of beef for consumers only (i.e., respondents who reported consuming beef in the survey) was used to estimate intake of beef in the HHRA. The US EPA (2011) provides average intake rates for eight different age groups. Intake rates were selected to match the age groups defined by Health Canada (2012) in Table 4. The intake rate for the age group 3 to 5 years was selected for toddlers because this group has the most similar body weight (18.6 kilogram [kg)]) to that defined by Health Canada for a toddler (16.5 kg) among age groups birth to 1 year, 1 to 2 years and 3 to 5 years. The intake rate for the age group 20 to 49 years was selected for adults because this group had the highest intake rate among age groups 20 to 49 years, 50 years and older and females 13 to 49 years. The following equation was used to calculate beef ingestion rates:

$$IR_{ww} = FIR_{ww} \times BW \times CF$$

Where:
IR_{ww} = ingestion rate of cattle (beef) in wet weight units (kg/day)
FIR_{ww} = consumers only food intake rate in wet weight units (g/kg/day)
BW = body weight (kg)
CF = conversion factor 0.001 (g/kg)

The calculated cattle ingestion rates are presented in Table 4.

Edible berries and traditional plants, deer meat, deer liver, moose meat, moose liver, grouse meat and fish muscle were considered the representative food items consumed by people. As noted above, in the absence of specific ingestion rates for the T'exelc and Xatśūll First Nations, data provided from the FNFNES study (Chan et al. 2011) were used for the subsistence and traditional land user. The objective of the FNFNES was to gather information on the food consumed by various First Nations groups across Canada (University of Northern British Columbia 2016). Chan et al. (2011) completed a food survey in 2008-2009 on 21 First Nations communities throughout BC. The survey results were presented by ecozone and cultural area. The T'exelc and Xatśūll First Nations are within the Montane Cordillera ecozone and plateau cultural area. Therefore, results for this ecozone and cultural area were selected to represent the food consumption patterns of the T'exelc and Xatśūll First Nations. The communities surveyed in this ecozone/cultural area included the Lower Nicola and Splatsin First Nation groups.

Chan et al. (2011) reports 95th percentile and average ingestion rates for traditional foods by gender and age groups 19 to 50 years, 51 to 70 years and 71 years and older. The highest 95th percentile ingestion rate for deer meat, deer liver, moose meat, moose liver and grouse meat between men and women of all age groups was selected as the adult subsistence and traditional land user ingestion rate for this assessment. It is noted that grouse was not listed as one of the top 10 traditional food items consumed and was not listed on the 24-hour recall survey for the Montane Cordillera ecozone, plateau cultural area (Chan et al. 2011). Nonetheless, consumption of grouse was included in the HHRA to represent game birds.

The non-First Nations Consumer was not considered to rely on traditional foods to the same extent as the subsistence and traditional land user. It was assumed that the non-First Nations Consumer would not be consuming traditional plants other than berries and would not be consuming wild game organs. Health Canada (2012) does not provide berry or wild game ingestion rates for the general Canadian population. Therefore, the highest average ingestion rates for deer meat, moose meat and grouse meat between men and women of all age groups reported in Chan et al. (2011) was selected as the adult non-First Nations Consumer ingestion rate for this assessment. This was considered appropriate since people living in more remote areas may consume more wild game than people living in urban centres.

Blue huckleberry, red huckleberry and soapberries were among the top 10 consumed traditional food items for First Nations living on reserve in the Montane Cordillera ecozone, plateau cultural area (Chan et al. 2011). Blueberry and cranberry were also reportedly consumed in this area based on the results from the 24-hour recall (Chan et al. 2011). The berry ingestion rate was assumed to be the sum of the consumption rate of the above listed berries reportedly consumed by First Nations in the Montane Cordillera ecozone, plateau cultural area. The 95th percentile and average berry ingestion rates are provided in APPENDIX B-2.

Salmon, including “any type”, sockeye and chinook, were listed as three of the top 10 consumed traditional food items for First Nations living on reserve in the Montane Cordillera ecozone, plateau cultural area (Chan et al. 2011). Salmon are anadromous fish, migrating from freshwater as juveniles to the ocean where they mature. Adult sockeye salmon spend two to three years in the ocean before returning to the freshwater where they originated to spawn. The Department of Fisheries and Oceans is following productivity of sockeye salmon in Quesnel Lake and, to date, has not found evidence of an impact on fish condition or productivity as a result of the breach. Since salmon are migratory fish, and salmon stop eating when spawning, their tissues would not be expected to reflect local conditions. Therefore, it is unlikely that the breach has impacted tissue concentrations in adult salmon.

Resident fish (i.e., rainbow trout, lake trout) were used to estimate exposure in the risk assessment. Given the known fate and uptake kinetics of copper (Dallinger and Kautzky 1985; Miller et al. 1993; Kamunde et al. 2002; Dang et al. 2009) in rainbow trout, increased concentrations of copper in fish muscle tissue are not expected. Concentrations of copper in muscle tissue are well regulated; dietary copper uptake in fish exposed to high copper conditions is characterized by low uptake efficiency and high rates of elimination. Liver and the gastrointestinal tract are the primary sites of whole body regulation of copper in fish exposed to dietary copper. Kamunde et al. (2002) reported that liver copper concentration rose 22-fold in the fish exposed to high dietary copper and fell by 80% in fish on low dietary and waterborne copper levels. No effects on growth were observed in these fish. Copper is detoxified in the liver through the production of metal-binding proteins, metallothioneins, and excreted through the biliary fecal route. Similarly, the copper concentrations in the gastrointestinal tract rose sharply for higher exposure conditions and fell rapidly in low exposure conditions, supporting the contention that copper, as a nutritionally essential element, is well-regulated in fish.

Based on the scientific literature, it is unlikely that fish muscle tissue would be impacted by the COPCs from the breach, and unlikely to be a significant exposure pathway. However, incremental exposure from consumption of fish was included in the HHRA. Fish ingestion rate was determined by summing the fish muscle ingestion rates for the freshwater fish species reportedly consumed by First Nations groups throughout BC (Chan et al, 2011). The 95th percentile and average fish ingestion rates are provided in APPENDIX B-2. The 95th percentile fish ingestion rate was used for the sport fisher because this receptor was assumed to consume a larger quantity of fish than the average person.

Labrador tea leaves was listed as one of the top 10 consumed traditional food items for First Nations living on reserve in the Montane Cordillera ecozone, plateau cultural area (Chan et al. 2011). The traditional plant ingestion rate for the subsistence and traditional land user was assumed to equal that of the Labrador tea leaves consumption rate.

To adjust the consumption rates provided for adults to consumption rates for toddlers, the relative ingestion rate for the toddler for similar food items provided in Richardson (1997) was used. For example, in Richardson (1997) the adult wild game consumption rate is 269 grams per day (g/day) while that of the toddler is 84 g/day. To

calculate a toddler deer meat ingestion, the adult deer meat ingestion rate of 77 g/day was multiplied by the ratio of the toddler's ingestion rate to the adult ingestion rate (i.e., 77 g/day × [84/269] = 24 g/day). The mean rates for females and males, combined, from Richardson (1997) were used to estimate the ratios of the relative ingestion rates for berries and traditional plants. The "fruits and juices" ingestion rate was used for berries and the "other vegetables" ingestion rate was used for traditional plants. Consumption data for Native Canadian males and females, combined, eaters only (i.e., not including people who don't consume these food categories at all) were used to estimate the ratios of the relative ingestion rates for wild game.

The ratios used to convert the adult ingestion rates from Chan et al. (2011) to infant, toddler and teen ingestion rates are presented in Table 5.

Table 5: Consumption Ratios Used to Convert Adult Ingestion Rates from Chan et al. (2011) to Other Life Stages

Consumption Rates and Ratios	Units	Infant (0 to 6 months)	Toddler (7 months to 4 years)	Teen (12 to 19 years)	Adult (age 20+ years)
Wild game consumption rate from Richardson (1997)	g/day	0	84	n/a[1]	269
Ratio of receptor consumption rate/adult consumption rate for wild game[2]	unitless	0	0.31	n/a[1]	1
Berry (fruits and juices) consumption rate from Richardson (1997)	g/day	136	234	258	245
Ratio of receptor consumption rate/adult consumption rate for berry (fruits and juices)	unitless	0.56	0.96	1.05	1
Traditional plant (other vegetables) consumption rate from Richardson (1997)	g/day	72	67	n/a[1]	137
Ratio of receptor consumption rate/adult consumption rate for traditional plants (other vegetables)	unitless	0.53	0.49	n/a[1]	1

1) Inoperable exposure pathway; vegetation, game and fish ingestion exposure pathways were not applicable for the ATV/snowmobile user.

2) The ratio was also applied to deer and moose liver.

g/day = gram per day; n/a = not applicable.

4.2 Receptor Exposure Frequency and Duration

The subsistence and traditional land user may be exposed to sediment and surface water during recreational activities such as swimming and playing along the shoreline. It was assumed that recreational activities occur 5 days/week during the warmer months of the year (i.e., May through October). This is consistent with the high contact sediment exposure durations presented in Intrinsik (2011). It was also assumed that the subsistence and traditional land user obtains all their drinking water from Quesnel Lake. The subsistence and traditional land user was also assumed to be exposed to soil and consume berries, plants, wild game and fish from the remediation areas (defined in Section 3.2). Plants may only be in season for short periods of the year and hunting may only occur during certain parts of the year. However, it was conservatively assumed that the subsistence and traditional land user could collect a large amount of traditional food items and store them for consumption throughout the year.

The hiker/camper was assumed to visit the remediation areas for recreational activities 3 days/week during the warmer months of the year (i.e., May through October). During this time, the hiker/camper may be exposed to sediment and surface water during recreational activities such as swimming and playing along the shoreline. The hiker/camper may also be exposed to soil and consume berries harvested from the remediation areas when they are in season (i.e., July through September).

The ATV/snowmobile user was assumed to visit the remediation areas where they may be exposed to soil and consume berries 1 day per week.

The boater/kayaker was assumed to visit the remediation areas (Polley Lake, Quesnel Lake and Quesnel River) for recreational boating and/or fishing 3 days/week during the warmer months of the year (i.e., May through October). The sport fisher was assumed to visit the remediation areas for fishing year-round.

The hunter/trapper may be exposed to soil and harvest wild game and fish from the remediation areas 1 day/week. Similar to the subsistence and traditional land user and Quesnel Lake resident, it was assumed that the hunter/trapper could harvest wild game meat and fish and store them for consumption year-round.

The Quesnel Lake resident may be exposed to sediment and surface water during recreational activities such as swimming and playing along the shoreline 3 days/week during the warmer months of the year (i.e., May through October). It was also assumed that the Quesnel Lake resident obtains all their drinking water from Quesnel Lake. The Quesnel Lake resident may also consume berries, hunt wild game and fish while visiting the remediation areas and consume cattle that used the remediation areas for grazing. Similar to the subsistence and traditional land user, it was assumed that the Quesnel Lake resident could harvest berries, wild game meat and fish when they are in season and store them for consumption year-round. Cattle have typically been observed at the Mine in June through September; therefore, exposure to COPCs would occur for this four month period. It was conservatively assumed that the Quesnel Lake resident purchases beef from cattle that have been exposed to COPCs during these four months and freezes it for consumption year-round.

The logger may be present in the remediation areas where they may be exposed to soil and consume berries 5 days per week.

The mine/rehabilitation worker was assumed to work 4 days per week during the snow/ice-free months (i.e., April through November). During this time, the mine/rehabilitation worker may be exposed to soil, consume berries and harvest fish in the remediation areas.

The hiker/camper, ATV/snowmobiler, boater/kayaker, sport fisher, hunter/trapper, logger and mine/rehabilitation worker were assumed to use surface water as drinking water while they are in the Study Area.

The receptor exposure frequencies and durations are presented in Table 6.

Table 6: Receptor Exposure Times

Parameters	Subsistence and Traditional Land User	Hiker/ Camper	ATV/ Snowmobile User	Boater/ Kayaker	Sport Fisher	Hunter/ Trapper	Quesnel Lake Resident	Logger	Mine/ Rehabilitation Worker
	Infant[1], Toddler[2], Adult	Infant[1], Toddler[2], Adult	Teen, Adult	Toddler[2], Adult	Toddler[2], Adult	Toddler[2], Adult	Infant[1], Toddler[2], Adult	Adult	Adult
Hours per day exposed (hours)	10	10	10	n/a	n/a	10	n/a	10	10
Days per week exposed (days)	5	3	1	3	3	1	3	5	4
Days per week drinking water (days)	7	3	1	3	3	1	7	5	4
Dermal events per day (event/day)	1	1	1	1	1	1	1	1	1

1) The infant was the most sensitive receptor used to evaluate the ingestion of berry and traditional plant exposure pathways.

2) The toddler was the most sensitive receptor used to evaluate the sediment, soil and surface water exposure and ingestion of wild game, fish and cattle exposure pathways.

n/a = not applicable, inoperable exposure pathway.

4.2.1 Exposure Amortization

To estimate risks for the food ingestion pathways, exposures were not amortized beyond days per week. For example, the hiker/camper, ATV/snowmobile user, logger and mine/rehabilitation worker receptors are unlikely to consume berries collected from the Hazeltine Channel corridor remediation areas year round. Additional amortization was not considered appropriate, as the food ingestion rates provided in Chan et al. (2011) were averaged over a year. To be conservative, averaging the berry exposure was not completed.

Similarly, to avoid underestimating risks from short term exposures, the exposure dose for the sediment exposure pathways, exposure amortization was limited to average weekly exposure. Toxicity reference values are predominantly derived using chronic health effects; therefore, in the absence of a suitable sub-chronic TRV for threshold-acting substances, the receptors were assumed to consume food and be exposed to sediment, soil and surface water at the seasonal rate for an entire year.

4.2.2 Consideration of Acute Exposure

Exposure to berries for the hiker/camper, ATV/snowmobile user, logger and mine/rehabilitation worker receptors was assumed to occur 1, 3, 4 or 5 days per week on an ongoing basis (Table 6). Therefore, risks were assessed assuming chronic (i.e., long term) exposure to chemicals, and risk estimates were calculated using chronic TRVs. To estimate the chronic exposure, exposure doses were amortized to account for receptors spending only 1, 3, 4 or 5 days per week in the remediation areas (i.e., exposure dose divided by seven [7]). Therefore, it is important to check that short term exposures are not associated with acute effects. Unfortunately, few reliable TRVs exist for assessing acute effects for metals. Theoretically, if the acute toxicity of a chemical is less than seven times greater than the chronic toxicity, then the potential exists for acute risks to be greater than the risks predicted in the current chronic assessment.

Wilson Scientific Consulting Inc. and Meridian Environmental Inc. (2007) reported acute-to-chronic ratios for select metals (arsenic, cadmium, lead and thallium) that were all greater than 1,000. This comparison considered acute toxicity information based on minimum lethal dose; it is possible that sub-lethal endpoint may result in lower acute-to-chronic ratios. While there is no universal conversion factor for deriving acute TRVs from chronic TRVs, these studies found that a value of at least seven has been used by some agencies to convert chronic TRVs to sub-chronic or acute TRVs for chemicals that are not known to be especially potent on a short-term exposure basis. For example, a 10-fold uncertainty factor is often used to convert sub-chronic study to chronic TRV.

Therefore, given the relatively low hazard indices estimated for chronic exposure at the Study Area (Section 6.1), and the high acute-to-chronic ratios for metals (at least seven times greater), it is unlikely that acute exposures would result in unacceptable risks at the Study Area.

4.3 Exposure Concentrations

The purpose of the HHRA is to evaluate the potential risks to receptors related to the TSF embankment breach. Concentrations of potential contaminants in soil and tailings related to the TSF embankment breach were found to exceed the standards for the protection of soil invertebrates and plants, but are less than the standards for the protection of human health. However, for the purposes of calculating risk, reasonable worst-case exposure concentrations were calculated for COPCs found to exceed the standards for the protection of soil invertebrates

and plants in soil. Potential exposure for these COPCs in sediment, soil, surface water, berries, traditional plants and fish were estimated. The 95% UCLM was selected as the reasonable worst-case exposure concentration in the HHRA and was calculated using ProUCL software (US EPA 2016c). The dataset used to calculate exposure concentrations was the same as that used to identify COPCs (APPENDIX B-1). The particulate concentrations were predicted using metals assay results from on-site air quality monitors and total suspended particulate concentrations measured for the particulate monitoring program. The methods are presented in APPENDIX C-1. The maximum concentrations were selected as the exposure concentrations. The exposure concentrations used in the HHRA are presented in Table 7.

Table 7: Exposure Concentrations for the Human Health Risk Assessment

COPC	Sediment[1] (mg/kg)	Soil[2] (mg/kg)	Particulate[3] (mg/m^3)	Surface Water[1] (mg/L)	Berries (mg/kg ww)	Traditional Plants (mg/kg ww)	Fish[4] (mg/kg ww)
Aluminum	24,149	14,984	0.00024	0.031	32.1	127	1.6
Copper	410	737	0.000014	0.0019	5.2	4.4	0.69
Vanadium	280	177	0.000003	0.00056[a]	0.21	0.71	0.033

1) Copper and vanadium measured in Quesnel Lake and aluminum measured in Hazeltine Channel.
2) Measured in tailings soil.
3) Maximum predicted concentrations.
4) The 95% upper confidence limit of the mean concentration was calculated using the combined results for lake trout and rainbow trout from Quesnel Lake, Polley Lake and Frypan Creek and Quesnel River.
a) The maximum concentration was used because there were an insufficient number of detected values to calculate a 95% upper confidence limit of the mean.

COPC = contaminant of potential concern; mg/kg = milligram per kilogram; mg/L = milligram per litre; mg/m^3 = milligram per cubic metre; ww = wet weight.

Wild game and cattle tissue samples were not collected for the HHRA. Concentrations of aluminum, copper and vanadium in deer, moose, grouse, and cattle tissues were estimated using uptake models and biotransfer factors (BTFs). The BTFs were obtained from the Risk Assessment Information System (2016) and presented in Table 8. These BTFs were based on the ingestion of beef parameters reported in Baes et al. (1984), which are representative of the fraction of daily elemental intake in feed that is transferred to and remains in a kilogram of beef until slaughter. Using beef BTFs for deer and moose may be conservative since domestic ruminants are more sensitive to copper uptake than wildlife (Ward and Nagy 1976). Furthermore, domestic ruminants tend to remain in one location for longer durations (e.g., weeks), while deer and moose do not. The beef BTF was applied to the grouse in the absence of transfer factors for birds.

Table 8: Biotransfer Factors

COPC	Deer BTF (day/kg ww)	Moose BTF (day/kg ww)	Grouse BTF (day/kg ww)	Cattle BTF (day/kg ww)
Aluminum	0.0015	0.0015	0.0015	0.0015
Copper	0.01	0.01	0.01	0.01
Vanadium	0.0025	0.0025	0.0025	0.0025

BTF = biotransfer factor; COPC = contaminant of potential concern; day/kg ww = day per kilogram wet weight.

Concentrations of aluminum, copper and vanadium in deer, moose, grouse and cattle tissues were estimated using the equation below. The estimated daily intake (EDI) of aluminum, copper and vanadium for each wild game and cattle was calculated using a mechanistic food chain model. The exposure point concentrations used in the food chain model were 95% UCLM concentrations. The exposure parameters and model outputs for the deer, moose, grouse and cattle are provided in APPENDIX B-3.

$$C_T = \sum(EDI) \times BTF \times BW$$

Where:
C_T = concentration of COPC in tissue (mg/kg ww)
∑EDI = estimated daily intake (sum of exposure dose from consumed media [food, water and soil]; mg/kg bw/day)
BTF = bio-transfer factor (day/kg)
BW = body weight of game or cattle (kg)

Although measured organ tissue samples were not collected for the HHRA, Chan et al. (2011) have summarized the measured concentrations of essential trace metals, including calcium, copper, iron, potassium, sodium, zinc and selenium, in several traditional food items. The Chan et al. (2011) results for copper are shown in Table 9 and indicate the copper concentrations are greater in liver than muscle tissue, which is consistent with copper uptake kinetics (Section 5.1.2). It is also known that the concentrations of copper and other nutritionally essential elements is regulated in the liver. Therefore, the ratio of copper in liver to muscle is expected change with changing dietary concentrations. For the purposes of this risk assessment, the ratio of calculated copper concentrations in deer and moose liver to muscle were applied to the predicted muscle tissue concentration to obtain a liver exposure concentration. This was considered to be a preliminary estimate and would require further evaluation if found to be a potentially significant exposure pathway.

Table 9: Measured Concentrations of Copper in Deer and Moose Muscle and Liver Tissue (Chan et al. 2011)

Traditional Food	n	Average (mg/kg ww)
Deer meat	15	2.09
Deer liver	5	28.26
Deer liver to meat ratio		13.52
Moose meat	17	1.79
Moose liver	7	43.68
Moose liver to meat ratio		24.40

mg/kg ww = milligram per kilogram wet weight; n = number of samples.

Measured tissue concentrations for aluminum and vanadium were not available in the Chan et al. (2011) study. Literature on aluminum and vanadium concentrations in liver and muscle of ruminants was limited. Therefore, the liver to muscle ratio for aluminum and vanadium was assumed to be the same as copper. However, this was considered highly conservative for the following reasons:

- Based on professional experience with other projects where measured tissue samples were available, the concentrations of aluminum and vanadium in muscle and liver were similar (i.e., liver to muscle ratio is close to one).
- Aluminum is poorly absorbed following oral exposure (Section 5.1.2).
- Based on the toxicokinetics of vanadium, a large portion of absorbed vanadium is excreted either via feces or urine (Section 5.1.2).

The predicted muscle tissue exposure concentrations used in the HHRA are presented in Table 10.

Table 10: Predicted Game and Cattle Tissue Concentrations

COPC	Deer (mg/kg ww)	Deer Liver (mg/kg ww)	Moose (mg/kg ww)	Moose Liver (mg/kg ww)	Grouse (mg/kg ww)	Cattle (mg/kg ww)
Aluminum	3.4	46.2	3.5	86.1	0.020	4.7
Copper	1.0	13.8	1.0	24.4	0.0089	1.6
Vanadium	0.051	0.69	0.052	1.27	0.00036	0.074

COPC = contaminant of potential concern; mg/kg ww = milligram per kilogram wet weight.

4.4 Exposure Equations

Exposure was estimated in terms of a daily dose for each exposure pathway retained for assessment. This value is called the EDI and is typically expressed as milligrams of a chemical per kilogram of body weight per day (mg/kg bw/day). The EDI was calculated from site-specific and estimated concentrations of COPCs in environmental media (i.e., sediment, soil, surface water, berries, traditional plants, wild game, fish and cattle) (Section 4.3), the amount of time a person would spend in the remediation area (Section 4.2) and receptor group-specific parameters such as body weight, ingestion rate and dietary preferences (Section 4.1).

Exposure equations were obtained from Health Canada (2012) and the US EPA (2004), and are presented below. The calculated exposure doses for the receptors of concern (i.e., model outputs) are provided in APPENDIX B-4. Sample calculations were also completed manually to provide an additional check for the model calculations, and are included in APPENDIX B-5.

Incidental Ingestion of Sediment/Soil

$$DR_{SI} = \frac{C_S \times IR_S \times RAF_O \times D_1 \times D_2}{BW}$$

Where:

DRSI = estimated dose rate from ingestion of COPC in sediment/soil (mg/kg bw/day)
CS = COPC concentration in sediment/soil (mg/kg)
IRS = sediment/soil ingestion rate (kg/day)
RAFO = bioavailability via sediment/soil ingestion (i.e., relative absorption factor from the gastrointestinal tract) (unitless)
D1 = days per week exposed / 7 days
D2 = weeks per year exposed / 52 weeks (assumed to be 52 weeks; no amortization for weeks per year)
BW = body weight (kg)

Dermal Contact with Sediment/Soil

$$DR_{DC} = \frac{C_S \times [(SA_H \times SL_H) + \sum(SA_O \times SL_O)] \times RAF_D \times D_1 \times D_2}{BW}$$

Where:

DR_{DC} = estimated dose rate from dermal contact with COPC in sediment/soil (mg/kg bw/day)
C_S = COPC concentration in sediment/soil (mg/kg)
SA_H = skin surface area available for dermal contact (hands) (m^2)
SL_H = sediment/soil loading to exposed skin (hands) ($kg/m^2/day$)
SA_O = skin surface area available for dermal contact (other than hands) (m^2)
SL_O = sediment/soil loading to exposed skin (other than hands) ($kg/m^2/day$)
RAF_D = bioavailability via dermal contact (unitless)
D_1 = days per week exposed / 7 days
D_2 = weeks per year exposed / 52 weeks (assumed to be 52 weeks; no amortization for weeks per year)
BW = body weight (kg)

Inhalation of Soil Particulates

$$DR_{Inh} = \frac{C_A \times IR_A \times RAF_{Inh} \times D_1 \times D_2 \times D_3}{BW}$$

Where:

DR_{Inh} = estimated dose rate from inhalation of COPC in air (mg/kg bw/day)
C_A = COPC concentration in air (mg/m^3)
IR_A = inhalation rate (m^3/day)
RAF_{Inh} = bioavailability via inhalation (unitless)
D_1 = hours per day exposed / 24 hours
D_2 = days per week exposed / 7 days
D_3 = weeks per year exposed / 52 weeks (assumed to be 52 weeks; no amortization for weeks per year)
BW = body weight (kg)

Ingestion of Surface Water (As Drinking Water)

$$DR_{WI} = \frac{C_W \times IR_W \times RAF_O \times D_1 \times D_2}{BW}$$

Where:

DR_{WI} = estimated dose rate from ingestion of COPC in surface water (mg/kg bw/day)
C_W = COPC concentration in surface water (mg/L)
IR_W = water ingestion rate (L/day)
RAF_O = bioavailability via water ingestion (i.e., relative absorption factor from the gastrointestinal tract) (unitless)
D_1 = days per week exposed / 7 days
D_2 = weeks per year exposed / 52 weeks (assumed to be 52 weeks; no amortization for weeks per year)
BW = body weight (kg)

Dermal Contact with Surface Water (While Swimming)

$$DAD = \frac{DA_{event} \times SA \times EF \times D_1 \times D_2}{BW}$$

Where:

DAD = dermally absorbed dose (mg/kg/day)
DA_{event} = absorbed dose per event (mg/cm^2/event); see below for equation
SA = skin surface area (cm^2)
EF = exposure frequency (events/day)
D1 = days per week exposed / seven days
D2 = weeks per year exposed / 52 weeks (assumed to be 52 weeks; no amortization for weeks per year)

$DA_{event} = k_p \times C_W \times t_{event}$Where:

DA_{event} = absorbed dose per event (mg/cm^2/event)
Kp = dermal permeability coefficient (cm/hour)
C_W = COPC concentration in water (mg/cm^3)
t_{event} = event duration (hour/event)

Ingestion of Food Items

$$DR_{FI} = \frac{\sum(C_{Foodi} \times IR_{Foodi} \times RAF_O)}{BW}$$

Where:

DR_{FI} = estimated dose rate from ingestion of COPC in food (mg/kg BW/day)
C_{foodi} = COPC concentration in food i (mg/kg ww)
IR_{foodi} = receptor ingestion rate for food i (kg ww/day)
RAF_O = relative absorption factor from the gastrointestinal tract (i.e., bioavailability via food ingestion) (unitless)
BW = body weight (kg)

5.0 TOXICITY ASSESSMENT

5.1 Toxicokinetics of Aluminum, Copper and Vanadium

5.1.1 Humans

Aluminum

In general, absorption of aluminum in humans and animals is poor via inhalation or oral exposure pathways, and dermal absorption is even less significant (ATSDR 2008). Absorption of aluminum through normal dietary uptake is estimated at 0.1%, while more bioavailable forms (e.g., complexes with some carboxylic acids) can be absorbed at a rate closer to 1.0%. In addition, the aqueous and pH conditions of the gut will also affect absorption (ATSDR 2008). Two human studies that examined the bioavailable of aluminum in diet reported absorption efficiencies of 0.28 to 0.76%. When the exposure dose was increased, the absorption decreased to 0.094% (ATSDR 2008). Therefore, absorption of aluminum from soil, tailings and food is expected to be less than 1%.

Elimination of aluminum following oral uptake in humans occurs in the kidneys (via urine) with unabsorbed aluminum being excreted primarily in the feces. Inhalation exposure studies on humans have found occupational exposure to aluminum fumes, dusts and flakes resulted in increased serum levels, and that direct absorption in the brain may occur through the olfactory tract via axonal transport. Autopsy results from a stonemason exposed to aluminum showed elevated concentrations (compared to normal baseline levels) in the lungs, hilar lymph nodes, liver and spleen (ATSDR 2008).

Excretion in humans occurs via urine, and a correlation exists between exposure duration and urinary concentrations; welders exposed to 0.2 to 5.3 mg/m^3 aluminum for 10 years had urinary aluminum half-lives of over 6 months compared to 9 days in individuals with less than 1-year exposure (ATSDR 2008). A study was conducted applying aluminum chlorohydrate to the underarms of two subjects, the conclusions of the study estimated 0.012% of the applied aluminum was absorbed through the skin (ATSDR 2008). No studies were found on the excretion of aluminum following dermal exposure in humans (ATSDR 2008).

Copper

Copper is an essential element that is well regulated in the human body (Linder 2002, CCME 1997). Uptake of copper is primarily through oral ingestion. The majority of copper absorption occurs in the stomach and small intestine (Bearn and Kunkel 1955) as either ionic copper or bound to amino acids (binding proteins). Of this, the majority of copper is absorbed on the absorptive surface (Crampton et al. 1965), involving mucosal uptake and binding to metallothioneins and other intestinal binding proteins (Evans and LeBlanc 1976). The copper bound to metallothionein can be slowly released to the blood (Marceau et al. 1970) or is excreted when the mucosal cell is sloughed off.

The average absorption efficiencies of orally ingested copper ranged from 24 to 60% in healthy adults (Jacob et al. 1987; Johnson et al. 1988, Turnlund et al. 1982, 1983; Turnland 1989, 1998) but was found to be inversely related to the amount of copper in the gastrointestinal tract (Strickland et al. 1972; Turnlund et al. 1989). In a study of 11 young men administered various copper doses in food over a period of 42 to 98 days, absorption efficiencies of 55 to 56, 36, and 12% were found at doses of 0.785, 1.68, and 7.53 milligram per day (mg/day), respectively (Turnland et al. 1989). Absorption did not appear to be influenced by the amount of copper stored in the human body (Strickland et al. 1972). A nutrient reference value review completed by the Australian National

Health and Medical Research Council and the New Zealand Ministry of Health (Australian National Health and Medical Research Council 2006) indicated that copper absorption ranged from more than 50% at intakes less than 1 mg/day to less than 20% at intakes above 5 mg/day.

There are a number of factors effecting copper absorption, including; i) competition with other metals, ii) the amount of copper in the stomach, iii) certain dietary components and iv) the form of copper (Canadian Council of Ministers of the Environment [CCME] 1997).

Following absorption, copper levels in the blood rise rapidly. The majority of copper is bound to albumin and transcuprein, proteins capable of carrying a large portion of the exchangeable copper in circulation before releasing the copper to other carriers for cell-specific uptake (ATSDR 2004). Most of the initially absorbed copper goes to the liver, where it will be converted to ceruloplasmin for delivery to the other organs (Linder 2002). Copper is very actively recycled between the digestive tract, body fluids and tissues (particularly the liver) (Linder 2002). Ultimately, dietary copper is taken up by the liver and kidneys (ATSDR 2004).

Copper is stored bound to methallothionein in association with copper-dependent enzymes in the liver and other tissues. Binding of copper to metallothionein provides a temporary storage for cytoplasmic copper, preventing it from occurring as (potentially toxic) free ionic metal (Luza and Speisky 1996).

The majority of copper excretion is through the biliary route and largely accounts for hepatic turnover (Luza and Speisky 1996). Following oral administration of copper acetate in healthy humans it was found that 72% was excreted in the feces (Bush et al. 1955). The copper in feces would represent the fraction excreted through the biliary pathway, unabsorbed copper and copper from desquamated mucosal cells (ATSDR 2004). A small portion of daily copper intake (0.5 to 3.0%) is excreted in urine (Cartwright and Wintrobe 1964). Regulation of copper excretion and absorption are the main mechanisms of copper homeostasis (Linder 2002, CCME 1997).

There was limited data regarding uptake of copper through inhalation exposure and through dermal exposure. What information was available suggested that copper is poorly absorbed through intact skin (ATSDR 2004).

Vanadium

The majority of studies on vanadium uptake, distribution, metabolism, excretion and toxicity in humans are for inhalation exposure in an occupational setting, generally to vanadium pentoxide aersols, dusts or fumes. Human studies surrounding inhalation exposure are from occupational exposure in the following industries involving high temperature processing of vanadium; ferroalloy plants (Gylseth et al. 1979), processing of vanadium rich ores and slags, oil combustion, vanadium catalyzed reactions and from cleaning oil-fueled boilers and furnaces (IARC 2006). Vanadium pentoxide was found to be rapidly absorbed following inhalation exposure, but poorly through dermal contact or when ingested as ammonium vanadyl tartrate (Dimond et al. 1963; Gylseth et al. 1979; Kiviluoto et al. 1981).

There is very little uptake kinetics data available for humans exposed to vanadium through oral ingestion. Studies on animals indicated that vanadium can also enter the body via the stomach, although most dietary vanadium is excreted (Rehder 2013). For humans given vanadium orally, 0.1 to 1% is absorbed from the gut, although absorption of more soluble vanadium compounds is greater (IARC 2006). Absorption of vanadium compounds from oral ingestion is known to be strongly effected by dietary components such as fibre protein concentrations, carbohydrates, chelating agents, electrolytes and other trace elements (IARC 2006).

Once absorbed, vanadium becomes distributed to the bones, kidney, spleen, liver, muscle and blood (Rehder 2013; IARC 2006) accumulating mainly in bones, followed by kidneys, spleen and liver (Health Canada 2016). In an acute study using rats, it was found that upon cessation of orally administered vanadium, accumulated vanadium mobilized rapidly from the liver and other tissues but slowly from the bones (Edel et al. 1984). Bones can act as storage pool for vanadate (Rehder 2013).

Vanadium is predominantly excreted through the kidney in animals (ATSDR 2012) and body retention is relatively low (Health Canada 2016). About 60% of absorbed vanadium is excreted in the urine within 24 hours (as cited in IARC 2006). However, since vanadium is poorly absorbed in the gastrointestinal tract, the major fraction of vanadium is unabsorbed and excreted in feces (ATSDR 2012). Of the administered dose of ammonium metavanadate or sodium metavanadate over 80% accumulated in the feces after 6 or 7 days (Adachi et al. 2000; Patterson et al. 1986).

5.1.2 Mammals

Aluminum

In general, absorption of aluminum in animals is poor via inhalation or oral exposure pathways, and dermal absorption is even less significant (ATSDR 2008). Elimination of aluminum following oral uptake in animals occurs in the kidneys (via urine) with unabsorbed aluminum being excreted primarily in the feces. No studies were found on the excretion of aluminum following dermal exposure in humans or animals (ATSDR 2008).

Copper

Dietary consumption of copper in soils and foods is the primary route of exposure for animals on the Study Area. Similar to humans, ingested copper is primarily absorbed in the stomach and small intestine (CCME 1997). In studies using rats, copper absorption was found to be approximately 30 to 50% of the dietary concentration (Linder 2002). As daily oral doses increased from 12 to 200 micrograms/day (10-fold increase over average ingestion) absorption rates steadily decreased to 10% where it leveled off with increasing concentration (Linder and Goode 1991).

Once absorbed, copper is transported in blood by albumin and transcuprein (as cited by Linder 2002). Absorbed copper will primarily accumulate in the liver and kidney, with relatively little accumulation in other organs and tissues (Zervas et al. 1990).

Microbial activity in the gut of the ruminant digestive tract can decrease the bioavailability of ingested copper (Ivan 1988). Deer are thought to accumulate copper at a slower rate than sheep (CCME 1997). A study of red deer stags (*Cerbus elaphus)* and Coopworth wether sheep fed equivalent diets found an 11-fold difference in hepatic copper concentrations between the two species (Freudenberger et al. 1987).

The primary method of copper regulation is excretion through the biliary pathway (CCME 1997). Because bile is the main route for excretion of copper from mammals, copper from peripheral tissues must return to the liver to exit the body (Linder 2002).

Vanadium

Vanadium can enter the body of animals via the stomach, although most dietary vanadium is excreted. Based on animal data, gastrointestinal absorption is rapid and can vary from less than 0.1% to 16.5% (ATSDR 2012). In general, vanadium accumulation is greatest in bones, followed by kidney, spleen, liver and to a lesser extent muscle and blood (Mongold et al. 1990; Yuen et al. 1993) Vanadium concentrations in bones, kidneys and liver as compared to muscle tissues were approximately; 50 to 80-fold, 30 to 50-fold and 7 to 8-fold higher, respectively (Mongold et al. 1990; Yuen et al. 1993). Accumulated vanadium mobilizes rapidly from the kidneys, liver and other tissues but slowly from bones (Edel et al. 1984). In a study of rats exposed to high doses of vanadium (100 mg/L in drinking water), significant increases, compared to controls, were found in bone, kidney and liver but no alterations in vanadium muscle levels were found (as cited in ATSDR 2012).

Since vanadium is poorly absorbed, a large portion of orally administered vanadium is excreted in feces (ATSDR 2012; Section 5.1.1). The remaining, absorbed vanadium, is primarily excreted through the kidneys in urine (ATSDR 2012; Section 5.1.1).

5.2 Contaminant Classification

Several organizations have developed classification systems based on the carcinogenic properties of chemicals. The classification systems for Health Canada (2010b), the IARC (2016) and the US EPA IRIS database (US EPA 2016a) are presented in Table B-6-1 of APPENDIX B-6. Parameters classified as Group I/II (Health Canada), Group 1/2A (IARC), or Group A/B1/B2 (US EPA), and for which acceptable carcinogenic TRVs were available were assessed as carcinogens in the HHRA.

The carcinogenicity classification for COPCs is provided in Table B-6-2 of APPENDIX B-6. Aluminum, copper and vanadium are not considered to be carcinogens and were therefore assessed as threshold acting substances in the HHRA.

5.3 Toxicity Reference Values

For threshold acting contaminants, a reference dose or reference concentration represents an estimated daily intake to which people can be exposed to every day over a lifetime without experiencing a significant or adverse health impact. Reference doses are expressed as milligram of contaminant per kg of body weight per day (mg/kg bw/day) and reference concentrations (used for the inhalation pathway) are expressed in units of milligram contaminant per cubic metre of air (mg/m^3).

The TRVs were selected preferentially from the US EPA (2016a), followed by Health Canada (2010b) in accordance with Technical Guidance 7 (BC MoE 2015a). There is limited information on the oral toxicity of vanadium in humans. The US EPA (2009) and the Netherlands National Institute for Public Health and the Environment (2009) have derived provisional TRVs for vanadium using limited toxicity information. For this reason, these provisional TRVs were not considered appropriate for use in the HHRA. The selected vanadium oral reference dose was based on the US EPA (1988) reference dose of 0.009 mg/kg/day for vanadium pentoxide, and was calculated based on the proportion of the compound that is vanadium metal (i.e., 0.009 mg/kg/day x 56% = 0.005 mg/kg/day). This is consistent with the oral reference dose presented in US EPA (2016b). The TRVs used in the HHRA are presented in Table B-6-2 of APPENDIX B-6.

5.4 Relative Absorption Factors

The potential for absorption detection of COPCs in environmental media depends on the matrix it is in, how tightly bound the COPC is to the matrix and how easily it moves from the matrix into the human body. When a person ingests a COPC in soil, sediment or food, or is exposed to a COPC on skin, some portion (from 0 to 100%) of the total amount of chemical concentration is absorbed by the body. Relative bioavailability allows for corrections to be made for the matrix to which a receptor is exposed. For example, TRVs are often based on studies in which exposure occurs via contaminated water or food. Chemicals in sediment and soil are typically much less bioavailable than in water or food. The COPCs in diet from a bioassay can be significantly more bioavailable than the same COPC in natural dietary items. This lower availability relates to the binding of the chemical to the inorganic and/or organic matrix. Consequently, when comparing exposure from sediment and soil ingestion to oral TRVs generated from laboratory studies of exposure to COPCs in water or food, some correction for relative bioavailability is generally accepted as being reasonable.

The physiologically based extraction test (PBET) is an in vitro test system for predicting the bioavailability of metals from soil by simulating the conditions in the human gastrointestinal tract (including stomach and small intestinal pH and chemistry, soil-to-solution ratio, stomach mixing, and stomach emptying rates (Ruby et al. 1999). This model system has been validated for both arsenic and lead (US EPA Method 200.8), a metalloid and a metal that range in solubility properties from cationic and oxyanion-forming elements (Stumm and Morgan 1996). Lead and copper are both cationic species that have increasing solubility with decreasing pH. Arsenic and vanadium are both oxyanion-forming elements with similar behavior in terms of mobilisation that have generally increasing solubility with increasing pH (Stumm and Morgan 1996). Aluminum has a U-shaped concentration trend (Langmuir 1997); therefore, PBET results were not considered for this assessment.

This assay was used to determine the bioavailability of copper and vanadium from exposure to soil/tailings along the Hazeltine Corridor. The results for were 45% for copper and 1.2% for vanadium (APPENDIX A-7).

PBET results have been approved by regulators for assessing the amount of metal in soil available for uptake for other metals, on the basis of our understanding of the mechanisms that control the solubility of metals and the conditions in the human gastrointestinal tract (e.g., other mine sites in BC and other sites in Ontario [Portlands Energy Centre[4]]). This is based on the findings of Ruby et al. (1999) that the rate limiting step in metal uptake kinetics is dissolution in the free metal in the stomach, rather than absorption across the gut epithelium, which may be different for different metals.

Although the results of the PBET model system indicate that the oral bioavailability of copper and vanadium from soil/tailings are considerably less than 100%, the PBET results were not applied to risk estimates as a conservative measure.

The dermal RAF for copper was obtained from Health Canada (2010b). A default dermal RAF of 1% was applied for aluminum and vanadium based on analysis of other inorganics with sufficient data (Ontario Ministry of the Environment 2011). The oral and dermal RAFs used in the HHRA are presented in Table B-6-2 of APPENDIX B-6.

6.0 RISK CHARACTERIZATION

For a threshold acting chemical, the risk characterization for each exposure pathway is expressed as a hazard quotient (HQ), which is the ratio of the estimated exposure dose to the reference dose. The HQs for a COPC associated with the different pathways of exposure are added to determine the potential risk associated with total exposure to a chemical. The sum of HQs over all exposure pathways is termed a hazard index. A hazard index of 1 is considered acceptable (BC MoE 2016a).

6.1 Results

A summary of hazard indices for the receptors of concern is provided in Table 11. The human health model results are provided in APPENDIX B-4 and a summary of the HQs by exposure pathway is presented in Table B-4-1 of APPENDIX B-4.

Table 11: Hazard Indices for Receptors of Concern

COPC	Infant	Toddler	Adult
Aluminum			
Subsistence and Traditional Land User	0.35	0.38	0.14
Hiker/Camper	0.14	0.17	0.055
ATV/Snowmobile User	n/a	0.0050[a]	0.0041

Hiker/Camper	0.32	0.37	0.12
ATV/Snowmobile User	n/a	0.0075[a]	0.0062
Boater/Kayaker	n/a	0.28	0.12
Sport Fisher	n/a	0.0098	0.0053

COPC	Infant	Toddler	Adult
Hunter/Trapper	n/a	0.035	0.0086
Quesnel Lake Resident	0.28	0.33	0.14
Logger	n/a	n/a	0.048
Mine/Rehabilitation Worker	n/a	n/a	0.038

Bold and shaded cells indicate a hazard index greater than the threshold of 1.

a) Hazard index is for the teen life stage.

n/a = not applicable, this life stage was not evaluated for the receptor of concern; ATV = all-terrain vehicle; COPC = contaminant of potential concern.

Pre-rehabilitation soil data were used to represent current conditions in the HHRA. However, remediation and rehabilitation activities are on-going in the Hazeltine Channel remediation areas and excavation of soil and tailings has taken place in various sections. The soil data used in the HHRA is reflective of conditions prior to rehabilitation activity and is, therefore, an overestimate, as approximately 8.86 ha (0.089 square kilometers) of tailings deposition have been removed so far, and more is planned for the future. Even with the conservative assumptions applied in the HHRA, the results of the HHRA indicate that risks are low for the subsistence and traditional land user, hiker/camper, ATV/snowmobile user, boater/kayaker, sport fisher, hunter/trapper, Quesnel Lake resident, logger and mine/rehabilitation worker exposed to aluminum, copper and vanadium in sediment, soil, surface water and dietary items (i.e., berries, plants, deer meat, deer liver, moose meat, moose liver, grouse, fish and cattle). The calculated hazard indices were below the threshold of 1 for each of the exposure pathways.

For the subsistence and traditional land user, hiker/camper, boater/kayaker and Quesnel Lake resident, where sediment exposure is an operable exposure pathway, the driving pathway for risk is dermal contact with sediment. For example, for the toddler subsistence and traditional land user, dermal contact with sediment makes up approximately 33% of the total hazard index. However, it should be noted that the dermal loading rates for sediment used in the HHRA are conservative and there is little regulatory guidance on dermal adherence factors for sediments.

When more than one COPC exhibits similar critical effects or acts on the same target organ, the hazard indices for these COPCs are generally summed to provide a hazard index by target organ/critical effect. Aluminum, copper and vanadium do not exhibit similar critical effects; therefore, hazard indices were not summed.

The copper risk estimates should be interpreted within the context that copper is an essential nutrient. Copper is a nutritionally essential element that is required to maintain homeostasis. The World Health Organization (WHO) (1996, 2002; as cited in Health Canada 2010b) considers copper to be essential for human nutrition. Copper is highly regulated in the human body and is part of many metabolic processes (Section 5.1.1). The body has a system that manages and regulates trace metals including incorporation into the blood, transportation to cells and excretion from the body when excess amounts are consumed (Osredkar and Sustar 2011). Copper is needed for metabolism, maintaining skin strength, blood vessels and connective tissue (Osredkar and Sustar 2011).

The WHO (1996) recommends a daily copper intake of 0.34 mg/day for toddlers and 1.3 mg/day for adults. The predicted exposure doses for the toddler and adult subsistence and traditional land user (the most conservative exposure scenario) were lower than the recommended intakes from the WHO (1996), respectively. The results of this assessment indicate that exposure to copper from the Study Area is well below the daily requirement necessary to regulate the body.

There is some evidence to suggest that vanadium also plays a role in human metabolism; however, data are inconclusive. The WHO (1996; as cited in Health Canada 2010b) considers vanadium to be a probably essential trace element. Therefore, the above considerations may also apply to vanadium exposure at the Study Area. Nonetheless, even with the conservative assumptions applied in the HHRA, risks are acceptable from exposure to vanadium at the Study Area.

6.2 Uncertainty

Conservative assumptions were applied in the HHRA. These assumptions likely result in overestimates of actual risks associated with the contaminants in the Study Area. Uncertainties associated with various aspects of the assessment are summarized in Table 12.

Table 12: Evaluation of Uncertainty in the Human Health Risk Assessment

Assumption	Uncertainty	Under/ Overestimate of Risk	Rationale
Food ingestion rates for the First Nations Consumer (i.e., subsistence and traditional land user)	Moderate	Overestimate	Traditional food ingestion rates were based on the results from Chan et al. (2011) because food consumption patterns on local T'exelc and Xatśūll First Nations were not provided. The highest 95th percentile ingestion rates of berries (sum of blue huckleberry, blueberry, red huckleberry, low bush cranberry and high bush cranberry), plants (Labrador tea), deer meat, deer liver, moose meat, moose liver, grouse meat and fish muscle (sum of freshwater fish species) out of adult men and women from the FNFNES were used in the HHRA. Use of the highest 95th percentile ingestion rates was considered conservative as Health Canada (2012) uses average rates for receptor characterization. Furthermore, it was conservatively assumed that all traditional food items are obtained from the Hazeltine Channel corridor. It is expected that traditional hunting and gathering territory ranges well beyond this area
Selection of COPCs for the HHRA	Low	Neutral	Based on the outcome of the problem formulation, there were no COPCs in soil or tailings present in concentrations exceeding human health protection standards. Vanadium concentrations in sediment exceeded the generic soil standard in sediments near the Hazeltine Corridor. Therefore, vanadium in sediment was conservatively retained as an operable exposure pathway warranting further evaluation. At the request of project reviewers, aluminum, copper and vanadium were assessed for all potential exposure pathways.
Bioavailability	Low	Overestimate	The bioavailability for incidental sediment and soil ingestion was assumed to be 100% as a conservative measure. However, site-specific bioavailability data are available for the Study Area and results indicate that bioavailability is much lower than 100% (12%, 45% and 1.7% for aluminum, copper and vanadium, respectively).
Body weights, contact rates, and skin surface areas used in HHRA	Low	Neutral	The receptor characteristics used in the HHRA were based on average Canadian exposure characteristics (Health Canada 2012).

Assumption	Uncertainty	Under/ Overestimate of Risk	Rationale
Food ingestion rates for the non-First Nations Consumer (i.e., hiker/camper, ATV/snowmobile user, hunter/trapper, Quesnel Lake resident, logger, mine/rehabilitation worker)	Moderate	Overestimate	Health Canada (2012) does not provide food ingestion rates for berries, wild game or fish for the general Canadian population. The highest average ingestion rates of berries (sum of blue huckleberry, blueberry, red huckleberry, low bush cranberry and high bush cranberry), deer meat, moose meat, grouse meat and fish out of adult men and women from the FNFNES were used in the HHRA. Use of the highest average ingestion rates was considered conservative as Health Canada (2012) uses average rates for receptor characterization.
Food consumption frequencies	Moderate	Natural/ Overestimate	The traditional food consumption frequencies for the subsistence and traditional land user was assumed to be 365 days per year for all dietary items (i.e., berries, traditional plants, deer meat, deer liver, moose meat, moose liver, grouse meat and fish muscle). However, the reported average consumption rates for the Montane Cordillera ecozone, plateau cultural area in Chan et al. (2011) are lower. Specifically: ■ the highest berry consumption rate is 14 days per year for blue huckleberries ■ the Labrador tea leaves consumption rate, which was used as a surrogate for plant consumption rates, is 14 days per year ■ the deer meat ingestion rate is 62 days per year ■ the moose meat ingestion rate is 30 days per year Based on the above consumption frequencies, risks from exposure to berries, traditional plants and moose may be overestimated. Grouse meat was not identified as one of the top ten food items consumed in the Montane Cordillera ecozone, plateau cultural area. Grouse meat was also not identified as a traditional food item in the 24 hour recall survey (Chan et al. 2011). Therefore, the risks from ingestion of grouse meat may be overestimated.

Assumption	Uncertainty	Under/ Overestimate of Risk	Rationale
Traditional food ingestion	High	Neutral	The traditional food ingestion rates were obtained from the FNFNES, which were based on survey results collected for the Lower Nicola and Splatsin First Nation groups (Chan et al. 2011). It was assumed that the T'exelc and Xatśūll First Nations would have similar traditional food harvesting practices and consumption patterns as these First Nations groups. Without any information about the T'exelc and Xatśūll First Nations food consumption habits, it is unknown if they have higher or lower consumption rates for certain food items.
Consumption of fish	Moderate	Neutral	Although fish tissue results are considered preliminary, the available data were used to characterize risks from exposure to aluminum, copper and vanadium in fish tissue. Fish tissue data will continue to be monitored as part of the CEMP. If results indicate that tissue concentrations are changing, then the risk assessment should be updated to include a fish ingestion pathway.
Less than chronic exposure duration	Moderate	Overestimate	The hiker/camper, ATV/snowmobile user, logger and mine/rehabilitation worker were assumed to consume berries from the remediation areas 13 weeks of the year (i.e., July through September). Similarly, the subsistence and traditional land user, hiker/camper and Quesnel Lake resident were only assumed to swim during the warmer months of the year (i.e., May through October). To evaluate chronic exposure for these pathways, no amortization beyond days per week was applied to the exposure dose. That is, the risk calculations were conducted assuming the above receptors were exposed 52 weeks of the year. This assumption is considered highly conservative; however, sub-chronic or acute duration TRVs were not available to evaluate shorter-term exposure durations.
Cattle (beef) consumption	Moderate	Overestimate	The Quesnel Lake resident may consume cattle that use the remediation areas for grazing. Prior to the TSF embankment breach, cattle were observed grazing at the Mine in June through September. It was assumed that the Quesnel Lake resident only consumes cattle that have grazed in the remediation areas during these four months (i.e., beef is purchased and frozen for consumption year round). Since the COPCs evaluated in this risk assessment are known to not accumulate in muscle, the significance of this overestimate is moderate.

Assumption	Uncertainty	Under/ Overestimate of Risk	Rationale
Sediment contact pathway parameters (e.g., sediment adherence)	High	Overestimate	Use of the sediment adherence factors from Shoaf et al. (2005a) is considered very conservative as these were derived based on children playing in tidal mud flats where a high level of sediment contact and adherence occurs, particularly for the feet. The dermal adherence factors for sediment were for medium to coarse sand (34% medium, 26% coarse). Sediment in Quesnel Lake is primarily coarse sand, reported as 89.2% at near-field stations and 61.6% at far-field stations (Appendix A-7), which would likely have a lower dermal adherence factor.
Use of 95% UCLM as exposure concentrations	Low	Overestimate	Sufficient samples were available to reliably calculate 95% UCLMs for aluminum, copper and vanadium. 95% UCLMs represent reasonable maximum exposure concentrations, and are, therefore, conservative estimates. However, these values represent a more realistic estimate of exposure compared to the maximum concentration, which is highly conservative.
Use of literature BTFs	Moderate	Overestimate	Biotransfer factors were obtained from literature and were based on studies with cattle. The use of beef BTFs is likely to overestimate risk from ingestion of deer and moose meat since domestic ruminants are more sensitive to copper than wildlife (Ward and Nagy 1976). A literature BTF was not available for a grouse; therefore, the deer and moose BTF was conservatively used as the grouse BTF.
Use of food chain modelling to estimate concentration of aluminum, copper and vanadium in deer, moose, grouse and cattle tissue	Moderate	Overestimate	Deer, moose, grouse and cattle muscle tissue concentrations were estimated using the BTF approach, which includes an estimation of the daily intake of a COPC by a wildlife receptor. Modeling the daily dose of aluminum, copper and vanadium uses some generally conservative assumptions. The BTF approach to estimating deer, moose, grouse and cattle tissue concentrations likely overestimates risks to people consuming these meats. For example, information on the size of the area that cattle use for grazing relative to the size of the Study Area was not available. The habitat range factor was assumed to be 20% for the purpose of estimating concentrations of COPCs in cattle muscle. The food chain model used for the HHRA assumed 100% bioavailability of aluminum, copper and vanadium; however, actual bioavailability from soil and dietary items may be less.

Assumption	Uncertainty	Under/ Overestimate of Risk	Rationale
Organ tissue concentrations	Low/High	Overestimate	Copper concentrations in deer and moose liver were predicted using the liver to muscle ratio from measured data presented in Chan et al. (2011). The data indicated that copper concentrations in liver were much higher than in muscle; approximately 14 times higher in deer and 24 times higher in moose. This ratio was applied to the predicted deer and moose muscle tissue concentrations to obtain the liver tissue concentrations. The same data were not available for aluminum and vanadium; therefore, the aluminum and vanadium liver to muscle ratios were assumed to be same as copper. There is more uncertainty regarding the predicted concentrations of aluminum and vanadium in organ tissues than copper in organ tissues.
Toxicity reference values	Low (based on humans) to high (based on animals)	Overestimate	Toxicity data are based on sensitive endpoints. Uncertainty and safety factors are applied to account for inter and intra species variability.

% = percent; COPC = contaminant of potential concern; ATV = all-terrain vehicle; BTF = beef transfer factor; CEMP = Comprehensive Environmental Monitoring Plan; FNFNES = First Nations Food and Nutrition Study; HHRA = human health risk assessment; TRV = toxicity reference value; TSF = tailings storage facility; UCLM = upper confidence limit of the mean.

6.3 Risk Controls

According to the CSR, it is required to document: (a) the principal risk controls necessary to ensure that risk-based standards are and continue to be met at a site and (b) the actions needed to ensure that these risk controls are implemented and maintained. This information is documented in a Performance Verification Plan (Administrative Guidance #14).

MPMC conducts an annual Comprehensive Environmental Monitoring Plan (CEMP) as part of their EMA Permit (#11678). In addition to meeting the requirements of the EMA Permit, the MPMC CEMP meets the requirement of a Performance Verification Plan, as outlined in Administrative Guidance 14 as it:

viii) includes the requirements to monitor potential contaminant concentrations in groundwater, surface water, sediment, plants and fish

ix) outlines monitoring locations and a schedule

x) confirms that conditions continue to meet the assumptions used in the risk assessment

xi) outlines the measures to be taken if conditions change from the assumptions used in the risk assessment

xii) is reviewed annually by an approved professional (as required by the BC MoE)

xiii) requires an annual report be submitted to the BC MoE

The only risk control for the human health risk assessment is that groundwater in the Hazeltine Corridor should not be used for drinking water purposes unless found acceptable by a qualified professional. The rationale behind this risk control includes:

i) Based on the investigations of the tailings impacted groundwater, the following metals exceeded the drinking water standards: iron, manganese, arsenic, molybdenum, sulfate.

ii) Test wells were installed within the tailings deposition overlying the native till. The tailings thickness at the test well locations was generally 1-1.5 metres in the areas where the test wells were installed.

iii) Currently, there are no groundwater supply wells in the Hazeltine Corridor and no exposure pathway to groundwater.

iv) If groundwater supply wells are installed along the Hazeltine Corridor in the future, installation and evaluation of groundwater quality should be conducted under the supervision of a qualified professional.

This HHRA was conducted according to Technical Guidance 7, Supplemental Guidance for Risk Assessment. Risks to human health were quantified and found to be less than 1.0. Therefore, in accordance with the CSR **18**(3)(b), risks to human health are acceptable under current and future conditions.

7.0 CONCLUSIONS

The HHRA was conducted in accordance with provincial guidance. The approach generally followed that of the CSR, although selection of COPCs was expanded to consider substances not typically regulated under the CSR (i.e., aluminum), in response to reviewer's comments. No COPCs were identified in soil; however, aluminum, copper and vanadium were conservatively retained for the assessment of the ingestion of berries, traditional plants, wild game fish tissue and cattle pathways as part of a multi-media evaluation.

Risks to the subsistence and traditional land user, hiker/camper, ATV/snowmobile user, boater/kayaker, sport fisher, hunter/trapper, Quesnel Lake resident, logger and mine/rehabilitation worker from exposure to aluminum, copper and vanadium were evaluated in the HHRA. Specifically, the following exposure pathways were evaluated:

- **Subsistence and traditional land user**: incidental sediment and soil ingestion, dermal contact with sediment, soil and surface water, inhalation of soil particulates, ingestion of surface water and ingestion of berries, traditional plants, deer meat, deer liver, moose meat, moose liver, fish and grouse
- **Hiker/Camper**: incidental sediment and soil ingestion, dermal contact with sediment, soil and surface water, inhalation of soil particulates, ingestion of surface water and ingestion of berries
- **ATV User**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of berries
- **Boater/Kayaker**: incidental sediment ingestion, dermal contact with sediment, ingestion of surface water and ingestion of fish
- **Sport Fisher**: ingestion of surface water and ingestion of fish
- **Hunter/Trapper**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of deer, moose, fish and grouse
- **Quesnel Lake Resident**: incidental sediment ingestion, dermal contact with sediment and surface water, ingestion of surface water and ingestion of berries, deer, moose, fish, grouse and cattle
- **Logger**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of fish
- **Mine/Rehabilitation Worker**: incidental soil ingestion, dermal contact with soil, inhalation of soil particulates, ingestion of surface water and ingestion of berries and fish

The estimated risks for the above receptors were considered acceptable because the hazard indices were below the threshold of 1.0. The majority of hazard indices were less than 1. Therefore, human health risks associated with the TSF embankment breach are considered to be very low.

8.0 CLOSURE

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this report.

We trust the above meets your present requirements. If you have any questions or requirements, please contact the undersigned.

STUDY LIMITATIONS

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by Golder for the sole benefit of MPMC. It represents Golder's professional judgement based on the knowledge and information available at the time of completion. Golder is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document pertain to the specific project, Site conditions, design objective, development and purpose described to Golder by MPMC, and are not applicable to any other project or Site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by Golder are considered its professional work product and shall remain the copyright property of Golder. MPMC may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

REPORT

Golder Associates

Executive Summary

Golder Associates Ltd. (Golder) was retained by the Mount Polley Mining Corporation (MPMC) to conduct a Detailed Site Investigation (DSI) at the Mount Polley Mine, located near Likely, BC (the Site).

A DSI report (Golder 2016a) was prepared for the Site and submitted to the British Columbia Ministry of Environment (MoE) in January 2016 (also referred to as the "2016 DSI"), in accordance with a Pollution Abatement Order that was issued for the Site. This DSI Update report is a continuation of site investigation work previously completed at the Site and forms part of the on-going remediation and rehabilitation works at the Site (also referred to as the "DSI Update"). This report presents the findings of investigation and monitoring works conducted at the Site between August 2015 and August 2016, and incorporates the findings of the previous DSI report for the Site as well as the Post-Event Environmental Impact Assessment Report (PEEIAR) update that was completed in June, 2016 (Golder 2016b).

Rehabilitation and remediation works at the Site, including excavation of tailings material and re-grading and re-sloping of materials, have been ongoing in parallel to the site investigation activities described in this report. These rehabilitation and remediation works have reduced the volume of tailings and lowered the metal concentrations in surficial soils in the tailings impacted areas since the DSI field programs were undertaken (2014, 2015 and 2016); and as reported in the 2016 DSI report and this DSI Update report. Therefore the sampling results discussed in these DSI reports represent a conservative interpretation of the contamination related to the Tailings Storage Facility (TSF) embankment breach.

The overall objective of the DSI Update was to collect additional data to support the completion of a Human Health Risk Assessment (HHRA) and an Ecological Risk Assessment (ERA) for the Site.

Based on the combined information provided in the 2016 DSI report (Golder, 2016a) and the DSI Update report (this report), we conclude that the DSI requirements of the Pollution Abatement Order has been met, including:

- Identification of areas of potential environmental concern
- Determination of the potential contaminants of concern based on the applicable CSR standards
- Delineation of the horizontal and vertical extent of contamination
- Confirmation that the contamination at the site is stable or decreasing in concentration and extent over time

Summary of Key Findings

The TSF embankment breach in August of 2014, resulted in physical impact of Hazeltine and Edney Creeks, Polley Lake and Quesnel Lake. Approximately 136 hectares (1.36 km^2) of the Site was scoured of forest and topsoil (floodplain zone). Tailings were also deposited on top of relatively undisturbed forest floor (halo zone) across an additional 100 hectares (1.0 km^2) at the Site. It is estimated that approximately 12.8 million m^3 of tailings was discharged to Quesnel Lake (plus an additional 5.8 million m^3 of native soil and TSF water); and that 1.6 million m^3 of tailings were deposited in the Polley Flats area and the Hazeltine Channel Corridor. In areas where the tailings distributed across the forest floor in the halo zone, air exchange was impeded with plant roots and the soil microbial community causing hypoxic or anaerobic environment of the tree roots, and tree mortality. In 2016, the soil, forest, and plant communities showed signs of recovery, especially in areas where the tailings layers were thin.

The initial physical impacts and contaminant concentrations have been mitigated by on-going rehabilitation and remediation works. MPMC immediately implemented a rehabilitation and remediation strategy including removal of tailings, construction of a new creek channel and sedimentation ponds, and rehabilitation and replanting of large portions of the impacted area. This work is ongoing and will continue to change and improve the site conditions.

To date, the rehabilitation and remediation works have reduced the volume of tailings and lowered the metal concentrations in surficial soils in the tailings impacted areas. Therefore, the site conditions documented in the 2016 DSI and this DSI Update report do not represent the current conditions in the field. As discussed in this report, some of the areas that were identified by the 2014, 2015 and 2016 sampling to contain tailings with copper and vanadium concentrations exceeding the soil standards have now been remediated. The remediation and rehabilitation work will be described in a separate report to be issued at a later date.

The following is a summary of the key findings of the DSI in relation to contamination associated with the tailings released by the TSF embankment breach:

- Copper is the main contaminant in the tailings with an estimated mean concentration (95%UCLM) of 737 mg/kg. The concentrations of copper exceeded the applicable CSR standards in tailings but not in groundwater. The geochemical assessment found that the tailings are not potentially acid rock drainage (ARD) generating and that the leaching that would occur under the neutral to basic pH conditions would be low. Kinetic laboratory testing and groundwater investigation confirmed the leaching rate of copper is low, and that the concentrations in groundwater will likely reduce over time as the tailings age and weather. For tailings materials with water flow paths longer than half a metre, mineral solubility controls for copper are expected with the formation of secondary copper minerals, which would limit the concentrations of copper in groundwater. The median copper concentration in groundwater is about one order of magnitude lower than the concentrations predicted by mineral solubility limits, likely due to dilution by precipitation.
- Vanadium, which is associated with the orange-black sandy tailings (contains magnetite), exceeded the CSR standards based on the 90th percentile of 212.8 mg/kg (CSR standard = 200 mg/kg). The estimated mean concentration (95%UCLM) for vanadium in tailings was less than the CSR standards. Based on geochemical characterization, vanadium was not considered to be enriched in tailings compared to concentrations in typical basalt rock in the region. Vanadium concentrations in groundwater did not exceed the CSR standards.

- Selenium is not a contaminant related to the TSF embankment breach in soil, groundwater, sediment or surface water.
- Other substances that exceeded the CSR standards for soil and groundwater are believed to be associated with natural conditions and were not derived from the tailings. These substances included sulfur and molybdenum in soil (exceedance of agricultural land use standards only); and arsenic, iron, manganese and molybdenum in groundwater.
- In the first few months after the breach, an initial increase in turbidity and concentrations of total metals in surface water was observed extending to the mouth of Quesnel River. During the monitoring period considered to be representative for the purposes of evaluating long term impacts related to the breach (June 2015 to 1 December 2015), concentrations of metals and turbidity decreased or stabilized below BC WQGs and/or are within the pre-event range in Polley Lake and Quesnel Lake. However, in Hazeltine Creek and Edney Creek, concentrations of copper consistently exceeded BC WQGs during that time.
- Sediment quality in Polley Lake, Hazeltine Channel and Quesnel Lake indicated concentrations of copper exceeding the CSR Schedule 9 (typical and sensitive) criterion and concentrations of arsenic exceeding the CSR Schedule 9 (sensitive) criterion. Copper concentrations in reference Bootjack Lake and Polley Lake prior to the TSF embankment breach also exceeded the CSR Schedule 9 (typical) standard. Concentrations of copper in sediments in Polley Lake were generally lower than those measured in Quesnel Lake. This is consistent with the results of the Tetra Tech (2015) report that indicated inputs to Polley Lake were largely aqueous, compared to Quesnel Lake that received both aqueous and solid phase inputs.
- Monitoring and confirmation sampling of soil, groundwater, surface water and sediment will be undertaken as part of the comprehensive environmental monitoring plan (CEMP). The sampling results will be evaluated for seasonal variability and long term trends, and compared to the assumptions made in the DSI and human health and ecological risk assessments.

Contaminants of Concern

Based on the findings of the 2016 DSI conducted in 2015 and the DSI Update conducted in 2016, the contaminants listed in the table below have been determined to exceed the applicable CSR standards for soil, groundwater and sediment; and BC Water Quality Guidelines for surface water. The concentrations of contaminants of concern on the Site are considered to be stable or decreasing in concentration.

Table A: Summary of Contaminants of Concern

Remediation Area	Contaminant	Medium	Applicable CSR Standard	CSR Schedule	Contaminant Concentration
Area 2 – Polley Plug/Polley Flats and Area 4, 5, and 6 – Hazeltine Channel	Copper	Soil	150	5 – Toxicity to soil invertebrates and plants	Refer to Table 6
	Vanadium	Soil	200	4 – Residential and Agricultural	
	Sulfur	Soil	500	4 – Agricultural	
	Molybdenum	Soil	5	4 – Agricultural	
	Iron	Groundwater	5	6 – Irrigation	Refer to Section 5.2.3.1
			6.5	6 – Drinking Water	
	Manganese	Groundwater	0.2	6 – Irrigation

1.0 INTRODUCTION

Golder Associates Ltd. (Golder) was retained by the Mount Polley Mining Corporation (MPMC) to conduct a Detailed Site Investigation (DSI) at the Mount Polley Mine, located near Likely, BC (Mine).

A DSI report (Golder 2016a) was prepared for MPMC and submitted to the British Columbia Ministry of Environment (MoE) in January 2016 (also referred to as the "2016 DSI"), in accordance with a Pollution Abatement Order that was issued for the Mine. This DSI update report is a continuation of site investigation work previously completed at the Mine and forms part of the on-going remediation and rehabilitation works at the Mine (also referred to as the "DSI Update"). This report presents the findings of investigation and monitoring works conducted at the Mine between August 2015 and August 2016, and incorporates the findings of the previous DSI report for the Mine as well as the Post-Event Environmental Impact Assessment Report (PEEIAR) update that was completed in June 2016 (Golder 2016b).

Rehabilitation and remediation works at the Mine, including excavation of tailings material and re-grading and re-sloping of materials, have been ongoing in parallel to the site investigation activities described in this report. These rehabilitation and remediation works have reduced the volume of tailings and lowered the metal concentrations in surficial soils in the tailings impacted areas since the DSI field programs were undertaken (2014, 2015 and 2016); and as reported in the 2016 DSI report and this DSI Update report. Therefore the sampling results discussed in these DSI reports represent a conservative interpretation of the contamination related to the Tailings Storage Facility (TSF) embankment breach.

1.1 Objectives and Scope of Work

The overall objective of the DSI Update was to collect additional data to support the completion of a Human Health Risk Assessment (HHRA) and an Ecological Risk Assessment (ERA) for the Mine.

In order to meet this objective, the following scope of work was implemented as part of the 2016 site investigation program:

- collection of additional samples to improve estimation of local background soil concentrations
- preparation of a physical hydrogeological assessment, to describe the groundwater flow regime at the site
- updated screening of 2014, 2015 and 2016 soil results against applicable regulatory criteria, including the added agricultural land use standards
- confirmation of the Conceptual Site Model (CSM)

The overall approach and background information related to this DSI Update is provided in Section 2.0, below.

1.2 Professional Statement and Author Qualifications

Pursuant to Section 63 of the Contaminated Sites Regulation, Golder confirms that this DSI Update report has been prepared in accordance with the applicable sections of the Contaminated Sites Regulation (Part 5, 6 and 14).

Golder certifies that the senior reviewer for this report is an Approved Professional under the BC Contaminated Sites Approved Professional (CSAP) society, has demonstrated experience in the assessment and/or remediation described in this report and is familiar with the assessment work carried out at the Mine.

1.2.1 Qualifications of Lead Authors

Reidar Zapf-Gilje, PhD, PEng, CSAP

Dr. Reidar Zapf-Gilje, PhD, PEng, CSAP, has been providing contaminated site consulting and professional development services for 35 years. He is the Founder and Principal of GeoEnviroLogic. His experience includes development of management plans for contaminated soil, groundwater, and sediment from initial investigations stages, risk assessment and to implementation of remediation and/or risk management solutions. His experience includes work on remote and First Nations communities dealing with hydrocarbon and metals contaminated sites, as well with closure of former landfills and mines. He has also been involved with developing contaminated site framework and guidance documents for the Province of BC, Health Canada, CCME, DFO, Public Works Canada and Environment Canada.

Reidar also organizes and teaches professional development seminars on contaminated sites topics and has taught graduate and undergraduate courses on a part-time basis as Adjunct Professor in the departments of Civil Engineering and Earth and Ocean Sciences at UBC. He has been involved with development of new courses and programs for contaminated site education and training at the British Columbia Institute of Technology and Kwantlen University College. He was the Chair of the former Roster of Contaminated Site Experts (now replaced by the Contaminated Site Approved Professional (CSAP) Society), and in that role he led the development of the new CSAP Society. He currently sits on the CSAP Board and is the Chair of the Performance Assessment Committee. He is an Approved Professional in BC for both numerical standard-based and risk-based submissions.

Trish Miller, MSc, RPBio, CSAP

Trish Miller, MSc, RPBio, CSAP, is a senior environmental scientist and Principal with Golder Associates Ltd. with more than 25 years' experience in human health and ecological risk assessment. Ms. Miller is active in all aspects of contaminated sites risk assessment and remediation, including oversight of the development of sampling plans, integrating objectives and data requirements of a risk assessment into work plans and site investigations, designing toxicology testing programs for ecological assessments, coordinating data analysis, developing site-specific remediation standards, liaising with clients, and reporting. Ms. Miller has developed provincial matrix standards and water quality guidelines, derived numerous site-specific risk-based soil, groundwater and surface water standards. She works with a variety of First Nations on both large and small scale projects ranging for investigation and remediation of large scale diesel contamination to risk assessments of risk-based closure of remote dump sites.

Ms. Miller works with Health Canada to develop guidance including how to conduct site investigations to support risk assessments in remote northern communities, guidance for sediment quality guidelines for human health and including risk assessments in federal environmental impact assessments. She conducts workshops for professional development of managers and consultants on the advantages of risk assessment for contaminated site remediation and on general principles and procedures involved in the conduct of risk assessments. Ms. Miller was appointed by the Province to the B.C. Contaminated Sites Approved Professionals (CSAP) in Risk Assessment. She regularly reviews reports and makes recommendations related to remediation of contaminated land in BC on behalf of the Provincial Ministry of the Environment. Also as an Approved Professional, Ms. Miller currently serves on the CSAP Technical Review Committee, conducts peer Performance Assessments and was a member of the Board of Directors from 2011-2013. Confirmation of CSAP membership can be made by visiting the MoE website: http://www.csapsociety.bc.ca/member_database.htm

2.0 BACKGROUND AND APPROACH

MPMC developed a Rehabilitation and Remediation Strategy (the Strategy) in order to plan and implement the rehabilitation and remediation of the areas that were identified following the TSF embankment breach at the Mine. The Strategy is outlined in Figure 1, below, and combines and builds on existing processes outlined in the *Canadian Environmental Assessment Act,* the British Columbia *Environmental Management Act* and the CSR.

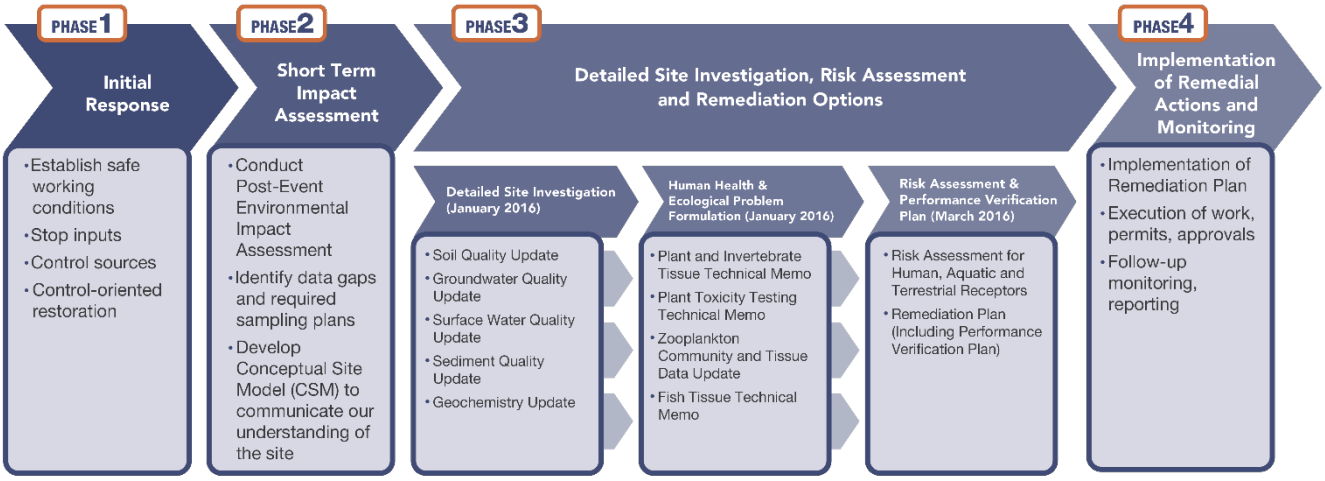

Figure 1: Rehabilitation and Remediation Strategy

The initial DSI report that was submitted to the BC MoE in January 2016 falls under Phase 3 of the Strategy and was completed in accordance with Pollution Abatement Order #107461 that was issued for the Mine. The 2016 DSI report and the current DSI Update report provide information on the area, depth, and degree of contamination in each of the remediation areas at the Mine (refer to Figure A-1) and also identified contaminants of concern (COCs) in soil, groundwater, surface water, and sediment.

As described in the 2016 DSI, the extent of the impacted area was determined to be large. Approximately 136 hectares (ha) (1.36 km^2) was scoured of forest and topsoil and an additional 100 hectares (1.0 km^2) was inundated with tailings deposited on top of relatively undisturbed forest floor. The deposited tailings consisted of two types, classified in the field as ‘grey tailings’ and ‘magnetite sands’. The grey tailings had a fine silty texture, whereas the magnetite sands were speckled pinkish-orange and black. The grey tailings were found along upper benches of the floodplain and in the forest halo zone, whereas the magnetite sands were found in low-lying areas near the creek. The thickness of the tailings deposits ranged from tens of centimetres in the forest halo zone, to more than a metre near in the plug area and in some parts of the Hazeltine Channel floodplain. Some of the tailings deposits contain a mixture of tailings and native soil as a result of scouring of native soil and subsequent mixing with tailings as it flowed down Hazeltine Creek.

Both types of tailings had similar chemical concentrations and geochemical characteristics and were found to be homogeneous and uniform in terms of physical and chemical characteristics throughout the impacted area. The 2016 DSI reported that the concentrations of copper and vanadium were greater than the CSR PL standards (parkland use) across the impacted areas of the site. The current DSI Update added comparison to the CSR AL standards (agricultural use), as a small part of the area near Hazeltine Channel Corridor is zoned agricultural. Sulfur and boron were found to exceed the CSR AL standards.

As described in the 2016 DSI, the main geochemical findings by SRK in 2015 were that the MPM tailings are not potentially acid rock drainage (ARD) generating and that any leaching would occur under neutral to basic pH conditions. SRK identified copper and selenium as the only elements that were enriched when compared to typical crustal rocks and concluded that the potential for leaching from tailings deposited on land or in the lakes was low.

This conclusion was in part based on results from the preliminary testing which indicated that ARD is not expected from the tailings and leaching will be under neutral to alkaline conditions. The preliminary results were from less than 40 weeks of testing. Further test results are now available as discussed in this DSI Update report, and confirm the preliminary results. The full SRK report can be found in Appendix A-2.

The groundwater assessment completed in 2015 as part of the DSI included a limited, focussed assessment of shallow groundwater within the tailings deposits (typical thickness of 0.5 m to 1 m). Because groundwater was encountered in 2015 within 1 m of the ground surface, and because of limited access due to soft ground conditions, hand-augered mini-piezometers and seeps were used instead of conventional drilled wells. The results from these samples of groundwater within the source material were considered to represent worst-case conditions. This assessment was considered sufficient to support the findings of the geochemical characterization (which indicated a low potential for leaching of copper and selenium).

The groundwater sampling results from 2015 confirmed the geochemical findings, as concentrations of metals parameters in shallow groundwater were less than applicable CSR Schedule 6 standards for protection of aquatic life and drinking water. A characterization of the regional groundwater flow systems and the installation of additional groundwater wells in the tailings and the underlying native till was completed as part of 2016 groundwater characterization work reported herein.

As described in the 2016 DSI report, the debris flow initially resulted in an increase in turbidity in Hazeltine Channel, Polley Lake and the west basin of Quesnel Lake. Some increase in turbidity was observed within the first few months after the breach extending to the mouth of Quesnel River. Results of surface water samples were collected from Polley Lake, Hazeltine Channel, Quesnel Lake and Quesnel River showed an initial increase in total metals associated with the turbidity plume that entered these water bodies, but that dissolved concentrations were generally below WQG for Polley and Quesnel Lakes. Exceedances of the WQG for the protection of aquatic life remained for Hazeltine Creek, although concentrations were less than the drinking water quality standards. These results also confirmed geochemistry findings (i.e., low leachability of metals).

As described in the 2016 DSI, concentrations of copper in sediment samples from Polley Lake, Hazeltine Channel (sedimentation ponds) and Quesnel Lake were found to exceed the CSR Schedule 9 standard for a typical site and concentrations of arsenic exceeded the standard for a sensitive site. Concentrations of copper in sediments in Polley Lake were generally lower than those measured in Quesnel Lake. This is consistent with the results of the Tetra Tech (2015) report that indicated inputs to Polley Lake were largely aqueous, compared to Quesnel Lake that received both aqueous and solid phase inputs.

3.0 REGULATORY FRAMEWORK

As described in the DSI report, the Mine is under a Pollution Abatement Order (#107461)[1] under Section 83 (1c) of the *Environmental Management Act (EMA)*. Section 83 of *EMA* outlines the required actions to be taken to satisfy the Act, including 83 (2b) *"undertake investigations, tests, surveys and any other action the director considers necessary to determine the extent and effects of the pollution and to report the results to the director*". Section 14 of the Contaminated Sites Regulation (CSR; BC Reg. 375/96, amendments to BC Reg. 184/2016, 19 July 2016; BC MoE, 2016) outlines the requirements for investigations to satisfy *EMA* 83 (2b).

The CSR outlines environmental quality standards, protocols and technical guidance so that detailed site investigations are conducted in accordance with the *EMA*.

3.1 Soil

The CSR soil standards are defined for six land use categories including: Agricultural (AL), Urban Park (PL), Wildland (WL), Residential (RL), Commercial (CL), and Industrial (IL). The remediation areas 2-9 are undeveloped and with the primary purpose of supporting natural ecosystems; therefore, a wildlands use was considered to be the most applicable standard. In the absence of WL standards, and consistent with CSR guidance, PL standards were used to identify contaminants for current and future use of the Mine.

In addition to wildlands use, agricultural land use is also considered applicable at the Mine, based on the presence of land that is dedicated under the Agricultural Land Reserve (ALR). Soil standards for the protection of agricultural uses were therefore also considered applicable as part of the DSI Update. The area that is part of the ALR is outlined on Figure A-1. Although the portion of land dedicated under the ALR at the Mine is small relative to the overall investigation area, Site-wide soil results were conservatively screened against CSR AL soil standards.

Soil standards for metals are found in the following CSR Schedules:

- Generic Numerical Soil Standards for PL and AL (Schedules 4 and 10)
  - The generic Schedule 4 AL standard for boron is derived from the hot water soluble (HWS) method. In the DSI Update, only results from the HWS method are compared against this standard. Boron results from strong acid leachable (SAL) method are discussed further in Section 5.1.3.1.
  - The generic Schedule 4 AL standard for sulfur is derived for elemental sulfur. In the DSI Update, in the absence of elemental sulfur results, existing results from a total combustion method are compared against this standard. This is considered a conservative estimate for elemental sulfur, and is further discussed in Section 5.1.3.2.
- CSR Matrix Numerical Soil Standards for PL and AL (Schedule 5) for the following pathways:
  - Human health protection – intake of contaminated soil
  - Human health protection – protection of groundwater used as drinking water

[1] As detailed in the 24 February bridge letter from the MOE regarding "Clarifying requirements for PAO #107461".

- Environmental protection – toxicity to soil invertebrates and plants
- Environmental protection – groundwater flow to freshwater used by aquatic life
- Environmental protection – groundwater used for livestock watering (*added pathway since 2016 DSI*)
- Environmental protection – groundwater used for irrigation (*added pathway since 2016 DSI*)

The BC MoE has also developed regional background soil concentrations for metals parameters, which are summarized in the MoE's "*Protocol 4 for Contaminated Sites - Determining Background Soil Quality*" (Protocol 4, dated October, 2010). The Mine is located within Region 5 - Cariboo Regional Area, as specified in Protocol 4. The Region 5 background concentrations of 150 µg/g for chromium, 150 µg/g for nickel and 4 µg/g for selenium, which are above the CSR PL and AL standards, were considered applicable and applied to the site. Therefore only concentrations of these parameters exceeding the applicable regional background concentrations were considered as exceedances of the standards.

Regional background concentrations for other metals were not retained as the established concentrations are less than the applicable CSR soil standards.

3.2 Groundwater

Generic Numerical Water Quality Standards are listed in Schedule 6 and Schedule 10 of the CSR and were used to assess groundwater quality at the site. The Water Quality Standards are divided into four categories that provide standards for the protection of freshwater (AW-F) and marine aquatic life (AW-M) and for defined groundwater uses including irrigation water (IW), water for livestock (LW), and drinking water (DW).

A water well search was conducted as part of the DSI Update report. The results are included in Appendix A-5 at the end of this report. Based on the results of the water well search, and the known land uses in the vicinity of the Mine, the following groundwater uses were considered applicable:

- AW-F: shallow groundwater at the site is inferred to discharge into Hazeltine Channel and into Quesnel Lake, which are both considered aquatic life habitats. CSR standards for protection of AW-F were therefore applied to groundwater results.
- DW: although groundwater at the site is not used for drinking water, the CSR requires that groundwater be protected as a future source of drinking water if aquifers that may provide sufficient water for household use are present and if these aquifers are not protected by a sufficiently thick confining layer. However, Quesnel Lake is used as a drinking water source, and DW standards would apply to surface water.
- IW (*added water use since 2016 DSI*): as described in Section 3.2, land dedicated under the BC ALR passes through a portion of the Hazeltine Channel drainage (refer to Figure A-1). Based on the presence of the ALR, groundwater standards for the protection of groundwater used as irrigation water have been conservatively included in screening of groundwater results for the site.
- LW (*added water use since 2016 DSI*): groundwater standards for protection of groundwater used for livestock watering have also been conservatively included in screening of groundwater results for the site, based on the rationale provided for IW standards.

3.3 Sediment

Schedule 9 of the CSR provides Generic Numerical Sediment Criteria for protection of freshwater and marine water sediment. The criteria are further divided into sensitive contaminated sites (SCS) and typical contaminated sites (TCS). Based on the aquatic receiving environments at the site, the sediment criteria for SCS were considered applicable for interpretation of the DSI results.

3.4 Surface Water

The BC Water Quality Guidelines (WQGs) for the protection of AW-F and the Schedule 6 drinking water standards were used to identify contaminants in the surface water bodies of Polley Lake, Hazeltine Creek, Edney Creek, Quesnel Lake and Quesnel River.

In addition to these standard methods, specific requirements for Quesnel Lake surface water quality were specified in a Pollution Abatement Order amendment (#107461) issued June 15, 2015, by the BC MoE (2015b). The amendment specified that MPMC must meet the following requirements with respect to water quality at specific stations in Quesnel Lake.

- Turbidity at the monitoring sites QUL-54, QUL-55, QUL-56 (and subsequently replacement stations QUL-54a, QUL-55a, and QUL-56a) of no greater than 2 NTU rolling average above background (1 NTU - as recommended by MoE.), at any monitored depth, over a period of 30 days using a minimum of five weekly samples.
- Turbidity at the monitoring site QUL-18 of no greater than 1 NTU above background at any monitored depth.

To assess compliance with the Pollution Abatement Order (#107461), depth profile measurements of turbidity were plotted for near-field stations QUL-54/a, QUL-55/a, QUL-56/a and the western mid-field station QUL-18. The plots were then interpreted to identify time periods where non-compliance was observed.

On 19 November 2015, MPMC received an amendment to *Environmental Management Act* (*EMA*) Permit 11678, which authorizes treated mine contact water discharge to Hazeltine Creek and subsequent discharge to Quesnel Lake through twin pipelines and submerged diffusers. Discharge from the treatment plant to Hazeltine Creek commenced on 1 December 2015, and is presently authorized, with conditions, until 30 November 2017. One of the conditions under *EMA* Permit 11678 is that MPMC must develop and implement an alternative to the discharge to Hazeltine Creek. An evaluation of discharge alternatives is in progress and is reported under a separate cover.

The key point for this DSI Update (and subsequent HHERA and Remediation Plan) is that surface water quality data included in this assessment included data from August 2014 to December 2015. During this time period, the mine was holding mine contact water in Springer Pit. The main source of water to Hazeltine Creek was Polley Lake. As of 1 December 2015, mine contact water has been treated and discharged to Hazeltine Creek with subsequent discharge to Quesnel Lake through twin pipelines.

Water quality conditions have changed significantly since the breach occurred, relative to changes that have occurred in other media. Water quality conditions immediately following the breach were evaluated in the PEEIAR. The water quality conditions from January 2015 to June 2015 were considered to be reflective of a short term construction period when the main Hazeltine Creek channel was being re-constructed. Water quality conditions following channel reconstruction were considered to be representative of long term conditions resulting from the breach. As noted above, MPMC began discharging treated mine water from Springer Pit into Hazeltine Creek on 1 December 2015 under permit. Therefore, for the purposes of evaluating long term impacts related to the breach, the water quality data from June 2015 to 1 December 2015 were considered to be representative.

4.0 RATIONALE AND METHODS

This report is referred to as the DSI Update report. The purpose of the DSI Update was to collect additional site investigation data during the sampling season of 2016 to complete work that was underway but had not been completed by the time the 2016 DSI was due; and to fill data gaps and add information requested by reviewers. A work plan describing the additional work planned for 2016 was developed for each of the abiotic media that were presented in the DSI report, including soil, groundwater, surface water, and sediment.

The additional site investigation, and the updated interpretation presented in the DSI Update report, were designed to fulfill the requirements for a Detailed Site Investigation which, as described in Section 59(2) of the CSR and the DSI report from January 2016, includes the following elements:

- Identification of substances that may cause or threaten to cause adverse effects to the environment.
- Identification of the specific areas, depths, and degree of contamination on the site, including areas and extent of migration, if applicable.
- Evaluation of contamination relative to the standards outlined in the CSR and the HWR (Hazardous Waste Regulation).

The rationale and methods for additional characterization of soil, groundwater, surface water, and sediment are detailed in the following sections.

4.1 Soil

Preliminary estimates of local background concentrations in soil were presented in the 2016 DSI. These estimates were based on samples collected by SNC Lavalin in 2014, and samples collected by Golder for the 2016 DSI. To improve the determination of local background concentrations, an additional 12 background soil samples were collected from four selected locations as described in Appendix A-1.

Twenty six additional background soil samples were collected from co-located plant sample locations as part of the terrestrial risk assessment sampling program carried out in 2016. At each location, the humus layer was removed, and the top 0.2 m of soil from the base of the plant was sampled. Additional detailed information related to soil sampling methodology and the nature of the soil samples obtained at the background locations was documented, including physical characteristics of the soil, depth of sample collection, GPS coordinates of the sampling point, and chemical analysis. A Golder-directed Field Technician documented observations at each soil sample location. A detailed summary of the background soil sampling program is presented in Appendix A-1.

Additional soil sampling carried out expressly for characterization and/or delineation purposes was not conducted as part of the DSI Update, because sufficient information on extent and concentrations of contaminated soil within the floodplain and halo zone was previously conducted by SNC in 2014 and by Golder in 2015 and were presented in the 2016 DSI report submitted in January 2016. However, fifty seven tailings soil samples were collected as part of the terrestrial risk assessment. Co-located soil and plant samples were collected at locations as described above. These samples were opportunistically included in the DSI Update, and are presented in Table 2 after the text.

Therefore, the following tasks were completed in order to update the soil conditions at the site:

- Re-screening of 2014 and 2015 soil results against CSR AL soil standards. The re-screening was completed because a small part of the land in the Hazeltine Channel corridor is dedicated under the ALR (Agricultural Land Reserve).
- Analysis of selected archived soil samples for boron using a HWS boron procedure. During the re-screening process of soil results against CSR AL standards, it was determined that the boron results were not analyzed using the method specified by MoE (CSR Schedule 4). This method is based on a HWS analysis, whereas the previous results were analyzed using a SAL method. A comparison of the two analytical methods is provided in the soil results section in Section 5.1.3.1.
- Incorporating results from soil samples collected as part of the terrestrial risk assessment (co-located soil and plant samples) such that the soil data reported in this DSI Update reflects the contribution from these additional sample results.

4.2 Geochemistry

As described in Section 2 above, SRK findings in 2015 were preliminary as the long-term kinetic testing had not been completed. SRK provided an updated report in early 2017, which is included in Appendix A-2. This DSI Update report presents the results of the completed kinetic tests as well as additional geochemical investigation work that was undertaken in 2016.

The updated geochemical results were used to confirm the overall Conceptual Site Model of the tailings impacts.

4.3 Groundwater

To confirm the preliminary findings of the 2016 DSI; namely that copper, vanadium, selenium in the tailings did not significantly leach into the groundwater, additional investigation was conducted in 2016 (Appendix A-4), including:

- Description of regional physical hydrogeological characteristics based on information from regional geological maps and various groundwater investigation of the mine site (Appendix A-5).
- Installation and sampling of 18 additional monitoring wells (typical installations are shown in Figures 2 and 3 below), including nested monitoring well pairs within tailings material and underlying till material (12 wells were sampled in 2016).
- Installation of three additional monitoring wells to evaluate background groundwater quality at the site.
- Incorporation of relevant hydrogeological information from the TSF groundwater assessment modeling work.
- Collection of additional groundwater samples to monitor temporal and/or seasonal changes in the groundwater quality.
- Measurement of groundwater elevations to provide an understanding of groundwater flow directions.
- Estimation of hydraulic conductivity at selected monitoring wells to provide an understanding of groundwater flow velocities in the various stratigraphies that were encountered during the investigation work.

The results of additional groundwater quality sampling are presented in Appendix A-4, and the physical hydrogeological properties are presented in Appendix A-5.

Figure 2: Typical drilling set-up, Including Installation of a Monitoring Well at the Mine

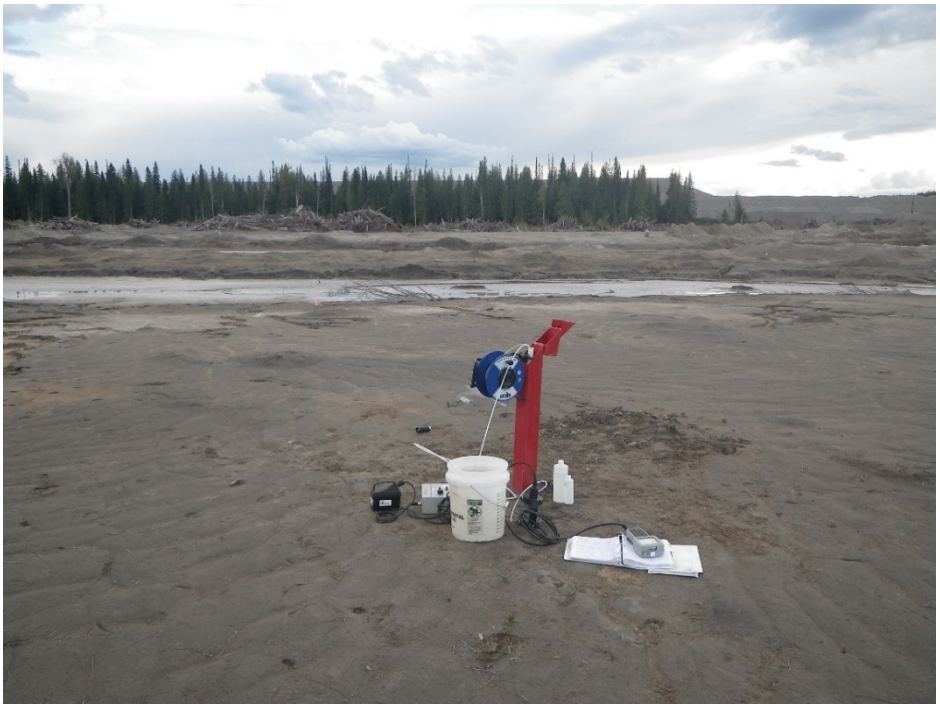

Figure 3: Groundwater Sampling at MW16-02

4.4 Surface Water

Since the embankment breach, the surface water monitoring program has evolved, in consideration of factors that included, but were not limited to: monitoring results, safety and logistical constraints, recommendations from BC MoE, and seasonal conditions (e.g., Lake Turnover, onset of winter). A number of stations in Polley Lake, Hazeltine Creek, and Quesnel Lake were consistently monitored, either weekly or monthly; while other stations were monitored on a more intermittent basis or were briefly monitored for a specific purpose. A summary of discrete water quality monitoring data that been reported since the breach is shown on Table 1, below.

Table 1: Summary of Surface Water Quality Reporting

Report	Time Period
Post-Event Environmental Impact Assessment Report (June 2015)	August 2014 to March 2015
Detailed Site Investigation Report (January 2016)	August 2014 to August 2015
Post-Event Environmental Impact Assessment Report Update (June 2016)	August 2015 to December 2015

This DSI Update report therefore includes a summary of surface water quality data that was collected between June 2015 and December 2015, that is related to the breach, and that is relevant to the site investigation works. The stations that were monitored between August 2015 and December 2015 are shown on Figure 4, below. A detailed description of the surface water quality results collected in 2015 and is included in Appendix A-6. Water quality data collected during 2016 is not included in this report, as it will be presented in MPMC's Annual Report that will be submitted to MoE in March 2017.

4.5 Sediment

Additional sediment sampling was conducted by Minnow in 2016. Sediment samples were collected from Polley Lake, Quesnel Lake, Hazeltine Creek sedimentation pond and the reference location, Bootjack Lake (Figure 5) for the following purposes:

- To characterize sediment and porewater quality at locations sampled in 2014 and/or 2015 and provide temporal comparisons of sediment quality from year to year. Samples collected for this purpose were collected at the same locations as 2014 and 2015, using the same sampling methods, where possible.
- To provide sediment quality data from previously unsampled locations to augment the existing spatial extent characterization. Seventeen additional sampling locations (14 in Quesnel Lake and 3 in Polley Lake) were selected in 2016 to supplement historical sampling locations

Sample collection methods are outlined in detail in Appendix A-7. Samples were analyzed for metals, particle size, total organic carbon (TOC), pH, total nitrogen, and total sulfur. For samples collected from the Hazeltine Channel Sedimentation Pond, laboratory analyses also included oil and grease and polycyclic aromatic hydrocarbons (PAHs). The sediment sampling results were compared to the applicable CSR Schedule 9 criteria for sediment quality.

5.0 RESULTS

This section of the report presents the results of the DSI Update, including field observations and laboratory results. The results for each media that was tested are presented under separate headings, below. Further details and a compilation of data from this investigation as well as from the PEEIAR (MPMC 2015) are provided in the supporting appendices attached to this report, as follows:

- Appendix A-1: Determination of Local Background Soil Concentrations – Mount Polley Mine, Likely, BC, prepared by Golder, dated 26 January 2017.
- Appendix A-2: Mount Polley Mine Tailings Storage Facility Embankment Breach: Laboratory Kinetic Tests on Spilled Tailings - Final, prepared by SRK, dated February 2017
- Appendix A-3: Mount Polley Spilled Tailings: Polley Flats Copper Geochemical Conceptual Model – Final, prepared by SRK and Minnow, dated 23 December 2016
- Appendix A-4: Updated Factual Data Report on Groundwater Quality, Hazeltine Channel Floodplain, 2015 & 2016, prepared by Golder, dated 28 October 2016
- Appendix A-5: Detailed Site Investigation for Hazeltine Channel at Mount Polley Mine – Physical Hydrogeological Assessment and Conceptual Model, prepared by Golder, DRAFT dated 25 January 2016
- Appendix A-6: Addendum to Mount Polley Surface Water Quality Impact Assessment Update, prepared by Golder, dated 30 March 2016
- Appendix A-7: Sediment and Sediment Porewater Quality Data Report – August 2016 Collections, prepared by Minnow, dated 6 December 2016
- Appendix A-8: Co-Located Soil Samples – Laboratory Certificate of Analysis

5.1 Soil Results

As described in the 2016 DSI, the term “soil” in this report refers to the following material types that were sampled as part of the investigation:

- Tailings.
- Native soils underlying deposited tailings (native). As part of the DSI update, native soils were further categorized as organic and mineral soil, based on observations made during sample collection.
- Native background soils (local background). Local background soil was also categorized as organic or mineral, based on observations made during sample collection.

5.1.1 Soil Conditions and Stratigraphy

Rehabilitation and remediation works at the site have been ongoing in parallel to the site investigation activities described in this report. Therefore, the site conditions as observed during the 2014, 2015 and 2016 sampling have changed at many locations. Rehabilitation works that were completed in 2015 and 2016 along the length of the Hazeltine Channel Corridor included (Pers. Com, G Holmes at Mount Polley, 29 November 2016):

- Excavation and removal of tailings material over approximately 9 ha in the vicinity of the Hazeltine Channel and in parts of the floodplain and halo zone.
- Removal of deceased tree and vegetation cover in the halo zone.
- Re-sloping on 46 ha of the floodplain zone that were scoured (i.e., areas with little topsoil or tailings material).
- Mounding of tailings through mixing with underlying organic soils on 32 ha of the site.
- Addition of transplanted soil in areas where tailings were removed. Transplanted soils consisted of a mix of topsoil and mineral soil.
- Addition of coarse woody debris (CWD) throughout the floodplain zone.
- Seeding and planting of various plant species along the Hazeltine Channel corridor.

A discussion of the rehabilitation works is presented in Golder's technical memorandum entitled "*Update to the Terrestrial Ecosystem Assessment of the Hazeltine Channel Corridor – Mount Polley Mine*" (Golder 2017). Additional rehabilitation work completed since 2015 is shown in Table 2, below. The terrestrial plot locations assessed in the Terrestrial Ecosystem Assessment (Golder 2017) are shown on Figures A2-A10 at the end of this report, while Figure 6, below, shows the rehabilitation work completed in the area of Plot 4. Plots 3, 4, 5, 10, 11, and 12 are located in the Upper Hazeltine Channel corridor, while Plots 24 and 25 are located in Lower Hazeltine Channel corridor. As of the date of this report, rehabilitation activities had not occurred in the halo plots not shown in Table 2 (plots 2, 6, 7, 8, 13, 15, 16, 21, 22, 23, 27, 29).

Table 2: Rehabilitation Activities that have Occurred Since 2015

25	-	Yes	-	Yes	-	Yes	Yes

Figure 6: Rehabilitation Work along Hazeltine Channel Corridor

The general observations made along the length of Hazeltine Channel in relation to stratigraphy at the site, immediately following the TSF embankment breach included:

- Tailings deposits that were observed to be greater than 3 m thick in certain locations in the vicinity of Polley Flats. The layer of fine-grained tailings material was observed to be up to 1 m thick. At the time of the soil investigation work in August 2016, rehabilitation work involving the removal of tailings had begun in the Polley Flats area on the east side of Hazeltine Channel.
- The thickness of tailings material within Upper Hazeltine Channel was observed to be up to 2.5 m at Golder station ST15. Up to 269,000 m^3 of deposited tailings material was excavated from Upper Hazeltine Channel (as part of creek rehabilitation work completed in 2015). Further rehabilitation work was completed in the vicinity of ST15 in 2016, however an estimate of the volume of additional tailings that has been removed was not yet available at the time of this report.

- Tailings material was not observed within Hazeltine Canyon (except thin, isolated pockets), as material within the canyon was scoured to bedrock.
- A mixture of native till and tailings deposition was observed in Lower Hazeltine Channel and at the mouth of Edney Creek. The soil mixture is consistent with the scouring and deposition that occurred following the event. Based on survey information available at the time of this DSI Update report, approximately 6,000 m^3 of material were excavated from the vicinity of the sedimentation ponds at the downstream end of Hazeltine Channel, as part of works completed in 2015. The 2015 rehabilitation work also included mixing with native soil, re-sloping, placement of CWD and wood chips, and replanting.

5.1.2 Site-Specific Background Concentrations

Local background concentrations were determined for organic and mineral soils using local background soil samples collected in 2014, 2015 and 2016.

Four background soil sample datasets were combined to determine the background soil concentrations:

- Samples collected by SNC Lavalin 2015 (seven organic samples and 16 mineral samples)
- Samples collected by Golder in 2015 as part of the 2016 DSI (19 organic samples and six mineral samples)
- Samples collected by Golder in 2016 in anticipation of the DSI Update (12 mineral samples)
- Samples collected by Golder in 2016 as part of the terrestrial plant and invertebrate soil sampling program (26 organic samples)

Appendix A-1 provides the sampling locations (Figure 1) and details on the sampling methods and results.

As shown in Table 3, the estimated local background concentrations (i.e. the 95th percentile) were less than the applicable standards (or regional background concentrations where noted) for all substances listed, except for sulfur. No substances that exceeded standards were “overruled” using the estimated local background soil concentrations.

The local background concentrations were requested by project reviewers. A Director’s determination of the local background concentrations will not be sought.

The estimated local background concentrations and the corresponding lowest applicable CSR standards are shown in Table 3 below.

Table 3: Estimated Local Background Concentrations (ug/g)

Parameter	95th Percentile – Organic Soil	95th Percentile – Mineral Soil	Most Conservative Applicable CSR Standard
Antimony	9.2	9.5	20 (AL and PL -G)
Arsenic	0.48	0.43	15 (AL – DW/LW and PL - DW)
Barium	252	132	400 (AL– DW/LW and PL- DW)
Beryllium	1.1	0.6	4 (AL and PL – G)
Boron (HWS)	-	0.15[2]	2 (AL – G)
Cadmium	1	0.3	1.5 (AL – DW/I)
Chromium[1]	57	58	150 (Regional background)
Cobalt	19	17	40 (AL-G)
Copper	79	39	90 (AL and PL – GWtoFSW)
Lead	12.2	10.3	100 (PL – DW/I)
Lithium	28.63	23.56	1600 (AL and PL – G)
Manganese	1252	899	1800 (AL and PL – G)
Mercury	0.2	0.1	0.6 (AL – LI)
Molybdenum	1.4	0.7	5 (AL –G)
Nickel[1]	49.5	36.3	150 (Regional background)
Selenium[1]	0.5	0.2	4 (Regional background)
Silver	0.94	0.14	20 (AL and PL –G)
Strontium	137	66	47,000 (AL and PL – G)
Sulfur	900[2]	600[2]	500 (AL – G)
Thallium	0.20	0.09	2 (AL –G)
Tin	2	2	5 (AL – G)
Uranium	1.3	0.7	16 (AL and PL – G)
Vanadium	83.0	88.1	200 (G)
Zinc	144	75	150 (AL – GWtoFSW/LI/DW/I and PL - GWtoFSW)

1) The CSR standard has been substituted with the regional background concentration as the CSR standard is below regional background.

2) Maximum concentration used to estimate local background concentration. Less than 12 samples were available, which was considered to be insufficient for statistical estimation. Refer to Appendix A-1 for details.

AL – Agricultural Land use; PL – Park Landuse; LW – livestock Watering Protection Standard; DW – Drinking Water Protection Standard.

GWtoFSW Protection of groundwater flow to freshwater aquatic life. Standard is pH dependant.

G – Generic Standard; I – Intake of contaminated Soil Standard; LI – Livestock Ingestion Standard; Units are shown in µg/g.

Local background concentrations are based on the 95th percentile value for each parameter, except where noted.

All units are expressed in ug/g.

5.1.3 Laboratory Analytical Results

Laboratory analytical results of the soil investigation were screened against the applicable CSR PL and AL soil standards. In Table 4, native soil samples are shown separately from tailings samples. Native soil was further categorized as being native organic soil or native mineral soil. Detailed laboratory analytical results are presented on Tables 2, 3A and 3B at the end of this report. Statistical analysis of the soil data for determining the contaminants of concern is presented in Table 6 in Section 5.1.3.3.

Table 4: Summary of Exceedances in Soil based on Maximum and Mean Concentrations

Parameter	Number AL Exceedances	Number of PL Exceedances	Maximum	Mean	MCS AL	MCS PL
Native Under Tailings (Organic)						
Arsenic	1/24	1/24	**16.4**	5.5	**15**	15
Cadmium	1/24	1/24	**3.37**	0.62	**1.5**	1.5
Copper	3/24	3/24	**352**	84.6	**100**	100
Selenium	2/24	1/24	**8.89**	0.85	**2**[1]	3[1]
Zinc	1/24	0/24	**209.0**	76.0	**200**	200
Native Under Tailings (Mineral)						
Arsenic	3/52	3/52	**15.7**	8.8	**15**	15
Copper	6/52	6/52	**366**	89.1	**90**	90
Tailings						
Arsenic	2/182	2/182	**16.5**	10.4	**15**	15
Barium	1/182		**697**	152	**400**	400
Cadmium	1/182	1/182	**3.4**	0.19	**1.5**	1.5
Copper	178/182	178/182	**1560**	**702**	**150**	150
Molybdenum	28/182	0/182	**7.3**	3.8	**5**	10
Vanadium	42/182	42/182	**289**	171	**200**	200
Zinc	2/182	1/182	**552**	58.6	**200**	300

Concentrations shown are in mg/kg, unless otherwise noted.

mg/kg = milligrams/kilogram; MCS = Most Conservative Standard.

- Indicates there is no applicable CSR standard.

Cadmium, copper and zinc standards are pH dependant.

Where a result was below MDL, the MDL was used for the purpose of calculation.

The number of exceedances does not include results that were reported below MDL, even if the MDL was above standard.

1) The regional background concentration for selenium is 4 mg/kg.

5.1.3.1 Comparison of Boron Analyses

Boron concentrations reported in 2014, 2015 and 2016 were analysed via a SAL (strong acid leachable) method. Boron was not identified as a potential contaminant of concern in the 2016 DSI because the soil investigation results were not compared to the AL standard at that time. As discussed in Section 3.1, the soil investigation results have been re-screened against the CSR AL standard, because a small part of the land in the Hazeltine Channel Corridor is in the ALR (Agricultural Land Reserve). For this reason, archived samples (15 samples) were analyzed for boron using the hot water soluble (HWS) method specified by MoE (CSR Schedule 4). This section provides a comparison of the results obtained using these two different methods. Table 5 and Figure 7 provide the comparative results of the two methods.

Table 5: Comparison of SAL and HWS Boron Data in Tailings Samples

Sample Location	Boron (SAL)	Boron (HWS)
P2 - T Sand	8.0	<0.10
Rye Grass soil - 11	8.6	0.13
SS15-01	10.9	0.27
SS15-05	7.8	0.19
SS15-06	6.7	<0.10
SS15-08	6.3	<0.10
SS15-09	5.9	<0.10
SS15-10	7.6	0.10
SS15-11	<5.0	<0.10
SS15-12	5.9	<0.10
SS15-16	8.6	0.18
SS15-16	5.9	<0.10
SS15-18	8.0	<0.10
SS15-14 (FDA)	6.3	0.13
SS15-14 (FD)	6.0	<0.10

The HWS results ranged from <0.1 to 0.27 mg/kg. For the same samples, SAL concentrations ranged from <5.0 to 10.9 mg/kg. The HWS results were in the order of only 1-2% of the SAL results, and generally more than an order of magnitude below the CSR standard of 2 mg/kg.

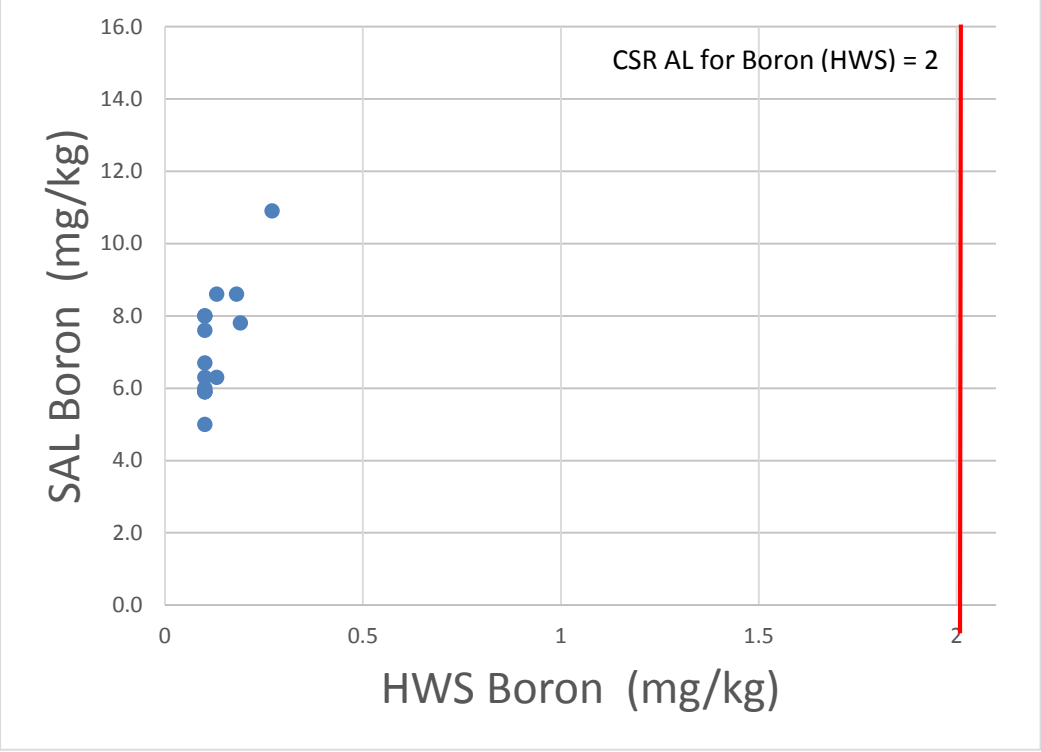

Figure 7: HWS vs SAL Boron Concentrations in Tailings

5.1.3.2 Sulfur Analysis

Sulfur results presented throughout this report are considered to be “total sulfur” results, and were analysed by the laboratory using a total combustion method. The generic Schedule 4 AL standard for sulfur is derived for elemental sulfur. In the absence of elemental sulfur results, these results are considered a conservative estimate for elemental sulfur. The reported sulfur concentrations exceed the CSR AL standard.

5.1.3.3 Summary Statistics and Contaminants of Concern

Summary statistics of each dataset, including number of samples, minimum, maximum, mean, and 90th percentile concentrations were calculated for each metal. The 95% upper confidence limit on the mean (95% UCLM) was calculated for metals with concentrations exceeding the applicable CSR standards. These statistics are presented in Tables 4A, 4B and 4C at the end of this report and summarized in Table 7 below.

Summary statistics were used to determine which of the parameters with exceedances shown in Table 5 should be retained as contaminants of concern, summarized below in Table 6.

Table 6: Summary of Contaminants of Concern Based on TG2

Parameter	Maximum	90th Percentile	95% UCLM	MCS AL	MCS PL
Native Under Tailings (Organic)					
Copper	**352**	**148**	**120**	**100**	100
Sulfur	**7000**	**6380**	NC	**500**	-
Native Under Tailings (Mineral)					
Copper	**366**	**177.7**	**107**	**90**	90
Sulfur	**1100**	**900**	855	**500**	-
Tailings					
Copper	**1560**	**1000**	**737**	**150**	150
Molybdenum	**7.3**	**5.4**	4.0	**5**	10
Sulfur	**3500**	**1550**	**1615**	**500**	-
Vanadium	**289**	**212.8**	177	**200**	200

Concentrations shown are in mg/kg, unless otherwise noted.

mg/kg = milligrams/kilogram; MCS = Most Conservative Standard.

NC = not calculated.

The copper standard is pH dependent.

Where a result was below MDL, the MDL was used for the purpose of calculation.

BC MoE Technical Guidance #2 (TG2) provides guidance on the use of statistics for interpreting soil concentrations. The recommendation of checking if the maximum concentration is greater than 2 times the standard is intended as a check on whether the data set represents a single population. For cases where the maximum is greater than two times the standard, a rationale must be provided if statistics is used.

In this case, the maximum concentrations for copper, cadmium, selenium, and zinc were greater than two times the lowest applicable standards. However, these higher concentrations were considered to be representative of the overall data set and part of the population for the following reasons:

- As described earlier in this report, the tailings are the only source of contamination and the concentrations are relatively homogeneous. The maximum concentration is therefore not considered to be related to a “hot spot” or point source of contamination, but rather a part of the population.
- With respect to the “native under tailings" soil, it appears that the maximum concentrations are part of the range of naturally occurring concentrations because:
  - vanadium concentrations at the locations with maximum cadmium, selenium, and zinc concentrations were lower than the vanadium values observed in tailings and similar to background concentrations
  - the copper concentrations at these sample locations (maximum value of 151 mg/kg) were about an order of magnitude lower than the maximum concentration of copper that was observed in tailings samples (1560 mg/kg)

5.1.3.4 QA/QC

Soil field duplicate samples were collected during each soil sampling program, and are shown alongside primary soil samples in Tables 2, 3A and 3B. Soil field duplicates collected in 2014 and 2015 are discussed further in the 2016 DSI. Soil field duplicates for background soil samples collected as part of the background soil quality determination are discussed further in Appendix A-1.

Field duplicate soil samples collected in 2016 as part of the terrestrial plant and invertebrate soil sampling program are discussed below. Results of analyses for these field duplicates are provided in Table 5 after the text of this report.

Field

In soil, RPDs were greater than 35% for the following parameters: copper, chromium, molybdenum, total carbon, total organic carbon, and potassium. Elevated Reportable Percent Differences (RPDs) were observed in two of the four duplicate samples, both of which were collected in floodplain area. The majority of the observed variability is likely attributed to the higher heterogeneity of floodplain soils. Although this variability could affect the precision of the individual results, selection of the duplicate samples was random, meaning that there would be no systematic bias in results due to the variability.

Laboratory

Laboratory data reports for samples collected during field sampling are provided in Attachment A-8. The following data quality issues were identified in the ALS laboratory reports for soil:

- recommended hold times were exceeded prior to analysis of organic carbon, inorganic carbon, available nitrate, pH, and mercury in some samples

- detection limits for several nutrients were adjusted in some samples due to high concentrations of test analytes, sample matrix effects, limited sample amount, or high percent moisture

The DQOs were met for copper, selenium and vanadium in all samples and were met for the majority of samples for other parameters; therefore, the data were considered reliable for the purposes of DSI Update.

5.1.4 Geochemistry

The geochemical characterization program carried out by SRK in 2015 and 2016 provided information on the potential for leaching from the spilled tailings. The kinetic tests conducted simulate subaerial weathering of the spilled tailings along Hazeltine Channel Corridor and the results confirm that the risk of ARD and metal leaching in the spilled tailings is low and that any leaching will be under neutral pH conditions.

The investigation involved the development of a geochemical conceptual model, and laboratory kinetic testing, which included humidity cells and water unsaturated columns. The kinetic testing provided estimates of solute release rates for predicting metal leaching and ARD potential of exposed tailings along Hazeltine Channel Corridor.

Copper and selenium were the main focus of SRK's investigations as they were identified to be enriched in the tailings compared to regional basalt rock and possibly have potential for leaching. Other parameters with guidelines for the protection of freshwater aquatic life were also included in the kinetic tests conducted by SRK.

The preliminary results based on 40 weeks of kinetic testing were reported in the 2016 DSI report (and in Appendix A-3). The kinetic testing continued through 2016 and the updated results after 90 weeks of testing is reported in SRK's February 2017 report (Appendix A-2). SRK concluded that the test objective of obtaining stable solute release rates have been met. The tests remain on-going, but could be decommissioned according to SRK.

SRK also updated the geochemical conceptual model to address the observed seasonal variations in pH and metal concentrations in groundwater in Polley Plug/Polley Flats. The SRK reports are included in Appendix A-2 and C and discussed separately in the following sections.

5.1.4.1 Kinetic Testing Updates

The results and interpretations presented by SRK in Appendix A-2 are a continuation of the geochemical characterization studies undertaken on representative samples of tailings that spilled into Hazeltine Channel Corridor.

Kinetic testing results have been obtained for up to 90 weeks as of the date of SRK's report. Based on these results and the update geochemical model of seasonal variability, SRK concluded that:

- ARD is not expected from the tailings and that leaching will be under neutral to alkaline conditions.
- The leaching rates in the kinetic tests have reached steady state or are slowly declining, and are suitable for predicting long term water quality from weathering of subaerial tailings.

- For tailings materials with water flow paths longer than half a metre, mineral solubility controls for copper are expected with the formation of secondary copper minerals which would limit the concentrations of copper in groundwater. Where dilution from precipitation is expected to be high, resulting copper concentrations could be lower than those predicted by mineral solubility limits.
- Longer flow paths in the fine grained materials may also be conducive to lower rates of oxygen diffusion and therefore conditions that support sequestration of selenium through selenium reduction to more insoluble forms such as selenite and elemental selenium.

5.1.4.2 Geochemical Conceptual Model

SRK and Minnow (Memo, December 23, 2016) updated the geochemical conceptual model (GCM) for the Polley Plug/Polley Flats area as part of geochemical investigations conducted in 2016. The GCM was developed in order to understand the copper concentrations what were observed at water quality monitoring points in the Polley Flats Area, and to make predictions about groundwater quality in rehabilitated areas. A detailed description of the geochemical GCM is included in Appendix A-3.

The findings indicated that a number of hydrogeological and geochemical processes contribute to copper leaching in the Polley Flats area, as depicted on Figure 5-1, Appendix A-3. The main processes, as presented in SRK and Minnow's memo are (verbatim):

- *"Oxidation of the tailings and release of copper (A). Atmospheric oxygen diffusion may be limited to the near surface (black dashed line in Figure 5-1) with a portion of the tailings not reactive due to sub-oxic conditions.*
- *Weathering of organics (B), with copper complexation by dissolved organic carbon.*
- *Precipitation, infiltration, and transport of copper and other oxidation products (C), including neutralization of sulphide acidity by carbonates and release of carbon dioxide.*
- *Run-off along the surface of the tailings (D) and collection in ditches along Hazeltine Channel, with some ditches draining into the creek.*
- *The till/tailings interface which may direct water laterally (E) and create seepage due to a lower hydraulic conductivity in the glacial till as compared to the tailings. A possible ground water table is depicted by the blue dashed line in Figure 5-1. If the materials below the sediment were at least as permeable as the tailings then infiltration would continue to groundwater.*
- *Contact water from tailings in the Polley Flats area may partially drain to Hazeltine Channel or contribute to groundwater (F). The weathered waste rock from the MPM used to rock armour Hazeltine Creak may have leached copper initially".*

The investigation conducted by SRK and Minnow was initiated to address dissolved copper concentrations upwards of 0.05 mg/L found in the ditches and pools alongside the upper reaches of Hazeltine Channel by MPM and the BC MoE. Rehabilitation works of the Hazeltine Channel and the surrounding area at the Polley Flats involved excavating the tailings and placement of soil and coarse woody debris as well rock armouring the creek channel. The ditches were created partly as temporary water diversion structures, but also to collect tailings contact water during the construction. BC MoE requested the copper leaching from tailings at the Polley Flats area be addressed. The GCM presented by SRK and Minnow provides input in support of effective seep management decisions.

Based on their investigation, SRK and Minnow concluded that the higher copper concentrations observed in the Polley Flats area in ditches and pooled water can be explained from geochemical first principles considering processes that release copper to solution then constrain the resulting copper concentrations by the solubility of copper oxides, as described in the GCM. Copper concentrations that were not constrained by mineral solubility were shown to be predominantly complexed with DOC. The resulting free copper concentrations are low and typical for waters in contact with non-acidic carbonate-containing materials with copper concentrations expected to be stable in the long term.

Detailed findings included:

- Seasonal increase in copper concentrations may be a result of oxidation products and acidity accumulation around sulphide grains during periods of low precipitation (winter and late summer/early fall). During later stages of freshet or times of year when precipitation is infiltrating the tailings, porewater concentrations are expected to decrease as pH goes above 8.0. Conservatively, it should be assumed that these upper end predictions are reached each season, but long term downward trends are probable. This seasonal variation is expected to reduce over time as the tailings age and weather.
- The upper end of free copper concentration is constrained by the formation of secondary copper minerals (e.g. malachite and tenorite) mineral solubility control, and is expected to be in the order of 0.04 mg/L based on the 95th percentile copper concentrations measurements of porewater in unsaturated (i.e., drained) tailings. Dissolved organic complexation would increase the apparent solubility of copper bound in mineral phases; however, it would also decrease the bioavailability and toxicity of dissolved copper.
- Application of water quality criteria that account for organic complexation indicate no exceedances of chronic guidelines for copper in any of the Hazeltine Channel samples. Copper concentrations in Hazeltine Channel are expected to decrease over time due to the aging processes and MPM's ongoing rehabilitation of Hazeltine Channel and its watershed.

5.2 Groundwater Results

The additional groundwater assessment presented in this DSI Update report include:

- An update to groundwater quality at the site, including details on the installation of 18 new monitoring wells and sampling of existing and newly installed monitoring wells is presented in Appendix A-4 "Updated Factual Data Report on Groundwater Quality Hazeltine Channel Corridor, 2015 and 2016".
- A description of the physical hydrogeology at the site is included in Appendix A-5 "Detailed Site Investigation for Hazeltine Channel at Mount Polley Mine – Physical Hydrogeological Assessment and Conceptual Model".

The following sections summarize the field results, physical hydrogeology, and analytical results for investigation work completed at the site.

5.2.1 Field Results

The condition of both the 2015 and 2016 wells was noted during the field work including recharge rates, volume of water in the well, and visible turbidity in the groundwater during sampling. These observations are summarized in Table 7 below. A photograph log of select photos taken during drilling and installation, development, sampling and surveying is included in Attachment 4, Appendix A-4.

Table 7: Field Observations of Well Condition, Volume and Groundwater Turbidity in 2016

Well Name	Well Condition	Volume	Sampled in 2016	Turbidity
MW16-02	Fast recharge	Low volume	Yes	Not turbid
MW16-01S	Dry	None	No	-
MW16-01D	Slow recharge	Low volume	Yes	Not turbid
MW16-03S	Dry	None	No	-
MW16-03D	Slow recharge	Low volume	Yes	Slightly turbid
MW16-05S	Dry	None	No	-
MW16-05D	Slow recharge	Low volume	Yes	Turbid
GW15-06	Destroyed	-	No	-
GW15-04	-	-	No	-
GW15-05	-	-	No	-
MW16-06S	Fast recharge	Low to mid volume	Yes	Not turbid
MW16-06D	Slow recharge	Mid volume	Yes	Slightly turbid
MW16-04	Fast recharge	Mid volume	Yes	Clear
GW15-03	Very slow recharge	Low volume	No	Black organic stained water
GW15-02	Fast recharge	Mid volume	Yes	Slightly turbid
MW16-07	Fast recharge	Mid volume	Yes	Slightly turbid
GW15-01	Slow recharge	Very low volume	No	Turbid
MW16-08S	Dry	None	No	-
MW16-08D	Slow recharge	Very low volume	Yes	Slightly turbid
MW16-09	Slow recharge	Low volume	Yes	Slightly turbid
MW16-10	Dry	None	No	-
MW16-11	Slow recharge	Mid to high volume	Yes	Slightly turbid
MW16-12	Dry	None	No	-
MW16-13	Dry	None	No	-
GW15-BKG-01	Destroyed	-	No	-

Notes: Dry – The well did not have any water at the time of monitoring in August 2016. Very low volume – Wells were considered very low volume if they had less than 0.05 litres of water. Low volume – Wells were considered low volume if they had less than 0.5 litres of water.

Mid volume – Wells were considered mid volume if they had between 0.5 litres and 1.5 litres of water.

Slow recharge – Recharge was considered slow where the lowest setting on a peristaltic pump was greater than the well recharge.

Fast recharge – Recharge was greater than the rate the well was pumped; approximately 150-200 mL/min. Well volume did not have an effect on development or sampling.

"-" = Not Applicable.

5.2.2 Physical Hydrogeology Assessment and Conceptual Model

The climate and hydrology for the mine site have been assessed as part of the water management plan for the TSF 970 m design. The mine site experiences high summer precipitation due to summer storms, with the lowest precipitation in February. Precipitation typically occurs as snowfall in November and accumulates until March. Average annual precipitation at Mount Polley is estimated to be 670 mm.

Groundwater recharge occurs through the infiltration of precipitation in the topographic high area of Polley Mountain and the surrounding slopes, excluding the existing mine pits. Groundwater recharge also occurs as infiltration through the tailings at the TSF, although this recharge (i.e., tailings seepage) is limited because of the basal liner of low permeability glacial till.

Based on the inferred water level elevations measured in August and September 2016, the overall regional shallow groundwater flow direction was primarily towards the southeast, from Bootjack Lake and the TSF, towards Hazeltine Channel and Quesnel Lake. The local groundwater regime near the TSF was inferred to be a radial outward flow system because of the high water level in the tailings ponds. Under this regime, some groundwater from below the TSF was inferred to flow towards the east and south towards Hazeltine Channel, and some towards the southwest towards Edney Creek and its tributaries. Deep (regional) groundwater flow in the area was inferred to discharge directly to Quesnel Lake.

Comparison of the shallow versus deeper groundwater level elevations at the paired well locations around the TSF indicates that the vertical component of groundwater flow was generally directed upward on the west side (and possibly also the northeast side) of the TSF and strongly downward on the southeast side of the TSF.

Hazeltine Channel is inferred to be predominantly a groundwater discharge area. This is based on a comparison of the approximate surface water level elevations along the channel with nearby groundwater level elevations, and is supported by an upward hydraulic gradient observed at one of the well pairs next to Hazeltine Channel. This comparison indicated that the creek is primarily a “gaining stream” (i.e., groundwater seeps into the creek as baseflow rather than the creek losing surface water to the groundwater environment). Figures 8 and 9, below show the conceptual groundwater flow directions at the cross-section locations selected as part of the physical hydrogeological assessment. Figure 10 shows the inferred groundwater flow direction at the site.

Based on a search in the BC MoE iMapBC online database in January 2017, no regional aquifers were mapped in the vicinity of the Mine. The closest mapped aquifer, Fraser Plateau Lave Aquifer No. 124 IIIB (11), is a laterally extensive bedrock unit. The northern terminus of this aquifer is located more than 15 km south of the Mine and is not considered to be hydraulically connected to groundwater from the Mount Polley Mine area or the Hazeltine Channel corridor.

The results of *in situ* hydraulic conductivity (K) testing along the Hazeltine Channel corridor are summarized in Table 8 below. These results indicate a range in permeability that is in general accordance with soil type and depositional conditions. In order of decreasing permeability, K values were obtained for tailings mixed with till (K= 2×10^{-4} m/s), tailings (6×10^{-6} m/s to 7×10^{-7} m/s) and native till (2×10^{-7} m/s to 3×10^{-8} m/s).

Table 8: Summary of Hydraulic Conductivity Results

Well ID	Lithology of Screened Interval	K (m/s)
MW16-06S	Till and Re-deposited Tailings (SAND and GRAVEL, fine to medium)	2×10^{-4}
MW16-02	Tailings (SAND, some fines)	6×10^{-6}
MW16-07	Tailings (SILT)	7×10^{-7}
MW16-01D	Till (gravelly clayey SILT; some coarse sand)	2×10^{-7}
MW16-11	Till (SILT, some gravel and sand)	3×10^{-8}

5.2.3 Laboratory Analytical Results

5.2.3.1 Comparison of Groundwater Quality in Tailings versus "Native under Tailings"

Groundwater chemistry results from wells screened in tailings and native substrates are shown in Table 9 and Table 10 below. Results are shown for the metals of concern related to tailings (copper, selenium and vanadium) and other metals with one or more exceedances of applicable standards.

Table 9: Groundwater Chemistry Results from Wells Installed in Tailings

Concentrations of copper in groundwater in wells installed in tailings ranged from <0.0010 to 0.0091 milligrams per litre (mg/L) with a median value of 0.0021 mg/L. This was similar to groundwater from wells installed in native soils underlying tailing which had copper concentrations ranging from <0.00050 to 0.0048 mg/L with a median value of 0.0025 mg/, and similar to the concentrations measured in two background wells of 0.00084 to 0.0024 mg/l.

Vanadium concentrations in groundwater from wells installed in tailings and wells installed in native soils underlying tailings had a similar range of concentrations, <0.00050 to 0.0016 mg/L and <0.00050 to 0.0017 mg/L, respectively. The median concentration of vanadium in both screened stratigraphy's was less than the method detection limit (MDL), although the detection limit was raised for samples collected in 2015.

Concentrations of selenium in wells installed in tailings and wells installed in native soils underlying tailings had a similar range of concentrations, <0.0010 to 0.00028 mg/L and <0.000050 to 0.00083 mg/L, respectively. The median concentration of selenium in wells screened in tailings was less than the MDL (<0.0010 mg/L), while the median concentration of selenium in wells screened in native soils underlying tailings was 0.0011 mg/L.

Based on a comparison of median concentrations, concentrations of arsenic, iron and molybdenum were elevated in wells screened in tailings compared to wells screened in native soils underlying tailings (Table 9 and Table 10). Concentrations of manganese in groundwater was similar between wells screened in tailings and wells screened in native soils underlying tailings (Table 9 and Table 10).

5.2.3.2 Comparing 2015 to 2016 Results

Groundwater chemistry results from samples collected in 2015 and 2016 are shown in Table 11 and Table 12 below. Results are shown for the metals of concern related to tailings (copper, selenium and vanadium) and other metals with one or more exceedances of applicable standards.

Table 11: Results of the 2016 Groundwater Investigation

Wells	Arsenic	Copper	Iron	Manganese	Molybdenum	Selenium	Vanadium

Median	0.0033	0.0020	1.1	5.4	0.0076	<0.0010	<0.030

All concentrations are in mg/L.

Red text indicates an exceedance of CSR standards protective of drinking water.

Underlined indicates an exceedance of CSR standards protective of water used for irrigation.

Concentrations of copper in groundwater collected in 2015 ranged from <0.0010 to 0.0091 mg/L with a median concentration of 0.0020 mg/L. Groundwater collected in 2016 had copper concentrations ranging from <0.00050 to 0.021 mg/L with a median value of 0.0025 mg/L.

Vanadium was detected in 6 of 11 samples collected in 2016, ranging from <0.00050 to 0.0017 mg/L, while all samples collected in 2015 had concentrations below the MDL (<0.030 mg/L). It was not possible to make a comparison between the concentrations of vanadium in groundwater collected in 2015 and 2016 as all detected concentrations in 2016 were below the MDL for the 2015 samples.

Selenium was detected in 10 of 11 samples collected in 2016, ranging from <0.00050 to 0.00083 mg/L, while all samples collected in 2015 had concentrations below the MDL (<0.0010 mg/L). It was not possible to make a comparison between the concentrations of vanadium in groundwater collected in 2015 and 2016 as all detected concentrations in 2016 were below the MDL for the 2015 samples.

The median concentrations of arsenic, iron, manganese and molybdenum were lower in samples collected in 2016 than samples collected in 2015 (Table 11 and Table 12). However, only GW15-02 was sampled during both events, and the concentrations at this location in 2016 were within two times of the concentrations measured in 2015 for arsenic, iron, manganese and molybdenum. Although this difference is small, it may be a result of a change to a reducing condition at this location as indicated by the change in oxidation-reduction potential (ORP) readings from 35.1 to -69.9 mV(Tables 1-1, Appendix A-4).

The concentration of copper collected in GW15-02 in 2016 (0.0014 mg/L) was somewhat lower that that measured in 2015 (0.0036 mg/L). Concentrations of selenium and vanadium could not be compared between the two years as the 2015 data was below the MDL. The detected levels of selenium and vanadium in 2016 (0.000073 and 0.00073 mg/L, respectively) was well below the MDL of the 2015 data (<0.0010 mg/L and <0.030 mg/L, respectively).

5.2.4 Background Wells

Background groundwater chemistry results for metals with a standard are shown Table 13. As shown, the background concentrations of metals were below applicable standards at both locations. GW-BKG15-01 was sampled in 2015 and MW16-11 in 2016.

Three new background monitoring wells were installed in accordance with the scope outlined in *Work Plan for Monitoring in Support of Risk Assessment at the Mount Polley Mine, Mount Polley Mine, BC* (Golder, 2016). Because of access problems, the installation was made by hand rather than using the pick-up mounted auger rig. Two attempts were made when installing MW16-12, both encountering rejection before reaching the reaching an apparent wet zone. It was decided to install a monitoring well with the goal of sampling during the wet season. Similarly, rejection was encountered at MW16-13 before reaching the water table. Both of these background wells (MW16-12 and MW16-13) were dry. The local background groundwater chemistry was collected for comparison of metals that do not exceed the standards to local background conditions. This comparison was of interest for the risk assessment.

Concentrations of copper background wells ranged from 0.00084 mg/L to 0.0024 mg/L (Table 13). The median copper concentration in wells installed in tailings and native soils underlying tailings was 0.0021 mg/L and 0.0025 mg/L, respectively. The range of copper concentrations in wells installed in tailings and native soils underlying tailings was <0.0010 to 0.0091 mg/L and <0.00050 to 0.0048 mg/L, respectively.

Vanadium concentrations in background wells were both below the MDL, although the detection limit for 2015 was considerably higher (Table 13). The median concentration of vanadium in both wells screened in tailings and in native underlying tailings was less than MDL. The range of vanadium concentrations in wells screened in tailings and in native underlying tailings was 0.00050 to 0.0016 mg/L and <0.00050 to 0.0017 mg/L, respectively.

Concentrations of selenium in background wells ranged from <0.0010 to 0.0022 mg/L. In wells installed in tailings and in native soils underlying tailings the selenium concentrations ranged from <0.0010 to 0.00028 mg/L and <0.000050 to 0.00083 mg/L, respectively. The median concentration of selenium in wells screened in tailings was less than the MDL (<0.0010 mg/L), while the median concentration of selenium in wells screened in native soils underlying tailings was 0.0011 mg/L.

Table 13: Groundwater Metal Concentrations in Background Wells

Metal	GW-BKG15-01	MW16-11	Median Tailings	Median Native Under Tailings
Aluminum	0.013	0.020	0.033	0.034
Antimony	<0.00050	0.00030	<0.00050	<0.00010

Zinc	<0.0050	0.031	<0.0050	<0.0030

All concentrations are in mg/L.

5.3 Surface Water Results

Water quality conditions have changed significantly since the breach occurred, relative to changes that have occurred in other media. Water quality conditions immediately following the breach were evaluated in the PEEIAR. The water quality conditions from January 2015 to June 2015 were considered to be reflective of a short term construction period when the main Hazeltine Creek channel was being re-constructed. Water quality conditions following channel reconstruction were considered to be representative of long term conditions resulting from the breach. As noted in Section 3.4, MPMC began discharging treated mine water from Springer Pit into Hazeltine Creek on 1 December 2015 under permit. Therefore, for the purposes of evaluating long term impacts related to the breach, the water quality data from June 2015 to 1 December 2015 were considered to be representative.

Results in the following Sections are presented according to each group of parameters (i.e., suspended particulate matter, metals, nutrients), then within each parameter group. Changes in specific parameters are discussed for each waterbody.

Data shown for Hazeltine Channel and Quesnel River represent discrete surface grab samples collected as described in the PEEIAR (Golder 2016b), except where a continuous data logger measured turbidity. Quesnel Lake and Polley Lake data are from discrete grab samples taken at various depths and were categorized as either surface (1–20 m) or deep (greater than [>] 20 m) for the purpose of evaluating changes over time.

5.3.1 Suspended Particulate Matter (Turbidity/TSS)

5.3.1.1 Hazeltine Creek and Edney Creek

Turbidity levels in Hazeltine Creek showed a progressive decrease from peak levels in the first few months of 2015 to levels closer to applicable BC WQGs by the end of the year. However, levels in upper Hazeltine Creek (HAC-10 and HAC-05/a) and the lower creek above the sedimentation ponds (HAC-08/a) fluctuated during September-December 2015. During this time monthly concentrations at these stations were occasionally above the maximum and 30-d BC WQGs (Appendix A-6, Figure 2).

In lower Edney Creek at EDC-01 turbidity levels were typically below maximum and 30-d guideline values, except for a spike in October 2015. Turbidity levels at EDC-02 exhibited a general decrease over time until the station was discontinued in July 2015; however, concentrations were predominantly above the 30-d guideline. Elevated turbidity observed at HAC-01/a/b/c throughout July and August continued through September and October (Appendix A-6, Figure 2) with reported concentrations above the 24-h aquatic life and/or 30-d guidelines. Turbidity concentrations in Hazeltine Creek and Edney Creek were routinely above the BC WQG for untreated drinking water but were within the turbidity range reported for the creek prior to the event.

A similar progressive decline in TSS concentrations was also observed in Hazeltine Creek from peak concentrations in the first few months of 2015 to concentrations below BC WQGs by the end of the year (with the exception of HAC-08/a). Concentrations of TSS at HAC-10, HAC-05/a, and HAC-01/ab/c in Hazeltine Creek and at EDC-01 in Edney Creek were consistently below the 24-h aquatic life and 30-d guidelines throughout September-December 2015 (Appendix A-6, Figure 3). Before the station was discontinued in July 2015, TSS concentrations at EDC-02 exhibited a general decrease that was similar to the temporal trend observed at HAC-01/a/b/c (Golder 2016b; Figure 3). Concentrations at HAC-08/a were variable throughout September–December 2015 and were intermittently above the 24-h aquatic life and 30-d guidelines.

5.3.1.2 Quesnel Lake

Turbidity concentrations measured at the surface and at depth in Quesnel Lake at stations QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a were below BC WQGs from approximately April through August 2015 (Golder 2016b). At the surface at QUL-66, turbidity levels generally remained below guideline values with the exception of a single exceedance of the aesthetic drinking water guideline for untreated water and the 30-d aquatic life guideline in spring 2015. Turbidity at QUL-66 continued to decline through September and remained below guidelines into December 2015 with concentrations close to or below background (1 NTU) (Appendix A-6, Figure 4).

5.3.1.3 Quesnel River

Daily average and in-situ turbidity concentrations at station QUR-1 in Quesnel River showed a progressive decrease over time throughout 2015. Turbidity levels remained well below guidelines with the exception of a few intermittent spikes measured by the continuous data recorder (Appendix A-6, Figure 5). The elevated values measured by the continuous recorder were not corroborated by the in-situ grab sample data and as discussed in (Golder 2016b) these measurements can be influenced by fouling associated with long-term deployment.

5.3.2 Copper

5.3.2.1 Polley Lake

Copper concentrations measured in Polley Lake were not elevated above BC WQGs during the March–August 2015 period, and so copper was no longer considered a contaminant by the WQIA update (Golder 2016b). However, copper was retained for analysis because it is considered a primary potential contaminant within the overall context of the PEEIAR. Both total and dissolved concentrations were below BC WQGs, with the exception of the total 30-d rolling average concentration associated with surface samples collected at P2 in early November 2015 that approximated the most conservative 30-d guideline based on pre-event hardness (Appendix A-6, Figure 6).

5.3.2.2 Quesnel Lake

Total and dissolved copper concentrations measured in Quesnel Lake were typically below maximum BC WQGs by the end of April 2015 (Golder 2016b). By late August 2015, copper concentrations reported for QUL-66 near the mouth of Hazeltine Channel were similar or only slightly elevated relative to concentrations reported elsewhere in the lake, including the far field station (QUL-120/120a) east of Cariboo Island (Golder 2016b). Total and dissolved copper concentrations at QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a were below maximum and 30-d guidelines from September through December 2015, with the exception of a single monthly sample collected at near-field (QUL-66) and far-field (QUL-120/120a) stations in September (Appendix A-6, Figure 7). The corresponding monthly sample in September at the mid-field west station (QUL-18) approximated the most conservative 30-d guideline based on minimum measured hardness.

5.3.2.3 Quesnel River

No metals were identified as contaminants of concern for the receiving environment in Quesnel River in the original WQIA and the WQIA update; this was also the case for data collected from September to December 2015.

5.3.2.4 Hazeltine Creek and Edney Creek

Discrete Grab Samples (Instantaneous values)

In upper Hazeltine Creek at HAC-05/a, total copper concentrations were above the maximum BC WQG (based on measured maximum hardness) from January to May 2015, after which concentrations decreased to concentrations below the maximum guideline (based on mean pre-event hardness) by the end of the year (Appendix A-6, Figure 8). Dissolved concentrations at HAC-05/a were within the WQG range based on measured hardness but were above the WQG based on pre-event hardness until May 2015. Dissolved concentrations decreased thereafter and were below the WQG based on pre-event hardness from May to December 2015. At the most upstream station (HAC-10) total and dissolved concentrations followed a similar trends to those described for HAC-05/a.

In lower Hazeltine Creek (HAC-08/a, EDC-01, EDC-02, HAC-01/a/b/c), total concentrations peaked above BC maximum WQGs and at least one CSR standard from February through April (Appendix A-6, Figure 8). Total concentrations then decreased at all four stations to concentrations within the BC maximum guideline range (based on measured hardness values) by the end of the year. Dissolved concentrations at HAC-08/a and HAC-01/a/b/c peaked above the maximum guideline and decreased thereafter at these stations and were below the maximum guideline based on pre-event hardness at both HAC-08/a and HAC-01/a/b/c by the end of the year. The same was true for EDC-01.

Thirty-Day Rolling Average Values

During the months prior to June, total copper concentrations in upper and lower Hazeltine Creek (HAC-05/a, HAC-08/a, EDC-02, HAC-01/a/b/c) peaked above the 30-d BC WQG range based on measured hardness (Appendix A-6, Figure 8). Concentrations then decreased to values within the 30-d guideline range based on measured hardness and remained above the guideline based on pre-event hardness. Dissolved concentrations in the lower creek (HAC-08/a, HAC-01/a/b/c) only peaked above the 30-d guideline range (based on measured hardness) from March to May, with a subsequent decrease to concentrations within this guideline range. Concentrations remained above the 30-d guideline based on pre-event hardness (Appendix A-6, Figure 8). Dissolved concentrations at the other Hazeltine Creek stations were within the 30-d guideline range based on measured hardness and either approximated or were above the guideline based on pre-event hardness.

5.3.3 Other Metals

5.3.3.1 Hazeltine Creek and Edney Creek

Aluminum

In upper Hazeltine Creek (HAC-10, HAC-05/a), total and dissolved concentrations remained below maximum guideline values in 2015, with the exception of a single sample in January at HAC-05/a. In lower Hazeltine Creek (HAC-08/a, EDC-01, EDC-02, HAC-01/a/b/c), concentrations peaked in February through April and were above or approximated maximum guideline values; concentrations then decreased below guidelines by May and remained stable until the end of the year. Concentrations at HAC-05/a in upper Hazeltine and HAC-08/a in lower Hazeltine showed slight increases in November and December, based on monthly sampling; in the case of HAC-08/a concentrations approximated maximum guidelines for the protection of aquatic life (Appendix A-6, Figure 9).

Dissolved concentrations were above the 30-d dissolved guideline in lower Hazeltine Creek until May and June, when they decreased below this guideline and remained relatively stable until November, when concentrations at HAC-05/a and HAC-08/a increased to approach but not exceed the 30-d guideline value (Appendix A-6, Figure 10).

Arsenic

Total arsenic was evaluated in the PEEIAR update, based on guideline exceedances that occurred in Hazeltine Creek in spring 2015 (Golder 2016b). During this time concentrations at HAC-08/a peaked above the CSR drinking water and wildlife standards as well as the BC drinking water maximum guideline. Thirty-day rolling average total concentrations at HAC-08/a also peaked above the 30-d BC WQG during this time, before decreasing to concentrations more typical of the other stations on the creek by August. Total concentrations at the stations in Hazeltine and Edney Creek (Appendix A-6, Figure 11) were typically well below the maximum and 30-d guidelines from June through December, with the exception of two measurements at HAC-08/a upstream of the sediment ponds in September and December.

Beryllium

Thirty-day rolling average total concentrations were elevated above the 30-d WQG at HAC-08/a and HAC-01/a/b/c during spring 2015 (Appendix A-6, Figure 12). Concentrations at EDC-02 were also elevated during this time. From July through December 2015, total concentrations at the Hazeltine Channel and Edney Creek stations were below guideline values and were at or near the MDL, with the exception of one sample collected at HAC-08/a in December 2015 that was detected above the WQG (Appendix A-6, Figure 12).

Chromium

As discussed in Golder (2015a), the available speciation data for Hazeltine Creek indicates the dominant chromium species in Hazeltine Creek was chromium (III), which is less toxic than the chromium (VI) form. However, as a conservative measure, guidelines and standards for both chromium species have been considered when assessing water quality in Hazeltine Creek.

Total chromium was evaluated in the WQIA update, largely based on guideline exceedances recorded in spring 2015 in Hazeltine Creek at stations HAC-08/a, HAC-05/a, and HAC-01/a/b/c (Golder 2016b). However, by June 2015, total concentrations in Hazeltine Creek had decreased below the most conservative guidelines (Appendix A-6, Figure 13). In 2015, concentrations at stations HAC-10 and EDC-01 and EDC-02 in Edney Creek exhibited temporal trends similar to those previously reported for other stations in Hazeltine Creek (Appendix A-6, Figure 13).

Total chromium concentrations measured at the Hazeltine and Edney Creek stations were below applicable maximum guidelines from June to December 2015, and many were at or near the MDL. The same was true for total 30-d rolling average concentrations that were below the Cr(III) and Cr(VI) 30-day guidelines at all stations, with the exception of intermittent exceedances of the Cr(VI) guideline by total concentrations at HAC-08/a and HAC-01/a/b/c that were still below the more applicable Cr(III) 30-day guideline.

Cobalt

Instantaneous total concentrations reported in 2015 for the Hazeltine Creek stations shown were below the maximum BC WQG (Appendix A-6, Figure 14). Thirty-day average total concentrations were above the 30-d BC WQG from March to June at HAC-08/a and March to May at HAC-01/a/b/c, then decreased below the 30-d guideline thereafter (Appendix A-6, Figure 14). Stations EDC-01 and EDC-02 exhibited a similar temporal trend over the time period leading up to the end of August 2015, but did not exceed the guideline. Total concentrations remained stable well below the 30-d guideline from September through December, with the exception of intermittent values in the monthly September and December samples at HAC-08/a that approached or approximated the guideline.

Iron

Total concentrations at stations in lower Hazeltine Creek were consistently above the BC maximum WQG for aquatic life and the CSR drinking water standard until May 2015 (Appendix A-6, Figure 15). The higher CSR standard was mostly exceeded at HAC-08/a and HAC-01/a/b/c, with only a few exceedances at other stations. From May to December, total concentrations remained below this guideline, with the exception of one sampling event in August, during which total values at HAC-08/a and HAC-01/a/b/c were more than ten times the preceding and subsequent values recorded in July and August (Golder 2016b). Intermittent values measured in September and December at station HAC-08/a were above the BC maximum guideline. Concentrations at the other stations monitored in 2015 were below the BC maximum guideline.

Lead

Total lead was assessed in the PEEIAR update (Golder 2016b). In upper Hazeltine Creek, instantaneous concentrations were typically below guideline values in 2015 and 30-d average concentrations were below the long-term average guideline, with the exception of a concentration reported for HAC-05/a in January that was also above the CSR drinking water standard (Appendix A-6, Figure 16). In lower Hazeltine Creek, after peaking in March through April, rolling 30-d average concentrations declined below the 30-d BC WQG in May and remained relatively stable through the end of December.

Manganese

Total concentrations were below BC maximum WQGs and the CSR drinking water standard (Appendix A-6, Figure 17). The exceptions were total concentrations at HAC-05/a (January and February) and HAC-08/a (February to April) that were within the BC maximum guideline range, and concentrations at HAC-01/a/b/c (February to April) that were below the BC maximum guideline but above the CSR drinking water standard. Rolling-average 30-d manganese concentrations in Hazeltine Creek stations were below the 30-day guideline based on measured hardness and pre-event hardness, with the exception of HAC-08/a (March through May) and HAC-05/a (January and February) (Appendix A-6, Figure 17).

Selenium

The PEEIAR update indicated that post-event selenium concentrations in Hazeltine Creek remained stable below applicable guidelines/standards or decreased below these regulatory benchmarks shortly after the event, remaining stable thereafter (Golder 2016b). In 2015, instantaneous and rolling 30-day average concentrations remained well below applicable BC WQGs and CSR standards with the exception of the monthly sampling event in December 2015 at HAC-05/a and HAC-08/a located below the authorized discharge of treated effluent that commenced in December 2015 (Appendix A-6, Figure 18). Therefore, selenium was not considered to be a COPC related to the breach but was investigated further as part of MPMC's discharge permit monitoring.

Zinc

Total and 30-d rolling average concentrations reported for HAC-05/a, HAC-08/a, EDC-02, and HAC-01/a/b/c between January and June were typically within the BC WQG range based on measured hardness and above BC WQGs calculated using mean pre-event hardness (Appendix A-6, Figure 19). Concentrations reported for the other stations shown on Figure 19 were below the BC maximum guideline range. Between June and December, total and 30-day rolling average concentrations for all stations shown on Figure 19 in Appendix A-6 were below the most conservative BC WQG, with the exception of a few intermittent values for HAC-08/a.

5.3.4 Nutrients: Total Phosphorus

5.3.4.1 Polley Lake

Following the event and through August 2015, concentrations of total phosphorus (TP) at the surface in Polley Lake were within the pre-event range of concentrations reported in the PEEIAR for Polley Lake (Golder 2015a). Pre-event TP concentrations were defined as: mean = 0.041 mg/L; 95th percentile = 0.094 mg/L.; minimum = 0.0046 mg/L. Both pre-event mean and upper limit concentrations were above applicable BC WQGs (i.e., 0.005 to 0.015 mg/L). This is consistent with the observation by Minnow (2014) that the trophic status of the lake changed from oligotrophic/mesotrophic to mesotrophic/eutrophic by 2012, two years prior to the event.

Prior to fall turnover in 2014, concentrations of all three forms of phosphorus at depth were elevated above pre-event concentrations, unlike surface concentrations that were within pre-event concentration ranges (Golder 2016b). Pre-event dissolved phosphorus concentrations were defined in Golder (2015) as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.002 mg/L; pre-event orthophosphate concentrations were defined as: mean = 0.03 mg/L; 95th percentile = 0.08 mg/L; minimum = <0.001 mg/L (Appendix A-6). Several months after the 2014 fall turnover, in April 2015, total and dissolved phosphorus and orthophosphate concentrations measured at depth were within or below these pre-event concentration ranges reported in the PEEIAR (Figure 20, Golder 2016b).

From July to October, there was a greater degree of disparity in phosphorus concentrations between those measured at the surface and those measured at depth. Higher concentrations above the TP WQG range were reported at depth and these concentrations remained relatively stable over the summer months, whereas surface concentrations decreased to concentrations within or below the TP WQG range. The noted disparity was likely the result of lake stratification during the summer, such that after mixing during fall turnover, concentrations measured at the surface and at depth in November were similar. Sampling in Polley Lake was suspended in November due to the onset of winter conditions.

Golder (2016) concluded that in 2015 there were no event related changes to phosphorus concentrations in Polley Lake based on an analysis of data collected from April through August 2015. This conclusion is supported by data collected from September through November shown on Figure 20 in the PEEIAR.

5.3.4.2 Quesnel Lake

After the event, TP concentrations at depth exceeded the BC WQG range in the West Basin of Quesnel Lake, but were not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Golder 2015a). By fall turnover in 2014, TP concentrations had substantially decreased in the West Basin of Quesnel Lake. Through August 2015, TP concentrations were below the BC WQG range and resembled pre-event concentrations with the exception of a few intermittent exceedances at near-field station QUL-66, near the mouth of Hazeltine Creek (Golder 2016b). At the near-field, mid-field, and far-field stations, dissolved phosphorus and orthophosphate concentrations reported between March and August were below pre-event concentrations (Golder 2016b).

Collectively, an evaluation of the phosphorus data collected between March and August 2015 suggest that event related changes of concern for phosphorus were not evident in Quesnel Lake (Golder 2016b). After September 2015, total phosphorus concentrations were intermittently above the most conservative BC WQG at near-field station QUL-66, near the mouth of Hazeltine Creek, but did not exceed the drinking water BC WQG or the upper boundary of the aquatic life guideline. Dissolved and orthophosphate concentrations remained at or near the MDL through to the end of December 2015 (Appendix A-6, Figure 21).

5.4 Sediment Results

Sediment samples were collected by Minnow in each of the three water bodies affected by the breach (Polley Lake, Hazeltine Creek and Quesnel Lake). In 2016, samples were collected to monitor temporal changes in sediment quality and to increase the sampling density in selected areas of the site. Overall, the sediment chemistry observed in 2016 was similar to the results observed in the 2014 and 2015 sampling events. 2016 mean concentrations are compared against the CSR Schedule 9 criteria. The following sections provide a more detailed description of the results for each water body.

5.4.1 Polley Lake

Sediment samples were collected from deep (POL-P1 and POL-P2) and mid-depth (POL-1 and POL-2) sampling locations, as well as three sampling locations for spatial extent in-filling. Sediment samples consisted almost entirely of silt and clay (over 93%).

Concentrations of metals in sediment were similar to those observed in 2014 and 2015. The 2016 mean copper concentration was greater than the CSR “sensitive” and “typical” criteria and reference (Appendix A-7, Table 2). The 2016 mean arsenic concentration was greater than the CSR “sensitive” criteria and reference (Appendix A-7, Table 2). However, copper concentrations in sediment in reference Bootjack Lake and in Polley Lake also exceeded the CSR “typical” criteria prior to the TSF embankment breach. Concentrations of arsenic and copper in sediment at three in-fill sampling locations were above CSR “sensitive” criterion at three locations, and above CSR “typical” criterion at two locations (Appendix A-7).

Similar to 2014 and 2015 results, total organic carbon (TOC) concentrations in sediment were also lower in Polley Lake than the reference location (Bootjack Lake).

In 2016, the mean copper concentration in deep Polley Lake sediment samples exceeded reference by approximately 1.7-times and the CSR “typical” criterion by approximately 2.9-times. The mean copper concentration for mid-depth Polley Lake sediment samples exceeded reference by approximately 1.1-times and the CSR “typical” criterion by approximately 2.3-times in 2016.

As described in the DSI report (Golder 2016a) a volume of 6.4 million m^3 of water was calculated to have entered Polley Lake immediately following the breach, based on aerial imagery and water level rise. This volume was considered to be primarily water. Therefore, the volume of tailings solids in Polley Lake is considered to be relatively small.

5.4.2 Hazeltine Channel

Sediment samples were collected from Lower Hazeltine Channel in 2014 (ST02) and from the Hazeltine Channel Upper Sedimentation Pond in 2015 and 2016. The sedimentation pond is a man-made maintained watercourse designed to collect suspended material prior to discharge to Quesnel Lake and is not currently a fish habitat (Appendix A-7), thus sediments in this area were evaluated against the CSR “typical” criterion only. Sediment samples collected in 2016 were similar to those observed in 2015 and consisted primarily of silt and clay (93%).

The 2016 mean copper concentration was the only analyte to exceed the CSR “typical” criterion and reference, exceeding by about 1.6- and 4.1-times, respectively (Appendix A-7, Table 8).

5.4.3 Quesnel Lake

In 2016, sediment samples were collected from reference (Horsefly Bay) and exposed (near-field and far-field) sampling locations, for both littoral and profundal sediments. Fourteen sediment samples were also collected for in-fill sampling purposes (Appendix A-7, Figure 2).

Sediment samples collected for in-filling purposes generally consisted of silt loam or silty clay loam, with a TOC content of less than 4%. Selected concentrations of arsenic and copper in sediment exceeded the CSR “sensitive” and/or “typical” criteria. The in-fill sampling locations were not categorized as being littoral (shallow) or profundal (deep) samples (Appendix A-7, Table D.11).

The results for littoral and profundal samples are presented in the following sections.

5.4.3.1 Quesnel Lake (Littoral)

Sediment collected from the littoral near-field area of Quesnel Lake in 2016 was predominantly sand (89.2%), and had a higher sand content than sediment collected from this location in both 2014 and 2015 (Appendix A-7, Table 6). This difference in sediment composition may be a result of washing of fine sediment from these locations between August 2014 and August 2016. The particle size distribution of sediment collected in the littoral far-field area (Appendix A-7) was similar to samples collected in 2014 and 2015 (approximately 60% sand), and was also similar to sediment collected in the Quesnel littoral reference area. Similar to results reported in 2014 and 2015, the concentrations of TOC and nitrogen in sediment in 2016 were lower than concentrations reported in the near-field area than in the far-field or reference areas.

Mean metal concentrations in 2016 were generally similar to those in 2014 and 2015, except for chromium, iron and vanadium which reported higher mean concentrations in the near-field area in 2016 relative to 2014. Iron and vanadium concentrations exceeded reference concentrations by 2.9 and 9.1 times, respectively (Appendix A-7, Table 6)

In 2016, mean arsenic and copper concentrations exceeded the CSR "sensitive" criteria as well as reference concentrations in the near-field area. The 2016 mean copper concentration also exceeded CSR "typical" criterion approximately 2.7 times on average, and exceeded reference concentrations by approximately 13.3 times on average. These results are similar to those reported in 2014 and 2015. 2016 mean metals concentrations were generally lower in the far-field area than in the near-field, with no exceedances of applicable criteria for mean metals concentrations in the far-field area.

5.4.3.2 Quesnel Lake (Profundal)

Sediment collected from the profundal near-field area of Quesnel Lake in 2016 was predominantly silt and clay (98.2%). (Appendix A-7, Table 4). The average clay content reported in these samples in 2016 (51.1%) was higher than 2014 and 2015 (22.6%-33.5%) due to the relocation of two sediment stations. Sediment collected from the profundal far-field area of Quesnel Lake in 2016 also reported a higher clay content (32.6%) compared to samples collected at the same locations from 2014 (14.4%). The 2016 mean TOC and nitrogen concentrations of sediment from both the near-field and far-field areas were lower than the concentrations observed in reference, as was also observed in 2014 and 2015.

2016 mean arsenic and copper concentrations were the only analytes to exceed the CSR "sensitive" criteria in the near-field and far-field areas. The 2016 mean arsenic concentration exceeded results from one reference area, while concentrations were similar to those reported at the second reference area (Appendix A-7, Figure 4). Elevated arsenic at the second reference area may be naturally occurring.

The 2016 mean chromium concentration at profundal sediment reference location PREF-1 exceeded the CSR "sensitive" criteria. However, given that the concentration was below the reference 95th percentile concentration of chromium (Appendix A-7, Table 4), this result is not considered to be related to the TSF embankment breach, and is thus not discussed further in the DSI Update.

The 2016 mean copper concentration also exceeded the CSR "typical" criterion and reference concentrations, as was also observed during previous sampling events. The mean copper concentration in Quesnel Lake near-field area sediment exceeded the CSR "typical" criterion by approximately 5.0 times on average, which is slightly higher than observed in 2014 (3.0 times higher) and in 2015 (3.6 times higher). The copper concentrations for far-field sediment samples exceeded the CSR "typical" criterion by 2.4 times on average, which is similar to 2014 results (2.0 times greater on average).

As described in the DSI report (Golder 2016a), the results of the profundal sampling indicate that contaminant migration extended beyond the near field location in the profundal environment of the west arm of Quesnel Lake.

6.0 DISCUSSION

Our understanding of the site conditions presented in the 2016 DSI report (based on data collected in 2015) has been updated based on the additional site investigation data collected in 2016. The updated CSM confirms and expands the understanding of the physical and chemical impacts that resulted in each of the remediation areas, the type and extent of the contamination, the transport and exposure pathways, and the receptors at the site.

6.1 Terrestrial Impacts in the Hazeltine Channel Area

6.1.1 Physical Impact

The initial physical changes to the landscape were documented by SNC as part of the PEEIAR. The TSF embankment breach resulted in physical changes to the Hazeltine Creek valley, including Polley Lake, the mouth of Edney Creek and the west basin of Quesnel Lake. Similar observations were made by Golder during the 2015 soil investigation, though rehabilitation works along the Hazeltine Channel was underway at that time and has continued since. As discussed previously (in Section 5.1), this rehabilitation and remediation work involves a combination of removal of tailings material and replacement with transplanted soil (transplanted soil generally consisted of a mixture of topsoil and mineral soil); re-grading and re-sloping of areas that were scoured following the TSF embankment breach; seeding and placement of coarse woody debris along the Hazeltine Channel corridor; removal of deceased tree and vegetation cover; and mounding of tailings in halo areas with underlying organic soils (Golder 2017a). The rehabilitation works have resulted in changes to the post TSF embankment breach stratigraphy and topography described in this report.

6.1.1.1 Geomorphological Impact (Erosion and Deposition)

Observations of the initial physical impacts made along the length of Hazeltine Channel corridor can be summarized as follows:

- The TSF embankment breach resulted in a complex sequence of debris flow and debris flood as described by SNC in the PEEIAR report. The initial surge consisted of a high sediment content debris flow that scoured a wide and deep channel along the Hazeltine Creek valley. This massive debris flow was followed by a debris flood caused by the blockage of the entrance to the Hazeltine Canyon with debris flow material. This blockage caused flooding into the surrounding forest leaving behind silty tailings material. The blockage gradually eroded, allowing the remaining water and sediment to be released.
- Tailings deposits were observed to be greater than 3 m thick in certain locations in the vicinity of Polley Flats. The layer of fine-grained tailings material was observed to be up to 1 m thick. At the time of the 2015 soil investigation work, tailings material within the Polley Flats area had not been removed as part of the rehabilitation efforts at the Mine. However, rehabilitation works were ongoing in the plug area throughout 2016. These results will be reported under separate cover.

- The thickness of tailings material within the Upper Hazeltine Channel corridor was observed to be up to 2.5 m (at ST15) during soil sampling work in 2015. Up to 269,000 m^3 of deposited tailings material was excavated from Upper Hazeltine Channel corridor (defined as the area from Polley Lake to the Gavin Lake Road Bridge) as part of creek rehabilitation work completed in 2015. The results of further excavation and remediation work in Upper Hazeltine Channel corridor during 2016 will be documented under separate cover.
- Tailings material was not observed within Hazeltine Canyon, as material within the canyon was scoured to bedrock and deposited within Lower Hazeltine Channel corridor.
- A mixture of native till and tailings deposition was observed in Lower Hazeltine Channel corridor and at the mouth of Edney Creek. The soil mixture is consistent with the scouring and deposition that occurred following the TSF embankment breach. Based on survey information available at the time of DSI report completed in January 2106, approximately 6,000 m^3 of material were excavated from the vicinity of the sedimentation ponds, as part of rehabilitation works completed in 2015. The results of further excavation and remediation work in Lower Hazeltine Channel corridor during 2016 will be documented under separate cover.

Based on the rehabilitation works completed in 2016, and described above, the topography at the site has changed significantly since the TSF embankment breach occurred. These changes can be observed on the updated aerial imagery shown on Figures A2 – A10 at the end of this report.

6.1.1.2 Impact on Forest

The terrestrial ecosystem assessment conducted in 2015 and again in 2016, was comprised of: i) field measurements of ecological impact including; forest floor and mineral soil properties; forest stand attributes; vegetation attributes; evidence of wildlife, and wildlife attributes, ii) laboratory evaluation of soil microbial communities, and iii) bioassays of the tailings mixture to determine causal factors for growth limiting conditions. The methods and results of the assessments are presented in the PEEIAR Update (Golder 2016b). The findings of the assessments indicated that a relatively sudden decline and die off of trees resulted from the physical habitat alterations caused by tailings deposits. The inundation of tailings across the forest floor in the halo zone impeded air exchange with plant roots and the soil microbial community causing hypoxic or anaerobic environment in the organic soils and lead to subsequent death of the tree roots and soil microbial community, as shown on Figure 11.

Figure 11: 2015 Site Conditions and the Pattern of Tree Mortality Suggest That the Mortality was caused by the Anaerobic Environment of the Tree Roots Created by the Thick Deposit of Fine Silty Material over the Forest Floor

In 2016, field observations indicated that the anaerobic conditions were no longer present in organic soil underlying the tailings in the halo zone. The soil and forest and plant communities showed signs of recovery, especially in areas where the tailings layer was thin, as documented in the 2016 update to the ecosystem assessment (Golder 2017a). These improvements included; development of a heavy litter layer, the initiation of “soil formation” in some halo areas, small overall increase in ground vegetation cover in 2016, an increase in species richness, and invasion of early successional and weedy species. Figure 12, below, shows some of the rehabilitation work that has been ongoing in the Lower Hazeltine Channel corridor. As described in Section 5.1, tailings material has been excavated and replaced with transplanted soil in approximately 9 ha of Upper Hazeltine Channel corridor, in halo areas mounding of tailings and underlying organic soils has been done over approximately 32 ha, and re-grading and re-sloping works have been completed in 46 ha of the corridor that were scoured following the TSF embankment breach.

Figure 12: 2016 Conditions along Hazeltine Channel Corridor

6.1.2 Chemical Impact - Contamination in Soil and Groundwater

The characterization and delineation of chemical impacts has included investigations of soil, groundwater, surface water and sediment. An approach was developed and implemented for the site that considered the unique circumstances at the site, specifically: one source (tailings), a linear migration path, a homogeneous contaminant distribution, and a visual difference between the background and impacted area. Representative cross sections were sampled in detail and used to interpolate environmental conditions in broad areas along the debris flow path of the tailings mixture.

There were two distinct types of tailings: a grey silt tailings that deposited in the eroded floodplain and the surrounding standing forest, during the debris flood that occurred after the initial debris flow; and a black or orange magnetite sand that was deposited in relatively thin layers within certain parts of the floodplain. Both tailings had similar chemical concentrations and geochemical characteristics. The tailings have low concentrations of available nitrogen and carbon. Concentrations of copper were greater than the CSR PL standard across the impacted areas of the site. Concentrations of vanadium, thought to be associated with the magnetite, exceeded the CSR PL Schedule 4 standard in 42 of 182 samples, but had an observed maximum concentration of approximately 1.4 times the standard. As part of the DSI update, soil results were screened against CSR AL standards. Based on the re-screening, exceedances of sulfur and molybdenum were also reported. Molybdenum concentrations exceeded the CSR AL standard in 28 of 182 samples, with a maximum observed concentration approximately 1.5 times the applicable standard. Sulfur concentrations exceeded the CSR AL standard in 34 of 40 samples.

6.1.3 Contamination Extent

As discussed in Section 7.1.2, the approach to the delineation of the soil contamination was based on several unique characteristics of the tailings debris flow/flood. The impacted area is large, but the tailings represent a single source of contaminants which was deposited on top of native soil and is distributed along a defined and visible linear flow path; the chemical composition of the tailings mixture is also relatively homogenous.

Lateral delineation is shown in Figures A-2 through A-10, and was achieved through:

- Interpretation of high resolution air photos taken in November 2014 and in May 2015. SNC used the November 2014 air photos for their estimates of the lateral extent of tailings deposition in the forest halo zone. The May 2015 air photos were used to refine the lateral extent, however the June 2016 air photos became available at a later date, and are used in figures A-2 through A-10.
- Field reconnaissance and visual observation of the limit of the tailings deposits at each of the investigated cross-sections using a field GPS unit.

Vertical delineation was achieved through test pit and borehole sampling at representative cross-sections. The cross-sections were selected to represent reaches of the creek valley with similar characteristics, e.g., topography, gradient, stratification and depth of tailings. The tailings depth ranged from a few centimetres in the forest halo zone to 3.5 m in the plug area. The depth at each sampling location is recorded on the borehole and test pit logs completed during the 2015 and 2016 investigations. As previously mentioned, rehabilitation work by MPMC is ongoing and involves removal or mixing of tailings, bringing in mineral and organic soil, and adding woody debris before replanting. This rehabilitation work often results changes to the ground elevation. The results of the rehabilitation work will be documented under separate cover.

6.1.4 Contamination Characterization and Migration Potential

Laboratory analytical results of the soil investigation were screened against the applicable CSR AL and PL soil standards and CSR regional background concentrations in order to define the nature and extent of soil contamination at the site. Detailed results for metals were presented in Section 6.1.3 and are shown on Figures A-2 to A-10 at the end of this report. Based on the maximum concentrations that were observed during the investigation the following metals exceeded applicable CSR AL or PL standards:

- Arsenic, barium, cadmium, copper, molybdenum, selenium, sulfur, vanadium, and zinc.

A statistical evaluation of the data set was conducted in order to determine whether the metals parameters with exceedances of CSR standards should be considered as contaminants of concern for the DSI. Based on the results of the summary statistics (maximum, 90th percentile, and 95% UCLM), the following metals are retained as soil contaminants of concern:

- For native soil, underlying tailings (organic and mineral soils): copper and sulfur
- For tailings: copper, molybdenum, sulfur, and vanadium

As expected, the tailings had higher concentrations of copper and vanadium than what were observed in the "native under tailings" soil.

Molybdenum and sulfur are retained as soil contaminants of concern based on exceedances of the standards for protection of agricultural land use only. The molybdenum concentrations observed at the site were less than the CSR PL standard of 10 mg/kg, but the 90th percentile for molybdenum was greater than the CSR AL standard of 5 mg/kg.

The sulfur standard of 500 mg/kg is for agricultural land use only (there are no applicable CSR standards for sulfur for other land uses) and is based on elemental sulfur present in a sample. Soil samples analyzed for sulfur as part of the 2014 and 2015 investigation work were analyzed for total sulfur and are therefore considered to be a conservative estimate of available elemental sulfur in the soil at the site.

The geochemical characterization program carried out by SRK in 2015 and 2016 provided information on the potential for leaching from the spilled tailings. The kinetic tests conducted to simulate subaerial weathering of the spilled tailings along Hazeltine Channel Corridor, confirmed that the metal leaching from the tailings is low and that the leaching is at steady state or decreasing. More detailed conclusions include:

- ARD is not expected from the tailings and that leaching will be under neutral to alkaline conditions.
- The leaching rates in the kinetic tests have reached steady state or are slowly declining, and are suitable for predicting long term water quality from weathering of subaerial tailings.
- For tailings materials with water flow paths longer than half a metre, mineral solubility controls for copper are expected with the formation of secondary copper minerals which would limit the concentrations of copper in groundwater. Where dilution from precipitation is expected to be high, resulting copper concentrations could be lower than those predicted by mineral solubility limits.
- Longer flow paths in the fine grained materials may also be conducive to lower rates of oxygen diffusion and therefore conditions that support sequestration of selenium through selenium reduction to more insoluble forms such as selenite and elemental selenium.
- Higher copper concentrations observed in the Polley Flats area in ditches and pooled water can be explained from geochemical first principles considering processes that release copper to solution then constrain the resulting copper concentrations by the solubility of copper oxides. Copper concentrations that were not constrained by mineral solubility were shown to be predominantly complexed with DOC. The resulting free copper concentrations are low and typical for waters in contact with non-acidic carbonate-containing materials with copper concentrations expected to be stable in the long term.
- Seasonal increase in copper concentrations may be a result of oxidation products and acidity accumulation around sulphide grains during periods of low precipitation (winter and late summer/early fall). During later stages of freshet or times of year when precipitation is infiltrating the tailings, porewater concentrations decrease as pH goes above 8.0. Conservatively, it should be assumed that these upper end predictions are reached each season, but long term downward trends are probable. This seasonal variation is expected to reduce over time as the tailings age and weather.

Copper and selenium concentrations in groundwater were less than applicable CSR standards during both the 2015 and 2016 sampling events. These results confirm the geochemistry findings of low leachability from the tailings. The median concentration of copper was about one order of magnitude lower than the concentrations predicted by mineral solubility limits, likely due to dilution by precipitation. Selenium concentrations are likely limited by low oxygen conditions that support sequestration of selenium through selenium reduction to more insoluble forms such as selenite and elemental selenium. Kinetic laboratory testing and groundwater investigation indicated that the concentrations of copper and selenium in groundwater will likely reduce over time as the tailings age and weather.

Vanadium, for which the 90th percentile concentration in soil (212.8 mg/kg) slightly exceed the applicable CSR standard (200 mg/kg), did not have any exceedances in groundwater.

Groundwater exceedances of sulfate, arsenic, iron, manganese, and molybdenum were observed in groundwater during monitoring events in 2015 and 2016. The exceedances of arsenic, iron, and manganese are likely related to reducing conditions caused by high dissolved organic carbon (DOC) concentrations, with corresponding low dissolved oxygen content and negative ORP in the groundwater.

The slight exceedance of sulfate in the Polley Flats area (MW16-02) is likely a result of geochemical processes which, according to SRK, may cause seasonal variation in pH and metal concentrations. The sulfate concentrations in all other monitoring wells were less than the applicable CSR standards.

Some detailed observations include:

- The arsenic exceedance was observed at GW15-01 during the 2015 monitoring round and exceeds the CSR standards for DW, IW, and LW. GW15-01 was installed within the tailings and is located within the floodplain of Hazeltine Channel. The exceedance is considered to be isolated and delineated, as arsenic concentrations at all other monitoring wells were less than applicable standards during monitoring events in 2015 and in 2016. The arsenic concentration in this well is believed to be related to natural materials and elevated because of reducing conditions (ORP = -40.5 mV).
- Iron concentrations exceeded the CSR DW and IW standards at two monitoring well locations in 2015 (GW15-06 and GW15-01). The monitoring wells installed in 2015 were completed within the tailings; field measurements at the time of sampling noted low dissolved oxygen readings in the groundwater, which may have contributed to dissolution of iron into the shallow groundwater. The exceedances are considered to be isolated and delineated. Dissolved iron concentrations were less that CSR standards for all samples that were collected as part of the 2016 monitoring program.
- Manganese exceedances were observed throughout the site in monitoring wells installed within tailings and native under tailings soil. The concentrations exceeded CSR DW and IW standards; there are no manganese standards for the protection of livestock or aquatic life. Similar to iron, the observed manganese concentrations are likely a result of reducing conditions in the groundwater.
- Molybdenum exceedances were observed at three monitoring well locations (MW16-02, GW15-02, and MW16-07) in 2016 and were above the IW and LW CSR standards, but were less than the DW and AW CSR standards. The molybdenum exceedance is considered to be isolated and delineated by MW16-01 and MW16-03.

Based on the physical hydrogeology assessment that was conducted at the site, shallow groundwater flow at the site is inferred to discharge to Hazeltine channel (i.e., groundwater seeps into the creek as baseflow rather than the creek losing surface water to the groundwater environment). This is supported by an upward hydraulic gradient observed at one of the well pairs next to Hazeltine Channel (MW16-06D). In addition, no regional aquifers were mapped in the vicinity of the Mine, and the closed aquifer, more than 15 km south of the Mine, is not considered to be hydraulically connected to groundwater from the Mine area or the Hazeltine Channel corridor.

Surface water quality monitoring between June 2015 and 1December 2015 indicated that the contaminants of concern identified in groundwater do not exceed the surface water criteria except for copper in Hazeltine and Edney Creeks. A discussion of the chemical impacts on aquatic environment, including Hazeltine Creek, is provided in Section 6.2, below.

It is recognized that the groundwater investigation to date has not collected sufficient information to assess seasonal variability. Future sampling will be undertaken as part of the comprehensive environmental monitoring plan (CEMP). The sampling results will be evaluated for seasonal variability and long term trends.

6.2 Impacts on the Aquatic Environment

6.2.1 Surface Water

The surface water and sediment results have similarities to findings for the terrestrial environment. The debris flow initially resulted in an increase in turbidity in Hazeltine Creek, Polley Lake and the West Basin of Quesnel Lake. Some increase in turbidity was observed in the first few months after the breach extending to the mouth of Quesnel River. The debris flow eventually settled out on the existing sediment surface environments in Polley and Quesnel Lakes, much like the terrestrial deposition in the halo area. The geochemistry results of the tailings have consistently shown low reactivity of the enriched metals, including low leachability potential. These geochemistry results are supported by the surface water results from within the TSF and in the aquatic receiving environments. A comparison of untreated water from within the TSF, prior to the breach, to CSR Schedule 6 found only a minor exceedance of the Schedule 6 standards. This supports the geochemistry findings of low leachability of the metals in the tailings material.

Based on the evaluation of water quality trends described in this report, the following parameters remain as COCs due to measured concentrations in December 2015 that remain above BC WQGs and CSR Standards (Table 14).

Table 14: Contaminants that Remain of Potential Concern in the Receiving Environment Based on Water Quality Monitoring as of December 2015

Waterbody	COC: Physical	COC: Total Metals	COC: Dissolved Metals	COC: Non-Metal Substances
Polley Lake	*no substances*	*no substances*	*no substances*	*no substances*
Hazeltine Channel and Edney Creek	**turbidity, TSS**	**copper**	**copper**	*no substances*
Quesnel Lake	*no substances*	*no substances*	*no substances*	*no substances*
Quesnel River	*no substances*	*no substances*	*no substances*	*no substances*

Notes: TSS = total suspended solids

A summary of water quality during 2015 in each receiving environment is provided in the following sections.

6.2.1.1 Hazeltine Channel

As described in Golder (2016b), there were exceedances of total metal WQGs in Hazeltine Creek in the first half of 2015, mainly during turbid flow periods typically associated with elevated concentrations of particulate matter. Clear-flow conditions ensued upon the completion of channel stabilization activities that typically resulted in much lower concentrations of particulate matter and subsequently lower concentrations of total forms of various metals.

The majority of metals identified as COCs by Golder (2016b) had decreased to below guideline levels by mid-summer and remained stable through to December 2015, with a few noted exceptions (e.g., beryllium, chromium, and cobalt at HAC-08/a). By December 2015, only total and dissolved copper consistently exceeded BC WQGs for the protection of aquatic life. Copper, turbidity and total suspended solids therefore remain the primary substances of concern in Hazeltine Creek.

6.2.1.2 Polley Lake

Levels of TSS, turbidity, and copper were low in Polley Lake and remained below guidelines throughout 2015. With respect to nutrients, total phosphorus concentrations were within the range observed in Polley Lake prior to the event. Therefore no contaminants remained of concern by December 2015 in Polley Lake.

6.2.1.3 Quesnel Lake

Levels of TSS and turbidity were low in the far-field area of Quesnel Lake as well as in the West Basin and remained below guidelines throughout 2015, with the exception of some higher levels recorded in the near-field area at the mouth of Hazeltine Creek when turbid inflows from Hazeltine Creek were present from March to May 2015. Close to the mouth of Hazeltine Creek, turbidity progressively declined between June and December to levels close to or below background (1 NTU).

Within the West Basin, total copper was below applicable BC WQGs and CSR standards in the near-field, mid-field and far-field stations. Exceptions to this were instances where concentrations were above applicable BC WQGs between March and May in the near-field close to the mouth of Hazeltine Creek and to a lesser extent at the western mid-field station further away from the mouth. These higher total concentrations coincided with turbid flow periods in Hazeltine Creek and dissolved concentrations did not exceed BC WQGs. Other metals monitored at the Quesnel Lake stations in 2015 were below applicable BC WQGs and CSR standards.

In agreement with Golder (2016b), phosphorus data collected throughout 2015 suggested that event related- changes of concern with respect to the potential for a change in lake trophic status were not evident in Quesnel Lake.

Based on the evaluation of the 2015 dataset, no contaminants remained of concern by December in Quesnel Lake.

6.2.1.4 Quesnel River

Similar to the eastern far-field area of Quesnel Lake, water quality in Quesnel River between March and August did not exhibit event-related changes that were identified to be of concern with respect to exceedance of water quality guidelines. Therefore no contaminants remained of concern by December 2015 in Quesnel River.

6.2.2 Sediment

6.2.2.1 Contaminant Impact

In contrast to the surface water results, 2016 sediment concentrations were similar to the 2014 and 2015 sampling. For Polley Lake, Hazeltine Channel and Quesnel Lake, concentrations of copper exceeded the CSR "sensitive" and "typical" criteria, and concentrations of arsenic exceeded "sensitive" criterion. Figure 10.1 (Minnow 2015) shows the distribution of copper concentrations in sediments Polley Lake, Hazeltine Creek, the sedimentation ponds, Quesnel Lake and Bootjack Lake. This figure shows a gradient of copper concentrations from Hazeltine Creek, with higher concentrations in the profundal sediments of Quesnel Lake compared to lower concentrations measured in the littoral sediments. This is consistent with the bathymetry study results from Tetra Tech (Tetra Tech, 2015) reporting that the tailings generally settled below the 100 m contour line.

6.2.2.2 Contamination Extent

A bathymetry comparison pre- and post- event shows that the estimated 15.5 million m^3 of displaced material that entered Quesnel Lake infilled a layer of over 10 m in the west arm with the upper surface of the deposited material at approximately 100 m depth. The area of event-related infill within the estimated depositional zone is 1.81 km^2 based on data from the bathymetric analysis and sub-bottom profiling of sediment layers. Most measurements of copper concentrations in Quesnel Lake deep sediments ranged in concentrations between 350 mg/kg to 800 mg/kg. This concentration range is somewhat less than that measured for the tailing mixture in the terrestrial environment and likely reflects mixing of the tailings with the native sediments.

Concentrations of copper in sediments in Polley Lake were generally lower than those measured in Quesnel Lake. This is consistent with the results of the Tetra Tech (2015) report that indicated inputs to Polley Lake were largely aqueous, compared to Quesnel Lake that received both aqueous and solid phase inputs.

6.3 Conceptual Site Model

The field observations and analytical results collected during the 2015 and 2016 investigations were used to update the conceptual site model. The following sections of the report present a description of the revised CSM for the receiving environments at the site.

6.3.1 Tailings Debris Flow and Immediate Physical Impact

The TSF embankment breach resulted in transportation and scouring of tailings, construction materials and natural sediments, deposition of the mixture of materials, termed “spilled tailings” in Polley Lake and the Polley Flats, and transportation, scouring and deposition of a mixture of tailings, construction and natural materials in the Hazeltine Creek valley. The impacted physical environment around Polley Lake, Edney Creek and Hazeltine Creek included approximately 136 ha (1.36 km^2) where topsoil was removed and an additional area of approximately 100 ha (1 km^2) where tailings were deposited overlying intact topsoil.

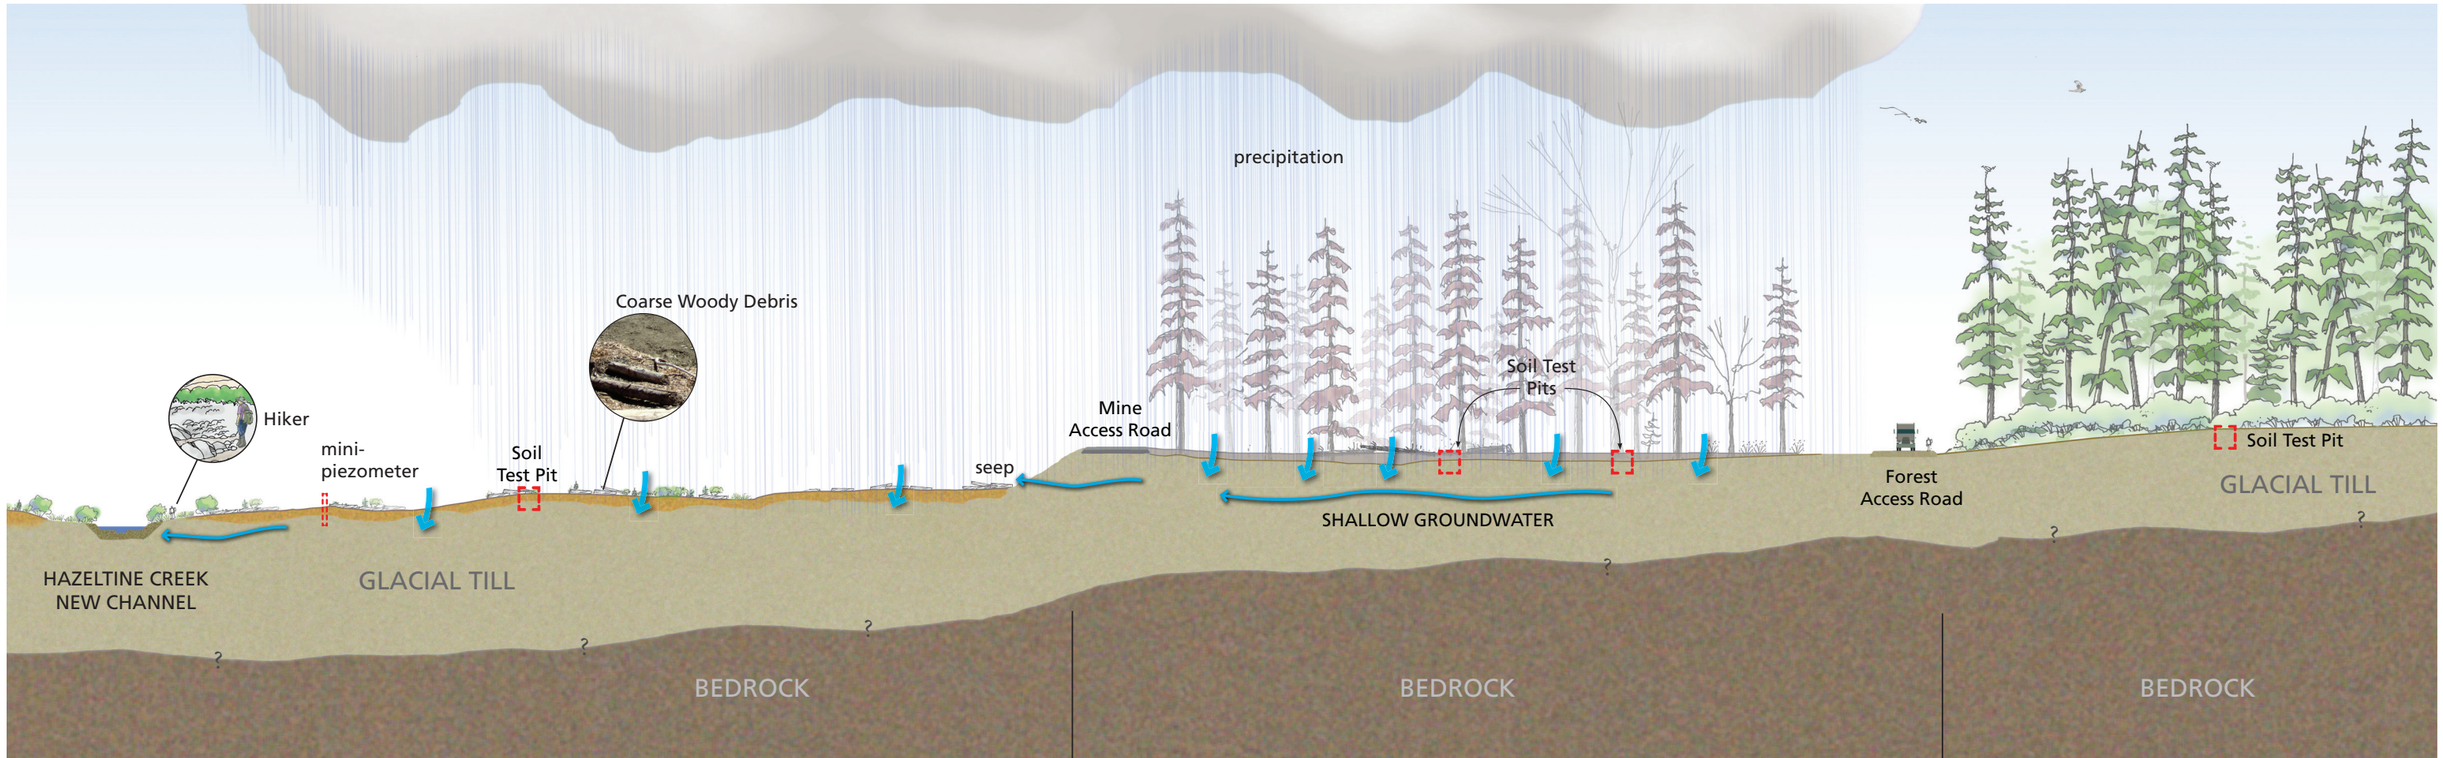
In some areas, the tailings settled out in two distinct layers: a grey fine silt and a black-orange sand. The two layers settled out according to particle size and density, generally with the finer material overlying the coarser sand. As the debris flow moved down the Hazeltine Creek valley, it picked up and mixed with native till. Approximately 20 million m^3 of tailings, native soil, water and debris were deposited into Quesnel Lake where a turbidity plume formed at about 20 to 30 metres below surface; which included a significant amount of fine-grained natural lake sediment that became suspended by the force of the debris flow from Hazeltine Creek. Turbidity in Quesnel Lake persisted into December 2014, but cleared over the winter. Some turbidity was measured in Hazeltine Creek and in Quesnel Lake near Hazeltine Creek in 2015; however, the source of this turbidity has been accounted for in creek channel rehabilitation work, as well as other remediation work.

Together, the soil, sediment, groundwater and surface water results all confirm that while some tailings-related metals are present in these media above CSR standards, the leachability and migration potential of the dissolved phase are low. These results are significant, as it is the dissolved phase that is associated with uptake and toxicity in biota. Furthermore, these results support the preliminary findings of the PEEIAR and the 2016 DSI; namely that the largest impact on terrestrial and aquatic habitats was caused by the physical nature of the debris flow from the TSF embankment breach.

6.3.2 Terrestrial – Hazeltine Channel Corridor

The CSM as of the summer of 2016, is shown in Figure 13. The cross section has been drawn to scale to better reflect the conditions at the site. The CSM shows the tailings deposits, which were thicker within the floodplain where the forest and some of the native till was scoured leaving behind tailings on top of native soil. Rehabilitation works at the site are ongoing and the landscapes and topography at the site are changing continuously. The forest halo was inundated during the flooding that happened when the debris flow formed a dam at the head of Hazeltine Canyon. The fine tailings deposited in the forest limited the oxygen diffusion and lead to tree mortality. As of the end of 2015, approximately a quarter million m^3 were removed by MPMC and placed in the TSF. In 2016, rehabilitation works continued along the length of the Hazeltine Channel corridor, including further excavation of tailings material, transplanting native soil, and re-sloping and re-contouring of scoured areas. This is important to note because the site conditions are changing continually.

The tailings contain copper and vanadium above the CSR PL standards as well as sulfur and molybdenum above CSR AL standards. The geochemistry findings suggest that the copper and vanadium are not reactive. The results of the groundwater investigation confirm that there is no transport pathway for metals observed in tailings to shallow groundwater. The surface water results in Hazeltine Creek, combined with the physical hydrogeological model, also indicate that there is no transport of groundwater exceedances to surface water. The significance of the soil and groundwater CSR exceedances will be evaluated further in the HHRA and ERA reports, prepared under separate cover.



FLOODPLAIN: TAILINGS EXCAVATED TO COMPETENT TILL ALONG CREEK. VARIABLE DEPTHS TAILINGS MIXED WITH NATIVE SOILS.

Trees, shrubs and ground covers absent. Organic soils absent, tailing deposition largely removed. Mitigation: wood mulch and coarse woody debris applied, new plantings installed.

HALO ZONE: VARIABLE DEPTH TAILINGS LAYER OVER NATIVE SOILS

Trees present, shrubs and ground covers absent or partially covered with tailings. Root zones compromised, vegetation die back.

TRANSECT 02

6.3.3 Aquatic – Quesnel Lake

The CSM for Quesnel Lake is shown on Figure 14, below.

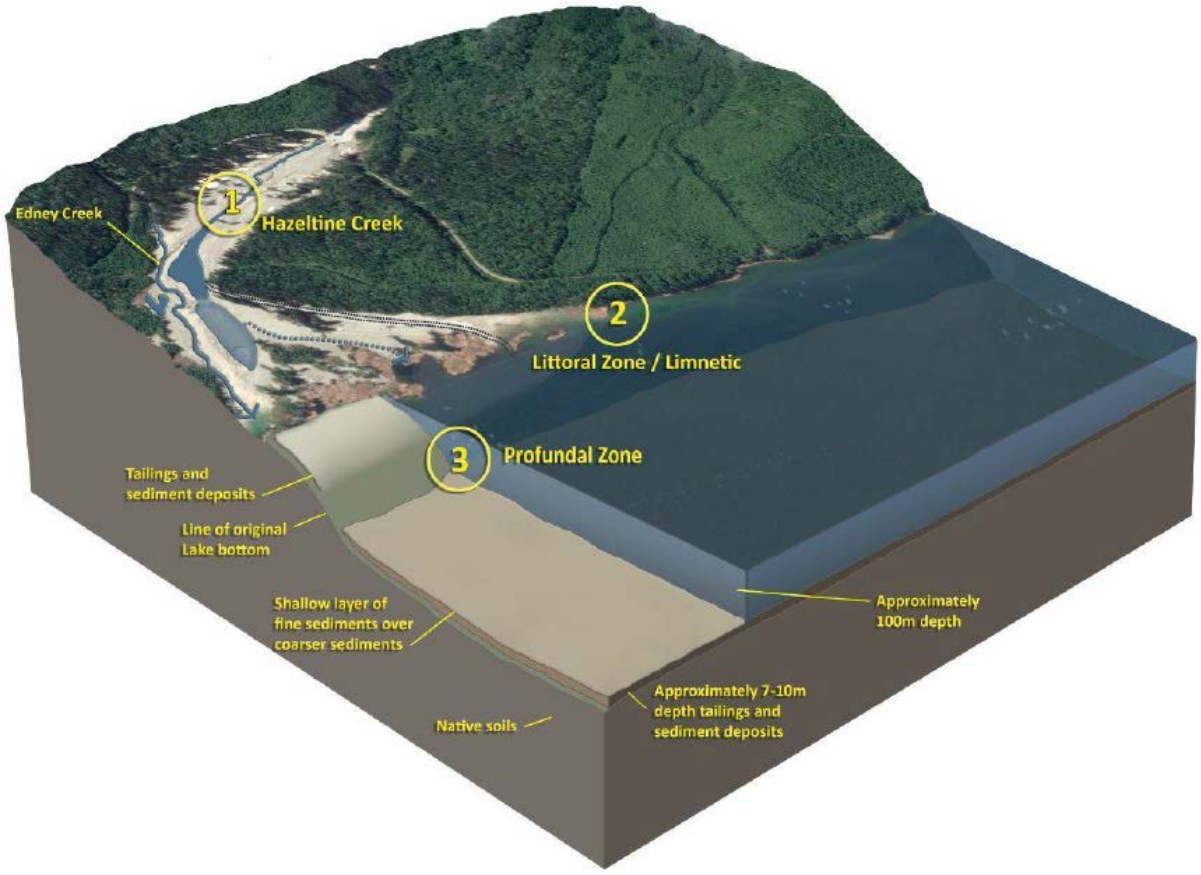

Figure 14: Conceptual Site Model for Quesnel Lake

The model shows a deposit on the lake bottom of approximately 10 m of a mixture of tailings and native material, with the upper surface of the deposited material at approximately 100 m depth. The distribution of tailings deposits shows the copper concentrations in Quesnel Lake sediment exceeding the CSR typical standard of 240 mg/kg, centered along an axis of about 5 km in the deepest portion of the West Arm. Concentrations in the littoral zone generally met the CSR sensitive standard, except in the immediate vicinity of Hazeltine Channel. This is significant as the littoral zone, where light can penetrate to the sediment surface, is the more biologically active sediment zone in the lake.

As described in the DSI, post TSF embankment breach changes in surface water quality in near field samples revealed three temporal populations of data. These describe the conditions: i) immediately following the breach characterized by high turbidity in Quesnel Lake at depths >20 m followed by a gradual decrease, ii) during construction of the creek channel and other restorative activities when turbidity increased a second time localized near Hazeltine Channel, and iii) during the period following completion of the creek channel construction when Hazeltine Creek was running under clear flow conditions. These three conditions were considered to be representative of: i) immediately following the breach, ii) during re-construction, and iii) current and future conditions. Based on water quality monitoring up to December 2015, contaminants of concern that remain at the site include total and dissolved copper in Hazeltine and Edney Creeks. Additional construction work is ongoing for Hazeltine Channel in the future, including the addition of side channels and complexity to enhance the habitat for rainbow trout and other aquatic receptors. This exposure scenario warrants evaluation in the risk assessment. Erosion management plans should be reviewed and enhanced to minimize the impact of construction activities on Hazeltine Creek water quality.

Contaminants requiring further assessment in the risk assessment include arsenic and copper in sediment for ecological exposure under current and future scenarios.

7.0 CONCLUSIONS

7.1 DSI Requirements

The DSI Update report completes the detailed site investigation at the Mount Polley Mine, located near Likely, BC. Based on the results of the investigation and the geochemical characterization discussed above we conclude, that the combined information provided in the 2016 DSI report (Golder, 2016a) and the DSI Update report (this report) satisfy the requirements of the Pollution Abatement Order for the site, and meet the CSR requirements of a DSI including:

- identification of areas of potential environmental concern
- determination of the potential contaminants of concern based on the applicable CSR standards
- delineation of the horizontal and vertical extent of contamination
- confirmation that the contamination at the site is stable or decreasing in concentration and extent over time

7.2 Summary of Key Findings

The TSF embankment breach in August of 2014, resulted in physical impact of Hazeltine and Edney Creeks, Polley Lake and Quesnel Lake. Approximately 136 hectares (1.36 km^2) of the Site was scoured of forest and topsoil (floodplain zone). Tailings were also deposited on top of relatively undisturbed forest floor (halo zone) across an additional 100 hectares (1.0 km^2) at the Site. It is estimated that approximately 12.8 million m^3 of tailings was discharged to Quesnel Lake (plus an additional 5.8 million m^3 of native soil and TSF water); and that 1.6 million m^3 of tailings were deposited in the Polley Flats area and the Hazeltine Channel Corridor. In areas where the tailings distributed across the forest floor in the halo zone, air exchange was impeded with plant roots and the soil microbial community causing hypoxic or anaerobic environment of the tree roots, and tree mortality. In 2016, the soil, forest, and plant communities showed signs of recovery, especially in areas where the tailings layers were thin.

The initial physical impacts and contaminant concentrations have been mitigated by on-going rehabilitation and remediation works. MPMC immediately implemented a rehabilitation and remediation strategy including removal of tailings, construction of a new creek channel and sedimentation ponds, and rehabilitation and replanting of large portions of the impacted area. This work is ongoing and will continue to change and improve the site conditions.

To date, the rehabilitation and remediation works have reduced the volume of tailings and lowered the metal concentrations in surficial soils in the tailings impacted areas. Therefore, the site conditions documented in the 2016 DSI and this DSI Update report do not represent the current conditions in the field. As discussed in this report, some of the areas that were identified by the 2014, 2015 and 2016 sampling to contain tailings with copper and vanadium concentrations exceeding the soil standards have now been remediated. The remediation and rehabilitation work will be described in a separate report to be issued at a later date.

The following is a summary of the key findings of the DSI in relation to contamination associated with the tailings released by the TSF embankment breach:

- Copper is the main contaminant in the tailings with an estimated mean concentration (95%UCLM) of 737 mg/kg. The concentrations of copper exceeded the applicable CSR standards in tailings but not in groundwater. The geochemical assessment found that the tailings are not potentially ARD generating and that the leaching that would occur under the neutral to basic pH conditions would be low. Kinetic laboratory testing and groundwater investigation confirmed the leaching rate of copper is low, and that the concentrations in groundwater will likely reduce over time as the tailings age and weather. For tailings materials with water flow paths longer than half a metre, mineral solubility controls for copper are expected with the formation of secondary copper minerals, which would limit the concentrations of copper in groundwater. The median copper concentration in groundwater is about one order of magnitude lower than the concentrations predicted by mineral solubility limits, likely due to dilution by precipitation.
- Vanadium, which is associated with the orange-black sandy tailings (contains magnetite), exceeded the CSR standards based on the 90th percentile of 212.8 mg/kg (CSR standard = 200 mg/kg). The estimated mean concentration (95%UCLM) for vanadium in tailings was less than the CSR standards. Based on geochemical characterization, vanadium was not considered to be enriched in tailings compared to concentrations in typical basalt rock in the region. Vanadium concentrations in groundwater did not exceed the CSR standards.
- Selenium is not a contaminant related to the TSF embankment breach in soil, groundwater, sediment or surface water.
- Other substances that exceeded the CSR standards for soil and groundwater are believed to be associated with natural conditions and were not derived from the tailings. These substances included sulfur and molybdenum in soil (exceedance of agricultural land use standards only); and arsenic, iron, manganese and molybdenum in groundwater.
- In the first few months after the breach, an initial increase in turbidity and concentrations of total metals in surface water was observed extending to the mouth of Quesnel River. During the monitoring period considered to be representative for the purposes of evaluating long term impacts related to the breach (June 2015 to 1 December 2015), concentrations of metals and turbidity decreased or stabilized below BC WQGs and/or are within the pre-event range in Polley Lake and Quesnel Lake. However, in Hazeltine Creek and Edney Creek, concentrations of copper consistently exceeded BC WQGs during that time.
- Sediment quality in Polley Lake, Hazeltine Channel and Quesnel Lake indicated concentrations of copper exceeding the CSR Schedule 9 (typical and sensitive) criterion and concentrations of arsenic exceeding the CSR Schedule 9 (sensitive) criterion. Copper concentrations in reference Bootjack Lake and Polley Lake prior to the TSF embankment breach also exceeded the CSR Schedule 9 (typical) standard. Concentrations of copper in sediments in Polley Lake were generally lower than those measured in Quesnel Lake. This is consistent with the results of the Tetra Tech (2015) report that indicated inputs to Polley Lake were largely aqueous, compared to Quesnel Lake that received both aqueous and solid phase inputs.
- Monitoring and confirmation sampling of soil, groundwater, surface water and sediment will be undertaken as part of the comprehensive environmental monitoring plan (CEMP). The sampling results will be evaluated

for seasonal variability and long term trends, and compared to the assumptions made in the DSI and human health and ecological risk assessments.

7.3 Contaminants of Concern

Based on the findings of the 2016 DSI conducted in 2015 and the DSI Update conducted in 2016, the following concentration of contaminants of concern have been determined to exceed the applicable CSR standards for soil, groundwater and sediment; and BC Water Quality Guidelines for surface water (Table 15).

Table 15: Summary of Contaminants of Concern

Remediation Area	Contaminant	Medium	Applicable CSR Standard	CSR Schedule	Contaminant Concentration
Area 2 – Polley Plug/Polley Flats and Area 4, 5, and 6 – Hazeltine Channel	Copper	Soil	150	5 – Toxicity to soil invertebrates and plants	Refer to Table 6
	Vanadium	Soil	200	4 – Residential and Agricultural	
	Sulfur	Soil	500	4 – Agricultural	
	Molybdenum	Soil	5	4 – Agricultural	
	Iron	Groundwater	5	6 – Irrigation	Refer to Section 5.2.3.1
			6.5	6 – Drinking Water	
	Manganese	Groundwater	0.2	6 – Irrigation	
			0.55	6 – Drinking Water	
	Arsenic	Groundwater	0.01	6 – Drinking Water	
			0.025	6 – Livestock	
	Molybdenum	Groundwater	0.01-0.03	6 – Irrigation	
			0.05	6 – Livestock	
	Sulfate	Groundwater	500	6 – Drinking Water	
	Total and dissolved copper	Surface Water	Variable[1]	BC WQG – AW	Refer to Section 5.3.2.4
	Copper	Sediment	140	9 – Typical	Refer to Section 5.4.2
Area 3 – Polley Lake	Arsenic	Sediment	11	9 – Sensitive	Refer to Section 5.4.1
	Copper	Sediment	120	9 – Sensitive	
			140	9 – Typical	
Area 7 – Edney Creek Mouth	Total and dissolved copper	Surface Water	Variable[1]	BC WQG - AW	Refer to Section 5.3.2.4
Area 8 – Quesnel Lake	Copper	Sediment – Littoral and Profundal	120	9 – Sensitive	Refer to Section 5.4.3
			140	9 – Typical	
	Arsenic	Sediment – Littoral and Profundal	11	9 – Sensitive	

1) WQG is variable dependant on hardness and 30-day rolling averages.

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:
Results are expressed in milligram per kilogram (mg/kg)
mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.
MPMC = Mount Polley Mining Corporation
Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.
*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations
AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:

Results are expressed in milligram per kilogram (mg/kg)

mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:
Results are expressed in milligram per kilogram (mg/kg)
mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.
MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion; S = Schedule 10; pH = standard is pH dependent.
*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Notes:
Results are expressed in milligram per kilogram (mg/kg)
mbgs = meters below ground surface; QA/QC = Quality Assurance / Quality Control; FDA = Field Duplicate Available; FD = Field Duplicate; mV = millivolt, % = Percent; mm = millimetre; "-" = no data available.
MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.
*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations
AL = Agricultural Land Use; PL = Parkland Use

MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation

Samples = Number of Samples; 95 UCL = 95th Upper Conifidence Limit of the Mean

'-' = no chemistry data available to calculate statistics; mV = millivolts; mm = millimetres; mg/kg = milligrams per kilogram

95 upper confidence of the means were only calculated for parameters that exceeded one or more of the applicable BC Contaminated Sites Regulations (CSR) Standards

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Where a concentration was reported below detection limit, the detection limit is used as a conservative measure.

MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation

Samples = Number of Samples; 95 UCL = 95th Upper Conifidence Limit of the Mean

'-' = no chemistry data available to calculate statistics; mV = millivolts; mm = millimetres; mg/kg = milligrams per kilogram

95 upper confidence of the means were only calculated for parameters that exceeded one or more of the applicable BC Contaminated Sites Regulations (CSR) Standards

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Where a concentration was reported below detection limit, the detection limit is used as a conservative measure.

* 95 UCLM = 103, however due to small sample size (n<8), the maximum concentration is presented

MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation

Samples = Number of Samples; 95 UCL = 95th Upper Conifidence Limit of the Mean

'-' = no chemistry data available to calculate statistics; mV = millivolts; mm = millimetres; mg/kg = milligrams per kilogram

95 upper confidence of the means were only calculated for parameters that exceeded one or more of the applicable BC Contaminated Sites Regulations (CSR) Standards

MPMC = Mount Polley Mining Corporation

Standards shown are from the British Columbia (BC) Contaminated Sites Regulation ("CSR"; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 4/2014, January 31, 2014), Schedule 4 (Generic), Schedule 5 (Human Health Protection and Ecological Protection)

The most conservative standard (MCS) of the reference site specific factors have been applied, including: G = Generic; I = Intake of Contaminated Soil; AW = Groundwater Flow to Surface Water used by Aquatic Life, F = Freshwater Aquatic Life, M = Marine Aquatic Life; T = Toxicity to Invertebrates and Plants; DW = Drinking Water; IR = Irrigation Water; LW = Livestock Watering; LI = Livestock Ingestion: S = Schedule 10; pH = standard is pH dependent.

*Where applicable CSR standards were lower than the MoE Protocol 4 regional background concentrations, the background concentration was considered appropriate for final screening against individual sample concentrations

AL = Agricultural Land Use; PL = Parkland Use

Where a concentration was reported below detection limit, the detection limit is used as a conservative measure.

N/A - 95 UCLM not determined due to low number of samples reported above laboratory detection limit

bold	exceeds BC CSR AL Ecological Health guideline
underline	exceeds BC CSR AL Human Health guideline

Notes:
QA/QC = quality assurance/quality control; FDA = field duplicate available; FD = field duplicate
NA = not applicable; NC = not calculated; Mean = average of two values
Relative percent difference (RPD) = the difference between two values divided by the mean of the two values. RPD is calculated when the concentration is greater than five times the detection limit.
Golders' acceptable RPD for soil is less than or equal to 35%.
Difference factor (DF) = absolute difference between two values divided by the method detection limit. The DF is calculated when the concentration is less than five times the detection limit.
Golders' acceptable DF is less than or equal to 2.0.
Bold values indicate an exceedance of the acceptable RPD or DF.

Notes:
QA/QC = quality assurance/quality control; FDA = field duplicate available; FD = field duplicate
NA = not applicable; NC = not calculated; Mean = average of two values
Relative percent difference (RPD) = the difference between two values divided by the mean of the two values. RPD is calculated when the concentration is greater than five times the detection limit.
Golders' acceptable RPD for soil is less than or equal to 35%.
Difference factor (DF) = absolute difference between two values divided by the method detection limit. The DF is calculated when the concentration is less than five times the detection limit.
Golders' acceptable DF is less than or equal to 2.0.
Bold values indicate an exceedance of the acceptable RPD or DF.

DETERMINATION OF LOCAL BACKGROUND SOIL CONCENTRATIONS – MOUNT POLLEY MINE

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with this technical memorandum for determination of local background concentrations for soil in support of the Detailed Site Investigation (DSI) and Human Health and Ecological Risk Assessment (HHERA) for the Mount Polley Mine (Mine). Work was carried out in accordance with the *Work Plan for Determination of Local Background Concentrations for Environmental Media, Mount Polley Mine, BC* (Golder 2016).

The background soil concentrations were determined in general accordance with BC MoE Protocol #4 – Determining Background Soil Quality but with modifications as noted to reflect the site nature of the project, and the intended use of the local background concentrations.

It is important to note that the local background concentrations are not being used for "overriding" exceedances of a standard. In fact, the local background concentrations are lower than the applicable soil standards for all metals.

The local background concentrations were requested by project reviewers. A Director's determination of the local background concentrations will not be sought.

1.0 SCOPE OF WORK

The scope of work related to the determination of background soil included the following tasks:

- Review of existing background soil sampling locations and results.
- Collection of supplementary background soil samples.
- Inclusion of results for co-located soil samples collected as part of the terrestrial plant and invertebrate soil sampling program completed by Golder in August and September 2016.

2.0 METHODS

2.1 Approach and Rationale

The emphasis in the background sampling procedure was on estimation of the range of substance concentrations in soil which can be shown to be attributable solely to natural (i.e., not related to the tailings spill) and generalized non-point anthropogenic sources. This is achieved by selection, analysis and comparison of background soil substance concentrations to those observed in native soil located outside the area impacted by tailings deposits.

MoE Technical Guidance #16 (TG16) suggests a process for soil sampling to determine background quality, including choosing a reference site and splitting the site into sections for random sampling. However, given the uniform nature of contamination at the site along a large, linear zone, a site-specific sampling program was developed to better suit site conditions.

Background samples were collected at 29 locations along the length of the impacted zone at least 10 metres beyond the extent of the 'halo' zone (based on visual observations of deposited tailings material). Figure 1 shows the locations of each background soil sample collected. Generally, one sample of either organic or inorganic soil was collected at each location. At SS16-BKG-01 through SS16-BKG-04, three samples from varying depths were collected at each sampling point, as suggested in TG16.

Fifty-six existing background soil samples previously collected at the site by SNC-Lavalin Inc. (SNC) in 2014 and by Golder in 2015 were also included in the dataset to determine background concentrations. These background samples were collected from locations at least 10 metres beyond the extent of the 'halo' zone (based on visual observations of deposited tailings material).

The preliminary assessment of the local background concentrations presented in the 2016 DSI combined all soil types as the data set was limited. Based on our review of the preliminary data, we concluded that it would be appropriate to separate the data into two datasets; organic soil and mineral soil. In general, the observed soil profiles included the following horizons:

- L and F horizons - surficial layers consisting of fresh and partly decomposed plant matter.
- H horizon – located under the L and F horizons, composed of well-decomposed plant residues in which plant structures are generally not recognizable.
- A horizon – located under the H horizon, contains <17% organic carbon by mass and has formed at or near the soil surface in the zone of leaching or eluviation of organic materials in solution or suspension (i.e., transport of organic material and minerals to lower layers), *or* of maximum accumulation of organic matter, or both.
- B horizon – located under the A horizon, it is a mineral soil characterised by enrichment in organic matter or clay; or by the development of soil structure by a change of colour denoting hydrolysis, reduction, or oxidation.
- C horizon – located under the B horizon, it is an unconsolidated material below the zones of greatest biological activity, and is comprised of mineral material.

For the purposes of this report, the organic soil dataset includes soil samples collected within the "H" and "A" soil horizons, and the mineral dataset soil includes soil samples collected within the "B" and "C" soil horizons.

2.1.1 Boron and Sulfur Analysis

After the 2016 DSI was completed, rescreening of soil data at the site was completed because a small part of the land in the Hazeltine Channel corridor is dedicated under the ALR (Agricultural Land Reserve). During this process, it was determined that the boron and sulfur results available at that time were not analyzed using the method specified by MOE (CSR Schedule 4).

Boron concentrations reported in 2014, 2015 and 2016 were analysed via a strong acid leach (SAL) method. The boron soil standard is based on a hot water soluble (HWS) laboratory analysis. To provide a meaningful comparison for DSI soil results, ten stored mineral background soil samples were submitted for HWS boron analysis.

Sulfur results for background soil samples were analysed by SNC in 2014 via a total combustion method. The sulfur soil standard is based on elemental sulfur. In the absence of elemental sulfur data, background concentrations for the available sulfur results are presented in this technical memorandum.

2.2 Local Background Site Selection

Golder reviewed the locations of existing background soil sample locations (56 samples at 38 sampling locations) and selected additional background sampling locations where necessary based on recent available aerial imagery and visual observations of the extent of the tailings deposition. Four additional background sampling locations for soil (SS16-BKG-01 through SS16-BKG-04) were selected as part of the 2016 DSI field sampling program. Each of the sample locations was located a minimum of 10 m outside the halo zone. As described in the DSI report, the demarcation between tailings impacted area and undisturbed native area was clearly visible in the field.

Samples were collected at three depth intervals, as outlined in TG16, within the B and C horizons at each sampling location (twelve samples per location). Additional sampling of organic (H and A layer) soil was not considered necessary in the 2016 DSI field program, as sufficient data was available from the previous sampling.

Background locations were selected outside the Hazeltine Channel corridor in order to capture representative soil conditions along its length, as follows:

- Area 4 – Upper Hazeltine (2016 soil sampling locations SS16-BKG-01, SS16-BKG-02, SS16-BKG-03).
- Area 6 – Lower Hazeltine (2016 soil sampling location SS16-BKG-04).

These areas of the Site are described in detail in the DSI report. Soil samples were not collected from Area 5 – Middle Hazeltine as the Canyon was scoured clean and little undisturbed soil remains.

Local background sampling locations from samples collected in 2014, 2015 and 2016 are shown in Figure 1.

2.2.1 2016 Soil Sampling

The scope of the 2016 soil sampling work included collection of 12 background soil samples at varying depths from the four locations selected (SS16-BKG-01 through SS16-BKG-04). The sample collection targeted the mineral soils from three different depths within the upper 1 m of soil. Two field duplicate samples were also collected as part of the sampling program, for quality assurance / quality control (QA / QC) purposes.

Additional detailed information related to the soil samples obtained at the local background locations was documented, including physical characteristics of the soil, depth of sample collection, GPS coordinates of the sampling point, and chemical analysis. A Golder-directed Field Technician documented observations at each soil sample location.

The soil samples were collected in pre-cleaned 125 millilitres (mL) glass soil sample jars supplied by the laboratory. Two jars of soil were collected for each sample interval. Samples jars were packed in cardboard boxes, placed in a cooler with a chain-of-custody form and several ice packs, and shipped to the laboratory.

Each sample was submitted to the laboratory for analysis of metals parameters and pH.

In addition to soil samples collected as part of the 2016 background soil sampling, background soil samples (CSS16-BKG series samples) were collected as part of the terrestrial plant and invertebrate soil sampling program completed by Golder in August and September 2016. Soil samples were collected with each co-located plant sample location. Surface soil within the top 0.2 m from the base of the plant was collected using a hand shovel. The humus layer was removed from samples collected in background areas. Soil was homogenized in a stainless steel bowl prior to transfer to clean, laboratory-supplied 125-mL, glass sample jars with Teflon™ lined lids. Background samples were collected from organic soil layers only during this investigation.

2.3 Laboratory Analysis

ALS Laboratory Group (ALS) of Burnaby, BC performed chemical analyses for the soil samples collected during the background soil sampling programs by SNC in 2014 and by Golder in 2015 and 2016. ALS is accredited by the Canadian Association for Laboratory Accreditation (CALA).

The analytical methods that were used to analyse soil samples are summarised below in Table 1. The methods are approved under the CSR and the BC Environmental Laboratory Manual. Furthermore, the analytical methods used (shown on Table 1 below) were the same methods used for the Detailed Site Investigation. Methods for physical parameters that were not included as part of the background determination (e.g., total organic carbon, pH, etc.) are not shown in Table 1, but are outlined in the laboratory report included in Attachment 1.

In particular, boron (hot water soluble; HWS) was analysed to measure concentrations of boron directly comparable to the CSR standard, which is related to plant uptake.

Table 1: Summary of Analytical Methods

Parameter	Method Reference	Comment
Metals	MET-200.2-CCMS-VA	Soil samples are digested with nitric acid and hydrochloric acids, followed by analysis by CRC ICPMS.
Mercury	HG-200.2-CVAF-VA	Soil samples are digested with nitric acid and hydrochloric acids, followed by analysis by CVAFS.
Boron (HWS)	B-HOTW-CL	Soil samples are extracted by boiling a 2:1 mixture of 0.01 M CaCl2 to soil for 5-15 minutes, prior to filtration of the extract and boron determination using ICPOES.
Sulfur	S-TOT-LECO-SK	Soil samples are ignited in a combustion analyzer where sulfur in the reduced SO_2 gas is determined using a thermal conductivity detector.

2.4 Quality Assurance / Quality Control

Methods for QA/QC are outlined in Attachment 2.

3.0 RESULTS

3.1 Pre-mining Baseline Results for Soil

The Mt Polley Mine commenced operation in 1997. A pre-mine baseline investigation was undertaken in 1995 by Hallam Knight Piesold Ltd. The soil samples were analyzed for metals. A figure showing the locations of the soil samples was not included in the material that Golder reviewed, however MPMC staff indicated that sample locations were placed and labelled in reference to planned mine infrastructure. Attachment 3 presents logs for select test pits where baseline soil samples were collected, as well as select photos showing the soil profile at those locations.

Results indicated the following concentrations for parameters with applicable CSR standards at the Site:

Table 2: Summary of Baseline Data Concentrations

Parameter	Minimum	Maximum	Average
Arsenic	3.6 or <30*	21 or <30*	24.9
Antimony	<10	<10	-
Barium	55	352	134.6
Beryllium	<1	<1	-
Boron	11	32	18.6
Cadmium	<0.25	1.3	0.3
Chromium	11	71	34.9
Cobalt	6	42	15.1
Copper	17	11100	702.6
Lead	2 or <5*	11	5.7
Lithium	No Data		
Manganese	191	5010	895.0
Mercury	0.018	0.76	0.1
Molybdenum	21	75	7.3
Nickel	14	42	25.8
Selenium	<0.5	20	3.0
Silver	<2	<2	-
Strontium	34	241	80.6
Sulfur	No Data		
Thallium	No Data		
Tin	<5	9	5.2
Uranium	No Data		
Vanadium	29	287	102.6
Zinc	28	242	94.9

Notes:
Units are shown in µg/g
Where a result was below detection limit, the detection limit was used for the purpose of calculating an average concentration
* The detection limit for some parameters varied between laboratory reports

The results shown above have been included in this technical memorandum to provide context on the overall soil conditions in the vicinity of the mine, prior to development of the mine facility. The results were not included in the calculation of background concentrations described in Section 4.0 below. Results for these samples are presented in Attachment 3.

3.2 Results of 2016 Soil Sampling

A total of 12 samples were collected from four local background locations (SS16-BKG-01 through SS16-BKG-04) in August 2016. An additional 26 soil samples were collected from 26 local background locations as part of the background plant and invertebrate tissue sampling program (CSS16-BKG series samples) in Areas 4 and 6. Depths and soil descriptions are described below in Table 3.

Table 3: Summary of 2016 Soil Sampling Locations

Sampling Location	Sampling Depths (m)	Number of samples, n	Area	Soil Description
SS16-BKG-01	0.25 – 0.35 0.6 – 0.7 0.9 – 1.0	3	4 - Upper Hazeltine	Silt, with some fine and coarse sand, some gravel
SS16-BKG-02	0.1 – 0.3 0.4 – 0.6 0.7 – 0.9	3	4 - Upper Hazeltine	Silt, with some fine and coarse sand, trace gravel
SS16-BKG-03	0.1 – 0.3 0.4 – 0.6 0.7 – 0.9	3	4 - Upper Hazeltine	Silt, with trace sand, trace gravel
SS16-BKG-04	0.1 – 0.3 0.4 – 0.6 0.75 – 0.95	3	6 – Lower Hazeltine	Silt, with some fine sand
Soil/Tissue Sampling Locations	0.05 – 0.2	26	4 - Upper Hazeltine 6 – Lower Hazeltine	Organic silt with variable amounts of sand, clay and gravel

Analytical results are shown in Table A, at the end of this report. Results indicate that concentrations of background samples collected during the 2016 sampling programs were below applicable CSR standards.

The results from the 2016 sampling program were combined with 56 samples collected previously and reported in the 2016 DSI.

3.2.1 QA/QC Results

The results of soil QA/QC analyses are shown on Table D, at the end of this report. Two soil duplicates were collected as part of the 2016 background soil sampling event, and three soil duplicates were collected as part of the terrestrial plant and invertebrate soil sampling program. The resulting field duplicate frequency of approximately 11% meets Golder's internal data quality objective (DQO) of 10% for the 2016 sampling program.

Relative percent differences (RPDs) and difference factors (DFs) were within acceptable limits as set out in Attachment 2, except for the following;

- Cobalt at 38.78% RPD (10.6 µg/g in the primary sample and 15.7 µg/g in the duplicate) in SS16-BKG-02A.
- Strontium at 54.7% RPD (44.1 µg/g in the primary sample and 77.3 µg/g in the duplicate) in SS16-BKG-02A.
- Antimony at 2.5 DF (0.51 µg/g in the primary sample and 0.26 µg/g in the duplicate) in CSS16-BKG-13.

As a conservative measure, the lower concentration of strontium in the primary sample was included in consideration of the 95th percentile value. In addition, the primary result is within the range of other background sample results for strontium in mineral soil, while the duplicate result is above the range for mineral soil. The lower concentration of cobalt in the primary sample was also included in consideration of the 95th percentile value.

Similarly, the lower antimony concentration was included in the calculation of the 95th percentile value.

Laboratory QA/QC indicated that the following results did not meet the laboratory DQO:

- Method blank results for copper, lead and manganese for select sample batches; however, the associated sample results were at least five times greater than the blank levels and are considered reliable.
- Laboratory duplicate RPD was slightly above the acceptable limit for chromium, lithium and titanium in some samples, due to sample heterogeneity.
- Detection limits were raised in some samples due to high concentrations, high moisture content, matrix interference, or limited sample amount.

Although some DQO outliers exist, the data from the 2016 sampling events are considered reliable for interpretation purposes.

4.0 STATISTICAL ANALYSIS OF BACKGROUND SOIL DATA

Results for background soil samples obtained in 2014, 2015 and 2016 are shown in Table A, at the end of this report.

Upper 95th percentile values of the results were calculated using Microsoft Excel. Prior to calculating the 95th percentile values for metals, Golder calculated the upper and lower cut-off values, as outlined in TG16, for each metal parameter. Detailed results are shown in Tables B and C (organic and mineral soils, respectively), at the end of this report.

As discussed in Section 2.1.1, ten mineral soil samples were submitted for re-analyses for boron using the specified HWS method. Six organic soil samples and ten mineral soil samples were analysed for sulfur by SNC in 2014.

We consider the number of soil samples analyzed for sulfur and boron (HWS) to be insufficient for statistical estimation of the local background concentrations. Instead, the maximum concentration was used. TG16 suggests that the statistical calculations should be based on a dataset of a minimum of 12 local background samples.

UC and LC values were calculated based on the entire data set. As stated in TG16, analytical results falling outside the UC or LC values may be considered as outliers. The analytical results falling outside the UC values are highlighted in bold italic font in Tables B and C at the end of this report. These results were checked for data quality and determined to be valid results and representative of the soil quality. The samples were therefore not re-analyzed. The number of values used for the calculation of each 95th percentile is shown for reference in Tables B and C.

The following results were found to exceed the UC and therefore excluded from the calculation of the 95th percentile background concentrations. No results were below the LC.

Table 4: Summary of Excluded Values Based on UC Values

Parameter	Excluded Sample Concentrations	
	Mineral Soil	**Organic Soil**
Arsenic	ST01-01	ST12-01A2, ST13-01, WILLOW SOIL-4
Antimony	SS16-BKG-03B	ST12-01A2, ST13-01,
Barium	P1 – B Layer	ST12-01A, ST12-01A2, ST13-01,
Beryllium	P1 – B Layer	ST12-01A2, ST13-01, CSS16-BKG-15
Cadmium	-	ST12-01A,
Chromium	-	ST12-01A2, ST13-01, ST16-01A
Cobalt	-	ST12-01A2, ST13-01, P9- A Layer
Copper	SS16-BKG-02C, SS16-BKG-03C,	ST12-01A2, ST13-01, CSS16-BKG-18
Lead	SS16-BKG-03A, SS16-BKG-03B	ST12-01A2, ST13-01, ST16-01A
Lithium	ST07-01, SS16-BKG-03A, SS16-BKG-03B	ST13-01, ST16-01A
Manganese	-	ST12-01A, ST12-01A2,
Mercury	-	P1-Spruce-AH Layer
Molybdenum	ST14-01, SS16-BKG-03A, SS16-BKG-03B	ST12-01A, ST12-01A2, CSS16-BKG-06
Nickel	SS16-BKG-03C	ST12-01A2, ST13-01, ST16-01A, CSS16-BKG-15
Selenium	-	ST12-01A, ST12-01A2, CSS16-BKG-15, CSS16-BKG-18, CSS16-BKG-19, CSS16-BKG-20
Silver	SS16-BKG-03B, SS16-BKG-04A, P1 – B Layer, P9 – B Layer	-
Strontium	-	WILLOW SOIL-9, CSS16-BKG-19, CSS16-BKG-20
Thallium	SS16-BKG-03B, SS16-BKG-03C, P1 – B Layer,	ST12-01A2, ST13-01, ST16-01A, WILLOW SOIL-4
Uranium	SS16-BKG-03A, SS16-BKG-03B	ST12-01A, ST12-01A2, ST13-01, CSS16-BKG-14, CSS16-BKG-15, CSS16-BKG-18, CSS16-BKG-19, CSS16-BKG-20
Vanadium	-	ST12-01A2, ST13-01, WILLOW SOIL-10
Zinc	ST01-01, ST17-01, P1 – B Layer,	-

The exclusion of the data points above the UC is conservative. Excluding the concentrations that were above the UC leads to lower estimated local background concentrations than would be the case had the data been included in the calculations.

The 95th percentile for each parameter in organic and mineral soils is shown in Table 5 below.

Table 5: Summary of 95th Percentile Values (ug/g)

Parameter	Organic Soil		Mineral Soil	
	Number of samples (n)	95th Percentile	Number of samples (n)	95th Percentile
Antimony	52	9.2	34	9.5
Arsenic	52	0.48	34	0.43
Barium	52	252	34	132
Beryllium	52	1.1	34	0.6
Boron (HWS)	0	-	10	0.15[1]
Cadmium	51	1	34	0.3
Chromium	52	57	34	58
Cobalt	52	19	34	17
Copper	52	79	34	39
Lead	52	12.2	34	10.3
Lithium	43	28.63	28	23.56
Manganese	43	1252	28	899
Mercury	42	0.2	34	0.05
Molybdenum	52	1.4	34	0.72
Nickel	52	49.5	34	36.3
Selenium	52	0.5	34	0.2
Silver	52	0.94	34	0.14
Strontium	42	137	28	66.4
Sulfur	6	900[1]	10	600[1]
Thallium	52	0.20	34	0.09
Tin	52	2	34	2
Uranium	52	1.3	34	0.7
Vanadium	52	83.0	34	88.1
Zinc	52	144	34	75

1) Maximum concentration

5.0 CONCLUSIONS – LOCAL BACKGROUND CONCENTRATIONS

The local background concentrations were determined by using a combined dataset from the site investigations and terrestrial plant and invertebrate soil sampling programs undertaken over the last three years. Local background concentrations were determined for metals parameters with regulated standards under the CSR.

The applicable CSR standards at the Site are for Parkland (PL) and Agricultural Land use (AL). The calculated local background soil concentrations are compared with the most conservative applicable CSR standard in Table 6 below.

Table 6: Estimated Local Background Concentrations (ug/g)

Parameter	95th Percentile – Organic Soil	95th Percentile – Mineral Soil	Most Conservative Applicable CSR Standard
Antimony	9.2	9.5	20 (AL and PL -G)
Arsenic	0.48	0.43	15 (AL – DW/LW and PL - DW)
Barium	252	132	400 (AL– DW/LW and PL- DW)
Beryllium	1.1	0.6	4 (AL and PL – G)
Boron (HWS)	-	0.15[2]	2 (AL – G)
Cadmium	1	0.3	1.5 (AL – DW/I)
Chromium[1]	57	58	150 (Regional background)
Cobalt	19	17	40 (AL-G)
Copper	79	39	90 (AL and PL – GWtoFSW)
Lead	12.2	10.3	100 (PL – DW/I)
Lithium	28.63	23.56	1600 (AL and PL – G)
Manganese	1252	899	1800 (AL and PL – G)
Mercury	0.2	0.1	0.6 (AL – LI)
Molybdenum	1.4	0.7	5 (AL –G)
Nickel[1]	49.5	36.3	150 (Regional background)
Selenium[1]	0.5	0.2	4 (Regional background)
Silver	0.94	0.14	20 (AL and PL –G)
Strontium	137	66	47,000 (AL and PL – G)
Sulfur	900[2]	600[2]	500 (AL – G)
Thallium	0.20	0.09	2 (AL –G)
Tin	2	2	5 (AL – G)
Uranium	1.3	0.7	16 (AL and PL – G)
Vanadium	83.0	88.1	200 (G)
Zinc	144	75	150 (AL – GWtoFSW/LI/DW/I and PL - GWtoFSW)

Notes:

1. The CSR standard has been substituted with the regional background concentration as the CSR standard is below regional background.
2. Maximum concentration.

AL – Agricultural Land use

PL – Park Landuse

LW – livestock Watering Protection Standard

DW – Drinking Water Protection Standard

GWtoFSW Protection of groundwater flow to freshwater aquatic life. Standard is pH dependant

G – Generic Standard

I – Intake of contaminated Soil Standard

LI – Livestock Ingestion Standard

NC = Not Calculated

6.0 CLOSURE

We trust that the contents of this technical memorandum are sufficient for your current review purposes. Should you have any questions regarding this memorandum, please do not hesitate to contact the undersigned at 604-296-4200.

Golder. 2016. Work Plan for Determination of Local Background Concentrations for Environmental Media, Mount Polley Mine, BC, dated July. Vancouver BC: Golder.

Golder. 2016. Mount Polley Rehabilitation and Remediation Strategy: Detailed Site Investigation Mount Polley Tailings Dam Failure, Mount Polley, BC, dated January. Vancouver BC: Golder.

SNC (SNC-Lavalin). 2015. Mount Polley Tailings Dam Failure – Soil Quality Impact Assessment. 3 June 2015. Prepared for Mount Polley Mining Corporation. Appendix D of the Post-Event Environment Impact Assessment (MPMC 2015).

STUDY LIMITATIONS

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practising under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. No warranty, express or implied, is made.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, has been prepared by Golder for the sole benefit of Mount Polley Mining Corporation. It represents Golder's professional judgement based on the knowledge and information available at the time of completion. Golder is not responsible for any unauthorized use or modification of this document. All third parties relying on this document do so at their own risk.

The factual data, interpretations, suggestions, recommendations and opinions expressed in this document pertain to the specific project, site conditions, design objective, development and purpose described to Golder by Mount Polley Mining Corporation, and are not applicable to any other project or site location. In order to properly understand the factual data, interpretations, suggestions, recommendations and opinions expressed in this document, reference must be made to the entire document.

This document, including all text, data, tables, plans, figures, drawings and other documents contained herein, as well as all electronic media prepared by Golder are considered its professional work product and shall remain the copyright property of Golder. Mount Polley Mining Corporation may make copies of the document in such quantities as are reasonably necessary for those parties conducting business specifically related to the subject of this document or in support of or in response to regulatory inquiries and proceedings. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely solely on the electronic media versions of this document.

Notes:

MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation

m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; ug/g = milligram per kilogram; < = below detection limit; '-' = no data
a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent

underline	exceeds BC CSR DW guideline
double underline	exceeds BC CSR ICS guideline
(round brackets)	exceeds BC CSR TSIP guideline
[square brackets]	exceeds BC CSR GWtoFSW guideline
{braces brackets}	exceeds BC CSR Generic guideline

Notes:

MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation

m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; ug/g = milligram per kilogram; < = below detection limit; '-' = no data
a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent

underline	exceeds BC CSR DW guideline
double underline	exceeds BC CSR ICS guideline
(round brackets)	exceeds BC CSR TSIP guideline
[square brackets]	exceeds BC CSR GWtoFSW guideline
{braces brackets}	exceeds BC CSR Generic guideline

Table A - Results of Soil Analyses (Local Background)
MPMC - Background Determination of Soil
Mount Polley Mine, BC

Notes:

MPMC = Mount Polley Mining Corporation; BC CSR = British Columbia Contaminated Sites Regulation

m bgs = metres below ground surface; QA/QC = Quality Assurance / Quality Check; FDA = Field Duplicate Available; DUP = Duplicate
mV = millivolt; mm = millimetre; ug/g = milligram per kilogram; < = below detection limit; '-' = no data
a. Guidelines for groundwater used for drinking water (residential and urban park areas)
b. Guidelines for intake of contaminated soil (residential and urban park areas)
c. Guidelines for toxicity to soil invertebrates and plants (residential and urban park areas)
d. Guidelines for groundwater flow to surface water used by aquatic life (residential and urban park areas)
e. Generic guidelines from Schedule 4
f. Generic guidelines from Schedule 10
g. Guideline is pH dependent

underline	exceeds BC CSR DW guideline
double underline	exceeds BC CSR ICS guideline
(round brackets)	exceeds BC CSR TSIP guideline
[square brackets]	exceeds BC CSR GWtoFSW guideline
{braces brackets}	exceeds BC CSR Generic guideline

Notes:

All results shown in ug/g, unless otherwise noted.

Bold, italics indicates samples that exceeded the UC values and were excluded from calculation of the 95th percentile.

Blue font indicates that a result was below detection limit, and that the detection limit was used for the purpose of calculating statistics.

* Where the LC was calculated to be a negative number, the result is displayed as 0* in the table. Negative LCs are not statistically valid, but rather indicate that there is are no lower outliers in that specific dataset.

** Duplicate Concentration - see Section 3.2.1 in the report for details.

95th percentile value was not calculated due to insufficient sample size (n<12) for sulfur. The maximum concentration is presented in absence of a 95th percentile value

n<12 use Maximum: 0.15

n<12 use Maximum : 600

Notes:

All results shown in ug/g, unless otherwise noted.

Bold, italics indicates samples that exceeded the UC values and were excluded from calculation of the 95th percentile.

Blue font indicates that a result was below detection limit, and that the detection limit was used for the purpose of calculating statistics.

* Where the LC was calculated to be a negative number, the result is displayed as 0* in the table. Negative LCs are not statistically valid, but rather indicate that there is are no lower outliers in that specific dataset.

** Duplicate sample result used in absence of primary sample result

95th percentile value was not calculated due to insufficient sample size (n<12) for HWS boron and sulfur. The maximum concentration is presented in absence of a 95th percentile value

Notes:

All parameter units in milligrams per kilogram (mg/kg), unless otherwise noted.

FDA = Field Duplicate Available; FD = Field Duplicate; QA/QC = Quality Assurance/Quality Control

NA = Not Applicable; NC = Not Calculated; Mean = average of two values

"-" = no data; m bgs = metres below ground surface; mV = millivolt

Relative percent difference (RPD) = the difference between two values divided by the mean of the two values. **Golders' acceptable RPD is less than or equal to 35%.**

RPD is calculated when the concentration is greater than five times the detection limit.

Difference factor (DF) = absolute difference between two values divided by the method detection limit. **Golders' acceptable DF is less than or equal to 2.0.**

DF is calculated when the concentration is less than five times the detection limit.

Notes:

All parameter units in milligrams per kilogram (mg/kg), unless othen

FDA = Field Duplicate Available; FD = Field Duplicate; QA/QC = Qu

NA = Not Applicable; NC = Not Calculated; Mean = average of two v

"-" = no data; m bgs = metres below ground surface; mV = millivolt

Relative percent difference (RPD) = the difference between two valu

RPD is calculated when the concentration is greater than five times

Difference factor (DF) = absolute difference between two values div

DF is calculated when the concentration is less than five times the d

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Titanium (Ti)	DUP-H	L1826516-18

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
DLR	Detection Limit Raised due to required dilution, limited sample amount, and/or high moisture content (soil samples)
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

IC-CACO3-CALC-SK	Soil	Inorganic Carbon as CaCO3 Equivalent	Calculation
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.

Reference:
Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

RUSH

Priority processing

please log all highlighted soils for:

- CSR + Full Metals
- TOC/TIC
- Avail N, P, K

"Group A" soils are due Sept 15 with 'P' codes

"Group B" soils are due Sept 21, no priority code

SK sublets should go out Monday.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Method Blank	Copper (Cu)	B	L1826528-10, -11, -12, -13, -4, -5, -6, -7, -8, -9
Method Blank	Lead (Pb)	B	L1826528-10, -11, -12, -13, -4, -5, -6, -7, -8, -9
Method Blank	Manganese (Mn)	B	L1826528-10, -11, -12, -13, -4, -5, -6, -7, -8, -9
Duplicate	Chromium (Cr)	DUP-H	L1826528-1, -2, -3

Qualifiers for Individual Parameters Listed:

Qualifier	Description
B	Method Blank exceeds ALS DQO. All associated sample results are at least 5 times greater than blank levels and are considered reliable.
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
B-HOTW-CL	Soil	Available Boron, Hot Water	CSSS Ch. 4/EPA 6010B

Soil samples are extracted by boiling a 2:1 mixture of 0.01 M CaCl2 to soil for 5 - 15 minutes, prior to filtration of the extract and boron determination using ICPOES (EPA Method 6010B.");

C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.

Reference:
Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA

Reference Information

CL	ALS ENVIRONMENTAL - CALGARY, ALBERTA, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

G0145

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Lithium (Li)	DUP-H,J	L1826551-21, -22, -23, -24, -25, -26, -27, -28, -29, -30, -31

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DLR	Detection Limit Raised due to required dilution, limited sample amount, and/or high moisture content (soil samples)
DUP-H,J	Duplicate results outside ALS DQO, due to sample heterogeneity. Duplicate results and limits are expressed in terms of absolute difference.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.

Reference:
Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

G0148

Reference Information

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

RUSH

Priority processing

Please log all highlighted soils for:

- CSR + Full Metals
- TOC/TIC
- Avail N, P, K

"Group A" soils are due Sept 16 with 'P' codes

"Group B" soils are due Sept 21, no priority code.

SK sublets should go out Monday.

QA/QC Methods

Quality Assurance / Quality Control Methods

To ensure that the sampling and analytical data for the 2016 background soil sampling were interpretable, meaningful and reproducible, conformance to a Golder Quality Assurance and Quality Control (QA/QC) program was followed. This involved using QA/QC measures in both the collection (field program) and analysis (laboratory program) of samples. The following discussion includes a brief summary of the QA/QC measures implemented by Golder during the field program and during our review of the data, as well as the QA/QC measures implemented by the analytical laboratory.

Quality Assurance (QA) measures used in the collection, preservation and shipment of samples included the following measures:

- Sampling methods were consistent with established Golder protocols and provincial/federal requirements;
- Field notes were recorded during all stages of the investigation;
- Sample locations were recorded by a professional land surveyor, or were measured from fixed points and marked in the field; and
- Samples were subsequently transported to the laboratory using Golder chain-of-custody procedures.

Data was verified by checking the summary tables against the original laboratory reports and sample custody forms.

The Quality Control (QC) measures established for the field program included:

- Submission of field duplicate samples. A field duplicate sample is a second sample of a certain media (e.g., soil; water) from the same location that is submitted to the analytical laboratory under a separate label.
- The relative percent difference (RPD) between field duplicate sample results was used to assess duplicate sample data. The RPD is a measure of the variability between two outcomes from the same procedure or process and is calculated by:

$$RPD(\%) = absolute\left(\frac{(x_1 - x_2)}{average(x_1, x_2)}\right) \times 100$$

  Where x_1 is the original sample result and x_2 is the blind field duplicate result. In general, the RPD should not be more than 35% on average, or a maximum of 50%, depending on the parameter and the concentration. A RPD greater than 50% may reflect “within jar” variability, which reflects the nature of the contaminant distribution, or variation in the test procedures. RPD values exceeding this data quality objective (DQO) were examined and assessed on a case-by-case basis.

Where the concentration of a given parameter is less than five times the method detection limit (MDL), the laboratory results are considered to be less precise and the RPD is not calculated. For parameters with concentrations less than five times the MDL, the difference factor (DF) between the sample and its duplicate is calculated by:

$$DF = absolute\left(\frac{(x_1 - x_2)}{MDL}\right)$$

Where x_1 is the original sample result and x_2 is the blind field duplicate result. In general, the DF should not be more than two (2).

The following DQOs were established for the laboratory program:

- The laboratory that was used must have achieved proficiency certification by the Canadian Association for Laboratory Accreditation (CALA) for the analyses conducted; and
- An internal Quality Control Report was completed and reviewed by the laboratory prior to submission to Golder. Copies of these reports are provided in Appendix L.

The following criteria were considered acceptable for laboratory QA/QC samples:

- For organic analytes, analytical duplicates should exhibit less than 50%, for a specific set;
- For inorganic elements, analytical duplicates should exhibit less than 35% in soil samples, for a specific set;
- Analytical recovery results for reference materials or spiked standards should be within laboratory-applied certified values for inorganic elements and organic compounds; and
- Analytical blanks should have concentrations below the detection limits used for the specific analysis.

Results are reported as % on a weight basis VCS = very coarse sand CS = coarse sand FS - fine sand

Reported results are of a size which is less than the designated sieve opening, but greater than the next reported results designated sieve opening.

Particle size is determined by the pipette method. Sedimentation times are determined by using the Tanner and Jackson Nomograph I Sar[illegible]dent

is determined by wet sieving. Manual of Soil Sampling and Methods of Anal[illegible] 1978. J.A. McKeague, Canadian Society of Soil Science.

APPENDIX E

SOIL DESCRIPTIONS

SOIL PIT # MP95-11
Orthic Humo-Ferric Podzol with a Mv over Rj landform sampled near the primary crusher.

Horizon	Depth	Description
LFH	10-0cm	Leaf / needle litter with a moder humus layer.
Bf	0-20	Strong brown (7.5YR4/6m); sandy loam; 30% coarse fragments (cf); abundant fine roots; moderate medium subangular blocky structure; friable and slightly sticky consistence.
BC	20-40	Brown (10YR4/3m); sandy loam; 45% cf; plentiful very fine roots; moderate-strong coarse subangular blocky structure; firm and slightly sticky consistence.
R	40-100+	

SOIL PIT # MP95-12a
Brunisolic Gray Luvisol with a Mj landform sampled near the concentrator building.

Horizon	Depth	Description
LFH	15-0	Leaf / needle litter with a moder humus layer.
Bm	0-20	Brown (10YR4/3m); sandy loam; 20% cf; abundant coarse roots; weak-moderate medium subangular blocky structure; very friable and slightly sticky consistence.
Btg	20-60	Brown (10YR5/3m); dark yellowish brown (10YR4/6m) mottles; loam; 20% cf; few fine roots; strong fine platey structure; friable and sticky consistence.
BC	60-120	Brown (10YR4/3m); loam; 20% cf; moderate coarse subangular blocky structure; firm and sticky consistence.
Ck	120-180	Brown (10YR4/3m); loam; 25% cf; moderate coarse subangular blocky structure; firm and sticky consistence.

SOIL PIT # MP95-13
Orthic Humo-Ferric Podzol with a Mv over Rj landform sampled near crusher conveyor.

Horizon	Depth	Description
LFH	20-0	Leaf / needle litter with a moder humus layer.
Bf	0-28	Strong brown (7.5YR4/6m); loamy sand; 25% cf; abundant coarse roots; weak-moderate fine subangular blocky structure; friable and slightly sticky consistence.
BC	28-58	Brown (10YR4/3m); loamy sand; 85% cf; abundant medium roots; moderate medium subangular blocky structure; friable and slightly sticky consistence.
R	58+	

SOIL PIT # MP95-14a
Brunisolic Gray Luvisol with a Mj landform sampled near the coarse ore stockpile.

Horizon	Depth	Description
LFH	35-0	Leaf / needle litter with a moder humus layer; abundant coarse roots.
Bm	0-30	Brown (10YR4/3m); loam; 25% cf; plentiful medium roots; weak-moderate fine subangular blocky structure; very friable and sticky consistence.
Btg	30-80	Brown (10YR4/3m); dark yellowish brown (10YR4/6m) mottles; loam; 25% cf; few fine roots; strong coarse subangular blocky structure; friable and sticky consistence.
C	80-105+	Dark grayish brown (10YR4/2m); loam; 30% cf; moderate-strong coarse subangular blocky structure; very friable and sticky consistence.

SOIL PIT # MP95-15
Orthic Dystric Brunisol with a Mv over Rj landform sampled near crusher conveyor.

Horizon	Depth	Description
LFH	3-0	Leaf / needle litter with a mor humus layer.
Bm	0-35	Brown (10YR4/3m); sandy loam; 55% cf; abundant fine roots; weak-moderate medium subangular blocky structure; slightly sticky consistence.
R	35+	

SOIL PIT # MP95-16a
Podzolic Gray Luvisol with a Mv over R landform sampled near the fine ore stockpile.

Horizon	Depth	Description
LFH	15-0	Leaf / needle litter with a moder humus layer.
Bf	0-20	Brown (7.5YR4/4m); sandy loam; 20% cf; abundant coarse roots; moderate medium subangular blocky structure; very friable and slightly sticky consistence.
Btg	20-45	Brown (10YR4/3m); dark yellowish brown (10YR4/6m) mottles; loam; 20% cf; plentiful fine roots;moderate-strong coarse subangular blocky structure; firm and sticky consistence.
BC	45-110	Brown (10YR4/3m); loam; 45% cf; weak-moderate fine subangular blocky structure; friable and sticky consistence.
R	110+	

SOIL PIT # MP95-17
Typic Mesisol with a Ob over LG landform sampled at the concentrator building.

Horizon	Depth	Description
Om	0-200	Black (10YR2/1m); mesic; abundant coarse roots.
Cg	200+	Dark greenish gray (5GY4/1m); clay loam; 10% cf; moderate-strong massive structure; sticky consistence.

SOIL PIT # MP95-19
Brunisolic Gray Luvisol with a Ov over M landform sampled near the concentrator building.

Horizon	Depth	Description
Of/LFH	40-0	Black (10YR2/1m); fibric; leaf / needle litter with a organic/moder humus layer; abundant coarse roots.
Ah	0-15	Loam; 20% cf; abundant coarse roots.
Bm	15-30	Loam; 20% cf; plentiful fine roots.
Bt	30-60	Loam; 30% cf; few fine roots.
BC	60-90	Loam; 35% cf.
C	90-130	Loam; 35% cf. 15-0 Leaf / needle litter with a moder humus layer.
Bm	0-20	Brown (10YR4/3m); sandy loam; 20% cf; abundant coarse [s]
Om	0-20_	
Cg	200+	Dark greenish gray (5GY4/1m); clay loam; 10% cf;

moderates
Brunisolic Gray Luvisol with a Ov over M landform sampled_

Horizon	Depth	Description

Executive Summary

A geochemical characterization program was developed and carried out by SRK Consulting (Canada) Inc. on spilled tailings from the Mount Polley Mine (MPM) Tailings Storage Facility (TSF) embankment breach that occurred on August 4, 2014, approximately 55 km north-east of Williams Lake, BC. Results were provided in SRK (2015a, 2015b), including initial results from laboratory kinetic testing (humidity cells and columns). This report provides an update to the on-going kinetic testing program.

Copper and selenium were the main focus of continued investigations as they were identified to be enriched in the initial study of tailings geochemical characteristics and possibly have potential for leaching. However, all parameters with guidelines for the protection of freshwater aquatic life in British Columbia are being monitored.

Kinetic testing results have been reported for up to 90 weeks as of the date of this report. Results support the assessment that ARD is not expected from the tailings and leaching will be under neutral to alkaline conditions. Leaching rates are now either stable or slowing declining, which is expected to continue as the testing progresses. Variability in leaching rates has also been established and the necessary components for providing contact water chemistry predictions (i.e. geochemical source terms) are now available.

One of the considerations for water chemistry prediction will be flow paths as copper and selenium leaching rate differences were noted between the humidity cells and columns. Mineral solubility limits for tenorite (copper oxide), and malachite (copper carbonate) were reached in the columns but not in the humidity cells, with the formation of secondary copper minerals expected to limit concentrations of copper. Selenium does not have a known mineral solubility control under fully oxygenated conditions, but the longer water flow paths in fine grained materials may also be conducive to lower rates of oxygen diffusion and, therefore, conducive to conditions that support selenium reduction to more insoluble forms such as selenite and elemental selenium.

Kinetic testing is on-going, although the objectives of the kinetic testing program have been met and the program could be decommissioned.

1 Introduction

SRK was retained by the Mount Polley Mining Corporation (MPMC) to develop and execute a plan to geochemically characterize tailings materials that were released as a result of the TSF embankment breach on August 4, 2014 from the Mount Polley Mine (MPM), located approximately 55 km north-east of Williams Lake, BC. The plan included a review of existing operational data, development of a geochemical conceptual model to guide sampling design, and a sampling and analysis plan.

The majority of geochemical characterization work has been completed with interpretation of results previously reported by SRK (2015a, 2015b). The work presented in this report is from laboratory kinetic testing including humidity cells and water unsaturated columns. The objective of the kinetic testing program is to establish stable solute release rates to be used as one of the inputs to predicting water quality impacts from mine waste.

This report is a supporting document to the work completed to date and provides updates to the conclusions provided in the SRK (2015a, 2015b) reports on the metal leaching and acid rock drainage (MLARD) potential of exposed tailings along Hazeltine Creek.

2 Background

Geochemical characterization, including acid-base accounting (ABA) tests, trace element analyses, mineralogical analyses, sequential extractions, humidity cell tests and column tests were undertaken on representative samples of tailings that spilled into Hazeltine Creek, and Quesnel and Polley Lakes from the MPM. The characterization approach was based on SRK's sampling plan (SRK 2014) and the geochemical conceptual models presented along with complete details on the sampling and analytical methods used, field observations and analytical results are provided in SRK (2015a, 2015b). For ease of reference, relevant sections have been reproduced in this report.

Two types of tailings-bearing materials were observed along Hazeltine Creek. They were classified in the field as 'grey tailings' and 'magnetite sands'. Grey tailings were dominantly grey in colour and had a finer texture (silty sand) than the magnetite sands. Magnetite sands were speckled pinkish-orange and black. They were strongly magnetic and sandier than the grey tailings. The grey tailings tended to be most abundant along the embankments and upper benches of the creek, whereas the magnetite sands were commonly present in low-lying areas near the creek. With the exception of the area near the TSF embankment breach and Polley Lake, the tailings were deposited in relatively thin 'skiffs' (e.g. less than 10 and up to 20 cm deep). The thickest observed tailings deposits (e.g. around 1 metre deep) were in the immediate vicinity of the TSF embankment breach and Polley Lake (SRK 2015a).

The main geochemical finding was that the MPM tailings are not potentially ARD generating, which is consistent with historical understanding of the tailings and the low sulphur nature of the ore deposit. Any leaching would be expected to occur under neutral to basic pH conditions only, which tends to support low mineral and element specific solubility. The only elements that were

noted to be enriched when compared to typical crustal rocks (basalt) were copper and selenium. Both of these elements were expected to be associated with sulphide minerals and require oxidation to be leached. The potential for reductive dissolution processes to leach elements from natural oxidation components of the spilled tailings that settled in Quesnel and Polley Lakes was assessed and found to be low.

A significant portion of the copper (up to 66%) was found to be associated with the non-sulphide portion of the tailings. As extremely acidic conditions are required to leach this form of copper, it is considered to be non-reactive in the Hazeltine Creek environment because pH conditions are neutral and there is a low risk of acid rock drainage potential from the tailings.

Preliminary kinetic testing results supported the assessment that ARD is not expected from the tailings and leaching will be under neutral to alkaline conditions. However, the preliminary results were from less than 40 weeks of testing (typically the minimum requirement for testing duration) and longer term testing was needed to confirm stable leaching rates for use in long term assessment of water quality expected from leaching of the tailings exposed to the atmosphere.

3 Methods

3.1 General

The kinetic testing program consists of six standard laboratory humidity cells (HCs), three column leach tests, two blanks (a HC and a column), and one HC duplicate (Table 3-1). Samples were selected to represent the median and upper range of geochemical variability identified during the initial characterization work.

The intent of the program is to establish stable solute release rates under atmospheric conditions using humidity cell testing and then use column tests to evaluate the effect of longer water flow paths. Longer flows paths are more likely to represent field conditions and to assess potential attenuation processes such as formation of secondary minerals and surface sorption.

Geochemical composition and mineralogy characteristics were obtained during the initial characterization work and results are summarized in Section 4.5 for ease of reference.

Table 3-1: Composite preparation requirements and sample labelling.

Kinetic Test ID	Tailings Type	Original Sample IDs (SRK 2015a)

3.2 Humidity Cells

The HCs were set up according to the methods described in the 1991 Mine Environment Neutral Drainage Program's Acid Rock Drainage Prediction Manual (MEND 1991). A photograph of the set-up is provided in Figure 3-1.

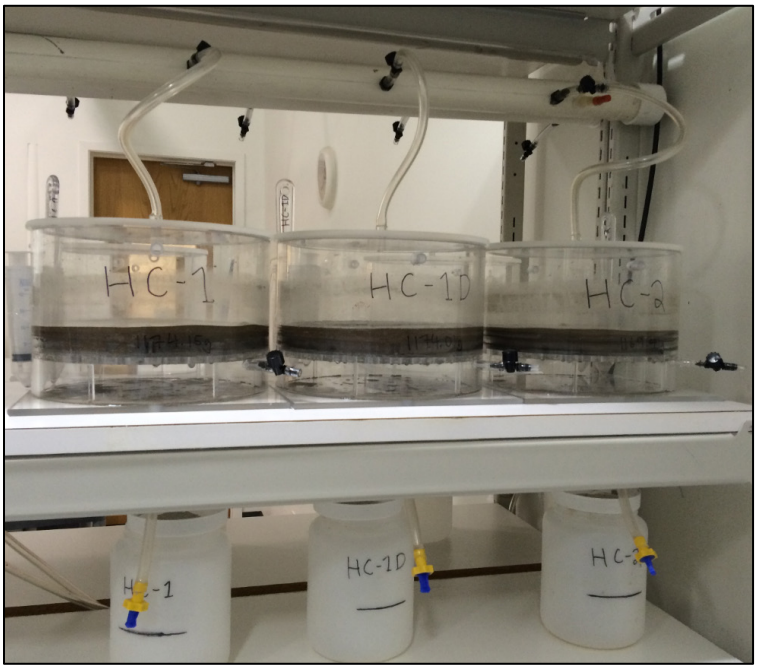

Figure 3-1: Set-up of tailings humidity cells at ALS Environmental. For scale, the diameter of the clear plastic cells is 20 cm.

The two major sample mixture/tailings types identified in the field, (1) magnetite sands tailings and (2) grey tailings, were both tested. The duplicate cell (HC-1D) is a split from HC-1. The blank cell (HC-7) was constructed using the exact same material and adhesives as the other cells and is operating according to the same procedures.

Weekly analyses of leachate included volume recovered, pH, and conductivity.

The following parameters were measured weekly for the first four weeks and then every two weeks thereafter:

- Acidity, alkalinity
- Oxidation-reduction potential (ORP)
- Sulphate
- Nitrate, nitrite, ammonia
- Bromide, chloride, fluoride
- Orthophosphate, total phosphorus

- 35 element scan by ICP-MS
- Low level mercury

The tests were initiated on March 6, 2015. Four of the six HCs and the duplicate were closed on May 27, 2016 after 64 weeks of leaching (Table 3-2). The remaining two HCs are ongoing and have been leached for 90 weeks as of November 25, 2016.

Table 3-2: Humidity cell test status

Humidity Cell	Tailings Type	Last Data	Status	Leach Weeks
HC-1	Magnetite Sand	27-May-2016	Closed	64
HC-1D	Magnetite Sand	27-May-2016	Closed	64
HC-2	Magnetite Sand	27-May-2016	Closed	64
HC-3	Grey Tailings	25-Nov-2016	Ongoing	90
HC-4	Grey Tailings	25-Nov-2016	Ongoing	90
HC-5	Magnetite Sand	27-May-2016	Closed	64
HC-6	Grey Tailings	27-May-2016	Closed	64

Source: \\VAN-SVR0\Projects\01_SITES\Mt_Polley\1CI008.003_Privileged_and_Confidential\410_Kinetic_Tests\Calculations+Charts\HCTs\[Mt. Polley_HCT_Outcomes _1CI008-003_rtc_rev00.xlsx]

3.3 Columns

The column tests, including the blank, were constructed from plexiglass (acrylic) with an 8.2 cm inner diameter and a perforated base supporting two layers of nylon screen (400 mesh). The columns were filled as follows:

- Column 1 (magnetite sand): 4.3 kg (dry weight) to a height of 45 cm
- Column 2 (magnetite sand): 4.5 kg (dry weight) to a height of 36 cm
- Column 3 (grey tailings): 1.5 kg (dry weight) to a height of 16 cm

ALS Environmental confirmed that heavier Column 2 had a lower height than Column 1, which is attributed to greater compaction compared to the other columns.

Each of the samples is being trickle leached. Columns 1 and 2 have about 90 mL added daily until 500 mL has been added in a work week (5 days). For Column 3, only 30 mL of water can be added in a day to avoid pooling on the surface and, as a result, only 150 mL is added in a week. Collection of leachate from the magnetite sands is performed weekly, whereas collection of leachate from the grey tailings column requires up to three weeks due to the fine grained nature of these materials resulting in slow infiltration rates. Laboratory analysis of leachate includes the same parameters as the humidity cells (Section 3.2). A photograph of the set-up is provided in Figure 3-2.

The tests were initiated on April 21, 2015. The magnetite sands samples have been leached for 83 weeks as of November 23, 2016, and the grey tailings for 77 weeks as of November 2, 2016.

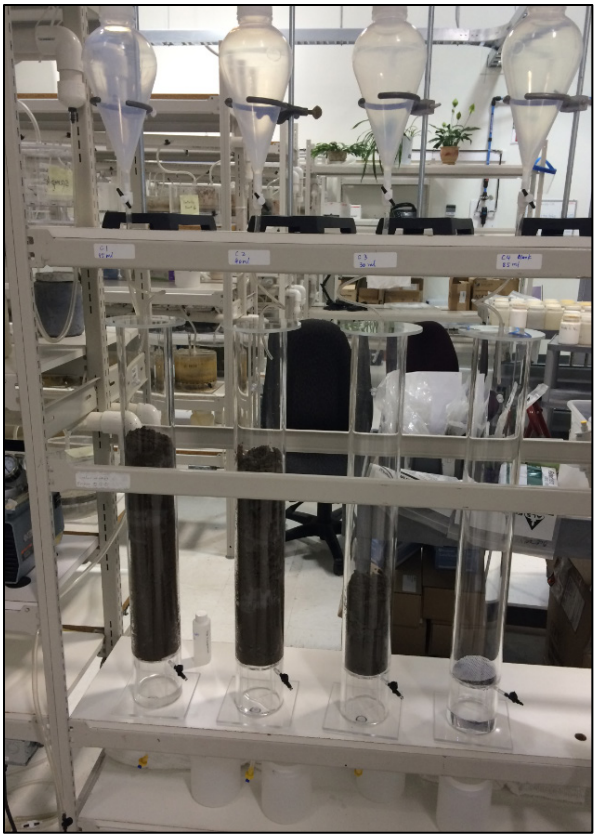

Figure 3-2: Column set-up at ALS Environmental. For scale, the diameter of the columns is 8 cm and the height of materials in column 1 (far left) is 45 cm.

4 Results

4.1 Quality Assurance and Quality Control

Various quality control and quality assurance (QA/QC) measures were included in the program. Duplicate comparisons were done for the non-sulphide copper analysis and kinetic tests. For the kinetic tests only, ion balance calculations and blank sample analysis were also done. Results were as follows:

- Duplicates – samples were assessed with a relative percent difference (RPD) target of 25% (set by SRK) when results were greater than ten times the limit of detection. RPD was calculated using the equation below, where 'x' is the concentration of the original sample and 'y' is the concentration from the duplicate sample:

$$\text{RPD}\,(\%) = \frac{x - y}{(x + y)/2} \times 100$$

- The RPD criterion does not apply at concentrations near the LOD because RPD is expected to frequently be greater than 25% due to reduced analytical accuracy at very low concentrations. This applied to silver and boron. All other parameters with guidelines for the

protection of freshwater aquatic life in British Columbia (BC FAL guidelines) were within the criterion.

- Ion balance – samples were assessed with an RPD target of ±15% (set by SRK) when major anions and cations were greater than ten times analytical detection limits. For all sampling dates the ion balance was within ±15%.
- Blanks – samples were assessed with a target of ten times the detection limit (set by SRK). None of the samples exceeded this criterion.

SRK's overall conclusion is that data quality is acceptable.

4.2 Solid Phase Composition

Geochemical properties and mineralogy of the kinetic test samples were provided in SRK (2015a), but for ease of reference key properties are provided in Table 4-1 and complete results are provided in Appendix A

Table 4-1: Geochemical properties of kinetic tests.

Kinetic Test	Tailings Type	TIC kg $CaCO_3$/t	Total S %	SO_4 %	AP kg $CaCO_3$/t	TIC/AP ratio	Cu mg/kg	Se mg/kg
HC-1/COL-1	Magnetite Sand	25	0.26	<0.01	8.4	3.0	1200	1.5
HC-1D	Magnetite Sand	-	0.27	<0.01	8.4	-	1200	1.7
HC-2/COL-2	Magnetite Sand	18	0.16	<0.01	4.7	3.8	950	1.3

Source:Z:\01_SITES\Mt_Polley\1CI008.003_Privileged_and_Confidential\500_Reporting\5.Kinetic+CuOxide_UpdateReport\Tables\[Kt+Cu_Memo_tables_1CI008.003_REV00_CBK.xlsx]

Sample mineralogy by QEMSCAN was dominated by silicates (88 to 95%) including feldspars, chlorite, and quartz, with lesser iron oxides (2.8 to 7.0%), calcite (0.72 to 4.5%), pyrite and chalcopyrite (0.10 to 0.63%) (Appendix A). Malachite was detected in four of the six samples at less than 0.1%. Magnetite was indistinguishable from other iron oxides analyzed by QEMSCAN but was found to account for approximately 75% of the iron oxide detected in the magnetite sands sample, HC-1/COL-1, by X-ray diffraction (SRK 2015a).

Copper, selenium, and sulphur concentrations for kinetic test samples and the entire dataset are compared in Figure 4-1 and Figure 4-2.

Figure 4-2: Solid phase selenium and sulphur concentrations in kinetic test selections compared to existing dataset.

4.3 Humidity Cells

Four of the six tests were placed into storage (sealed containers purged with nitrogen gas) in May 2016 after 64 weeks of leaching. The remaining two tests, HC-3 and HC-4 (grey tailings), were continued and have reached 90 weeks of leaching as of November 2016. Concentration charts of humidity cells results for all parameters that have BC FAL guidelines are provided in Appendix B and average element release rates are provided in Appendix C. Charts for pH and sulphate are provided in Figure 4-3 for ease of reference as these parameters are used to understand oxidation and leaching rates. Copper and selenium charts are also provided in Figure 4-3 as these are the two main elements noted to be of leaching concern by SRK (2015a).

Humidity cell results for all parameters except pH are presented as release rates in units of mg/kg/week. The laboratory data provides results as concentrations (i.e. mg/L), but given the known weight of each sample and a measured volume of water leached through the cells on a weekly basis, concentrations are converted to release rates.

Leachates from all humidity cell tests were alkaline and never fell below pH 7 (i.e. leachate was never acidic) with major ion chemistries dominated by calcium and bicarbonate alkalinity. Sulphate release rates were initially elevated in all tests in the first few weeks of testing, which is typical of these tests reflecting flushing of solutes that accumulated prior to testing. The initial flushing of sulphate dominated release rates between weeks 0 and 35 in the grey tailings, and weeks 0 and 15 in the magnetite sands. After this, sulphate release rates showed some variability (for example, sulphate release in HC-5 ranged from 5.3 to 13 mg/kg/week), but overall, the rates did not show a continued increasing or decreasing trend. On this basis, sulphate release rates are interpreted to have stabilized from week 35 onwards in the grey tailings, and from week 15 onwards in the magnetite sands.

Average sulphate and trace element release rates were calculated for the period of stability as defined above (Table 4-2). Average sulphate release rates were similar between the magnetite sands and grey tailings, and ranged from 3.7 mg/kg/week in HC-1 to 10 mg/kg/week in HC-5. For the trace elements, all tests except HC-4 generally leached at similar rates with average rates for copper ranging from 0.0014 to 0.0025 mg/kg/week, and 0.0011 to 0.0017 mg/kg/week for selenium.

HC-4 leached copper at the highest rate, and leached selenium at the lowest rate, compared to other samples. This is not consistent with the solid phase content of copper (Figure 4-4) or with the significant correlation previously established by SRK (2015a) between copper and selenium in the tailings. Nitrate release rates were also elevated for HC-4. Further investigation has found that the elevated copper concentrations were likely complexed with dissolved organic carbon (DOC), which was leaching at higher rates than the other tests (Figure 4-5) (SRK 2016). A small plant was observed growing from the base of HC-4 (Figure 4-6). The plant growth and elevated DOC and nitrate in HC-4 are consistent with the presence of organic material intermixed with the tailings.

An investigation performed by SRK and Minnow Environmental showed that high levels of DOC (typically over 30 mg/L) were complexing copper (SRK 2016), with the impact of complexation

having two effects: 1) to increase the apparent solubility of copper bound in mineral phases; and 2) to decrease the bioavailability and toxicity of dissolved copper (Stumm and Morgan 1996; Grosell 2012). As part of the evaluation by SRK and Minnow, HC4 was also assessed and found to be consistent with other samples containing elevated DOC. The resulting free or ionic copper was 90% lower and consistent with all other humidity cell results.

Other elements subject to BC FAL guidelines show either steady or slowly decreasing trends (Appendix B).

4.4 Columns

The columns containing magnetite sands (COL-1 and COL-2) have been leached for 83 weeks as of November 23, 2016, and the column containing grey tailings (COL-3) for 77 weeks as of November 2, 2016. Concentration charts for columns for all parameters with BC FAL guidelines are provided in Appendix D and average release rates are provided in Appendix C. When comparing concentration results to BC FAL guidelines it is important to note that porewater chemistry from the tests is not representative of the receiving environment. Results for pH, sulphate, copper, and selenium are provided in Figure 4-7, for the same reason as the humidity cell tests (Section 4.3).

Column leachates were alkaline (pH 7.8 to 8.2). Major ion chemistries were dominated by calcium and bicarbonate alkalinity in the magnetite sands columns (COL-1 and -2), and calcium and sulphate in the grey tailings column (COL-3). Similar to the humidity cells, sulphate release rates were initially elevated in all tests in the first few weeks of testing due to the initial flush of solutes that accumulated prior to testing. Sulphate release rates from COL-1 and COL-3 are still slowly decreasing. Sulphate release rates from COL-2 show no increasing or decreasing trend, and appear to have stabilized after week 25.

Average sulphate and trace element release rates were calculated for the period of stability as defined in Table 4-4. Average sulphate release rates were highest from the grey tailings (COL-3). This sample contained less sulphur than the grey tailings in COL-1 and had the same sulphur content as the magnetite tailings in COL-2. The difference in sulphate release rates is likely attributable to the smaller particle size of the grey tailings relative to the magnetite tailings, and consequently its larger particle surface area per unit of mass.

Copper and selenium release rates were consistent with the solid phase content (Table 4-1). Average copper release rates were highest from the magnetite tailings in COL-1. Selenium release rates were similar between all three columns.

Other elements subject to BC FAL guidelines show either steady or slowly decreasing trends (Appendix D).

4.5 Kinetic Test Comparison

Comparison of humidity cells and columns data for pH, sulphate, copper, and selenium provides the basis to understand how the different test configurations impact leaching rates in order to better predict how tailings materials in the field might react and impact water chemistry. The main difference between the columns and the humidity cells is that in the columns, water is trickle-fed at an average rate of 62 mL/day for the magnetite sands, and 21 mL/day in the smaller column containing the grey tailings giving pore water residence times in the order of days to weeks (Table 4-3). In contrast to the columns, 500 mL of water is added to the humidity cells once a week to flush solutes that have accumulated during the previous six days of subaerial weathering. The average pore water residence time in the humidity cell tests is less than one day.

The pH conditions were essentially the same for both tests at around pH 8.1 (Table 4-5). Relative to their humidity cell pair, the columns showed:

- Lower sulphate release rates for samples 1 and 2 (magnetite sands).
- Higher sulphate release rate for sample 3 (grey tailings).
- Lower copper and selenium release rates for all three samples.

Sulphate and trace element release rates from the columns are expected to be lower than their humidity cell pair due to oxygen diffusion limitations and secondary mineral solubility constraints in the columns. The higher sulphate release rate from the grey tailings column relative to its humidity cell test was unexpected, although the difference was minor (24% RPD) and may simply reflect measurement variability between the methods.

Table 4-5: Comparison of humidity cell and column average solute release rates.

Tailings Type	Test	pH avg	SO_4 mg/kg/wk	Cu mg/kg/wk	Se mg/kg/wk
Magnetite Sand	HC-1	8.1	3.7	0.0018	0.0015
	COL-1	8.2	2.3	0.0012	0.0010
	RPD		-48%	-43%	-44%
Magnetite Sand	HC-2	8.1	7.5	0.0019	0.0017
	COL-2	8.1	1.3	0.00066	0.00029
	RPD		-139%	-95%	-143%
Grey Tailings	HC-3	8.1	5.9	0.0014	0.0015
	COL-3	8.0	7.5	0.00043	0.00077
	RPD		24%	-105%	-61%

Source:Z:\01_SITES\Mt_Polley\1CI008.003_Privileged_and_Confidential\410_Kinetic_Tests\Calculations+Charts\COLs\[Mt. Polley_Col_Outcomes _1CI008-003_rtc_rev00.xlsx]

The difference in metal release rates was also evaluated by calculating mineral saturation indices (SI) for malachite ($Cu_2CO_3(OH)_2$) and tenorite (CuO) using the equilibrium modelling software package PHREEQC (version 3.0.6) (Parkhurst and Appelo 2013) and the minteq.v8 thermodynamic database. A number of secondary minerals were reviewed in the calculations but the above three were chosen as they illustrate the influence of longer flow paths and also potential controls on copper solubility (malachite and tenorite). Malachite and tenorite were also

shown to be controlling copper concentrations in seepage from sub-aerial tailings near the outlet of Polley Lake (also referred to as Polley Flats, SRK 2016). Ferrihydrite, an iron oxyhydroxide, is also likely at saturation in the tests and is an important secondary mineral for attenuating metals, but concentrations were always below detection and therefore SI calculations were not possible. In the SI calculation, the most recent chemistry from each of the tests was used, but the solutions were not equilibrated with the atmosphere in order to evaluate what was potentially controlling the copper concentration at the time of sampling.

Saturation indices showed that in addition to differences in sample oxidation rate, secondary mineral formation of copper containing minerals is likely decreasing the release rates of copper in the column tests when compared to the humidity cell tests. This is because as the mineral oxidizes and releases copper, it would precipitate as a secondary mineral and not be released from the sample. SI values were always higher in the column tests, indicating that mineral precipitation was potentially higher in the columns as compared to the humidity cells. An example of mineral saturation differences, malachite saturation in column-1 compared to humidity cell 1 (same sample material), as well as tenorite in column 1 is provided in Figure 4-8. Based on the modeling results, tenorite appears to be a likely mineral control for long term release rates.

5 Discussion

5.1 Overview

The overall geochemical characterization program outlined by SRK (2015a) was developed to provide information on the potential for leaching from the spilled tailings. The kinetic tests are specifically for subaerial weathering of the spilled tailings along Hazeltine Creek and are confirming that the risk of ARD and metal leaching in the spilled tailings is low and that any leaching will be under neutral pH conditions.

5.2 Tailings Leaching Rates

Leaching rates for subaerial tailings situated along Hazeltine Creek have been established with stabilized sulphate release rates observed from the humidity cell tests and either stable or slowly declining sulphate release rates in the column tests. As sample selection included materials that represented median and upper 95th percentile materials in terms of sulphur, copper, and selenium concentration, leaching variability has also been established.

As discussed in SRK (2015a), the presence of secondary copper minerals will tend to keep the concentration of copper in seepage and contact from tailings at a 'ceiling' concentration, which is supported by measured concentrations at other copper porphyry mines with neutral to basic pH site conditions (Day and Rees 2006). For locations along Hazeltine Creek where the tailings settled in thin layers (i.e. less than 0.5 metres), dilution from precipitation is expected to be high and concentrations could be even lower than predicted by mineral solubility limits. Copper concentrations not constrained by mineral solubility (i.e. HC-4) are predominantly complexed with DOC as described by SRK (2016). The non-complexed copper is well constrained by mineral solubility meaning that copper leaching is predicted to be well constrained and is only expected to continue deceasing over time.

Selenium is not expected to be influenced by a mineral solubility control at neutral pH and in surface waters that are fully aerated. However, there was a difference in leaching rates between HC-3 and COL-3 that was not observed with the sulphate leaching rates. Sulphate in the humidity cells and columns is considered a conservative tracer as concentrations are not high enough for mineral precipitation of sulphate minerals that could have a significant control on concentrations (i.e. precipitation of gypsum). The other removal mechanism for sulphate is through chemical reduction, which requires anaerobic and very reducing conditions that were not likely present in the columns.

The difference in selenium leaching rates is attributed to a selenium sequestration process. Selenium has several chemical forms (notably selenate, selenite, elemental selenium and selenide) and does not need to have very low reducing conditions like sulphate to be chemically reduced (it tends to occur either at or just below the redox conditions required for denitrification). When selenium (as selenate) is reduced to selenite, it becomes less soluble as it has a higher affinity for mineral surfaces than its more oxidized form selenate (MEND 2015). If environmental conditions become even more reducing, elemental selenium will precipitate from solution, also resulting in decreased dissolved selenium concentrations. As a result, the difference observed for the selenium leaching rate in COL-3 versus HC-3 is likely a result selenium being reduced from selenate to selenite in the column and being sequestered onto the mineral surfaces as opposed to leaching into solution. Conditions in the humidity cells likely remained full aerated and conditions supportive of selenium reduction did not develop.

5.3 Assessment for Test Completeness

A kinetic test is complete when the overall objective of the test has been met. The objective of the kinetic testing program is to obtain stable solute release rates. "Stable" in this context is defined as results that are either showing flat trends (i.e. no upward or downward trend), or changing

sufficiently slowly that the trend is predictable, and can be used to understand the future behaviour of the materials under investigation. As previously noted, the trends observed are for tailings with some of the highest solid phase copper concentrations along Hazeltine Creek and the leaching rates reported herein are expected to be conservative.

Based on the cumulative results of the program, the humidity cells and column tests are considered stable. Variability for leaching rates under neutral pH conditions has been established with leaching rates for all BC FAL parameters available. The objectives of the kinetic test program have been met and SRK recommends decommissioning the three remaining humidity cells.

6 Conclusions

The results and interpretations presented in this report are a continuation of the geochemical characterization studies undertaken on representative samples of tailings that spilled into Hazeltine Creek in August 2014 from the MPM TSF embankment breach.

Kinetic testing confirmed that leaching considerations are under neutral to alkaline conditions and continue to support the previous assessment that ARD is not expected in these materials. Based on more than 80 weeks of testing, leaching rates are either stable or slowly declining and are suitable for use in predicting long term water quality from weathering of subaerial tailings. Variability in leaching rates has also been established and water contact chemistry predictions (i.e. geochemical source terms) are now possible.

For any tailings materials with water flow paths longer than half a metre, mineral solubility controls for copper are expected. Longer flow paths in the fine grained materials may also be conducive to lower rates of oxygen diffusion and therefore conditions that support sequestration of selenium.

Testing remains on-going but given the objective of the testing has been met, SRK recommends that the cells be decommissioned.

Memo

To:	Colleen Hughes	**Client:**	Mount Polley Mining Corp.
From:	Chris Kennedy, SRK Pierre Stecko, Minnow Environmental Cheryl Wiramanaden, Minnow Environmental	**Project No:**	1CI008.003
Cc:	'Lyn Anglin, Imperial Metals Stephen Day, SRK	**Date:**	December 23, 2016
Subject:	Mount Polley Spilled Tailings: Polley Flats Copper Geochemical Conceptual Model – FINAL		

1 Introduction

This memo presents a geochemical conceptual model (GCM) to explain the dissolved concentrations of copper in ditches and various ponds and pools that are collecting contact water from tailings materials in the upper Hazeltine Creek area (also referred to as the Polley Flats or Polley Plug area). The tailings were released during the tailings dam breach on August 4, 2014 at the Mount Polley Mine (MPM), located approximately 55 km north-east of Williams Lake, BC. Note that what is referred to as tailings in this document is a mixture of tailings, native soils, glacial sediment including till, and vegetation debris.

Mount Polley Mining Corporation (MPMC) requested that SRK and Minnow Environmental develop the GCM presented herein to help explain and evaluate the current and future copper concentrations that may impact water quality in Hazeltine Creek. This memo has been prepared for internal use by MPMC and its consulting team in response to a request from the BC Ministry of Environment (BC MOE, letter to Dale Reimer dated June 20, 2016) for the MPM to manage copper leaching impacts on Hazeltine Creek from the Polley Flats area. SRK and Minnow understand that this memo may also be provided to the BC MOE, Williams Lake Indian Band, Soda Creek First Nation, and others including the public.

The Polley Flats Copper GCM provides a basis for the following components:

- Source of copper leaching;
- Solubility control of copper;
- Influence of suboxic conditions;
- Influence of organic acids on leaching; and

- A prediction of future copper concentrations.

Following the GCM, this memo also provides general inputs into reclamation planning based on the GCM, to limit copper loadings from the Polley Flats tailings (and sub-aerial tailings in general).

The GCM focuses mainly on copper, pH, and dissolved organic carbon (DOC) at this time given the need to specifically address the concerns raised by the BC MOE and the respective Indian Bands. Iron is also included in the latter part of the assessment to assist with data interpretation. More complete assessment of other parameters will be provided in a kinetic testing completion report to be provided at a later date.

2 Background

As part of investigations of the tailings materials that spilled from the August 2014 tailings dam breach, geochemical characterization studies were completed by SRK (2015a, 2015b) to determine the composition, mineralogy, and leaching rates of the spilled tailings.

The main geochemical finding of these previous studies was that the MPM tailings are not potentially acid rock drainage (ARD) generating, which is consistent with the mineralogy of the tailings, the historical understanding of the tailings, and the low sulphur nature of the ore deposit (SRK 2015a). Weathering and leaching of the tailings would be expected to occur under neutral to basic pH conditions only, which results in low mineral and metal-specific solubility compared to acidic conditions. This is fundamental to understanding the long term copper leaching from the spilled tailings at Mount Polley, as release rates and copper concentrations will be constrained at neutral pH conditions.

Examples of copper concentration control are seen in available data sets from waste rock seepage monitoring at MPM and a number of other copper porphyry mine sites in British Columbia (Day and Rees 2006) (Figure 2-1), where copper concentrations are constrained around an average of 0.01 mg/L at pH 8. As the MPM tailings have an excess of carbonate that will neutralize any acidity produced from sulphide oxidation, pH is not predicted to ever go below 7; and the much higher copper concentrations associated with lower pH in Figure 2-1 will not develop at Mount Polley. The Day and Rees (2006) dataset is for waste rock, which will have coarser particles along with fine-grained material, but the study illustrates the first principle relationship between copper and pH from mine sites. Given that the tailings from the MPM are crushed rock, SRK considers that the Day and Rees (2006) dataset is applicable to the GCM for the MPM.

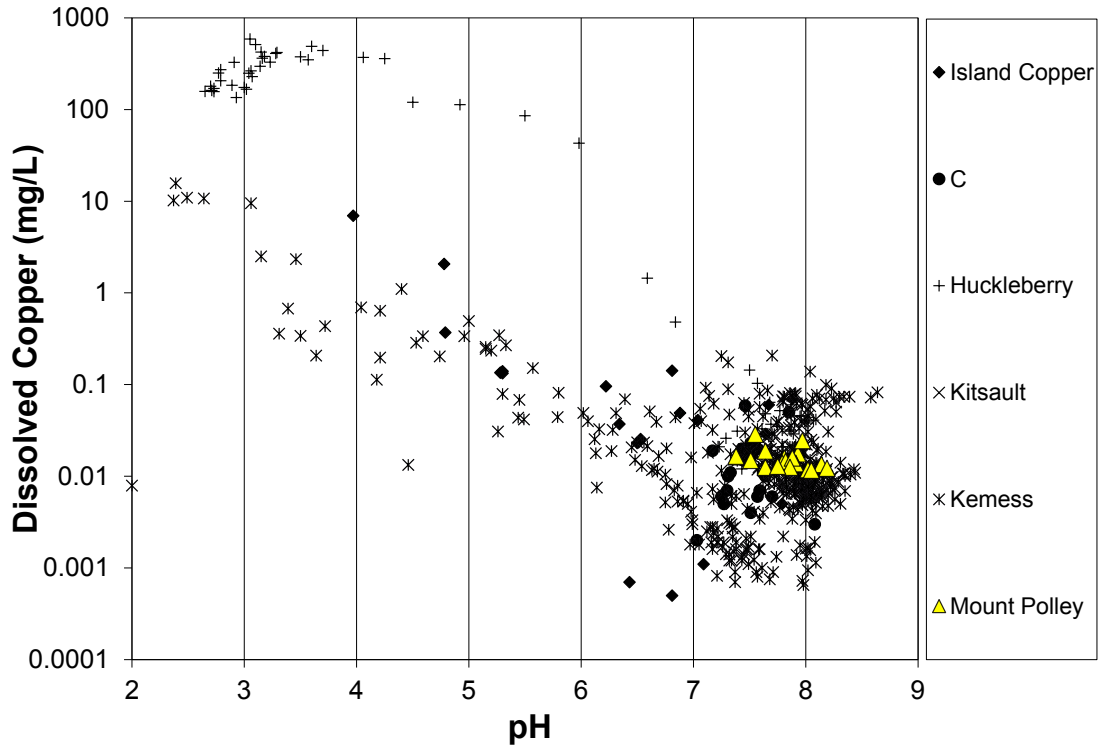

Figure 2-1: Copper concentrations in waste rock seepage from BC Copper Porphyry Mines.

Source: Modified from Day and Rees (2006)

MPM tailings are enriched in copper when compared to typical crustal rocks (basalt) (Price 1997). Previous work at MPM (SRK 2015a, b) indicates that the leachable or reactive portion of copper is only associated with sulphide minerals and requires oxidation to be leached. A significant portion of the copper in the tailings (often greater than 50%) is associated with a relatively inert non-sulphide phase.

MPM and the BC MOE have found dissolved copper concentrations upwards of 0.05 mg/L in the ditches and pools alongside the upper reaches of Hazeltine Creek. The ditches were created partly as temporary water diversion structures, but also to collect tailings contact water during the initial restoration efforts of Hazeltine Creek. Restoration efforts have included removing tailings down to native materials (i.e. glacial till) along the engineered flow path of Hazeltine Creek and rock-armoring the channel with low sulphur waste rock from the MPM.

SRK understands that the BC MOE has requested a plan from MPM to address copper leaching from the Polley Flats area. Before a remediation plan can be prepared, the source and fate of copper needs to be understood. The conceptual model presented herein provides input in support of effective seep management decisions.

3 Approach

An initial GCM was developed for the tailings (SRK 2015a) and the model presented herein builds from the initial work, but is more specific to the Polley Flats area. The initial GCM was based on

the current understanding of the site geology, ore processing, tailings deposition, and characterization results of tailings collected along the banks of Hazeltine Creek and within Quesnel Lake and Polley Lake.

Since the initial GCM, some of the tailings in the Polley Flats area have been excavated to natural ground as part of the remediation work on Hazeltine Creek. Additional data, including site monitoring data and over a year of laboratory column testing (i.e. a weathering test) are also available. The new configuration of the Polley Flats area and the additional data has been used to further develop the GCM model and confirm or revise previous assumptions. Data used in this GCM is presented in Section 4.

4 Supporting Information

4.1 Polley Flats Area

The Polley Flats (POF) area is located between the Tailings Storage Facility (TSF) and the upper portion of Hazeltine Creek immediately below Polley Lake but upstream of the water discharge location from the MPM water treatment plant (i.e. up to the HAC-13 monitoring location). This area is approximately 1 km at its widest (east-west) and extends from Polley Lake downstream (north-south) to HAC-13, over a distance of approximately 0.85 km, or a total surface area of 85 ha (Figure 4-1). Tailings in this area were also the deepest observed of the depositional areas downstream of the TSF and are typically over 1 metre, but less than 5 metres deep. Intermixed with the tailings materials are construction materials from the tailings dam and natural sediments (e.g. peat and soils as well as glacial sediments) and vegetation debris such as trees.

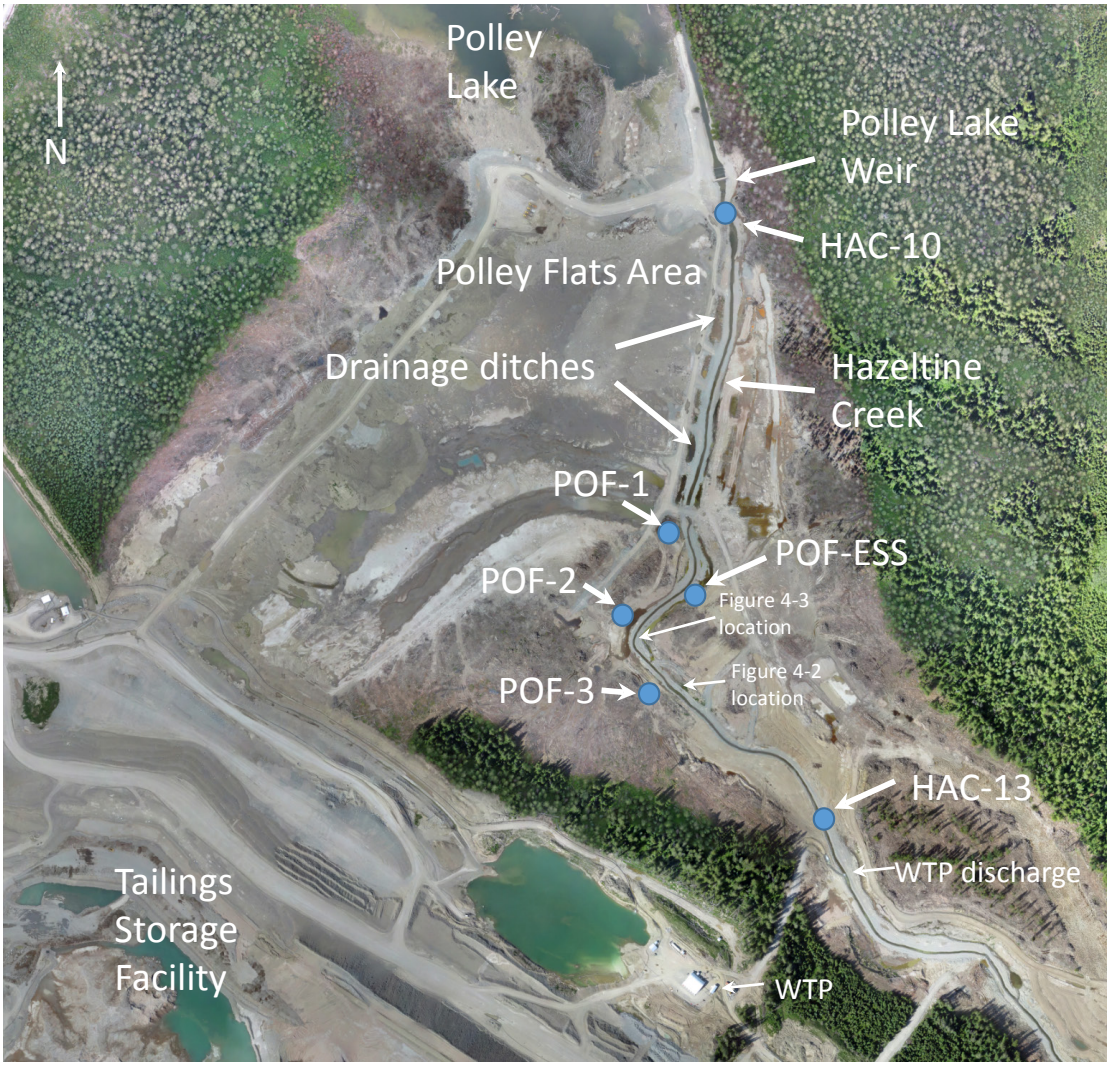

Figure 4-1: Aerial view of Polley Flats Area.

Source: Aerial image taken in June 2016 by MPMC.

Notes: Reclamation progress since the photo was taken has resulted in removal of POF-3, and POF-2 now flows to the water treatment plant (WTP) discharge location.

Crossing through the Polley Flats area from Polley Lake is Hazeltine Creek. As previously described (Section 2), the Hazeltine Creek flow path was created by excavating the tailings down to natural ground and lining the channel with low sulphur non-acid generating waste rock from the MPM. Water collection ditches have been established parallel to Hazeltine Creek, with some eventually draining into Hazeltine Creek, and others remaining isolated on the surface (although infiltration to groundwater is expected). Groundwater seeps can be seen in some of the locations and some are stained orange-red, likely due to neutral pH iron hydroxide precipitation. A photograph of one segment of Hazeltine Creek and a small drainage ditch is provided in Figure 4-2. A photograph of one of the larger pools of water beside Hazeltine Creek is provided in Figure 4-3. The locations of Figure 4-2 and Figure 4-3 are shown in Figure 4-1.

4.2 Field Monitoring

A large number of locations around the MPM are being monitored for water chemistry. Dissolved metal concentrations are being used rather than total metal concentrations because totals are affected by suspended sediment whereas dissolved concentrations provide a better measure of the metal fraction associated with leaching.

Six locations were chosen for use in this assessment to help understand copper concentrations in seeps associated with tailings prior to entering Hazeltine Creek and also within Hazeltine Creek itself. The locations are shown in Figure 4-1 and summarized in Table 4-1. Of note are the POF-2 and POF-3 locations, which were locations of water draining a cedar swamp that was passing through (and over) the tailings. These two locations no longer exist due to 2016 reclamation activities and the water now drains to the water treatment plant discharge location as opposed to through the tailings.

Table 4-1: Field sampling locations used in GCM.

		Location (UTM Zone 10U)	
Sample ID	**Sample Description**	**Easting**	**Northing**
HAC-10	Outlet of Polley Lake at weir	595754	5820776
HAC-13	Hazeltine Creek upstream of discharge	595924	5819913
POF-1	Contact water from tailings	595736	5820295
POF-2	Cedar swamp water passing through tailings	595663	5820169
POF-3	Cedar swamp water passing through tailings	595703	5820102
POF-ESS	East side contact water from tailings	595775	5820258

MPM and Z:\01_SITES\Mt_Polley\1CI008.003_Privileged_and_Confidential\500_Reporting\6.PolleyFlats_GCM\memo\[Tables_POF_GCM_1CI008.003_REV00_CBK.xlsx]

Monitoring results forwarded by BC MOE and MPMC for pH, copper, and DOC in 2015 and 2016 are provided in Figure 4-4, Figure 4-5, and Figure 4-6, respectively. SRK did not review the data for quality assurance or quality control, but samples collected by MPMC were subject to their internal QA/QC manual and SRK assumed the data were valid. Flow volumes were not available so it is not possible to present chemical loading. Relevant monitoring chemistry is provided as Attachment A.

Hazeltine Creek and the Polley Flats contact water have remained pH neutral to alkaline since the tailings spill. This is consistent with the geochemical characterization of the MPM solids which indicated that the potential for ARD from these tailings is negligible (SRK 2015a). A slight increase in pH (7.6 to 8.3) in the Polley Flats waters was noted from the early spring (March 2016) to the most recent sampling date (October 2016 (Figure 4-4)).

Higher copper concentrations in the Polley Flats seep waters, compared to Hazeltine Creek were not unexpected as the seep waters effectively represent tailings contact/pore water with minimal dilution. Hazeltine Creek is likely dominated by drainage from Polley Lake given that it is primarily acting as a drainage conduit to Quesnel Lake. Generally, copper concentrations in Hazeltine Creek were relatively stable. An increase at HAC-13 in March 2016 was noted at the same time that concentrations in the Polley Flats waters were also highest. Given that Hazeltine Creek is passing through nearly a 1 km stretch surrounded by tailings with many of the ditches draining

into Hazeltine Creek, the increase in HAC-13 was not unexpected. Two additional small increases in copper and DOC were also noted at HAC-13 in August and September 2016. These increases are believed to be a result of the extensive reclamation works on-going in Hazeltine Creek at that time which likely resulted in some of the suspended sediment passing through the field filter (0.45 µm) and subsequently getting reported as a dissolved number, when in fact the preserving agents likely partially digested sediment. The sluice gate at the Polley Lake weir was also closed during reclamation activities, resulting in a higher proportion of POF water contributing to the quality of Hazeltine Creek.

Copper concentrations at most stations decreased or were similar from March to June coincident with the observed increase in pH, but POF-2 was a clear exception (later supported by POF-3) (Figure 4-5). At these two locations, copper concentrations continued to increase despite pH being relatively unchanged. The most significant difference in these waters compared to POF-1 or HAC sites was the concentration of DOC at upwards of 40 mg/L as compared to 10 mg/L at the other sites (Figure 4-6). The high DOC at these locations is believed to be a result of a drainage from a cedar swamp. The potential impact of DOC and overall interpretation of the field monitoring results is provided in the GCM (Section 5).

4.3 Laboratory Column Testing Data

Complete details of testing set-up are provided in SRK (2015b), but for ease of reference the key components of the test are provided below.

Three column tests have been running since April 2015. Columns one and two are magnetite sands while the third is grey tailings. Eighty-one (81) weeks of data had been received as of the date of this memo. The grey tailings sample is finer grained than the magnetite sand samples and it takes several weeks to collect enough water to perform an analysis, as opposed to one week per magnetite sands samples, resulting in fewer data points for the grey tailings. The samples being tested represent the mean and upper (i.e. ~95th percentile) range of solid phase copper

content identified during the initial characterization work on the samples collected along Hazeltine Creek (i.e. between 900 and 1200 mg/kg Cu).

The intent of the column tests is to establish weathering rates under atmospheric conditions and to evaluate the effect of longer water flow paths and lower water to solids ratios than are represented by the standard humidity cells. The lower water to solids ratios were specifically chosen to simulate field conditions as closely as possible in order to evaluate reasonable worse-case concentrations expected from the tailings. Biasing the tests to worse-case concentrations also provided the basis to evaluate whether a concentration maximum would be reached through attenuation processes such as secondary mineral formation.

Leachates showed an initial increase in pH from around 7.5 to 8.2 (Figure 4-7) during the first five weeks of testing with a coincident copper concentration decrease in all tests from a maximum of 0.054 mg/L to 0.013 mg/L in COL-1, which is the test containing approximately 1200 mg/kg solid phase copper (Figure 4-8). The pH changes and related copper concentrations are similar to what were measured in the POF-1 samples. Concentrations of DOC were relatively low compared to the field and more typical of pore water in mine waste material (Figure 4-9). The interpretation of these concentrations is provided in the GCM (Section 5).

Note: data shown starts at week 45 due to laboratory filtering equipment contamination prior to this date.

5 Polley Flats Copper Geochemical Conceptual Model

5.1 Introduction

A number of hydrogeological and geochemical processes contribute to the leaching of copper from the tailings along Hazeltine Creek and specifically in the Polley Flats area. A summary of the main processes is provided below, with more specifics in the following sub-section. Letters refer to specific processes identified in the GCM, as illustrated in Figure 5-1.

The main processes are:

- Oxidation of the tailings and release of copper (A). Atmospheric oxygen diffusion may be limited to the near surface (black dashed line in Figure 5-1) with a portion of the tailings not reactive due to sub-oxic conditions.
- Weathering of organics (B), with copper complexation by dissolved organic carbon.
- Precipitation, infiltration, and transport of copper and other oxidation products (C), including neutralization of sulphide acidity by carbonates and release of carbon dioxide.
- Run-off along the surface of the tailings (D) and collection in ditches along Hazeltine Creek, with some ditches draining into the creek.
- The till/tailings interface which may direct water laterally (E) and create seepage due to a lower hydraulic conductivity in the glacial till as compared to the tailings. A possible ground water table is depicted by the blue dashed line in Figure 5-1. If the materials below the sediment were at least as permeable as the tailings then infiltration would continue to groundwater.
- Contact water from tailings in the Polley Flats area may partially drain to Hazeltine Creek or contribute to groundwater (F). The weathered waste rock from the MPM used to rock armour Hazeltine Creak may have leached copper initially.

Figure 5-1: Geochemical conceptual model overview of Polley Flats copper leaching pathways.

5.2 Weathering of Tailings by Oxygen

Some of the tailings in the Polley Flats area are now exposed to atmospheric conditions. As a result, sulphide minerals (e.g. pyrite (FeS_2) and chalcopyrite ($CuFeS_2$)) will react in the presence of atmospheric oxygen, produce acid, and leach copper. The acid produced is present in micro-environments (grain scale) but as water moves through the tailings, this acid will interact with carbonate minerals and be neutralized. Macro-scale acidity (i.e. acidic seepage) is not predicted as there is an excess of carbonate neutralization potential over acid potential in the tailings (SRK 2015a). Any copper that is leached from the tailings will be subject to an upper limit in terms of concentrations, as secondary minerals (e.g. malachite ($Cu_2CO_3(OH)_2$)) will precipitate from solution and provide mineral solubility control (Section 5.3).

The lower pH measured at the start of the column test, and in the Polley Flats drainage ditches in March 2016, is attributed to grain-scale acidity around oxidizing sulphide minerals before it is flushed and neutralized by carbonate minerals. The samples for the column test were collected and stored in the laboratory for several months before testing began. During this time, the sulphide minerals would still have been oxidizing but the acidity formed could not be neutralized by the available carbonate minerals as there was no flow of water through the sample. As the column test started and water was passed through the tailings, pH increased and copper concentrations decreased, reflecting the flushing of the (micro) grain-scale acidity (Figure 4-7 and Figure 4-8). The accumulation of sulphide oxidation products was also confirmed by sulphate concentrations in the column tests which started out relatively high (upwards of 2,000 mg/L) during the first few weeks of testing and decreased to less than 100 mg/L over the same time period as copper concentrations declined SRK (2015b).

A similar process is expected to occur in the Polley Flats tailings. During the winter, the majority of tailings are no longer receiving infiltration due to snow and ice cover allowing oxidation products and acidity to accumulate around the sulphide grains as most of the tailings are expected to remain above freezing temperatures and continue to oxidize. Once freshet begins, these oxidation products and acidity will be neutralized and get flushed from the tailings, with pH increasing while copper concentrations decrease each spring (Figure 4-4 and Figure 4-5). This process is also expected after prolonged periods of dry weather followed by precipitation, which could occur in the fall. This may present a bi-modal copper concentration in the Polley Flats waters of higher concentrations at the very beginning of freshet and early fall, with a repeating pattern year over year.

As sulphide weathering continues, oxidation products (e.g. iron hydroxides) will also build-up around the sulphide grains, which may limit oxygen diffusion and therefore sulphide reaction rates and result in lower rates of copper leaching. Over time, as the tailings age and weather, tailings contact waters are predicted to exhibit a slightly downward trending, oscillating curve. Seasonal precipitation and temperature variations year over year would also be expected to result in concentrations varying in magnitude, but overall the trend is expected to be downward as conceptually depicted in Figure 5-2. The role of DOC and mineral solubility controls on copper concentrations are discussed in the following sections.

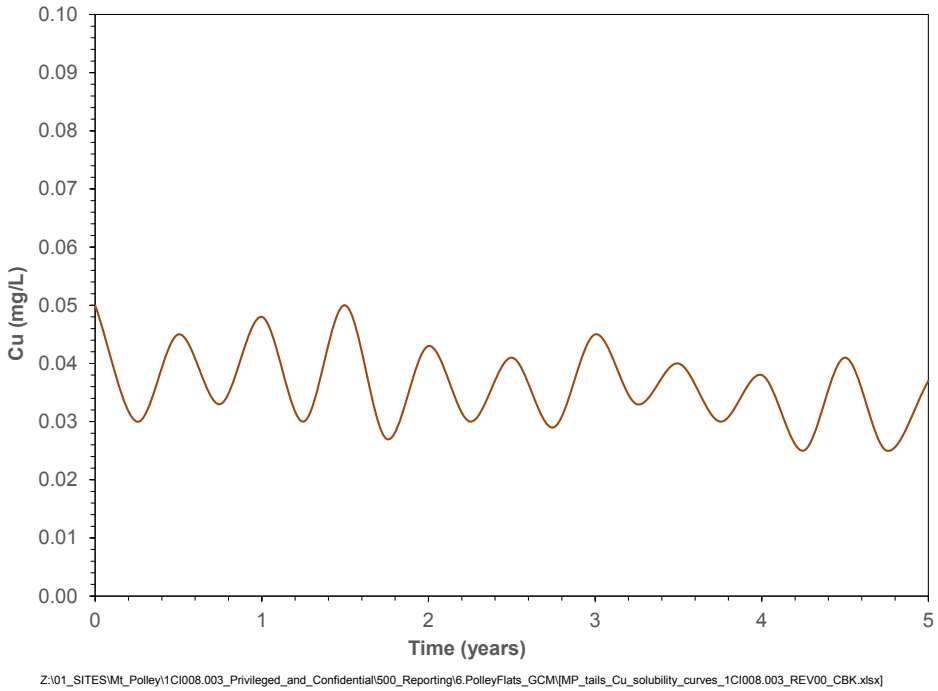

Figure 5-2: Conceptual copper concentration curve from Polley Flats tailings contact waters.

5.3 Mineral Solubility Control of Copper Concentrations

As acidic conditions are not predicted to develop in the spilled tailings, copper leaching at the MPM is considered only under neutral to basic pH.

In many mine settings, secondary minerals like malachite ($Cu_2CO_3(OH)_2$), tenorite (CuO), and copper hydroxides ($Cu(OH)_2$) control the solubility of copper, and hence the copper concentration in water, through reactions that either dissolve or precipitate these minerals, depends primarily on pH. What this means is that if these minerals are present, the concentration of copper (the ionic or non-complexed form) in water cannot exceed their solubility. If the copper concentration is below the solubility limit, the mineral can dissolve. At higher copper concentrations exceeding the solubility limit the mineral may precipitate from the water.

The potential for a mineral to dissolve or precipitate is determined by its saturation index (SI), which is calculated based on the total chemistry of the water. SI is the ratio of the product of activities (approximately equivalent to concentrations) of the dissolved ions of the mineral (ion activity product, IAP) to the thermodynamically-determined solubility product (K_{sp}):

$$SI = \log(IAP/K_{sp})$$

Geochemical equilibrium models like PHREEQC (Parkhurst and Appelo 1999) are often used to calculate SIs as they can conveniently access mineral thermodynamic data. In the interpretation of mineral SIs, positive values indicate that the given mineral phase is “oversaturated” and could precipitate whereas negative values indicate that the mineral phase could dissolve

("under saturated"). SIs close to zero ("saturation") indicate that the mineral will neither precipitate nor dissolve and that the concentration would be expected to show little fluctuation provided the concentrations of other ions do not change.

While solubility of secondary copper minerals under basic pH is low when compared to acidic conditions, even small changes in pH from 7.5 to 8.2 can impact solubility resulting in copper concentrations that can change by two to three times. To illustrate this effect, solubility curves of malachite, tenorite, and $Cu(OH)_2$ from pH 6 to 9 are provided in Figure 5-3. The curves were created using the geochemical equilibrium model PHREEQC (version 3.0.6.7757) (Parkhurst and Appelo 1999) with the thermodynamic database MINTEQ v8 for waters containing sulphate (585 mg/L), alkalinity (212 mg/L), and major cations (Ca, Mg, Na, K at 223 mg/L, 42 mg/L, 41 mg/L, and 4 mg/L, respectively) as reported in POF-1 waters on March 15, 2016 at 10°C. The pH was adjusted by adding sulphuric acid in the model and ionically balancing the solution with calcium under conditions assumed to allow instantaneous exchange with atmospheric gases. This latter assumption primarily affects how much carbon dioxide dissolves in the water which in turn affects the SI for carbonate-containing minerals such as malachite.

A saturation index of zero was used for all three secondary copper minerals, but a saturation index of 0.5 was also used for malachite. While theoretically minerals will precipitate at zero, often activation energy barriers need to be overcome before a mineral can precipitate, which requires a higher degree of saturation. Malachite was chosen to evaluate a range as it is the most likely mineral control based on its presence in the tailings (SRK 2015a) and it was slightly oversaturated in the column test once pH stabilized (Figure 5-4). Malachite is also present in the ore at MPM, and while it could be primary (i.e. formation during alteration of the ore before it was mined), the ability of this copper mineral to form as a secondary mineral is well established at this mine site (SRK 2015a).

Shown in Figure 5-3 are copper concentrations and pH from the laboratory column test (COL-1) (containing material with the 95th percentile copper solids concentration), Polley Flats sampling results, and the HAC-13 monitoring site. There is a reasonable fit for samples from the column test, POF-1 and HAC-13, but the fit for POF-2 and POF-3 is poor compared to the predicted concentrations based on laboratory pH and mineral solubility. The results from POF-2 and POF-3 are also not consistent with the relationship shown by Day and Rees (2006) (Figure 2-1).

5.4 Influence of Organics on Copper Leaching

Concentrations of copper in water samples collected from Polley Flats and Hazeltine Creek often exceeded the hardness-based BC MOE water quality guideline (Attachment A). Closer examination of the copper concentrations revealed higher concentrations than expected based on mineral phase solubility data (Figure 5-3) and that the elevated copper concentrations appear to coincide with elevated concentrations of DOC (Figure 4-5 and Figure 4-6). Somewhat elevated concentrations (i.e. greater than 0.1 mg/L) of iron were also found in the same samples (Appendix A), which is not typical of neutral pH waters where dissolved iron is typically below 0.01 mg/L. One hypothesis is that the solubility of copper (and potentially of iron) is enhanced by metal binding with DOC. Copper and iron are known to bind strongly with organic ligands in aquatic environments (Millero 1975; Tipping 2002), and copper speciation in the water column is often dominated by copper-organic complexes that are generally not bioavailable (Stumm and Morgan 1996). Because inorganic copper and the free (hydrated) ion (Cu^{2+}) are the most toxic forms of copper, copper binding by aquatic ligands such as DOC decreases copper bioavailability and toxicity (e.g., Grosell 2012). Therefore, organic complexation of copper would have two effects: 1) to increase the apparent solubility of copper bound in mineral phases; and 2) to decrease the bioavailability and toxicity of dissolved copper (Stumm and Morgan 1996; Grosell 2012).

Copper and iron speciation, and potential copper toxicity in these water samples, were investigated. Concentrations of appropriate parameters for the water samples from Hazeltine Creek and Polley Flats were input to two models: 1) a geochemical model called Visual MINTEQ; and 2) a biotic ligand model called the HydroQual BLM. The speciation of copper and iron can be modelled using the thermodynamic equilibrium model Visual MINTEQ and provides the predicted chemical forms (including organic forms) of each metal and their concentrations. These concentrations may then be applied to the existing geochemical model being used to understand copper concentrations in these creeks on the basis of mineral phase solubility products (Section 5.3). Biotic ligand models (BLM) account for key factors that influence the bioavailability and toxicity of metals (e.g., DiToro et al. 2001; Niyogi and Wood 2004; USEPA 2007; Erickson 2013). The models treat organisms as “biotic ligands” that are in competition for metal binding (and uptake) with other ligands (such as dissolved organic matter), and account for competition between metals and major ions for both abiotic and biotic ligands. BLMs are particularly well accepted for copper due to the strong affinity of copper and aquatic ligands (e.g., Santore et al. 2001; USEPA 2007; Peters et al. 2011). Although several BLM software tools are available, the HydroQual BLM (HydroQual 2007) was selected due to its broad use and its adoption by the United States Environmental Protection Agency as the basis for ambient water quality criteria for copper in freshwater (USEPA 2007).

Included in this section are brief summaries of the capabilities of the software tools that were used, followed by the methods and input data used. Results summarize the model outputs, and provide context for interpretation, and conclusions.

5.4.1 Models

Visual MINTEQ ver 3.1

Visual MINTEQ is a software tool that uses established thermodynamic equilibrium constants to numerically solve metal chemical speciation in a given system or water sample (Gustafsson 2014). The model assumes thermodynamic equilibrium for the final results, and requires all input parameters that will influence metal speciation, including all major cations and anions, pH, and concentrations of the metal of interest. In addition, DOC can be entered as a parameter. Briefly, the binding of a metal by DOC is modelled using the Stockholm Humic Model (SHM; Gustafsson 2001) which describes organic-metal binding and competitive interactions over a wide range of conditions. The SHM assumes metal complexation via two functional groups (phenolic acid and carboxylic acid), where each functional group has four sites, each with a slightly different acidity and affinity for the metal. The affinity for the metal is based on an acidity of the functional group which is distributed around the median acidity of the functional group.

Precipitation of solid phases was also allowed as a modelling option, and is particularly important for iron. If, after the first iteration of modelling, the remaining concentration of inorganic iron, (that which is not bound to DOC), is found to be supersaturated, then the model would recalculate the species distribution assuming that the solution is in equilibrium with respect to the solid (i.e., some of the inorganic iron would precipitate). The final concentrations of each species are solved iteratively, refining the amount of free ion with each iteration, and the component with the strongest binding affinity (in the case of copper and iron, this is DOC) for the metal taking priority in each iteration. However, allowing for precipitation may effectively remove iron from the system (the aqueous environment), which may not be representative of actual water samples, given that these high iron concentrations were measured as dissolved concentrations (e.g., if the high iron concentrations were stabilized by the presence of low abundance high affinity ligands, or if precipitation is hindered due to kinetic considerations). Therefore, as a worst case scenario, all samples were also modelled under a scenario where no precipitation was allowed. This may not necessarily reflect conditions of a thermodynamic equilibrium but it would provide an understanding of the variability in modelling results, ranging from assuming that precipitation occurs to not allowing for any iron to leave the system (i.e., by providing a lower bound [worst case] estimate of copper complexation by organic matter in the presence of higher than anticipated free iron concentrations).

Visual MINTEQ assumes thermodynamic equilibrium in order to predict a species distribution. Therefore, if the model predicts precipitation, it would mean that the sample (input dissolved concentration data) could not have been at thermodynamic equilibrium or that the modelling parameters are not representative of the water sample. If the water sample was not at thermodynamic equilibrium when collected, the lack of precipitation is likely due to kinetic constraints, and the water sample would have been supersaturated. These kinetic considerations would explain differences between *in-situ* water samples (with no precipitate) and their corresponding predictions (with precipitate). An alternative explanation is that the relative amounts of organic binding sites in the model are not representative of the DOC in the water sample.

HydroQual ver 2.2.3

The HydroQual BLM software tool was developed and maintained by HydroQual[1] (HydroQual 2007). It uses an acute toxicity endpoint, LA_{50} (i.e., the lethal accumulation of copper on the biotic ligand that results in 50% mortality during an acute exposure) and calculates the total dissolved concentration of copper that will result in 50% mortality of an exposed population (DiToro et al. 2001). Toxicity data is based on comprehensive studies of fathead minnows (*Pimephales promelas*), rainbow trout (*Oncorhynchus mykiss*), and Cladoceran species (e.g., *Ceriodaphnia dubia*). The model considers the free ion, Cu^{2+}, to be the only toxic species (chemical form) of copper. As Cu^{2+} is the important copper species, competition by Ca^{2+}, for example, at the biotic ligand receptor site has a strong influence on the final calculated acute toxicity threshold. HydroQual data inputs include major ions (calcium, magnesium, sodium, potassium, sulphate, and chloride), pH, and dissolved organic carbon (DOC) concentrations. The HydroQual BLM incorporates earlier equilibria models (CHESS- chemical equilibria of soils and solutions and WHAM- Windermere Humic Aqueous Model) which allow modelling of chemical and electrostatic interactions of organic molecules and use humic acids as the model organic molecules. If the humic acid (HA) component of the DOC is unknown, a 10% HA content of DOC is assumed (HydroQual 2007). This is likely a lower proportion of humic acid content than would be expected; typically, humic acids make up between 40 and 99% of the total DOC (Morel and Hering 1983). This lower proportion would result in an under-estimate of the amount of copper or iron that was complexed by DOC.

The HydroQual BLM has a US EPA Instantaneous Water Quality Criteria (EPA IWQC) calculation function for copper. The acute toxicity output for the EPA IWQC is the Final Acute Value (FAV), a concentration of copper that is an estimate of the 5th percentile of a sensitivity distribution represented by average LC_{50}'s and EC_{50}'s of the tested genera, (i.e., a hypothetical genus that is more sensitive than 95% of the tested genera). The criterion maximum concentration (CMC) is calculated as half the FAV, and is presented in order to provide a safety factor for effect concentrations. The criterion continuous concentration (CCC), a chronic value, is calculated from the FAV using a Final Acute-to-Chronic Ratio (FACR) of 3.22 (US EPA 2007).

5.4.2 Model Development

The Visual MINTEQ input parameters were selected from available water quality sampling results provided by BC MOE and MPMC (Attachment A) on the basis of three criteria: 1) if they contributed toward charge balance, 2) if they were deemed to directly influence copper or iron speciation, and 3) if they potentially influenced copper or iron speciation through competition for binding sites (e.g., aluminum is known to compete for organic binding sites). All input parameters provided in Attachment A were included in the model. There were two instances where input data were adjusted; this was because potassium concentrations for two samples were reported at 1,000x the concentrations of all other samples. In these two cases (POF-1 12-JUL-2016 BC MOE, and HAC-10 08-Sep-2015 BC MOE), it was assumed that a unit error had been made and the samples were run using assumed potassium concentrations at 1,000x less than the reported

[1] The HydroQual BLM is now maintained by Windward Environmental, LLC.

concentration. The temperature was input at a standard 15°C on the basis that the samples collected had a mean temperature of 13.4°C and a median temperature of 16.0°C.

HydroQual BLM input parameters were temperature, pH, DOC, alkalinity, calcium, magnesium, sodium, potassium, sulphate, chloride, and copper, with an assumed percent humic acid of 10% (conservative). An assumed negligible concentration of sulphide is also a required input. HydroQual input temperature data were the same as assumed for Visual MINTEQ and all samples were input at 15°C.

5.4.3 Model Results

Iron Speciation Distribution (Visual MINTEQ)

The iron speciation results, for all water samples, showed that at least 99.95% of iron was organically complexed (Attachment B, Appendix Tables B.3 and B.4). The remaining iron was predicted to be inorganically complexed. In all cases, iron was predicted to precipitate as an iron oxide. High concentrations of DOC had the effect of stabilizing high concentrations of iron that would otherwise have precipitated on the basis of the low solubility of iron (III) (Pullin and Cabaniss 2003). However, iron concentrations were sufficiently high that, despite the stabilizing effect of DOC, iron was still predicted to precipitate. The effect of the stabilization of high iron concentrations by DOC is well known in aquatic environments (Stumm and Morgan 1996; Tipping et al. 2002).

The discrepancy between prediction of iron precipitation in all samples, and the fact that *in-situ* samples did not contain solid phases (the input data were dissolved concentrations) may suggest that iron concentrations in the water were not at thermodynamic equilibrium, and kinetic constraints would be preventing iron from precipitating. Under this regime, it is possible that iron precipitation will occur in these receiving environments further downstream or later in time. An alternative explanation for the discrepancy between modelled and actual iron concentrations, is an actual higher proportion of the low abundance high affinity iron binding sites (i.e., the phenolic binding sites) in humic matter relative to that which was modelled in Visual MINTEQ which models lower concentrations of the four phenolic sites compared to the weaker carboxylic sites.

As the *in-situ* samples did not contain solid phases, the input data were also modelled with the constraint of not allowing precipitation. In this case, where more dissolved iron was present, a slightly lower proportion of iron was complexed to organic carbon (i.e., a minimum 98% complexation by DOC in a POF-ESS sample (Appendix Tables A.5 and A.6), compared to a minimum 99.99% complexation by DOC when precipitation was modelled (Attachment B)). These results show that precipitation of iron (and/or the presence of low abundance high affinity binding sites) does not have a large effect on the proportion of iron that is organically complexed.

Copper Speciation Distribution (Visual MINTEQ)

Speciation distribution for the water samples, showed that in all cases, 99 to 100% of the total dissolved copper at Hazeltine Creek and Polley Flats, was complexed by organic ligands when precipitation of iron was allowed (Attachment B). The remaining proportion of copper that was not organically bound was mostly inorganically complexed, with the free copper ion present at

concentrations at least an order of magnitude lower than the inorganic copper. These results are in keeping with the understanding that the majority of copper in natural surface waters is organically complexed if sufficient organic ligands are present (Millero 1975; USEPA 2007; Grosell 2012).

When iron was not allowed to precipitate in the model, the proportion of copper that was organically complexed was lower due to greater competition from iron for organic binding sites (Attachment C, Tables C.5 and C.6). When precipitation was allowed, the range of the proportion of organically complexed copper was 99 to 100%; this range decreased to 93 to 100% when precipitation was not allowed. The minimum of 93% was for one POF-ESS sample. This is explained by the competition of iron with copper for binding sites on organic carbon - when iron is allowed to precipitate, the total dissolved iron concentration decreases, resulting in decreased competition by iron for organic binding sites. Iron competition with copper for binding sites is well known (Peters et al. 2001). Under either scenario (with precipitate or no precipitate of iron allowed by the model), a high proportion of copper (≥93%) is organically bound.

The impact on the mineral solubility assessment of only using free copper and assuming an average carbon complexation of 95% is shown in Figure 5-5. All of the concentration data plot below the mineral tenorite, which is the most insoluble mineral used in the assessment and the mineral solubility control of free copper, appears to be well constrained and consistent with first principles and other mine sites.

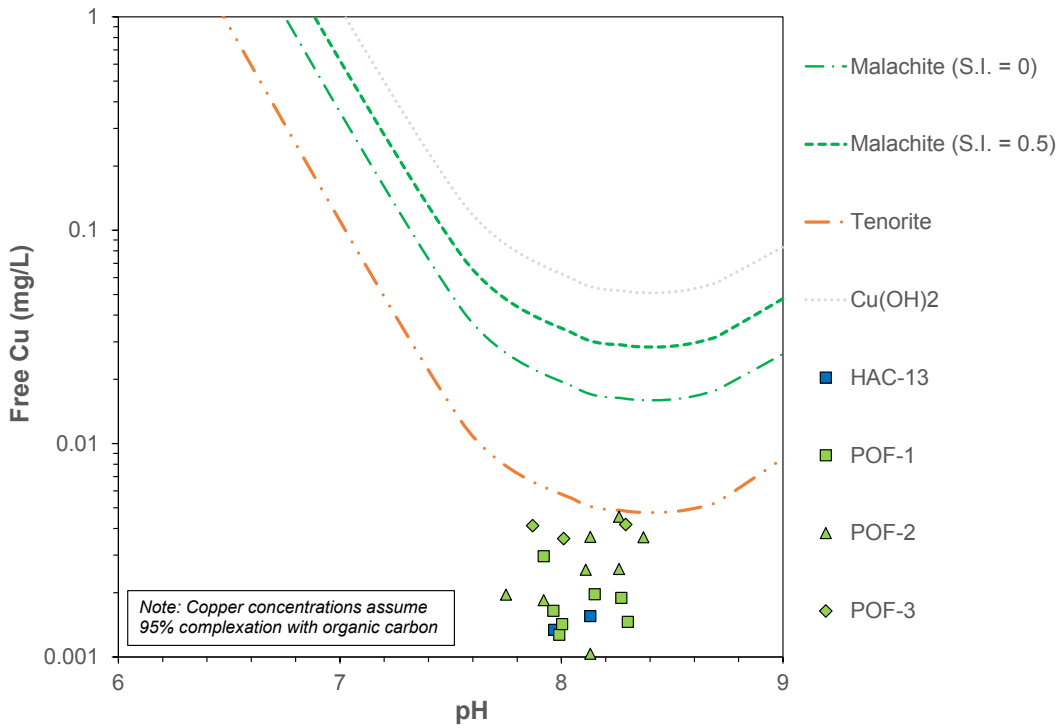

Figure 5-5: Secondary copper mineral solubility curves after removal of DOC complexed copper.

Copper Biotic Ligand Model (HydroQual)

The US EPA Instantaneous Water Quality Criteria (IWQC) calculation mode was used to calculate the CCC and the Criterion Maximum Concentration (CMC) for copper. There was one sample that exceeded the (chronic) CCC, and no samples exceeded the (acute) CMC (Attachment D). The one exceedance (of the CCC only) was a sample collected from Polley Flats (POF-1 15-Mar-2016).

5.4.4 Modelling Conclusions

The Visual MINTEQ modelling showed that, in all cases, 93 to 99% of copper was organically complexed whether or not precipitation by iron oxides were modelled. Iron was modelled to be 99 to 100% organically complexed. However, when allowed by the model, some iron was predicted to precipitate, suggesting that the water samples were not at thermodynamic equilibrium, or that the proportion of low abundance high affinity organic binding sites was under-represented by the model.

As an extension to the substantial organic complexation documented using Visual MINTEQ, application of the BLM (which accounts for complexation [including organic] and competition for copper uptake by aquatic organisms) showed that, despite copper concentrations of up to 0.091 mg/L, no water samples (seep or creek) exceeded the USEPA (2007) CMC (i.e., the IWQC acute concentration). No samples of Hazeltine Creek water exceeded the USEPA (2007) CCC (i.e. the IWQC chronic concentration), while only one sample from Polley Flats seeps exceeded the CCC. The tailings contact water POF samples are not considered to be representative of receiving environment water quality.

5.5 Weathering Effects under Sub-Oxic Conditions

A number of iron-oxide precipitating seeps have been observed along the base of the tailings alongside Hazeltine Creek. Since the pH of the seep waters are near neutral, iron is expected to be precipitating due to oxidation of dissolved ferrous iron to ferric iron as shown in Section 5.4.3. Ferrous iron formation is not unexpected as it forms by dissolution of iron-bearing minerals in natural soils and the tailings when oxygen concentrations are low, which has been observed by Golder (2016) within and below the fine-grained tailings near the forest edge along Hazeltine Creek. Carbon from overlying peat and vegetation debris can also provide an organic carbon source for microorganisms that facilitate the conversion of natural ferric oxides in the tailings and natural sediments to readily-soluble ferrous forms.

The sequential extraction work previously completed (SRK 2015a) showed that copper minerals are not susceptible to the same dissolution reactions as those for iron under low oxygen conditions. These low oxygen conditions actually help limit sulphide oxidation and therefore the release of copper.

The seeps may have one potential impact to slightly depress pH. A depression in pH may be caused by an excess of carbon dioxide in the water that has accumulated from carbonate mineral dissolution and that has not had a chance to off-gas to the atmosphere. This has been confirmed by comparing field and laboratory pH as well as PHREEQC modeling on the POF-1 samples,

which were calculated by the model to be oversaturated with respect to carbon dioxide by nearly an order of magnitude. Another possible impact on pH could be from the oxidation of ferrous iron and subsequent hydrolysis of ferric iron to form oxyhydroxides (i.e. the fluffy iron precipitates) as this process will release some acidity. While the Polley Flats ditch water had a slightly lower pH at times compared to Hazeltine Creek, it was always neutral and the acidity from iron precipitation is not likely an important process of copper leaching in the Polley Flats area. If iron hydrolysis acidity was controlling pH, then it might be expected that pH would remain below 8.0 and would not increase, unlike what is observed in the monitoring data. The flushing of the tailings during freshet (or other precipitation events) would also likely lower carbon dioxide oversaturation, which is what is observed in the alkalinity data from March to May 2016 in the POF samples.

5.6 Copper Concentration Predictions

The concentrations of copper measured at POF-1 in 2016 likely represent the upper end concentrations for free copper that can be expected at present and in the future from the Polley Flats. While this location is still impacted by DOC concentrations that are complexing copper, this site had the lowest amount of DOC compared to POF-2 and POF-3. The pH is not expected to change significantly other than potential minor fluctuations (e.g. between 7.5 and 8.3) during the beginning of freshet and following other extended dry times of the year. As a result, copper concentrations, especially free copper, will be well constrained.

The 99th and 95th percentile copper concentrations for porewater in unsaturated (i.e. drained) tailings predicted by SRK (2016) as part of other studies for the MPM were 0.05 and 0.04 mg/L, respectively. These concentrations are consistent with malachite solubility with an SI of between 0 and 0.5, upper end concentrations at POF-1 (even without considering carbon complexation), and other mine sites (e.g. Figure 2-1). During later stages of freshet or times of year when precipitation is infiltrating the tailings, porewater concentrations are expected to decrease as pH goes above 8.0. Conservatively, it should be assumed that these upper end predictions are reached each season, but long term downward trends are probable, as discussed in Section 5.1.

6 Inputs to Reclamation Planning

The presence of a secondary mineral control on copper concentrations is an important finding for reclamation planning. This is because any efforts to encourage surface run-off of precipitation from the Polley Flats (i.e. grading) or evapotranspiration through soil covers and vegetation growth will likely result in a decreased loading of copper to the receiving environment. Mineral solubility control will maintain free copper concentrations at a fixed level, so despite steady upper limit copper concentrations, with less water moving through the tailings, less copper can be transported. The establishment of vegetation on the top of the tailings will also help slow down oxygen diffusion into the tailings and probably result in lower rates of sulphide oxidation and therefore primary copper leaching rates, although penetration of the tailings by roots may limit this potential benefit.

Since the time of writing this memo, SRK and Minnow Environmental understand that the high DOC containing water at POF-2 has been redirected away from the Polley Flats towards the water treatment discharge location to avoid contact with the tailings. Monitoring of this water is

continuing under the site location name of the ‘Cedar Swamp Ditch’ (CSD). As a result, POF-3 has stopped flowing and less copper will likely be complexed with carbon from this location. Continued monitoring will help confirm this understanding and where possible, diversion of high DOC water away from direct interaction with the tailings will likely result in lower copper complexation with carbon.

7 Closing

The copper concentrations observed in the Polley Flats area in ditches and pooled water can be explained from geochemical first principles considering processes that release copper to solution then constrain the resulting copper concentrations by the solubility of copper oxides, as described in the GCM. Copper concentrations that were not constrained by mineral solubility were shown to be predominantly complexed with DOC. The resulting free copper concentrations are low and typical for waters in contact with non-acidic carbonate-containing materials with copper concentrations expected to be stable in the long term.

Application of water quality criteria that account for organic complexation indicate no exceedances of chronic guidelines for copper in any of the Hazeltine Creek samples. This is encouraging because copper concentrations in Hazeltine Creek are expected to decrease over time due to the aging processes discussed in this memo and MPM’s ongoing rehabilitation of Hazeltine Creek and its watershed.

Field monitoring should continue to help validate or, if necessary, revise the existing model. The GCM presented herein may also be considered for inclusion in a broader model for the spilled tailings incorporating hydrogeology and geochemistry processes to assess future water quality in Hazeltine Creek.

Groundwater Quality Update Technical Memorandum

TECHNICAL MEMORANDUM

DATE 10 February 2017 **REFERENCE No.** 1662612-024-TM-Rev1-22200

TO Art Frye, Colleen Hughes, and 'Lyn Anglin
Mount Polley Mining Corporation, Imperial Metals Corporation

CC Don Parsons (MPMC)

FROM Evin Zapf-Gilje,Trish Miller, and Reidar Zapf-Gilje **EMAIL** Evin@Zapf-Gilje@golder.com; Trish_Miller@golder.com

UPDATED FACTUAL DATA REPORT ON GROUNDWATER QUALITY HAZELTINE CHANNEL FLOODPLAIN, 2015 & 2016 – MOUNT POLLEY MINE

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with this updated technical memorandum for the groundwater quality investigation in support of the Detailed Site Investigation (DSI) and Human Health and Ecological Risk Assessment (HHERA) for the Mount Polley Mine (the Site). The investigation was carried out in accordance with the document entitled *Work Plan for Monitoring in Support of Risk Assessment at the Mount Polley Mine, Mount Polley Mine, BC* (Golder, 2016).

Golder previously undertook groundwater monitoring at the Site in 2015 to confirm the results of the geochemistry investigation conducted by SRK Consulting (SRK 2015), which was reported in *Factual Data Report on Groundwater Quality, Hazeltine Creek Floodplain, August 2015* (Golder, 2015) and included in the DSI report for the Site.

This factual report presents the data collected to date and compares them to the Contaminated Sites Regulation (CSR) standards protective of aquatic life, livestock water, irrigation water and drinking water. Interpretation for the selection of Contaminants of Potential Concern (COPCs) will be presented in subsequent DSI and Risk Assessment reports.

1.0 SCOPE OF WORK

The scope of work related to this groundwater quality update included the following tasks:

- Re-screen existing groundwater quality results from *Factual Data Report on Groundwater Quality, Hazeltine Creek Floodplain, August 2015* (Golder, 2015) against updated CSR standards (see Section 4.0 for details).
- Installation of 18 new groundwater monitoring wells at the Site including:
  - a second deeper well at selected existing mini-piezometers
  - new nested wells along select transects
  - additional reference stations

- Collection of groundwater samples from newly-installed monitoring wells for laboratory analysis of hardness, acidity, Total Suspended Solids (TSS), pH, anions, nutrients and metals.
- Collection of groundwater samples from 2015 monitoring wells, where possible, for laboratory analysis of hardness, acidity, TSS, pH, anions, nutrients and metals.
- Preparation of this technical memorandum.

Groundwater samples were analyzed for dissolved metals for the purposes of groundwater quality characterization, while samples were analyzed for anions, and nutrients in order to support the geochemistry and risk assessment studies. Samples were analyzed for TSS to provide additional information about the sample for interpretation purposes.

A hydrogeological assessment, including analysis of hydraulic conductivity tests and evaluation of groundwater flow directions was also completed in support of the HHERA. The results of the hydrogeological assessment will be presented in the forthcoming supplemental DSI report along with relevant information from investigation work currently being conducted in the vicinity of the Tailings Storage Facility at the Site.

2.0 APPLICABLE REGULATORY CRITERIA

In British Columbia, environmental matters pertaining to contaminated sites generally fall under the jurisdiction of BC Ministry of Environment (MoE), pursuant to the *Environmental Management Act* (EMA, SBC 2003, Chapter 53 assessed 23 October 2003, as amended on 8 July 2004). The two key regulations under the EMA that relate to the assessment and remediation of contaminated sites are the Contaminated Sites Regulation (CSR; BC Reg. 375/96, O.C. 1480/96 and M271/2004, as updated [includes amendments up to BC Reg. 184/2016, updated to 19 July 2016]), and the Hazardous Waste Regulation (HWR; BC Reg. 63/88, O.C. 268/88, as updated [includes amendments up to BC Reg. 63/2009, updated to 1 April 2009]).

The CSR provides Generic Numerical Water Quality Standards for the assessment of groundwater quality at sites subject to investigation. The Water Quality Standards are divided into four categories that provide standards for the protection of aquatic life (AW) and for defined groundwater uses including irrigation water (IW), water for livestock (LW), and drinking water (DW). Standards for the protection of aquatic life (AW) contain subcategories applicable on a site-specific basis where the proximity of the Site to receiving freshwater (F) and marine water (M) bodies must be considered.

Groundwater results for samples presented in the DSI were screened against the CSR groundwater standards (Schedules 6 and 10) for protection of AW-F and DW. Based on comments received following a review of the DSI for the Site, it was determined that a portion of land along Hazeltine Channel is dedicated under the Agricultural Land Reserve (ALR). CSR groundwater standards for the protection of IW and LW have therefore been added for screening of the groundwater results. In this memo, we present the comparisons of both the 2015 and 2016 groundwater results to all four standards, AW-F, DW, IW, and LW.

3.0 METHODS

3.1 Approach and Rationale

The groundwater investigation was designed to assess the impact of the tailings on the groundwater quality in the tailings and the underlying native till. Monitoring wells were installed at a minimum of ten meters away from surface water bodies and the locations were selected in order to provide coverage along tailings impacted portions of the Hazeltine Channel floodplain including new 5 wells in the Polley Flats area. Nested monitoring well pairs (one within the tailings impacted layer and one within the top metre of native till underlying the tailings) were installed at each location except at locations along Hazeltine Channel where tailings material had been removed. A single shallow well was installed in each of the three background locations.

Table 1, below, provides details on each of the monitoring well locations, including the stratigraphy in which monitoring well was screened. Monitoring well locations are shown in Figures 1 through 7, attached to this technical memorandum.

Table 1: Groundwater Monitoring Wells, Mini-Piezometers and Grab Samples

Well Name	Date Installed	Sample Type	Nested Wells Pairs	Screen Stratigraphy
Upper Hazeltine				
MW16-02	16 August 2016	Monitoring Well	-	Tailings
MW16-01S	10 August 2016	Monitoring Well	MW16-01D	Tailings
MW16-01D	10 August 2016	Monitoring Well	MW16-01S	Native underlying tailings

GW15-03	3 August 2015	Mini-Piezometer	MW16-04	Tailings
Lower Hazeltine				
GW15-02	2 August 2015	Mini-Piezometer	-	Reworked tailings
MW16-07	11 August 2016	Monitoring Well	GW15-01	Tailings below till cap
GW15-01	3 August 2015	Mini-Piezometer	MW16-07	Reworked tailings
MW16-08S	11 August 2016	Monitoring Well	MW16-08D	Reworked tailings
MW16-08D	11 August 2016	Monitoring Well	MW16-08S	Native underlying tailings
MW16-09	11 August 2016	Monitoring Well	-	Native underlying tailings
MW16-10	11 August 2016	Monitoring Well	-	Reworked tailings

Well Name	Date Installed	Sample Type	Nested Wells Pairs	Screen Stratigraphy
Background				
MW16-11	13 August 2016	Monitoring Well	-	Background (till)
MW16-12	16 August 2016	Monitoring Well	-	Background
MW16-13	16 August 2016	Monitoring Well	-	Background (till)
GW15-BKG-01	4 August 2015	Shallow-pit Well	-	Background

Notes: Reworked tailings—As a part of rehabilitation of the area tailings were either: intermixed with till and organic soils, or mostly removed. It is assumed there is some tailings remaining in these areas but that they comprise less than 50% of the substrate.

Wells are listed from upstream to downstream, top to bottom of Hazeltine Channel.

3.2 Borehole Drilling and Monitoring Well Installation

Between 10 August and 13 August 2016, 14 boreholes were advanced in the Hazeltine Channel floodplain for the purpose of installing groundwater monitoring wells. The boreholes were advanced using a truck-mounted solid stem auger drill rig, operated by Golder. One additional borehole was advanced using the same method in nearby un-impacted areas on 13 August 2016 for the purpose of installing background monitoring wells.

Three additional boreholes were hand drilled on 16 August, 2016 using an AMS Auger Kit attached to a Bosch Power Drill in areas inaccessible with a drill rig. Two background monitoring wells (MW16-12 and MW16-13) were installed using this method as well as one monitoring well in the floodplain (MW16-02). Soil conditions were recorded on borehole logs along with any field observations (i.e., odours, staining, etc.).

The drill augers and sampling equipment were cleaned and/or rinsed between borehole locations. A copy of the borehole logs and monitoring well construction details is included in Attachment 2.

3.3 2016 Groundwater Monitoring

3.3.1 Well Development

Following drilling and monitoring well installation, the newly-installed monitoring wells were developed in order to remove the fine sediments and water that may have been affected by the drilling or well installation and to improve the hydraulic connection between the wells and the surrounding aquifer. Monitoring well development was completed between 14 August and 18 August 2016.

The monitoring wells were developed by purging and removing groundwater using a peristaltic pump (suction lift) with dedicated silicon tubing at the pump head attached to 6 mm (1/4 inch) diameter high-density polyethylene (HDPE) tubing. Approximately ten well volumes were removed from the monitoring wells where possible, or where recharge was insufficient, the monitoring well was purged until dry approximately three times. Field parameters including temperature, electrical conductivity, pH, dissolved oxygen, and redox potential were recorded YSI Pro Plus water quality meter during development and were recorded on dedicated field forms provided in Attachment 3.

3.3.2 Monitoring and Sampling

Prior to sampling, groundwater elevations were measured using an electronic probe. Groundwater was then purged from monitoring wells using a peristaltic pump (suction lift) with dedicated silicon tubing at the pump head attached to 6 mm (1/4 inch) diameter HDPE tubing. During purging, a YSI Pro Plus water quality meter was used to collect field measurements of pH, temperature, dissolved oxygen, redox potential and conductivity. Once these parameters had stabilized (i.e., changes between three successive measurements were less than 10%) and/or the wells had been successively purged dry (due to low flow conditions) and permitted to recharge, groundwater samples were collected.

Groundwater samples were collected from monitoring wells between 30 August and 1 September 2016 in laboratory-supplied, verified clean plastic bottles. The samples were labelled, registered on chain-of-custody forms, stored in a refrigerator until being shipped in a cooler on ice for transport to the laboratory for analysis. Dissolved metals samples were filtered in the field using 0.45 micrometre filters, and then immediately preserved with nitric acid.

Copies of the groundwater sampling forms are included as Attachment 4.

3.4 2016 Laboratory Analysis

ALS Laboratory Group (ALS) of Burnaby, BC performed chemical analyses of groundwater samples collected during the monitoring event. Samples were transported to the laboratory in coolers with ice packs and chain-of-custody forms. Information pertaining to sampling location was not provided to the laboratory to ensure that unbiased analytical procedures were observed, and that the results of the duplicate analyses could be used to assess the quality of the laboratory analyses. The laboratory methods used by ALS to complete the analyses followed accepted national and international methodologies. ALS is accredited by the Canadian Association for Laboratory Accreditation (CALA) for the methods that were used to analyze the groundwater samples.

Copies of the analytical reports, and the corresponding chain-of-custody forms, are presented in Attachment 6.

3.5 Quality Assurance and Quality Control Procedures

To document that the sampling and analytical data were interpretable, meaningful and reproducible, conformance to the Golder quality assurance and quality control (QA/QC) program was followed. This involved using QA/QC measures in both the collection (field program) and analysis (laboratory) of environmental samples.

The following discussion includes a brief summary of the QA/QC measures implemented by Golder during the field program and during our review of the data, as well as the QA/QC measures implemented by the analytical laboratory.

Quality control measures use in the well development, sample collection, preservation and shipment included the following:

- Well development and sampling methods were consistent with established Golder protocols and provincial/federal requirements.
- Field notes were recorded during the investigation and have been stored in the project file.
- Sample locations were recorded and marked in the field.
- Samples were filtered, preserved (where appropriate), put on ice and subsequently transported to the laboratory using MPMC chain-of-custody procedures.

The quality assurance measures for the field program included:

- Submission of blind field duplicate samples for at least one in every ten samples. A blind field duplicate sample is a second sample of a certain media (e.g., soil; water) from the same location that is submitted to the analytical lab under a separate label such that the lab has no prior knowledge that it is a duplicate.
- For duplicate samples, either the relative percent difference (RPD) or difference factor (DF) was used to evaluate the sample result variability, depending on the magnitude of the concentrations. The RPD is a measure of the variability between two outcomes from the same procedure is calculated by:

$$absolute\left(\frac{(x_1 + x_2)}{average(x_1, x_2)}\right) \times 100$$

  Where x_1 is the original sample result and x_2 is the blind field duplicate result. In general, the RPD should not be more than 35% on average, or a maximum of 50%, depending on the parameter and the concentration. A RPD greater than 30% may reflect “in bottle” variability or variation in the test process. RPD is calculated when sample results are equal to or greater than five times the laboratory method detection limit. DF is the absolute difference between the two values divided by the method detection limit and is calculated when sample results are less than five times the method detection limit but not less than the method detection limit. In general, DF should be less than 2.

The following criteria were considered acceptable for laboratory QA/QC samples:

- For organic and inorganic analytes, analytical duplicates should exhibit less than 35% RPD on average, and no more than 50% for a specific analyte.
- Analytical results for reference materials or spiked standards should be within 10% of certified values for inorganic elements or 30% of certified values for organic compounds.
- Analytical blanks should be less than the detection limits used for the specific analysis.
- Certification by the Canadian Association for Laboratory Accreditation Inc. (CALA) for analytical methods used for this program.
- Reports from the laboratory were internally reviewed by MPMC prior to submission to Golder. If internal QA/QC problems are encountered, the field samples and/or internal QA/QC samples are re-analysed.

4.0 GROUNDWATER QUALITY RESULTS

4.1 Field Observations

The condition of both the 2015 and 2016 wells was noted during the field work including recharge rates, volume of water in the well, and visible turbidity in the groundwater during sampling. These observations are summarized in Table 2 below. A photograph log of select photos taken during drilling and installation, development, sampling and surveying is included in Attachment 5.

Table 2: Field Observations of Well Condition, Volume and Groundwater Turbidity in 2016

Well Name	Well Condition	Volume	Sampled in 2016	Turbidity
MW16-02	Fast recharge	Low volume	Yes	Not turbid
MW16-01S	Dry	None	No	-
MW16-01D	Slow recharge	Low volume	Yes	Not turbid
MW16-03S	Dry	None	No	-
MW16-03D	Slow recharge	Low volume	Yes	Slightly turbid
MW16-05S	Dry	None	No	-
MW16-05D	Slow recharge	Low volume	Yes	Turbid
GW15-06	Destroyed	-	No	-
GW15-04	-	-	No	-
GW15-05	-	-	No	-
MW16-06S	Fast recharge	Low to mid volume	Yes	Not turbid
MW16-06D	Slow recharge	Mid volume	Yes	Slightly turbid
MW16-04	Fast recharge	Mid volume	Yes	Clear
GW15-03	Very slow recharge	Low volume	No	Black organic stained water
GW15-02	Fast recharge	Mid volume	Yes	Slightly turbid
MW16-07	Fast recharge	Mid volume	Yes	Slightly turbid
GW15-01	Slow recharge	Very low volume	No	Turbid
MW16-08S	Dry	None	No	-
MW16-08D	Slow recharge	Very low volume	Yes	Slightly turbid
MW16-09	Slow recharge	Low volume	Yes	Slightly turbid
MW16-10	Dry	None	No	-
MW16-11	Slow recharge	Mid to high volume	Yes	Slightly turbid
MW16-12	Dry	None	No	-
MW16-13	Dry	None	No	-
GW15-BKG-01	Destroyed	-	No	-

Notes: Dry – The well did not have any water at the time of monitoring in August 2016. Very low volume – Wells were considered very low volume if they had less than 0.05 litres of water. Low volume – Wells were considered low volume if they had less than 0.5 litres of water.
Mid volume – Wells were considered mid volume if they had between 0.5 litres and 1.5 litres of water.
Slow recharge – Recharge was considered slow where the lowest setting on a peristaltic pump was greater than the well recharge.
Fast recharge – Recharge was greater than the rate the well was pumped; approximately 150-200 mL/min. Well volume did not have an effect on development or sampling.
"-" = Not Applicable.

4.2 Groundwater Chemistry

Groundwater quality results are presented in Table 1-1 in Attachment 1. Results were screened against CSR Schedule 6 Generic Numerical Water Standards for Protection of Freshwater Aquatic Life, Drinking Water, Irrigation and Livestock Watering.

4.2.1 Comparison of Groundwater Quality in Tailings versus "Native Under Tailings"

Groundwater chemistry results from wells screened in tailings and native substrates are shown in Table 3 and Table 4 below. Results are shown for the metals of concern related to tailings (copper, selenium and vanadium) and other metals with one or more exceedances of applicable standards.

Table 3: Groundwater Metal Concentrations from Wells Installed in Tailings

Parameter	Arsenic	Copper	Iron	Manganese	Molybdenum	Selenium	Vanadium
MW16-02	0.0034	0.0013	3.0	3.8	0.056	0.00013	0.0016
GW15-06	0.0031	<0.0010	13.4	9.3	0.0022	<0.0010	<0.030

MW16-08D	0.0025	0.0048	0.081	0.13	0.0013	0.00083	<0.00050
MW16-09	0.00051	0.0024	0.29	3.8	0.0011	0.000052	0.0011
Median	0.00089	0.0025	0.29	2.6	0.0014	0.00011	<0.00050

Notes: All concentrations are in mg/L.

Bolding indicates an exceedance of CSR standards protective of freshwater aquatic life.

Red text indicates an exceedance of CSR standards protective of drinking water.

Underlined indicates an exceedance of CSR standards protective of water used for irrigation.

Yellow highlighting indicates an exceedance of CSR standards protective of water used for livestock watering.

Concentrations of copper in groundwater in wells installed in tailings ranged from <0.0010 to 0.0091 milligrams per litre (mg/L) with a median value of 0.0021 mg/L. This was similar to groundwater from wells installed in native soils underlying tailing which had copper concentrations ranging from <0.00050 to 0.0048 mg/L with a median value oHazf 0.0025 mg/l, and similar to the concentrations measured in two background wells of 0.00084 to 0.0024 mg/l (see Table 9).

Vanadium concentrations in groundwater from wells installed in tailings and wells installed in native soils underlying tailings had a similar range of concentrations, <0.00050 to 0.0016 mg/L and <0.00050 to 0.0017 mg/L, respectively. The median concentration of vanadium in both screened stratigraphy's was less than the method detection limit (MDL), although the detection limit was raised for samples collected in 2015.

Concentrations of selenium in wells installed in tailings and wells installed in native soils underlying tailings had a similar range of concentrations, <0.0010 to 0.00028 mg/L and <0.000050 to 0.00083 mg/L, respectively. The median concentration of selenium in wells screened in tailings was less than the MDL (<0.0010 mg/L), while the median concentration of selenium in wells screened in native soils underlying tailings was 0.0011 mg/L.

Based on a comparison of median concentrations, concentrations of arsenic, iron, and molybdenum were elevated in wells screened in tailings compared to wells screened in native soils underlying tailings (Table 3 and Table 4). Concentrations of manganese in groundwater was similar between wells screened in tailings and wells screened in native soils underlying tailings (Table 3 and Table 4).

4.2.2 Comparing 2015 to 2016 Results

Groundwater chemistry results from samples collected in 2015 and 2016 are shown in Table 5 and Table 6 below. Results are shown for the metals of concern related to tailings (copper, selenium and vanadium) and other metals with one or more exceedances of applicable standards.

Table 5: Metal Results from the 2016 Groundwater Investigation

Wells	Arsenic	Copper	Iron	Manganese	Molybdenum	Selenium	Vanadium
MW16-01D	0.00095	0.021	1.9	12.5	0.0068	0.00025	0.0017

Table 6: Metal Results from the 2015 Groundwater Investigation

Wells	Arsenic	Copper	Iron	Manganese	Molybdenum	Selenium	Vanadium
GW15-06	0.0031	<0.0010	13.4	9.3	0.0022	<0.0010	<0.030
Seep15-01	0.0016	0.029	0.51	4.3	0.0074	<0.0010	<0.030
GW15-05	0.0020	<0.0010	<0.030	0.10	0.0072	<0.0010	<0.030
GW15-04	0.0012	0.0091	<0.030	0.15	0.0079	<0.0010	<0.030
GW15-03	0.0034	0.0028	2.1	13.2	0.0082	<0.0010	<0.030
GW15-01	0.029	0.0012	21.6	26.5	0.0036	<0.0010	<0.030
GW15-02	0.0037	0.0036	0.054	1.5	0.065	<0.0010	<0.030
Median	0.0033	0.0020	1.1	5.4	0.0076	<0.0010	<0.030

Notes: All concentrations are in mg/L.

Bolding indicates an exceedance of CSR standards protective of freshwater aquatic life.

Red text indicates an exceedance of CSR standards protective of drinking water.

Underlined indicates an exceedance of CSR standards protective of water used for irrigation.

Yellow highlighting indicates an exceedance of CSR standards protective of water used for livestock watering.

Concentrations of copper in groundwater collected in 2015 ranged from <0.0010 to 0.0091 mg/L with a median concentration of 0.0020 mg/L. Groundwater collected in 2016 had copper concentrations ranging from <0.00050 to 0.021 mg/L with a median value of 0.0025 mg/L.

Vanadium was detected in 6 of 11 samples collected in 2016, ranging from <0.00050 to 0.0017 mg/L, while all samples collected in 2015 had concentrations below the MDL (<0.030 mg/L). It was not possible to make a comparison between the concentrations of vanadium in groundwater collected in 2015 and 2016 as all detected concentrations in 2016 were below the MDL for the 2015 samples.

Selenium was detected in 10 of 11 samples collected in 2016, ranging from <0.00050 to 0.00083 mg/L, while all samples collected in 2015 had concentrations below the MDL (<0.0010 mg/L). It was not possible to make a comparison between the concentrations of vanadium in groundwater collected in 2015 and 2016 as all detected concentrations in 2016 were below the MDL for the 2015 samples.

The median concentrations of arsenic, iron, manganese and molybdenum were lower in samples collected in 2016 than samples collected in 2015 (Table 5 and Table 6). However, only GW15-02 was sampled during both events, and the concentrations at this location in 2016 were within two times of the concentrations measured in 2015 for arsenic, iron, manganese and molybdenum. Although this difference is small, it may be a result of a change to a reducing condition at this location as indicated by the change in ORP readings from 35.1 to -69.9 mV (Table 1-1).

Concentrations of copper collected in GW15-02 in 2016 (0.0014 mg/L) was somewhat lower that that measured in 2015 (0.0036 mg/L). Concentrations of selenium and vanadium could not be compared between the two years as the 2015 data was below the MDL. The detected levels of selenium and vanadium in 2016 (0.000073 and 0.00073 mg/L, respectively) was well below the MDL of the 2015 data (<0.0010 mg/L and <0.030 mg/L, respectively).

4.2.3 Summary of Exceedances

4.2.3.1 2016 Monitoring Results

Table 7 below summarizes the 2016 groundwater chemistry results shown for the metals of concern related to tailings (copper, selenium and vanadium) and other metals with one or more exceedances of applicable standards. There were no exceedances of standards for copper, selenium and vanadium.

Table 7: Summary of Exceedances in Groundwater - 2016

Metal	N	Min	Max	Median	AW	DW	IW	LW	Exceedances	#of Exceedances
Arsenic	11	0.0005	0.006	0.00095	0.05	*0.01*	0.1	0.025	None	0
Copper	11	0.0005	0.021	0.0025	0.08–0.09	*1*	0.2	0.3	None	0
Iron	11	0.03	3.04	0.29	-	*6.5*	5	-	None	0
Manganese	11	0.056	12.5	2.6	-	*0.55*	0.2	-	*DW*, IW	*7*, 9
Molybdenum	11	0.00007	0.106	0.0018	10	*0.25*	0.01-0.03	0.05	IW, LW	4, 3
Selenium	11	0.00005	0.0008	0.00011	0.01	*0.01*	0.02	0.05	None	0
Vanadium	11	0.0005	0.0017	0.00073	-	-	0.1	0.1	None	0

Notes: All values are in mg/L unless otherwise noted.

AW = CSR Schedule 6 Standard protective of Freshwater Aquatic life (**bold font**).

DW = CSR Schedule 6 Standard protective of Drinking Water (*italic font*); IW = CSR Schedule 6 Standard protective of Irrigation Water (underlined font); LW = CSR Schedule 6 Standard protective of Livestock Water (thick-underlined font); ' – ' = No standard.

4.2.3.2 2015 Monitoring Results

Table 8 below summarizes the 2015 groundwater chemistry results shown for the metals of concern related to tailings (copper, selenium and vanadium) and other metals with one or more exceedances of applicable standards. There were no exceedances of standards for copper, selenium and vanadium. Other metal concentrations were below applicable standards, except for arsenic, iron, manganese and molybdenum in some samples. Maximum concentrations of arsenic, iron and manganese were observed in GW15-01 which had an ORP of -40.5 mV. It is well understood that reducing environments increase the solubility of naturally occurring metals and therefore the higher concentrations of these metals is likely related to the reducing conditions found in this sample.

Table 8: Summary of Exceedances in Groundwater – 2015

Metal	N	Min	Max	Median	AW	DW	IW	LW	Exceedances	#of Exceedances
Arsenic	6	0.0012	0.029	0.0033	0.05	*0.01*	0.1	0.025	DW, LW	1
Copper	6	0.0010	0.0091	0.002	0.08–0.09	*1*	0.2	0.3	None	0
Iron	6	0.03	21.6	1.1	-	*6.5*	5	-	DW, IW	2
Manganese	6	0.101	26.5	5.4	-	*0.55*	0.2	-	DW, IW	4
Molybdenum	6	0.0022	0.065	0.0076	10	*0.25*	0.01-0.03	0.05	IW, LW	1
Selenium	6	0.0010	0.0010	<0.0010	0.01	*0.01*	0.02	0.05	None	0
Vanadium	6	0.030	0.030	<0.030	-	-	0.1	0.1	None	0

Notes: All values are in mg/L unless otherwise noted.

AW = CSR Schedule 6 Standard protective of Freshwater Aquatic life.

DW = CSR Schedule 6 Standard protective of Drinking Water; IW = CSR Schedule 6 Standard protective of Irrigation Water; LW = CSR Schedule 6 Standard protective of Livestock Water; ' – ' = No standard.

4.2.4 Background Wells

Background groundwater chemistry results for metals with a standard are shown Table 9. As shown, the background concentrations of metals were below applicable standards at both locations. GW-BKG15-01 was sampled in 2015 and MW16-11 in 2016.

Three new background monitoring wells were installed in accordance with the scope outlined in *Work Plan for Monitoring in Support of Risk Assessment at the Mount Polley Mine, Mount Polley Mine, BC* (Golder 2016). Because of access problems, the installation was made by hand rather than using the pick-up mounted auger rig. Two attempts were made when installing MW16-12, both encountering rejection before reaching the reaching an apparent wet zone. It was decided to install a monitoring well with the goal of sampling during the wet season. Similarly, rejection was encountered at MW16-13 before reaching the water table. Both of these background wells (MW16-12 and MW16-13) were dry. The local background groundwater chemistry was collected for comparison of metals that do not exceed the standards to local background conditions. This comparison was of interest for the risk assessment.

Concentrations of copper background wells ranged from 0.00084 mg/L to 0.0024 mg/L (Table 9). The median copper concentration in wells installed in tailings and native soils underlying tailings was 0.0021 mg/L and 0.0025 mg/L, respectively. The range of copper concentrations in wells installed in tailings and native soils underlying tailings was <0.0010 to 0.0091 mg/L and <0.00050 to 0.0048 mg/L, respectively.

Vanadium concentrations in background wells were both below the MDL, although the detection limit for 2015 was considerably higher (Table 9). The median concentration of vanadium in both wells screened in tailings and in native underlying tailings was less than MDL. The range of vanadium concentrations in wells screened in tailings and in native underlying tailings was 0.00050 to 0.0016 mg/L and <0.00050 to 0.0017 mg/L, respectively.

Concentrations of selenium in background wells ranged from <0.0010 to 0.0022 mg/L. In wells installed in tailings and in native soils underlying tailings the selenium concentrations ranged from <0.0010 to 0.00028 mg/L and <0.000050 to 0.00083 mg/L, respectively. The median concentration of selenium in wells screened in tailings was less than the MDL (<0.0010 mg/L), while the median concentration of selenium in wells screened in native soils underlying tailings was 0.0011 mg/L.

Table 9: Groundwater Metal Concentrations in Background Wells

Metal	GW-BKG15-01	MW16-11	Median Tailings	Median Native Under Tailings
Aluminum	0.013	0.020	0.033	0.034
Antimony	<0.00050	0.00030	<0.00050	<0.00010
Arsenic	<0.0010	0.00071	0.0034	0.00089
Barium	0.028	0.064	0.089	0.12
Beryllium	<0.0050	<0.00010	<0.0050	<0.00010
Boron	<0.10	0.056	<0.10	0.036
Cadmium	<0.000050	0.000048	<0.000050	7.3E-05
Chromium	<0.00050	<0.00050	<0.00050	<0.00050

4.3 2016 Groundwater Monitoring Event QA/QC Results

Two field duplicates were collected from MW16-06S and MW16-04 and analyzed for physical tests, nutrients and metals, for a total of 16.6 % field duplicate analysis; meeting the data quality objective (DQO) of 10%. The results of the field duplicate analysis are presented in Table 1-2 in Attachment 1.

RPDs and DFs were within acceptable limits as set out in Section 3.5, except for the following:

- Total suspended solids at 41.7% RPD in MW16-04 (119 mg/L in the primary sample and 77.9 mg/L in the duplicate).

Holding times were met for all parameters, except nitrate, nitrite and phosphorous parameters, which exceeded the recommended holding time of three days by three to eight days. Due to the 15-minute hold time for ORP and pH, these parameters were measured in the field, and data reported in Table 5 represent field measurements.

Although one DQO outlier exists, the RPD of 41.7% is lower than the DQO of 50% for a single sample, as such the data from the 2016 groundwater sampling event are considered reliable for interpretation purposes.

5.0 DISCUSSION OF RESULTS

In 2016 Golder undertook a groundwater investigation of the groundwater chemistry conditions along Hazeltine Channel. This included the installation of additional monitoring wells, adding nested well pairs to select existing wells locations and in new locations, sampling 2015 wells that contained sufficient groundwater for sampling, in order to provide a more complete picture of the conditions in the Hazeltine Channel floodplain. Chemistry data from both 2015 and 2016 was screened against CSR Schedule 6 standards for aquatic life, drinking water, irrigation water, and livestock water.

Similar to the 2015 groundwater investigation conducted by Golder (Golder 2015) there were no exceedances in groundwater of CSR Standards protective of aquatic life (Tables 7 and 8).

As part of the 2016 investigation all groundwater data was additionally screened against CSR drinking water, irrigation and livestock water standards. An agricultural land reserve was identified adjacent to and on a small portion of the Site. As such groundwater in all wells on Site were conservatively screened against irrigation and livestock water standards. Concentrations of manganese and molybdenum were found to exceed at least one of these standards in both 2015 and 2016.There was one arsenic and two iron exceedances of these standards in 2015.

Groundwater chemistry results from the 2016 investigation were similar to those in 2015 with a few exceptions; most notably iron which was found to be, on average, almost an order of magnitude higher in 2015. To a lesser degree arsenic, manganese and molybdenum were higher in 2015 groundwater samples than 2016 groundwater samples. It should be noted that, with the exception of samples from GW15-02, samples were taken from different wells / mini-piezometers.

Comparing results from GW15-02 in 2015 and 2016 it was found that copper concentrations were similar. Arsenic, iron and manganese were higher in 2016 but this was likely due to the change from oxidising conditions in 2015 (ORP of 35.1 mV) to reducing conditions in 2016 (ORP of -69.9 mV).

Groundwater chemistry results for copper, selenium and vanadium were similar between wells screened in tailings and wells screened in native soils underlying tailings. Of the metals of interest arsenic, iron, and molybdenum were elevated in wells screened in tailings as compared to wells screened in native soils underlying tailings.

During the 2015 investigation groundwater seepage (Seep15-01) was collected from pooled water in a temporary ditch nearby to GW16-06. Although not a “true” groundwater sample, the sample was collected to provide a more complete picture of water chemistry within the area impacted by tailings. This sample, along with select groundwater wells, as analyzed for nutrients to help with risk assessment and remedial planning. Seep15-01 was screened against CSR Schedule 6 standards. Nitrite and manganese were found to exceed at least one CSR standard.

6.0 CLOSURE

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this memorandum.

We trust that this technical memo provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at 604 787-6707.

STUDY LIMITATIONS

This report was prepared for the exclusive use of MPMC. The report is based on data and information collected during investigations conducted by Golder Associates Ltd. personnel. It is based solely on the conditions of the subject property at the time of the site investigation conducted in August and September, 2016, as described in this technical memorandum. The data presented in this memorandum represent groundwater conditions encountered at the sampling locations tested during this time period. Groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors. Golder Associates Ltd. makes no warranty, expressed or implied, and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

The findings and conclusions documented in this report have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this report at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this report, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this report. All third parties relying on this report do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder’s report or other work product. Golder is not responsible for any unauthorized use or modifications of this report.

MPMC may rely on the information contained in this report subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this report, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein. With respect to regulatory compliance issues, regulatory statutes are subject to interpretation. These interpretations and the regulations themselves may change over time, thus MPMC should review these issues.

If new information is discovered during future work Golder should be requested to re-evaluate the conclusions of this report and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this report is affected by any change of site conditions, purpose, development plans or significant delay from the date of this report in initiating or completing the project.

Notes:

All concentrations in milligrams per litre (mg/L), unless otherwise noted.

MPMC = Mount Polley Mining Company FDA = field duplicate available; DUP = duplicate sample; < = below detection limit; "-" = not measured; H = hardness-dependent; pH = pH-dependent; Cl = Chloride-dependent ; V = valence dependent, VI refers to chromium VI and III refers to chromium III; C = Standard varies with crop, soil drainage and Mo:Cu ratio; Crop = Standard applies to all crops; St8 - Refer to CSR Schedule 6 footnotes 58, 59, 60, and 61 for the application of iron and manganese standards; CA = continuous application on crops; N = Standard is for nitrate + nitrite and does not include ammonia; L = Standard varies with type of livestock. AO = Standard to protect against taste and odour concerns

1. Standards from British Columbia Contaminated Sites Regualtion (BC CSR; Updated to July 19, 2016), Schedule 6 Generic Numerical Water Standards.

a) Fluoride standard is hardness dependent. Since all samples had hardness >50 mg/L the applicable standard is 3000 mg/L for protection of freshwater aquatic life.

123	Indicates concentration exceeding the BC CSR Schedule 6 Groundwater Standard Protective of Freshwater Aquatic Life
123	Indicates concentration exceeding the BC CSR Schedule 6 Groundwater Standard Protective of Drinking Water

Notes:

All parameter units in milligrams per kilogram (mg/kg), unless otherwise noted.

FDA = Field Duplicate Available; FD = Field Duplicate; m bgs = metres below ground surface; QA/QC = Quality Assurance/Quality Control

NA = Not Applicable; NC = Not Calculated; Mean = average of two values

Relative percent difference (RPD) = the difference between two values divided by the mean of the two values.

Golders' acceptable RPD is less than or equal to 35%.

RPD is calculated when the concentration is greater than five times the detection limit.

Difference factor (DF) = absolute difference between two values divided by the method detection limit.

Golders' acceptable DF is less than or equal to 2.0.

DF is calculated when the concentration is less than five times the detection limit.

Matrix Spike	Manganese (Mn)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Manganese (Mn)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Molybdenum (Mo)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Potassium (K)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Sodium (Na)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Sodium (Na)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Sodium (Na)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Strontium (Sr)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Strontium (Sr)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Strontium (Sr)-Dissolved	MS-B	L1824847-1, -10, -11, -12, -13, -14, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Total Nitrogen	MS-B	L1824847-1, -10, -11, -12, -2, -3, -4, -6, -7
Matrix Spike	Total Nitrogen	MS-B	L1824847-1, -10, -11, -12, -2, -3, -4, -6, -7
Matrix Spike	Total Nitrogen	MS-B	L1824847-1, -10, -11, -12, -2, -3, -4, -6, -7
Matrix Spike	Total Nitrogen	MS-B	L1824847-8, -9

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLA	Detection Limit adjusted for required dilution
DLDS	Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
BR-L-IC-N-VA	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

Reference Information

CL-IC-N-VA	Water	Chloride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

F-IC-N-VA	Water	Fluoride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

HARDNESS-CALC-VA	Water	Hardness	APHA 2340B

Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.

MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

N-T-COL-VA	Water	Total Nitrogen in water by Colour	APHA4500-P(J)/NEMI9171/USGS03-4174

This analysis is carried out using procedures adapted from APHA Method 4500-P (J) "Persulphate Method for Simultaneous Determination of Total Nitrogen and Total Phosphorus" and National Environmental Methods Index - Nemi method 5735.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	APHA 4500 NH3-NITROGEN (AMMONIA)

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NO2-L-IC-N-VA	Water	Nitrite in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

NO3-L-IC-N-VA	Water	Nitrate in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

P-T-PRES-COL-VA	Water	Total P in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.

P-TD-COL-VA	Water	Total Dissolved P in Water by Colour	APHA 4500-P Phosphorous

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Dissolved Phosphorus is determined colourimetrically after persulphate digestion of a sample that has been lab or field filtered through a 0.45 micron membrane filter.

PO4-DO-COL-VA	Water	Diss. Orthophosphate in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.

SO4-IC-N-VA	Water	Sulfate in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TSS-VA	Water	Total Suspended Solids by Gravimetric	APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius. Samples containing very high dissolved solid content (i.e. seawaters, brackish waters) may produce a positive bias by this method. Alternate analysis methods are available for these types of samples.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

DETAILED SITE INVESTIGATION FOR HAZELTINE CHANNEL– PHYSICAL HYDROGEOLOGICAL ASSESSMENT AND CONCEPTUAL MODEL – MOUNT POLLEY MINE

1.0 INTRODUCTION

This technical memorandum summarizes the physical hydrogeological assessment of the Hazeltine Channel area near the Mount Polley Mine (Mine). This assessment was conducted as part of the Detailed Site Investigation (DSI) of this area in August and September of 2016 and is based on the Mine conditions at the time of the investigation work. Golder Associates Ltd. (Golder) notes that rehabilitation works in the Hazeltine Channel area have been ongoing at the Mine and current site conditions may differ from those described herein.

The focus of this assessment is the Hazeltine Channel corridor, from its headwater at Polley Lake to its mouth at Quesnel Lake. The Mine Tailings Storage Facility (TSF) area is included in this assessment because it lies directly upgradient of Hazeltine Channel. The Mine area, although situated further upgradient relative to the TSF, is also considered because it is also an area which contributes some flow to Hazeltine Channel, as described in the conceptual site model below.

2.0 CONCEPTUAL HYDROGEOLOGICAL MODEL

2.1 Information Sources

The conceptual understanding of groundwater conditions along Hazeltine Channel was interpreted from the field data collected as part of the DSI during August and September of 2016 (i.e., borehole logs, monitoring well water levels, surface water levels, and single-well response tests), the detailed topographic dataset for Hazeltine Channel and the regional geology map.

The conceptual understanding of groundwater conditions near the TSF was previously summarized by Golder (2016a) as part of the groundwater characterization and monitoring review for the Mine. It was interpreted from semi-annual monitoring well data collected by Mount Polley Mining Corporation (MPMC) together with the drilling observations described by Knight Piésold (KP; 1997), the geologic overview report by Golder (2015b), the TSF detailed design report by Golder (2015c), and the hydrogeological assessment and data review for the Mine site by AMEC Americas Ltd. (AMEC; 2013).

2.2 Topography

Hazeltine Channel is situated about 3 kilometres (km) southeast of the mill at the Mine, and about 200 metres (m) to the east of the TSF (Figure 1). Its headwater at Polley Lake is approximately 900 m to the northeast of the TSF and its mouth at Quesnel Lake is approximately 5.5 km to the east-southeast of the TSF. The total length of the Hazeltine Channel is about 8.4 km and the total elevation loss from headwater to mouth is about 190 m (based on surface water level elevations of 920 m above sea level (asl) at Polley Lake and 726 masl at Quesnel Lake in August 2016). The channel lies within a valley that is relatively wide and shallow near the headwater (about 500 m wide) but is progressively narrower and more steeply sloped in the downstream direction (about 100 m wide) before flowing through an approximately 1 km long canyon section. Downstream of the canyon, the channel widens onto the channel fan area before entering Quesnel Lake.

The Mine is situated to the northwest of the Hazeltine Channel. The main Mine area is a topographic high, centred on Polley Mountain, which reaches an elevation of approximately 1,250 masl. This topographic high is adjacent to the Mine's Cariboo Pit and Springer Pit, and is bounded to the northeast by Polley Lake and to the southwest by Bootjack Lake. The TSF is located about 3 km southeast of the mill in a topographically low area with an original ground elevation of approximately 920 masl to 940 masl. The current crest of the TSF dam embankment is approximately 967 masl, except for the area in Corner 1, which has a crest of 959 masl.

2.3 Regional and Local Geology

Based on the regional geology map (Logan et al, 2007), about two-thirds of the Hazeltine Channel corridor (the upstream portion) lies within thick quaternary deposits, while the remaining lower portion (which includes the canyon and the fan area) lies within bedrock (Figure 2). The bedrock consists of the Nicola Group volcanics from the Late Triassic period, except at the canyon and mouth of the channel where bedrock consists of the Kamloops Group volcanics from the Eocene period. The boundary between the Nicola Group and Kamloops Group volcanics is an assumed unconformity.

The surficial soils in the Hazeltine Channel corridor were altered by the TSF breach. The vegetation, topsoil and a large amount of till was carried into Quesnel Lake by the resulting debris flow, leaving behind deposits of tailings and mixed silt/tailings. Subsequent and on-going remediation and rehabilitation work carried out by MPMC has removed portions of the tailings and added soil and vegetation over much of the Hazeltine Channel corridor.

According to the borehole logs for the wells along the channel's banks (MW16-01 to MW16-11), the surficial soils along the entire Hazeltine Channel corridor consist of interbedded finer-grained and coarser-grained sediments (e.g., sand and gravel, clayey silt and silt and sand), with organic-rich sediments found at the mouth of the channel (MW16-8, MW16-10 and MW16-11). Tailings from the TSF embankment breach on 4 August 2014 overlies most of the alluvium along the channel banks as a result of the debris flow, except for the channel bed itself. Tailings were removed from the channel bed as part of rehabilitation works which are ongoing. The tailings deposits near the mouth of the channel and within the floodplain have, in some places, been overlain by up to 2.6 m of alluvium (see logs for MW16-07 and MW16-08) as a result of ongoing remediation works.

The maximum depth of drilling was limited to between 1 m and 6 m depth due to auger refusal at the contact with inferred dense till or bedrock. In the upper Hazeltine Channel corridor (i.e., upstream portion of the valley), the geological units underlying the surficial soils are expected to consist of dense glacial till which overlie bedrock of Nicola Group volcanics, consistent with the geology observed in the area of the TSF (described below). In the lower Hazeltine Channel corridor (i.e., downstream portion of the valley), the geologic units underlying the surficial soils are expected to be bedrock, consistent with the regional geology map.

In the TSF area, the overburden consists predominantly of glacial till with interbeds of glaciofluvial and glaciolacustrine sediments. The overburden ranges in thickness from approximately 5 m along a bedrock knoll near the South Embankment to approximately 50 m along portions of the Main Embankment (Golder 2015b, Figures 6 and 9) (TSF design described below in Section 2.4). The underlying shallow bedrock is weathered and/or fractured and predominantly volcanic conglomerate (IMC 1990). The thickness of this weathered bedrock zone is highly variable and is inferred to range from 2 m to 43 m (based on borehole logs for the 1996 series monitoring wells [KP 1997] and the 2015 series boreholes [Golder 2015d]). Competent bedrock that underlies the weathered zone consists of Nicola Group volcanics that, according to the regional geology map (Logan et al. 2007), likely consist of undivided mafic volcanic and volcanoclastic rocks and/or intrusive rocks (pseudoleucite syenite). The general stratigraphy between the TSF and Hazeltine Channel is shown on cross-section A-A' in Figure 3A.

The surficial geology of the Mine area is predominantly bedrock with a relatively thin overburden. The area of the open pits (e.g., Wight, Boundary, Springer, Cariboo) is underlain by monzonite bedrock that has been intruded by hydrothermal breccias and intersected by northwest–southeast striking faults. The bedrock in the area of the Springer Pit and Cariboo Pit is overlain by a discontinuous and relatively thin (i.e., a few metres) layer of overburden of glaciolacustrine and glaciofluvial origin: primarily silt/clay.

2.4 TSF Design

The TSF includes one dam embankment that is approximately 4.8 km in length and that partially surrounds the facility on the southern and eastern side. The embankment is subdivided into three sections: the Main Embankment, the Perimeter Embankment and the South Embankment. Seepage from the tailings through the embankment and foundation is collected in three seepage collection ponds situated next to the outer perimeter of the facility. During operations prior to the tailings embankment breach, water in the seepage collection ponds (seepage, runoff and precipitation) was pumped back to the TSF as required and/or was recycled to the mill for use in the milling process (MPMC 2009). Currently, seepage is either pumped into the TSF for use as mill process makeup water or otherwise temporarily stored on site prior to treatment and discharge.

The TSF was generally constructed over low permeability glacial till. Where natural surficial glacial till cover was thin (less than two metres) and was underlain by glaciofluvial/glaciolacustrine sediments, a low permeability glacial till basin liner was constructed (KP 1997). The tailings surface currently consists of a large beach area along the embankment and a single free water (reclaim) pond on the northwest side of the facility.

2.5 Hydraulic Conductivity

The results of *in situ* hydraulic conductivity (K) testing along the Hazeltine Channel corridor are summarized in Table 1 below. These results indicate a range in permeability that is in general accordance with soil type and depositional conditions. In order of decreasing permeability, K values were obtained for tailings mixed with till ($K= 2 \times 10^{-4}$ m/s), tailings (6×10^{-6} m/s to 7×10^{-7} m/s) and native till (2×10^{-7} m/s to 3×10^{-8} m/s). The K range for native till lies within the range observed below the TSF area described below.

Table 1: Summary of Hydraulic Conductivity Results

Well ID	Lithology of Screened Interval	K (m/s)
MW16-06S	Till and Re-deposited Tailings (SAND and GRAVEL, fine to medium)	2×10^{-4}
MW16-02	Tailings (SAND, some fines)	6×10^{-6}
MW16-07	Tailings (SILT)	7×10^{-7}
MW16-01D	Till (gravelly clayey SILT; some coarse sand)	2×10^{-7}
MW16-11	Till (SILT, some gravel and sand)	3×10^{-8}

The results of *in situ* hydraulic conductivity testing in the area of the TSF summarized by KP (1990) indicated an average hydraulic conductivity, calculated as a geometric mean of individual tests, for weathered (shallow) and competent (deep) bedrock of approximately 1×10^{-7} m/s and 1×10^{-8} m/s, respectively. Measured hydraulic conductivity values in the overburden, consisting of glacial till with interbeds of glaciofluvial and glaciolacustrine sediments, ranged from 5×10^{-6} m/s to 1×10^{-8} m/s, with a geometric mean of approximately 2×10^{-7} m/s.

The hydraulic conductivity of the monzonite bedrock in the area of the open pits was found to generally decrease with depth, from approximately mid-10^{-7} m/s to 10^{-6} m/s near the bedrock top, to 10^{-8} m/s at greater depth (Golder 2014). These values indicate that this bedrock has a low (and at greater depth very low) capacity to transmit groundwater. The northwest–southeast striking faults in the area of the Cariboo Pit and Springer Pit appear to be well healed and not conductive.

2.6 Recharge and Discharge Areas

The climate and hydrology for the Mine site have been assessed as part of the water management plan for the TSF 970 m design (Golder 2015c). The Mine site experiences high summer precipitation due to summer storms, with the lowest precipitation in February. Precipitation typically occurs as snowfall in November and accumulates until March. Average annual precipitation at the Mine site is estimated to be 670 mm.

Groundwater recharge occurs through the infiltration of precipitation in the topographic high area of Polley Mountain and the surrounding slopes, excluding the existing surface mining pits. Groundwater recharge also occurs as infiltration through the tailings at the TSF, although this recharge (i.e., tailings seepage) is limited because of the basal liner of low permeability glacial till (see TSF design in Section 2.4).

Hazeltine Channel is inferred to be predominantly a groundwater discharge area. This is based on a comparison of the approximate surface water level elevations along the channel with nearby groundwater level elevations (see Figures 3A and 3B), and is supported by an upward hydraulic gradient observed at one of the well pairs next to Hazeltine Channel, as described in Section 3.2 below. The primary groundwater discharge areas are Polley Lake and Bootjack Lake to the northwest and Quesnel Lake to the east. These lakes strongly control regional groundwater flow and act as significant hydrogeological boundaries. Edney Creek to the south has also been inferred to be a groundwater discharge area.

In the Mine area, the open pits act as sinks for groundwater flow when they are dewatered, and as both sinks and sources of groundwater seepage when flooded to the spillover elevation. The recharge rate along the topographic high near the open pits (i.e., Polley Mountain) was estimated during calibration of the groundwater model (Golder 2014) to be approximately 30% of average annual precipitation.

2.7 Groundwater Use Downgradient of the Mine

A search in the British Columbia Ministry of Environment's (MoE) iMapBC online database in January 2017 indicated that there are no mapped aquifers within a radius of 10 km from the Mine. The closest mapped aquifer, Fraser Plateau Lave Aquifer No. 124 IIIB (11), is a laterally extensive bedrock unit that was classified as having low demand and moderate vulnerability. The northern terminus of this aquifer is located more than 15 km south of the Mine and is not considered to be hydraulically connected to groundwater from the Mount Polley Mine area or the Hazeltine Channel corridor. This database search also indicated that water supply wells are not present in the immediate vicinity of the Mine. The closest wells are approximately 6 km east, on the opposite (eastern) shore of Quesnel Lake. The database also contains information on water wells that are located northwest from the Mine (near Little Lake) and southwest from the Mine (near Gavin Lake) at a distance of, at minimum, 7 km. Considering these distances, and the fact that several surface water features are between these wells and the Mine, it is unlikely that seepage from the Mine facilities could reach these wells or the closest mapped aquifer.

Maps of the water well search and aquifer extents are included in Attachment 1.

3.0 GROUNDWATER MONITORING RESULTS

3.1 Water Level Elevations

Figure 4 provides a summary of the groundwater and surface water level elevations in the vicinity of Hazeltine Channel in August–September 2016. The water levels in the monitoring wells along Hazeltine Channel were recorded by Golder as part of the groundwater sampling event for the DSI. The water level data for the monitoring wells at the TSF (GW series wells) was provided by MPMC from their groundwater monitoring program (data file 'SWL 2016 using only 1st purges.xlsx'). MPMC also provided coordinates and 'top of pipe' (casing) elevations for the TSF wells in a separate data file ('GW Well Locations - March 2016.csv'). Surface water level elevations for the surrounding lakes was provided by MPMC in a separate data file. The surface water level elevations along Hazeltine Channel was estimated from a detailed topographic dataset generated by a drone survey by MPMC (May 2016, June 2016).

Based on the water level data presented on Figure 4, water level elevations were highest in Bootjack Lake and the TSF ponds and lowest in Quesnel Lake. Although groundwater levels for the Mine area are not shown on Figure 4, previous assessments for the entire Mine area indicated that the highest groundwater level elevations (approximately 1,100 masl) occurred in the area of Polley Mountain (see Figure 3–24 in Golder 2016c). The surface water level elevations along Hazeltine Channel were estimated to decline from 920 masl at the headwater at Polley Lake to 726 masl at the mouth at Quesnel Lake.

3.2 Groundwater Flow Regime

Based on the inferred water level elevation contours on Figure 4, the overall shallow groundwater flow direction was primarily towards the southeast, from Bootjack Lake and the TSF, towards Hazeltine Channel and Quesnel Lake. Although groundwater flow from the Mine area towards the channel is not as apparent on Figure 4, previous assessments for the entire Mine area indicated some groundwater flow from the Mine area directed towards the channel (see Figure 3–24 in Golder 2016c). The local groundwater regime near the TSF was inferred to be a radial outward flow system because of the high water level in the tailings ponds. Under this regime, some groundwater from below the TSF was inferred to flow towards the east and south towards Hazeltine Channel, and some towards the southwest towards Edney Creek and its tributaries. Deep (regional) groundwater flow in the area was inferred to discharge directly to Quesnel Lake (not shown on Figure 4).

Comparison of the shallow versus deeper groundwater level elevations at the paired well locations around the TSF indicates that the vertical component of groundwater flow was generally directed upward on the west side (and possibly also the northeast side) of the TSF and strongly downward on the southeast side of the TSF.

The approximate surface water level elevation in Hazeltine Channel was compared to the measured groundwater level elevations in the monitoring wells adjacent to the channel at two locations (see cross-sections on Figures 3A and 3B). This comparison indicated that the channel is primarily a "gaining stream" (i.e., groundwater seeps into the channel as baseflow rather than the channel losing surface water to the groundwater environment). This is supported by an upward hydraulic gradient observed at one of the well pairs next to Hazeltine Channel (MW16-06D) which is located between the two cross-section locations.

4.0 CLOSURE

The reader is referred to the Study Limitations, which follows the text and forms an integral part of this memorandum.

We trust that the above information is sufficient for your needs at this time. Should you have any questions or require clarification, please do not hesitate contact the undersigned at 604-296-4200.

LEGEND

EXISTING MONITORING WELLS

INTRUSIVE ROCKS

Middle Jurassic (~163 Ma)
MJ qm — Hornblende-biotite quartz monzonite

Early Jurassic (193-195 Ma)
EJ mz — Hornblende quartz porphyritic monzonite

Late Triassic to Early Jurassic composite intrusions
TJ mz — Pyroxene-hornblende monzodiorite, hornblende-biotite monzonite and potassium feldspar megacrystic syenite

Late Triassic (205-200) Ma
px — Dikes: K-spar megacrystic syenite (sy), augite porphyry (px), monzonite (mz)
LT bx — Breccias: potassic-albitic-calcic altered, Matrix to clast-supported, polymictic intrusive-dominated pipes
LT Mdd — Biotite-pyroxene diorite
LT MPmz — Pyroxene/hornblende-biotite monzonite
LT BJmsy — Melanocratic (pyroxene + hornblende) pseudoleucite syenite
LT BJosy — Orbicular pseudoleucite nepheline syenite
LT MPic — Hydrothermal altered intrusive carapace holocrystalline monzonitic intrusions and volcaniclastic wall rock
LT Nubx — Undivided polylithic breccias

LAYERED ROCKS

Quaternary thick alluvium: Qal
Miocene to Pleistocene Chilcotin Group
M Cav — Vesicular alkali olivine basalt breccia flows
Eocene Kamloops Group
E Kcv — Undivided calcalkaline volcanic rocks
E Ks — Mudstone, siltstone, shale and fine clastic sedimentary rocks
Unnamed Cretaceous Conglomerate
K cg — Polymictic clast-supported cobble conglomerate, includes gneiss, marble, chert, granitoid and volcanic clasts
Middle Jurassic Dragon Mountain Formation
MJ Dcg — Polymictic conglomerate, sandstone, graded silstone
Unnamed Sinemurian to Pliensbachian Sediments
EJP sn — Brown-grey siltstone, sandstone and calcareous conglomerate
Sinemurian (196 Ma)
EJ t — Quartz phyric latite tuff
Late Triassic to Early Jurassic
TJ vcg — Well-bedded and sorted, polymictic volcanic conglomerate pink, monzonite to K-spar megacrystic syenite clasts
Late Triassic Nicola Group
LT Nvl — Red-brown, massive, polymictic breccia, feldspar and hornblende crystal tuff
LT Nhv — Hornblende phyric andesitic basalt flows and breccias
LT Npt — Plagioclase phyric, pyroxene lapilli tuff, breccia and minor flows
LT Nl — Limestone, ash and crystal-rich sandstone and maroon siltstone
LT Nav — Pink-white analcime pyroxene+/-olivine basalt breccia, flows and tuffs
LT Npv — Green and maroon pyroxene porphyry breccias, pyroxene-olivine basalt flows and crystal-rich sediments
LT Nvb — Massive, coarse polymictic volcanic breccias, graded sandstones, siltstone and rare limestone breccia horizons
LT Ns — Grey siltstone, normal graded sandstone and cherty shale with pyroxene and plagioclase-rich crystal sandstones
LT Nu — Undivided mafic volcanic and volcaniclastic rocks
Middle to Late Triassic
MLT Nv — Pyroxene/hornblende metabasalt, greenstone and plagioclase crystal tuff
MLT Ns — Graphitic and quartzose phyllite, shale, siltstone and sandstone

Pennsylvanian to Permian Crooked amphibolite
P SMum — Serpentine, sheared ultramafic rocks
Mississippian to Jurassic Cache Creek Group
MJ Cc — Ribbon chert, argillite, basalt, limestone, greenstone
Proterozoic to Mississippian Snowshoe Group
PP Sgn — Gneiss, schist, marble, amphibolite, conglomerate, quartzite

MOUNT POLLEY SURFACE WATER QUALITY IMPACT ASSESSMENT UPDATE, MARCH TO AUGUST 2015

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with the following update to the Surface Water Quality Impact Assessment (WQIA) that was submitted as part of the Post-Event Environmental Impact Assessment Report (PEEIAR) in June 2015 (Golder 2015a). The 'event' refers to the tailings dam failure that occurred at the Mount Polley Mine on August 4, 2014, when the Tailings Storage Facility (TSF) Perimeter Embankment failed and there was a subsequent debris flow into the receiving environment. The time period considered in the WQIA was August 2014 to April 2015. This update to the WQIA focuses primarily on data generated by post-event water quality monitoring undertaken by MPMC over a six month period between March and August 2015. This period was selected as a cutoff for this update, however, MPMC water quality monitoring is ongoing. Note that there is some overlap in dates covered by the original WQIA and this document because the dataset was being generated during the preparation of the PEEIAR in March and April 2015. Monitoring of post-event receiving environment has also been carried out by the BC Ministry of Environment (BC MoE) for audit purposes; these results are reported elsewhere (http://www.env.gov.bc.ca/epd/mount-polley/).

1.0 INTRODUCTION

The interim findings of the WQIA concluded that there were measured changes in water quality in Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River as a result of the event, but that evidence available at the time of report preparation did not indicate that constituents of the TSF materials had resulted in toxicity in the water column. Post-event monitoring is being undertaken by MPMC to support the continued evaluation of water quality and the potential for toxicity in these waterbodies.

This technical memorandum is intended to provide an update to the interim findings of the PEEIAR WQIA and to characterize water quality conditions relevant to the Detailed Site Investigation (DSI) and Human Health and Ecological Risk Assessment (HHERA). The DSI and HHERA are being undertaken as a requirement of the Pollution Abatement Order issued by the BC MoE in response to the tailings dam failure to satisfy the requirements of the Provincial *Environmental Management Act* and the *Contaminated Sites Regulation* (CSR).

Following consultation with the BC MoE in July 2015[1], Hazeltine Creek is to be considered a receiving environment for the DSI and HHERA, and accordingly, it is considered a receiving environment for this WQIA update. In order of water flow, the receiving environments evaluated are Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River (Attachment 1).

Following initial screening of water quality data using relevant BC water quality guidelines (BC WQGs) and CSR standards, contaminants of potential concern (COPCs) were identified (see Section 3.1) for the receiving environments listed above. Post-event changes in receiving environment water quality, with respect to identified COPCs, were evaluated relative to applicable BC WQGs and CSR standards for the time period from March to August 2015 (Section 3.2). In Section 4, the results from this updated water quality assessment are discussed with reference to whether each COPC will be carried forward for further assessment as contaminants of concern (COCs) in the DSI. In Section 5, COCs are identified for consideration in the problem formulation components of the HHERA.

2.0 METHODS

2.1 Data Collection and Compilation

The assessment relied on water quality data collected by MPMC from March to August 2015 in accordance with the Post TSF-Breach 2015 Monitoring Plan (MPMC 2015), in addition to post-event data previously reported in the PEEIAR WQIA (Golder 2015a). In general, 2015 monitoring focused on routine stations, but some station locations were moved, replaced, added, or removed, consistent with the evolution of the post-event program and in consultation with regulatory agencies (MPMC 2015). A summary of monitoring stations and sampling frequencies for the time period between March and August is presented in Attachment 2.

The monitoring program evolved during the first year following the event in consideration of factors that included, but were not limited to: monitoring results, safety and logistical constraints, recommendations from the BC MoE, and seasonal conditions. A number of stations in Polley Lake, Hazeltine Creek, and Quesnel Lake were consistently monitored, typically either weekly or monthly; while other stations were monitored on a more intermittent basis or were briefly monitored for a specific purpose. A compilation of discrete water sample data collected at stations monitored by MPMC from August 2014 to August 2015, inclusive, are appended at the end of this technical memorandum in Attachment 8.

Between March and August 2015, depth profiles of field parameters were recorded throughout the water column and water samples were collected for chemical analysis at designated stations shown in Attachment 1. At the Polley Lake stations, discrete water samples were taken at 5 m depth intervals from the surface to close to the lake bottom, except when the water column was fully mixed at overturn, when samples were taken at 10 m depth intervals. The depth range sampled in Polley Lake was 0 to 20 m and approximately 2 m from the lake bottom. In Quesnel Lake the depth range sampled was station dependent consistent with previous reported post-event sampling in Golder (2015a) (depths sampled are provided in Attachment 2). Field methods were consistent with those described in Appendix B of the PEEIAR for water quality monitoring undertaken by MPMC between August 2014 and April 2015 (Golder 2015a). Continuous data loggers were installed to record field parameter measurements at station HAC-01b at the outflow of Hazeltine Creek and QUR-1 in the Quesnel River (i.e., conductivity, dissolved oxygen, pH, temperature, and turbidity) at 15 minute intervals.

[1] Verbal communication with the BC MoE Land Remediation Section following their review of the July 15, 2015, DSI and HHERA work plan.

Analytical and field monitoring data verified as reliable based on a quality assurance/quality control (QA/QC) assessment by MPMC, as well as station location information, were uploaded by MPMC to their water quality database. MPMC provided Golder with electronic data collected from March to August 2015 for this WQIA update. These data were used as received from MPMC with an additional check of transcription by Golder prior to use in COPC screening. The process of sample continuity and data quality verification by MPMC is documented in Appendix B of the PEEIAR for post-event data collected prior to March 2015 (Golder 2015a). These QA/QC procedures were followed through August 2015 and a summary of the findings of the MPMC QA/QC program for water quality data collected from March to August 2015 is provided in Attachment 3.

The majority of data collected between March and August 2015 met data quality objectives specified in Appendix B of Golder (2015a). Objectives that were not met mainly related to variability between duplicate samples, possibly due to environmental heterogeneity or interferences in the analytical method. The QA/QC results were considered acceptable because the overall number of data that did not meet objectives was low, and the observed variability did not influence the findings of this WQIA update.

2.2 COPC Identification

Discrete water quality data collected by MPMC at stations monitored between March and August 2015 (shown in Attachment 1) were compiled and screened to identify COPCs. The purpose of the COPC screening shown in Attachment 4 was to identify those parameters that remained elevated as of March 2015, in order to focus the WQIA update on those substances that might be of longer-term consequence regarding potential impacts on water quality. Data compiled for all stations sampled within a given area (i.e., Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River) were evaluated as one dataset for COPC screening. Subsequent data analysis of COPC temporal trends focused on a representative subset of monitoring stations for each area (as described in Section 2.3).

Substances were identified as COPCs if they were greater than pre-event concentrations and applicable guidelines based on the most sensitive receiving environment water use. Golder (2015a) identified the following known environmental uses on Quesnel Lake, particularly with respect to the West Basin, to determine the most sensitive water use for the downstream receiving environment.

- Commercial, recreational, and aboriginal fisheries;
- Recreational uses such as scenery and wildlife viewing, swimming, boating, kayaking, canoeing, waterskiing/tubing/wakeboarding, and in the winter snowmobiling and ice fishing when ice conditions allow; and
- Drinking and residential water use for domestic purposes.

For the WQIA update, maximum and 95th percentile parameter concentrations calculated for each receiving environment area were compared to the following regulatory criteria:

- BC WQGs for aquatic life (or most sensitive end use identified in Table 3-4 of Golder 2015a[2]);
- BC drinking water guidelines (BC MOE 2015a);
- CSR Schedule 6 standards for aquatic life (CSR 2014);
- CSR Schedule 6 drinking water standards (CSR 2014); and
- CSR Schedule 6 livestock water standards (as a surrogate for wildlife water) (CSR 2014).

Based on this screening, COPCs were conservatively identified for the four receiving environment areas for the purpose of evaluating potential water quality impacts to aquatic life, wildlife water, or drinking water. The screening was two-tiered: first, an initial screening stage identified parameters with maximum upper limit concentrations below BC WQGs. These water quality parameters were not carried further in the screening process. Second, for parameters with concentrations above BC WQGs, 95th percentile concentrations were calculated and screened against the regulatory criteria listed above. Water quality parameters were identified as COPCs if 95th percentile concentrations were above the lowest applicable criteria (Attachment 4, Tables 1-5) and were higher than the 95th percentile pre-event baseline concentration provided in Golder (2015a).

Maximum and 95th percentile concentrations represented upper limit concentrations in the post-event water quality dataset. Water quality parameters were not identified as COPCs if post-event upper limit concentrations were below the lowest applicable criteria. The lowest applicable criteria were typically BC WQGs; conservative environmental quality benchmarks with built-in safety factors that represent concentrations below which adverse impacts on water quality are not expected. Pre-event data were available for Polley Lake, Hazeltine Creek, and Quesnel River and these data are summarized in Golder (2015a). As described in Golder (2015a), pre-event data for Quesnel Lake data were limited to nutrient-related monitoring surveys primarily focused around Horsefly Bay just east of Cariboo Island.

Parameters without BC WQGs were not identified as COPCs in the PEEIAR WQIA based on an evaluation of post-event data up to February 2015. Concentrations of these parameters in the weeks and months following the event were not considered to be of environmental concern. Subsequently, the same parameters were not considered to be COPCs in the WQIA update.

[2] With the exception of molybdenum, total aluminum, and pH, the most sensitive receiving environment use was the protection of aquatic life. For molybdenum, the most conservative 30-d BC WQG value was adopted (i.e., irrigation assuming the copper: molybdenum ratio is less than 2:1 *in lieu* of a 30-d value for wildlife). For total aluminum, the most conservative maximum BC WQG was adopted (i.e., water for wildlife) because aquatic life guidelines are based only on dissolved aluminum.

2.3 COPC Evaluation

Changes in COPC concentrations were evaluated qualitatively (see Section 2.3.2) over time at representative stations previously assessed in the PEEIAR WQIA (Golder 2015a), although replacement stations were included as appropriate, consistent with the evolution of the post-event monitoring program.

2.3.1 Representative Station Selection

Ten representative stations in the downstream aquatic receiving environment for the WQIA update were monitored either weekly or monthly from August 2014 to August 2015. Datasets for some monitoring stations were combined to provide a continuous data record[3]. Rationale for the selection of each representative monitoring station is provided below.

- **Two stations on Polley Lake (P1 and P2).** Station P1 located at the north end of Polley Lake and Station P2 located to the south of the lake. These two stations represented the deepest areas of the lake and provided geographical coverage.
- **Three stations in Hazeltine Creek.** One station in upper Hazeltine Creek (HAC-05), one station in lower Hazeltine Creek (HAC-08) above the two sedimentation ponds, and one station at the outflow of Hazeltine Creek (HAC-01) below the sedimentation ponds. These ponds became operational in December 2014 and were designed to reduce loadings of suspended particulate matter in lower Hazeltine Creek and as a consequence inputs to Quesnel Lake. In upper Hazeltine Creek, Station HAC-05 has been the most frequently sampled since the event, and in lower Hazeltine Creek, Station HAC-01 has been the most frequently sampled (Attachment 2). Data from HAC-01 represent water quality at the outflow of Hazeltine Creek below the sedimentation ponds at the confluence with Quesnel Lake. Monitoring at Station HAC-08 began in late January 2015.
    - As described in Attachment 2 and Golder (2015a), the HAC-01 water quality monitoring station in lower Hazeltine Creek was moved slightly over time to adapt to changes in the creek channel due to rehabilitation activities and construction of sedimentation ponds (a change in location was indicated with a subsequent letter in the station code). Samples collected at HAC-01, HAC-01a, HAC-01b, HAC-01c in lower Hazeltine Creek have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-01/a/b/c).
- **Four stations in Quesnel Lake**. One near-field station, two mid-field stations located west of Cariboo Island, and one far-field station located east of Cariboo Island.
    - *Near-field:* Station QUL-66 is located close to the mouth of Hazeltine Creek, and was replaced by stations QUL-55 in March 2015 and QUL-55a in July 2015, when the creek mouth was re-routed. The Pollution Abatement Order 107461 amendment issued June 15, 2015, by the BC MoE (2015b), specified turbidity requirements for this station and surrounding profile data stations.

[3] As described in Golder (2015a) some lake stations were not sampled during the winter months due to health and safety concerns and issues related to access. Hazeltine Creek was a managed system undergoing rehabilitation and so some stations had to be moved over time consistent with activities within the creek.

- *Mid-field:* Station QUL-18 represents one of the deepest points in the West Basin and is located north-west of the Hazeltine Creek mouth, towards the Quesnel River between QUL-66 and QUL-21. The Pollution Abatement Order 107461 amendment issued June 15, 2015, by the BC MoE (2015b) also specified turbidity requirements for this station. Station QUL-2/2a is a mid-field station located east of the Hazeltine Creek mouth west of Cariboo Island. Both stations QUL-2 and QUL-2a were monitored following the event until lake turnover in 2014, but monitoring only at QUL-2a was continued in 2015. Data from stations QUL-2 and QUL-2a were pooled to provide a combined post-event dataset that extended to August 2015.
- *Far-Field:* Station QUL-120/120a is located east of Cariboo Island towards the main body of the lake and was assessed with regards to turbidity measures of the plume. Data from stations QUL-120 and QUL-120a were pooled to provide a combined post-event dataset that extended to August 2015.

- **One Quesnel River station:** Station QUR-1 is located at the Quesnel River Research Centre near the community of Likely and reflects water quality at the outflow of Quesnel Lake. This station was routinely monitored by MPMC during the post-event period.

2.3.2 Changes in COPC Concentrations Over Time

Instantaneous measurements and rolling 30-day (d) average values for each COPC were assessed qualitatively and were compared against applicable provincial guidelines and standards to assess changes in water quality as a result of the event[4].

- Instantaneous measurements were compared against the short-term maximum BC WQGs (where available) for the most sensitive water use to evaluate intermittent or transient impacts on aquatic life. These concentrations were also compared against CSR Schedule 6 standards for aquatic life, CSR Schedule 6 drinking water standards, and CSR Schedule 6 livestock water standards (as a surrogate for wildlife water). CSR standards were shown on relevant graphs where reported concentrations exceeded these standards; otherwise the CSR standards were not shown because they are often much higher than the y-axis maxima and therefore including them would compress the observed data downwards.
- Rolling 30-d average values were calculated and compared against long-term average BC WQGs that are intended to prevent sub-lethal and lethal effects on the most sensitive species and life stage for an indefinite time period. The 30-d mean guidelines are intended to be applied to mean concentrations of a minimum of five samples collected over a 30-d time period (BC MoE 2015a).

Temporal and spatial trends in the concentrations of each COPC were discussed (see Section 3.0) with a focus on those parameters that remained elevated from March to August 2015, under the assumption that these parameters could therefore be of longer-term potential consequence regarding impacts on water quality.

[4] Substitutions were not made for values that were reported as less than the method detection limit (MDL) and these values were set equal to the MDL for purposes of plotting data, calculating 30-d averages.

2.3.3 Turbidity Requirements of Pollution Abatement Order 107461

A Pollution Abatement Order 107461 amendment was issued June 15, 2015, by the BC MoE (2015b) and specified that MPMC must meet the following requirements with respect to water quality.

- Turbidity at the monitoring sites QUL-54, QUL-55, QUL-56 (and subsequently replacement stations QUL-54a, QUL-55a, and QUL-56a) of no greater than 2 NTU rolling average above background (i.e., 1 NTU), at any monitored depth, over a period of 30 days using a minimum of five weekly samples.
- Turbidity at the monitoring site QUL-18 of no greater than 1 NTU above background at any monitored depth.

To assess compliance with amended Pollution Abatement Order 107461, depth profile measurements of turbidity were plotted for near-field stations QUL-54/54a, QUL-55/55a, QUL-56/56a and the western mid-field station QUL-18. The plots were then interpreted to identify time periods where non-compliance was observed.

3.0 RESULTS

3.1 COPC Identification

The screening process described in Section 2.2 for data collected between March and August 2015 identified the following COPCs that required further evaluation of post-event concentrations (bolded in Table 1):

- molybdenum in Polley Lake;
- turbidity in Quesnel Lake and Quesnel River;
- copper in Quesnel Lake; and
- turbidity, TSS, and a number of metals in Hazeltine Creek.

Table 1: Contaminants of Potential Concern Identified in the Receiving Environment Based on Water Quality Monitoring from March through August 2015[1]

Waterbody	COPC: Physical[2,3]	COPC: Total Metals[2]	COPC: Dissolved Metals[2]	COPC: Non-Metal Substances
Polley Lake	*no substances*	**molybdenum**	**molybdenum**	*no substances*
Hazeltine Creek	**turbidity, total suspended solids**	**aluminum**, **arsenic, beryllium,** cadmium, **chromium, cobalt, copper**, **iron, lead, manganese, molybdenum**, titanium, **zinc**	**copper, molybdenum**	*no substances*
Quesnel Lake	**turbidity**	**copper**	*no substances*	*no substances*
Quesnel River	**turbidity[4]**	*no substances*	*no substances*	*no substances*

Notes:
1) Parameters were identified based on 95th percentile of measured values exceeding the BC WQG or CSR standard for the most sensitive end use and exceedance of the pre-event 95th percentile concentration.
2) Bolded COPCs were evaluated further in the WQIA update. Metals not bolded had 95th percentile concentrations that only exceeded CSR standards (i.e., total cadmium, total titanium), but did not exceed BC WQGs (dissolved cadmium concentrations did not exceed BC WQGs). These metals were not evaluated further and were conservatively retained for the HHERA.
3) Background turbidity concentrations are 1.5 NTU in Hazeltine Creek and 1 NTU in Quesnel Lake and Quesnel River.
4) Turbidity was identified as a COPC for Quesnel River based on in-situ data from a continuous logger.

With respect to Hazeltine Creek, suspended particulate matter, measured as TSS and turbidity, and the total forms of 14 metals were identified as COPCs for the period March to August 2015 (Table 1). Of those 14 metals, copper and molybdenum were also identified as COPCs in their dissolved forms. Subsequent evaluation of COPCs identified for Hazeltine Creek focused on those metals that exceeded BC WQGs, while metals that only exceeded CSR standards (i.e., total cadmium, total titanium) were conservatively retained as COPCs in Section 5 for further evaluation in the HHERA. Levels of suspended particulate matter in Hazeltine Creek initially decreased in December and January to those that represented 'clear-flow conditions' in the creek following the commissioning of the sedimentation ponds in December (Golder 2015a) and the onset of low flow freezing conditions. From February to May 2015, particulate matter levels increased in the creek as a result of construction activities along the creek channel that coincided with an early freshet (as illustrated in the photos provided in Attachment 6). These turbid flow episodes were associated with peak concentrations of metal COPCs above BC WQGs and pre-event concentrations in Hazeltine Creek.

In-situ pH values measured when discrete samples were taken from the four waterbodies were mostly within the BC WQG range of 6.5 to 9.0 for aquatic life[5] and the BC WQG range of 6.5 to 8.5 for drinking water[6]. Based on these data, pH was not identified as a COPC consistent with the PEEIAR WQIA.

The PEEIAR WQIA identified dissolved oxygen (DO) as a COPC in Polley Lake, but DO was not of potential concern in Quesnel Lake, Hazeltine Creek, or Quesnel River. From May to June 2015, DO concentrations in Polley Lake were above the minimum BC WQG of 5 mg/L, but in July and August 2015 concentrations at depth were less than 5 mg/L, indicative of hypoxic conditions (as shown for Station P2 in Attachment 5). These late summer DO conditions were similar to those described for Polley Lake prior to the event by Minnow (2014): in late summer the lake underwent thermal stratification and hypoxic conditions were evident at depths greater than 20 m. Given that DO conditions in Polley Lake resemble pre-event conditions, DO was not identified as a COPC for this lake.

3.2 Changes in COPC Concentrations Over Time

The following section describes post-event changes in receiving environment water quality with respect to COPCs identified in Section 3.1. Changes in COPC concentrations over time from March to August 2015 are discussed below relative to relevant BC WQGs and CSR standards. Post-event concentrations from August 2014 to February 2015 previously reported in the PEEIAR WQIA (Golder 2015a) are provided in each figure for context and discussed where appropriate in the text to facilitate interpretation of data collected between March and August 2015. Results are presented according to each group of COPCs (i.e., suspended particulate matter, metals, nutrients), then within each COPC group. Changes in specific COPCs are discussed for each waterbody.

Data shown for Hazeltine Creek and Quesnel River represent discrete surface grab samples collected as described in the PEEIAR WQIA, except where a continuous data logger measured turbidity. Quesnel Lake and Polley Lake data are from discrete grab samples taken at various depths and were categorized as either surface (1-20 m) or deep (>20 m) for the purpose of evaluating changes over time.

[5] With the exception of 4% of samples in Polley Lake and 2% of samples in Quesnel River that exceeded BC WQG upper limit of 9.0 (MPMC unpublished data)

[6] With the exception of: 20% of samples in Polley Lake and 4% of samples in Quesnel Lake that exceeded BC WQG upper limit of 8.5 (MPMC unpublished data)

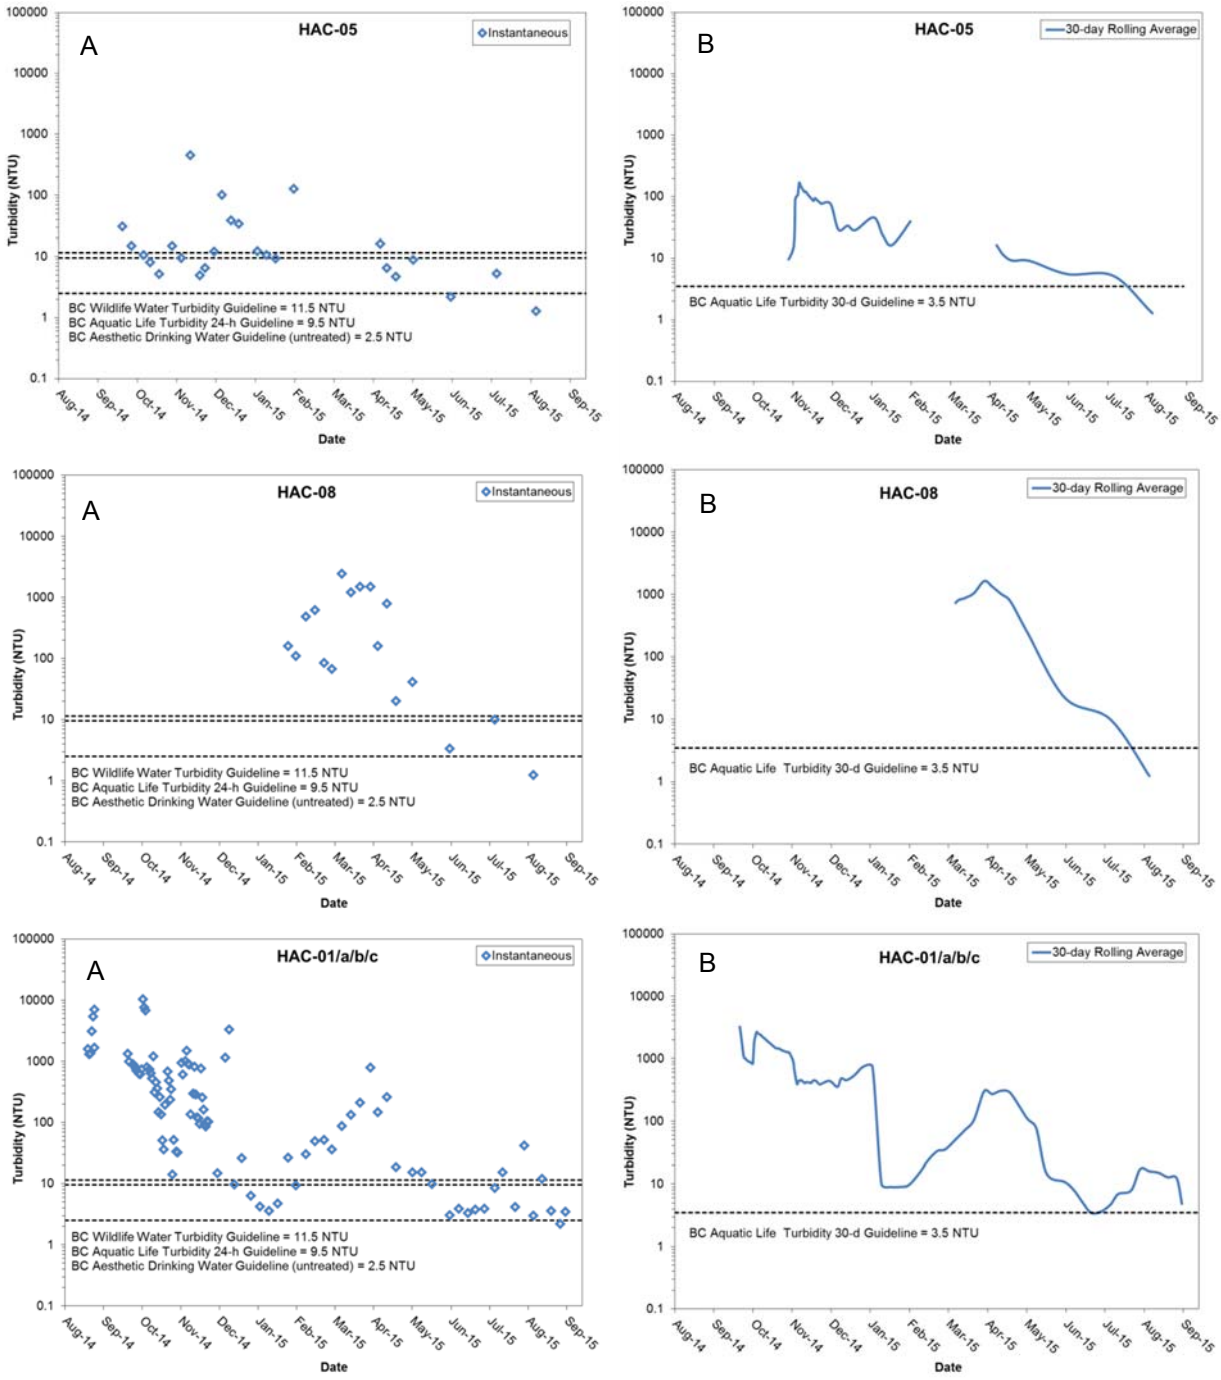
3.2.1 Suspended Particulate Matter (Turbidity/TSS)

Both TSS and turbidity, were identified as COPCs in Hazeltine Creek from March to August 2015, whereas downstream in Quesnel Lake and Quesnel River, only turbidity was identified as a COPC. Larger suspended solids captured in the TSS measurement tend to settle out more quickly that the finer particulates measured by turbidity that might travel further downstream.

3.2.1.1 Hazeltine Creek

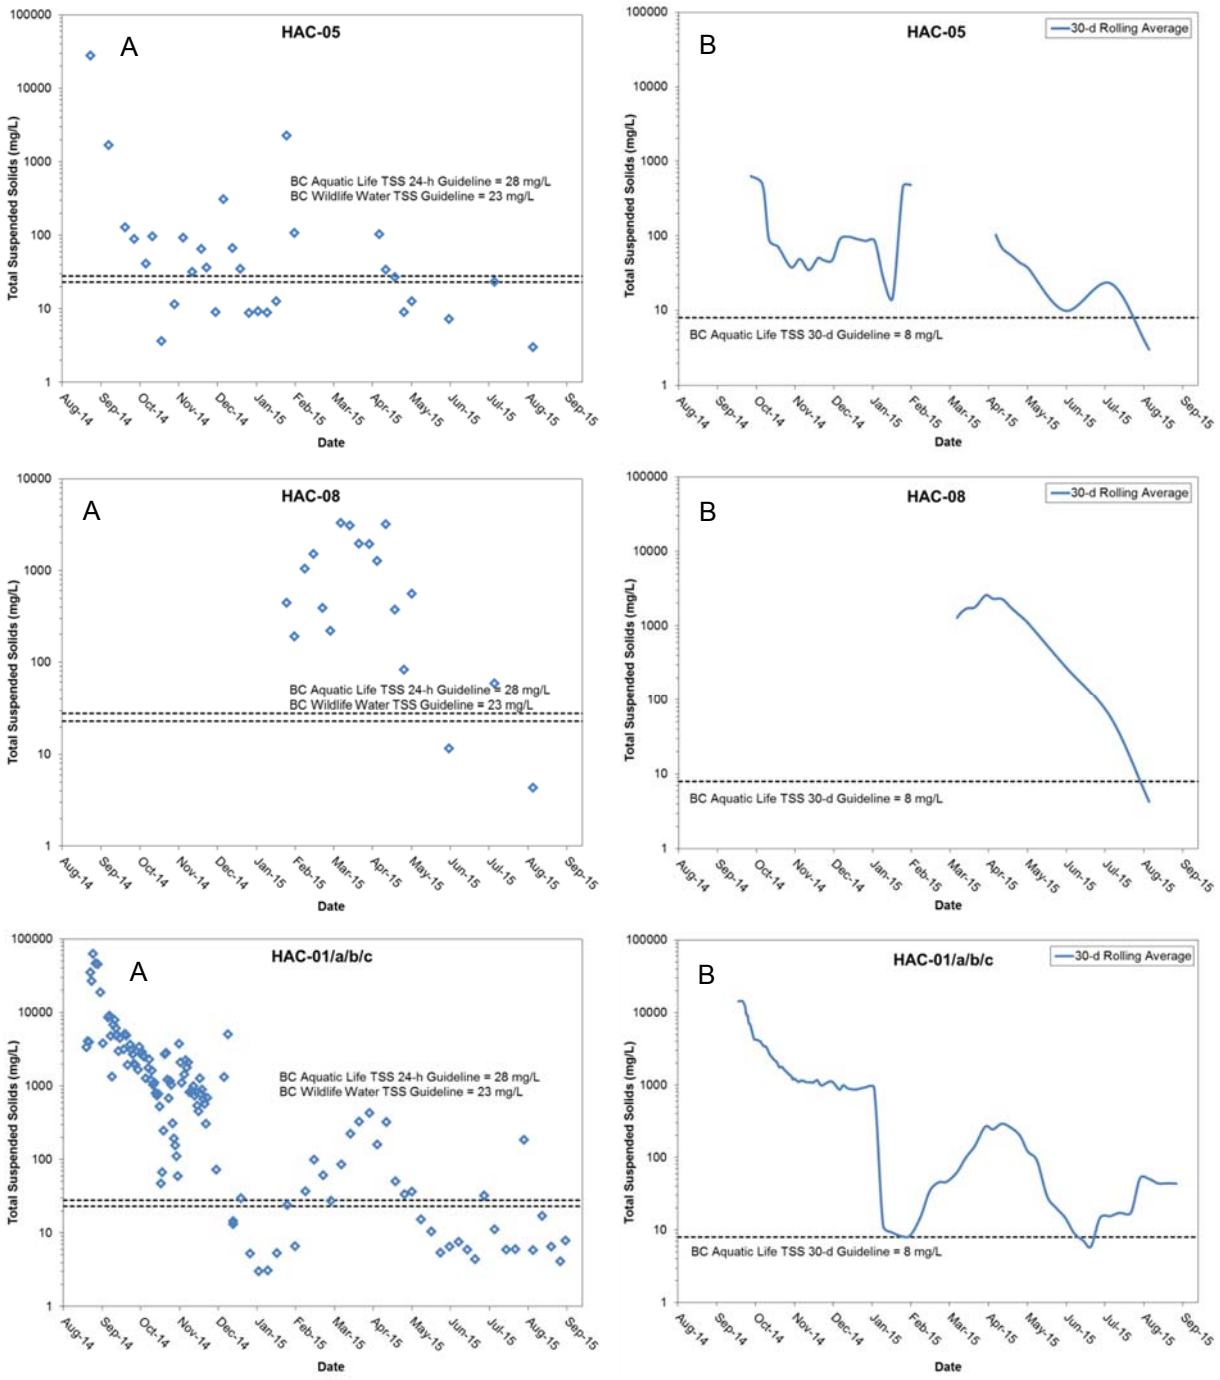
Turbidity and TSS in Hazeltine Creek were measured above BC WQGs following the event and exhibited a general decrease over time at stations HAC-05 and HAC-01/a/b/c from August 2014 through August 2015, and at HAC-08 from April to August 2015 (Figure 1 and Figure 2). Although two sedimentation ponds were commissioned in lower Hazeltine Creek in December 2014, and have been considered to be effective at reducing sediment loads most of the time, spikes in turbidity and TSS were observed downstream at HAC-01/a/b/c between late January and April 2015. This increase in turbidity was attributed to an early freshet and ongoing remediation works along the creek channel. Stabilization and rock armouring of the creek channel was completed on May 11, 2015, which corresponded with a reduction in turbidity. Peaks in turbidity at HAC-01/a/b/c again in late July and mid-August corresponded with construction activities related to a change in discharge location of the creek and maintenance of the sedimentation ponds at that time (pers. comm. S. Litke), rather than due to specific precipitation events (Attachment 6, Figure 5).

In upper Hazeltine Creek (HAC-05) and lower Hazeltine Creek above the sedimentation ponds (HAC-08), turbidity and TSS decreased below the 24-h BC WQG for aquatic life and BC WQG for wildlife water as of May 2015. The corresponding 30-d average concentrations decreased below the 30-d BC WQG for aquatic life in August 2015. As indicated in Figure 1, Station HAC-05 was not sampled between February and April due to active construction activity in the surrounding area. As of May 2015, the majority of measurements of both TSS and turbidity at the outflow of Hazeltine Creek (HAC-01/a/b/c) decreased below the 24-h BC WQGs for aquatic life and BC WQGs for wildlife water, but remained above the 30-d BC WQGs through August 2015. Turbidity at the outflow of Hazeltine Creek remained above the BC aesthetic drinking water guideline for untreated water through August.



Note: Baseline assumed equal to pre-event median turbidity of 1.5 NTU. Gaps represent >30 d between sampling.

Figure 1: Post-event Instantaneous (A) and Rolling 30-day Average (B) Turbidity Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

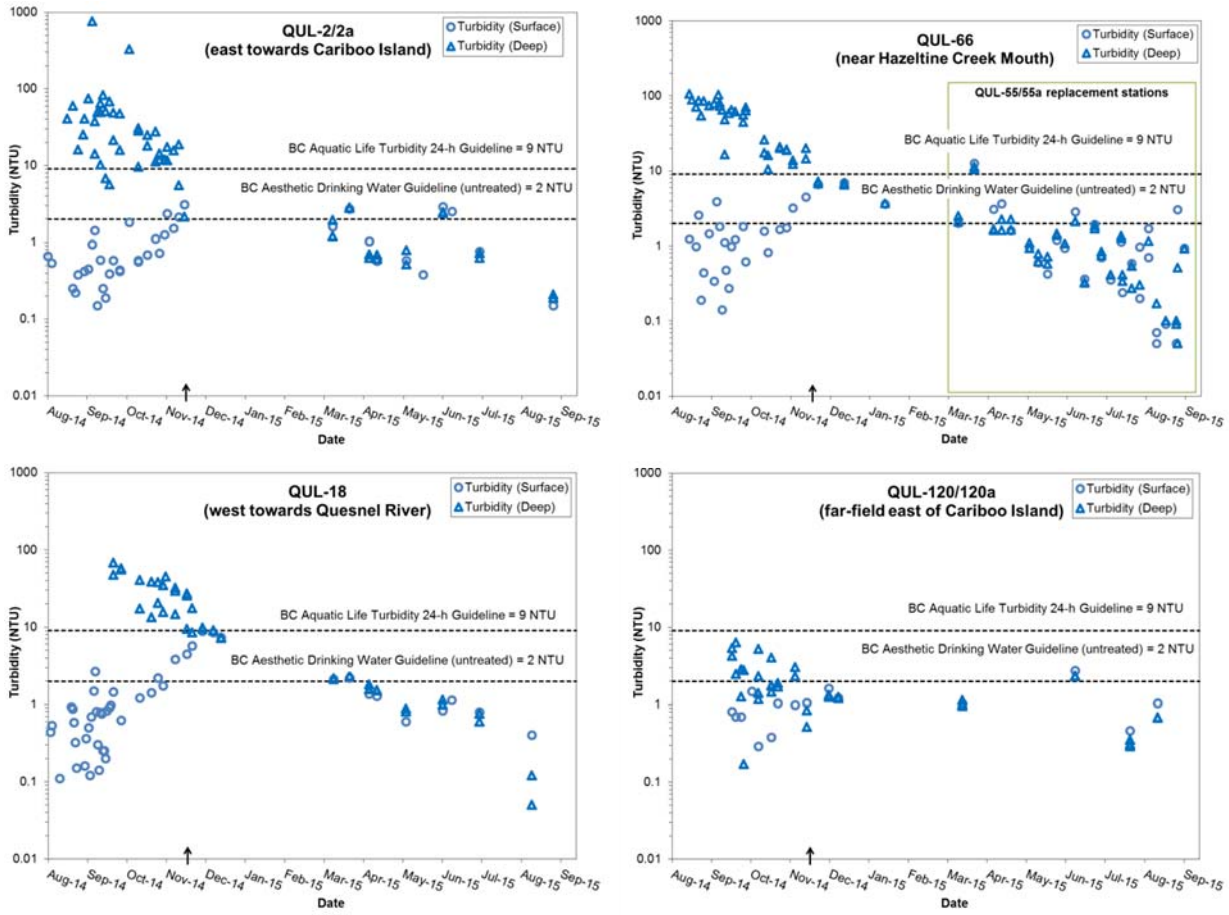


Note: Baseline assumed equal to the MDL of 3 mg/L. Gaps represent >30 d between sampling.

Figure 2: Post-event Instantaneous (A) and Rolling 30-day Average (B) TSS Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

3.2.1.2 Quesnel Lake

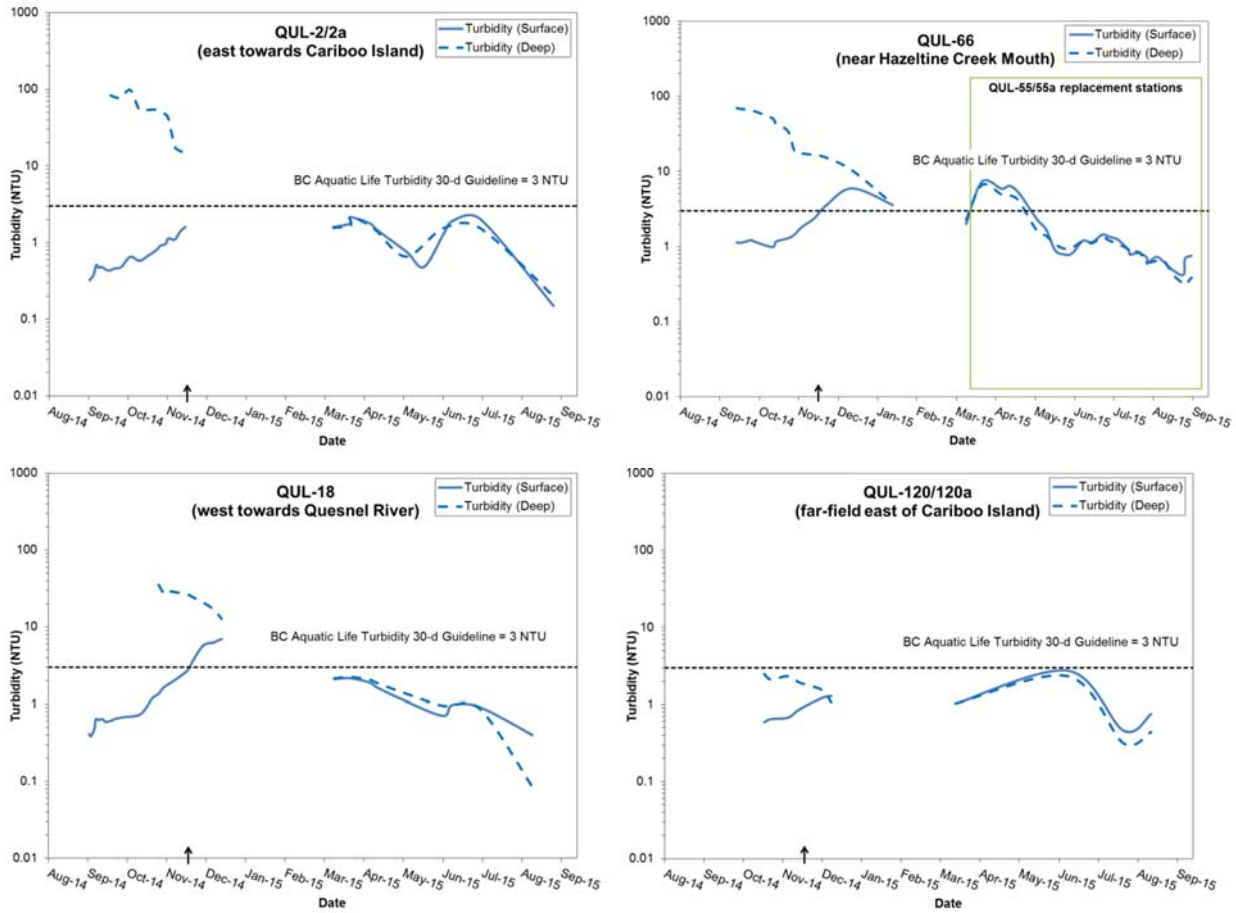
Following the event, turbidity was elevated at depth above 24-h BC WQGs in the West Basin of Quesnel Lake, but was not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Figure 3). Turbidity concentrations at depth decreased over time at stations QUL-2/2a, QUL-66/55/55a, and QUL-18 and were below or near BC WQGs by April 2015. Concentrations remained below BC WQGs through August 2015. At the surface, turbidity levels generally remained below guideline values with the exception of some exceedances of the aesthetic drinking water guideline for untreated water around the time of fall lake turnover in mid-November 2014 and occasionally into spring (Figure 3). Turbidity was measured above 2 NTU in June at both surface and depth at QUL-2/2a, QUL-66/55/55a, and QUL-120/120a. Given that the increase was observed at several stations including the far-field station, and turbidity in Hazeltine Creek was not abnormally high during that period, the temporary increase in turbidity was likely due to factors besides the mine, such as natural inputs from tributaries. Relative to the changes in turbidity that were observed during fall turnover in 2014, water quality did not appear to be influenced by spring turnover in 2015 as turbidity concentrations were similar at surface and depth during March and April, which is when turnover is expected to occur.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Background assumed equal to 1 NTU.

Figure 3: Post-event Instantaneous Turbidity Concentrations at Stations QUL-2/2a, QUL-66/55/55a, QUL-18, and QUL-120/120a, Quesnel Lake.

Thirty-day average concentrations of turbidity at depth were above the 30-d BC WQG at stations in the West Basin following the event and decreased over time to below the guideline at all four stations by May 2015 (Figure 4). Concentrations at surface were generally below the guideline, except where fall turnover in mid-November 2014 resulted in vertical mixing and elevated turbidity at the surface. At QUL-66/55/55a, near the mouth of Hazeltine Creek, the 30-d average concentrations at surface and at depth were elevated throughout March and April 2015 due to inputs of turbid water from Hazeltine Creek during this period. Turbidity declined from May through August 2015 consistent with a similar general decline in Hazeltine Creek as described in Section 3.2.1.1. For the other stations located further away from the mouth of Hazeltine Creek, 30-d average concentrations remained below the respective guideline from March through August 2015 (Figure 4). Overall, 30-d average concentrations of turbidity at the four Quesnel Lake stations showed a decreasing trend over time to below BC WQGs, from August 2014 to August 2015.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Background assumed equal to 1 NTU. Gaps represent >30 d between sampling.

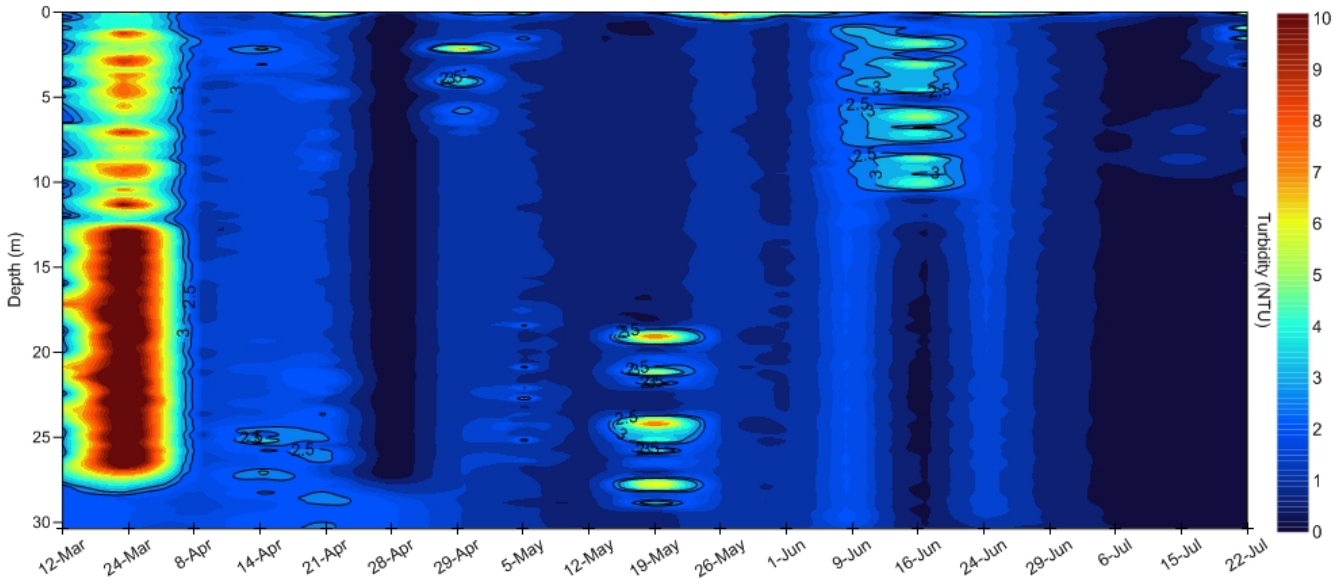
Figure 4: Post-event Rolling 30-day Average Turbidity Concentrations at Stations QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a, Quesnel Lake.

Pollution Abatement Order Requirements: Turbidity

Near-Field Stations

Weekly depth profiles of field parameters were conducted at stations QUL-54, QUL-55, and QUL-56 near the mouth of Hazeltine Creek from March until late July 2015, when the outlet of Hazeltine Creek was redirected. Stations QUL-54a, QUL-55a, and QUL-56a were established near the new outlet to replace the previous stations and monitoring was continued at the same frequency.

- At QUL-55, turbidity was elevated up to 13 NTU throughout the water column on March 24, 2015, but thereafter rarely exceeded 3 NTU (i.e., criterion of 2 NTU above background of 1 NTU) between weekly sampling events (Figure 5). The same trends were observed for QUL-54 and QUL-56 during this period, but at these stations turbidity values in March were typically lower than those reported for QUL-55, remaining below 7 NTU (Attachment 6, Figures 6-7).
- From late July to August 2015 turbidity was less than 3 NTU at stations QUL-54a, QUL-55a, and QUL-56a except for an exceedance of up to 14 NTU around 7 m depth at QUL-56a in late July (Attachment 6, Figures 8-10). It is possible the observed temporary increase in turbidity close to the mouth of Hazeltine Creek was due to sediment mobilization as a result of construction of the new outlet to Quesnel Lake that occurred within this time period.

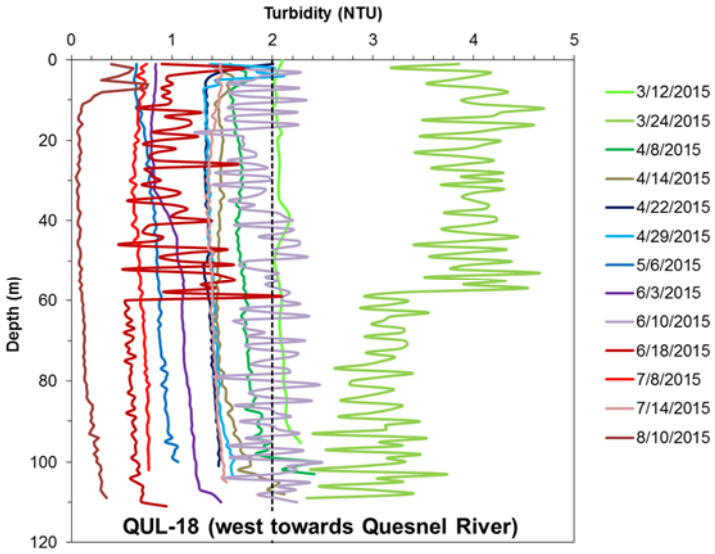


Note: The contour at 3 NTU represents the criterion of 2 NTU above background (1 NTU).

Figure 5: Contours of Turbidity Measured In-situ over Time at Station QUL-55 in Quesnel Lake (March to July 2015).

Western Mid-Field Station

At Station QUL-18, depth profiles of field parameters were recorded on 13 dates between March and August 2015, at a frequency of twice per month. On March 24, 2015, turbidity ranged from 2.5 to 4.5 NTU throughout the water column and exceeded the criterion of 1 NTU above background (Figure 6). This corresponded with observations of elevated turbidity at near-field Quesnel Lake stations on this date (i.e., QUL-55, see Figure 5). At other mid-field stations (QUL-2a east and QUL-21a west) turbidity was 2.8 NTU throughout the water column on this date (data not shown). Other than slight exceedance of this turbidity criterion at QUL-18 on March 12 and June 10, turbidity throughout the water column was below 2 NTU through to August.

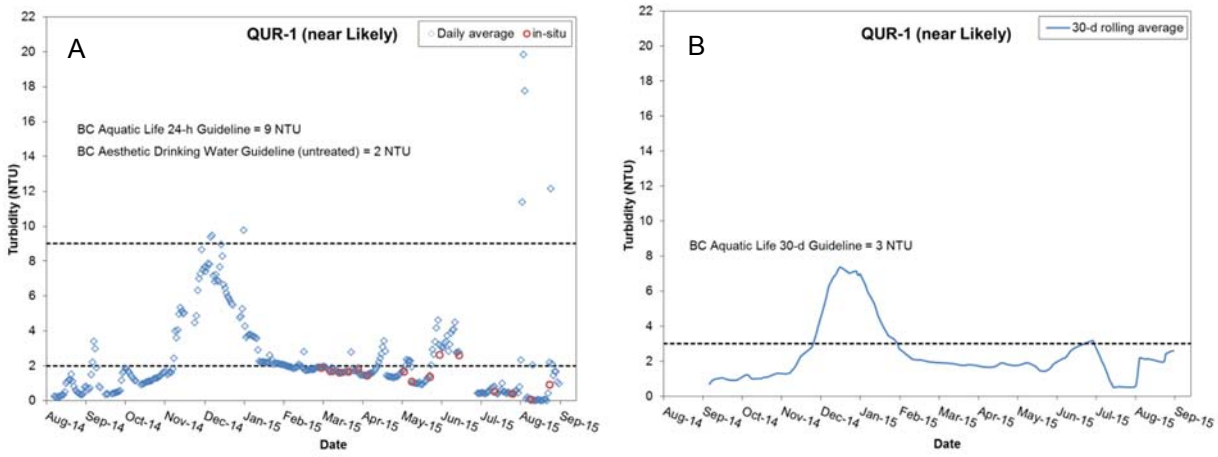


Note: Dotted line indicates criterion of 1 NTU above the background (1 NTU).

Figure 6: Depth Profiles of Turbidity at Station QUL-18 in Quesnel Lake (March to August 2015).

3.2.1.3 Quesnel River

Following the event, turbidity concentrations at Station QUR-1 were below the 24-h BC WQG for aquatic life, with the exception of a few exceedances in December 2014 and July and August 2015 (Figure 7). Turbidity spiked from late November 2014 to late January 2015, due to fall turnover of Quesnel Lake and mixing of deep turbid water, and the 30-d average concentration exceeded the 30-d BC WQG for aquatic life during this period. From mid-February through to the end of August 2015, turbidity concentrations in the river were below the 30-d BC WQG (Figure 7). Turbidity intermittently exceeded the BC aesthetic drinking water guideline for untreated water through to August 2015, but daily averages were typically below this guideline. The higher turbidity values recorded in June and August were not corroborated by in-situ measurements taken with a portable turbidity meter during collection of water samples on an alternating weekly basis (Figure 7). These higher turbidity readings are thought to be attributed to sensor fouling, in addition to the Sonde potentially being exposed from the water in August (pers. comm. S. Litke). The Sonde was moved and redeployed in early September 2015.



Note: Background assumed equal to 1 NTU.

Figure 7: Post-event Instantaneous (A) and Rolling 30-day Average (B) Turbidity Concentrations at Station QUR-1 near Likely, Quesnel River.

3.2.2 Metals

Screening of data collected between March and August 2015 identified molybdenum to be a COPC in Polley Lake and copper to be a COPC in Quesnel Lake. No metals were identified to be of potential concern in Quesnel River. A number of metals were identified to be COPCs in Hazeltine Creek, including copper and molybdenum (Table 1).

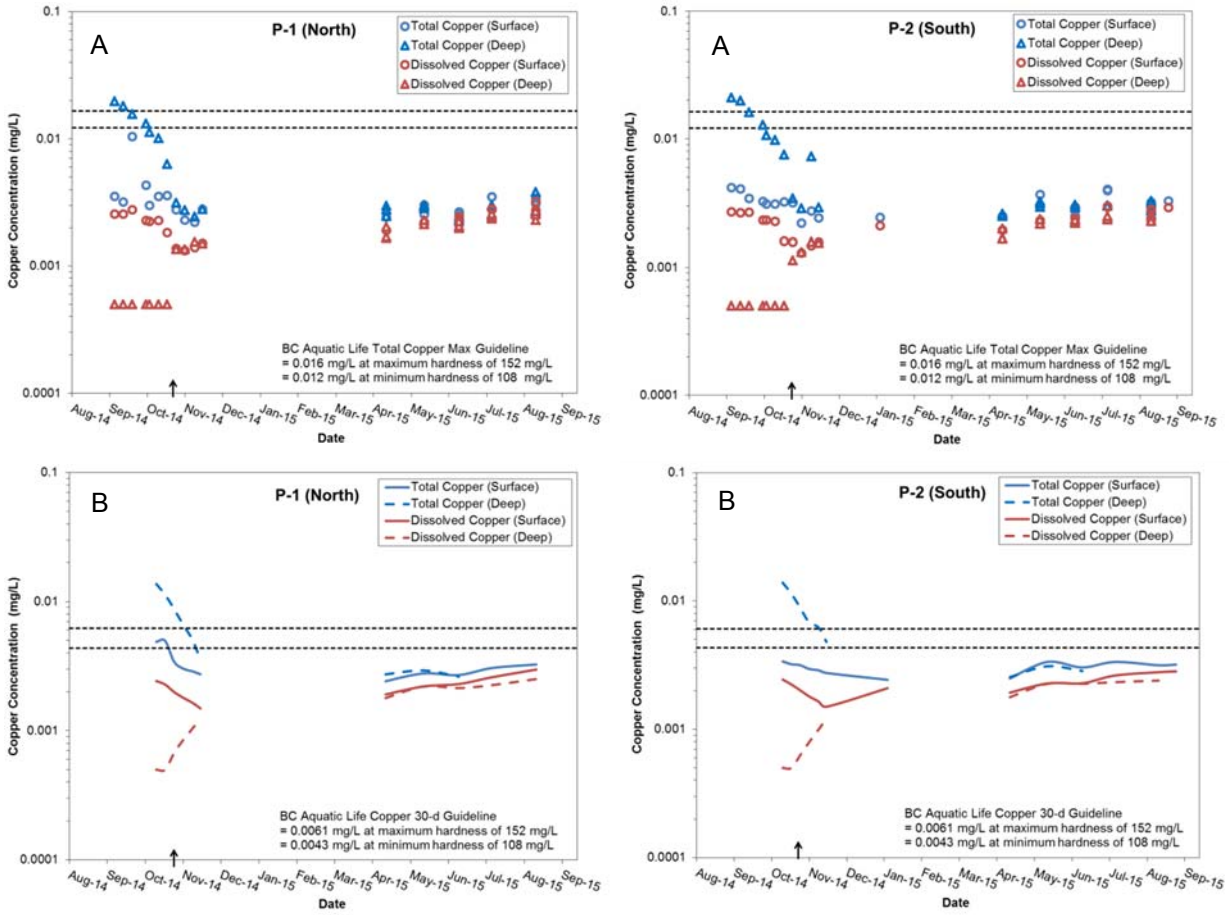
The PEEIAR WQIA identified copper as the COPC of primary interest because total and dissolved forms were reported to be above BC WQGs during the post-event period evaluated from August 2014 to February 2015 (Golder 2015a). It was therefore appropriate in this WQIA update to evaluate post-event changes in copper concentrations over a one-year period until August 2015 in the four monitored waterbodies, regardless of whether copper screened in as a COPC based on concentrations measured from March to August. With respect to other metals identified as COPCs in the PEEIAR WQIA, they were only evaluated further if they screened in as COPCs based on concentrations measured from March to August (Table 1).

Selenium was not identified as a COPC in Table 1 given that concentrations were below guidelines in the monitored waterbodies. However, due to previous concerns regarding a historic selenium source to Polley Lake that has since been mitigated and related monitoring efforts prior to the event (Minnow 2014), trends in selenium concentrations were evaluated further in Polley Lake, Hazeltine Creek, and the near-field area of Quesnel Lake close to the Hazeltine Creek mouth.

3.2.2.1 Polley Lake

Copper

Although initially elevated after the event, total copper concentrations at depth in Polley Lake decreased over time to below applicable BC WQGs by fall turnover in mid-November (Figure 8). Post-event dissolved copper concentrations were consistently below BC WQGs. By April 2015, total and dissolved copper concentrations had converged and stabilized to between 0.002 and 0.003 mg/L through the end of August 2015 (Figure 8).



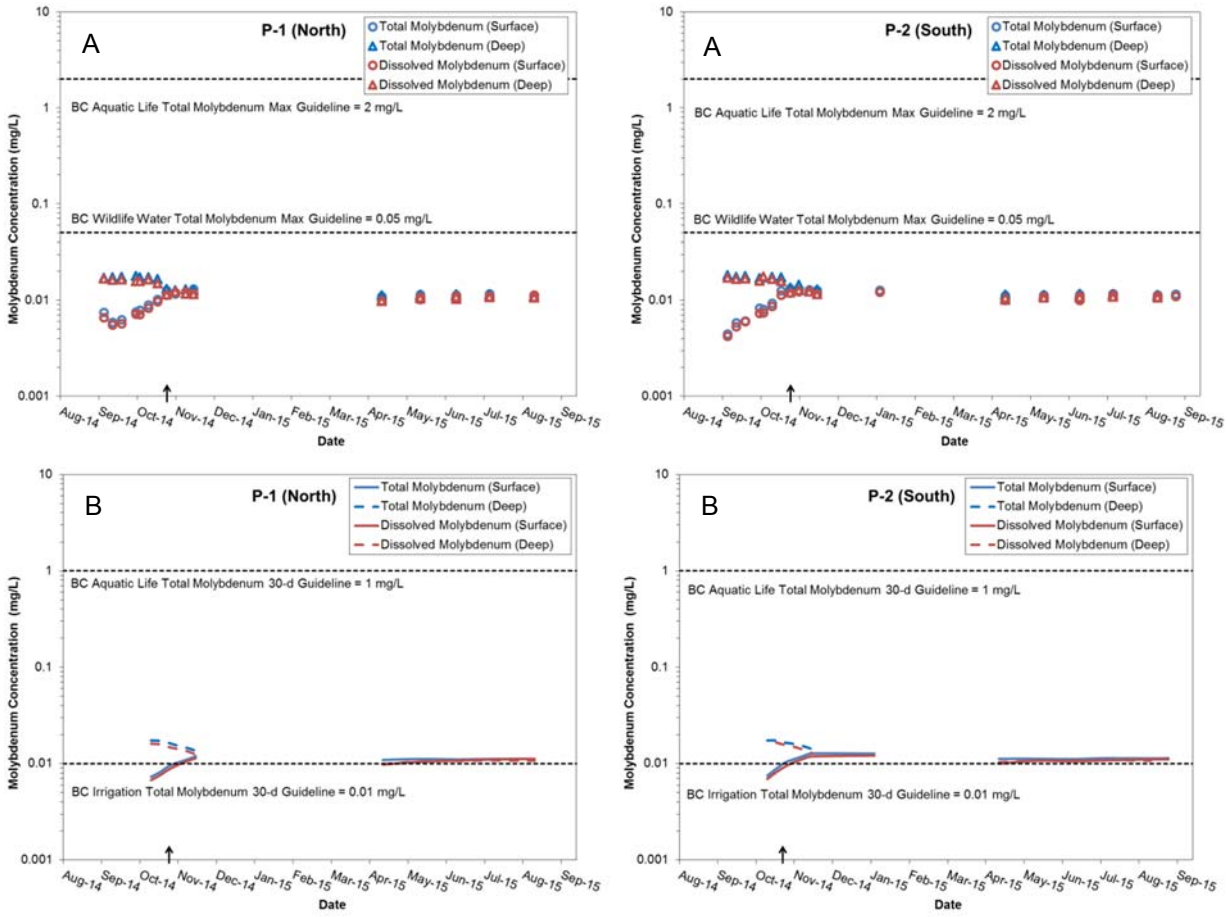
Note: Arrow represents the approximate timing of late-October turnover in Polley Lake. Gaps represent >30 d between sampling.

Figure 8: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Stations P1 and P2, Polley Lake

Molybdenum

Total and dissolved molybdenum concentrations at stations P1 and P2 in Polley Lake were similar and consistently below the maximum BC WQGs for aquatic life and wildlife water following the event through August 2015 (Figure 9). Concentrations at depth were higher than at the surface until fall turnover, when the water column was vertically mixed and concentrations remained stable at around 0.01 mg/L thereafter.

The 30-d average concentrations of molybdenum were consistently below the 30-d BC WQG for aquatic life, but slightly exceeded the 30-d BC WQG for irrigation (Figure 9). The BC WQG for irrigation was considered in the assessment because it is conservatively expected to be protective of ruminant wildlife that might be exposed through dietary uptake from irrigated plant foods. However, only aquatic vegetation along the edges of Polley Lake is expected to be in contact with lake water because the lake is not used as an irrigation source; consequently, there has been little potential for uptake of molybdenum by ruminant wildlife. Additional discussion regarding the potential for molybdenum uptake by ruminant wildlife in Polley Lake is provided in Golder (2015a).



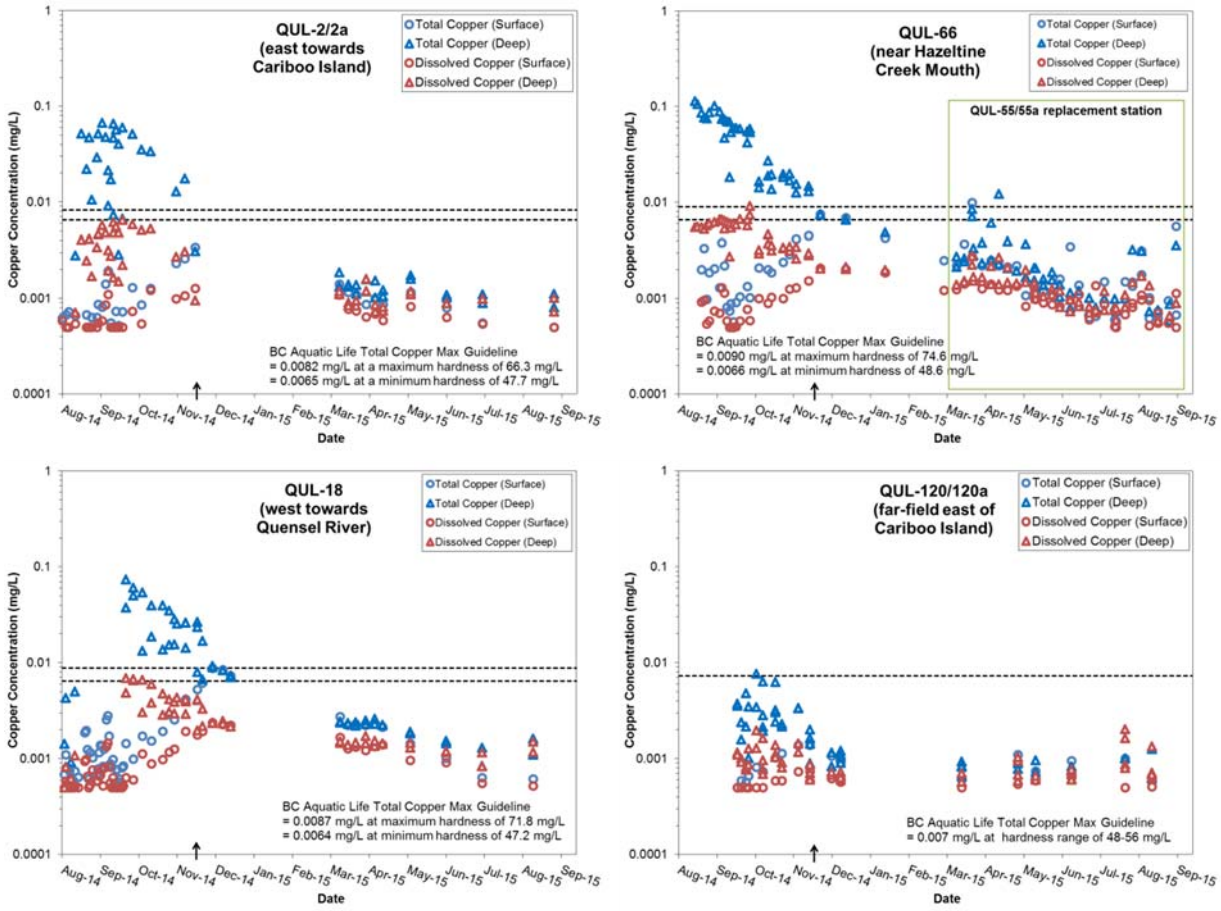
Note: Arrow represents the approximate timing of late-October turnover in Polley Lake. Gaps represent >30 d between sampling.

Figure 9: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Molybdenum Concentrations at Stations P1 and P2, Polley Lake.

3.2.2.2 Quesnel Lake

Copper

Following the event, total copper concentrations at depth were elevated above the maximum BC WQG for aquatic life in the West Basin of Quesnel Lake, but were not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Figure 10). Dissolved concentrations (surface and depth) and total concentrations at the surface were typically below the maximum BC WQGs. Total copper concentrations at depth decreased over time, converged with surface and dissolved concentrations by early March 2015, and were below the maximum BC WQG by April. As of late August 2015, copper concentrations reported for QUL-66/55/55a (near the mouth of Hazeltine Creek) were generally similar to concentrations reported elsewhere in the lake, including the far-field station (QUL-120/120a) east of Cariboo Island (Figure 10), with the exception of a few measurements that were higher than the norm, but nonetheless below guidelines. These elevated measurements at the near-field stations are likely associated with periods when Hazeltine Creek flows were more turbid and contained higher TSS levels, as a result of rehabilitation and construction work during that period.

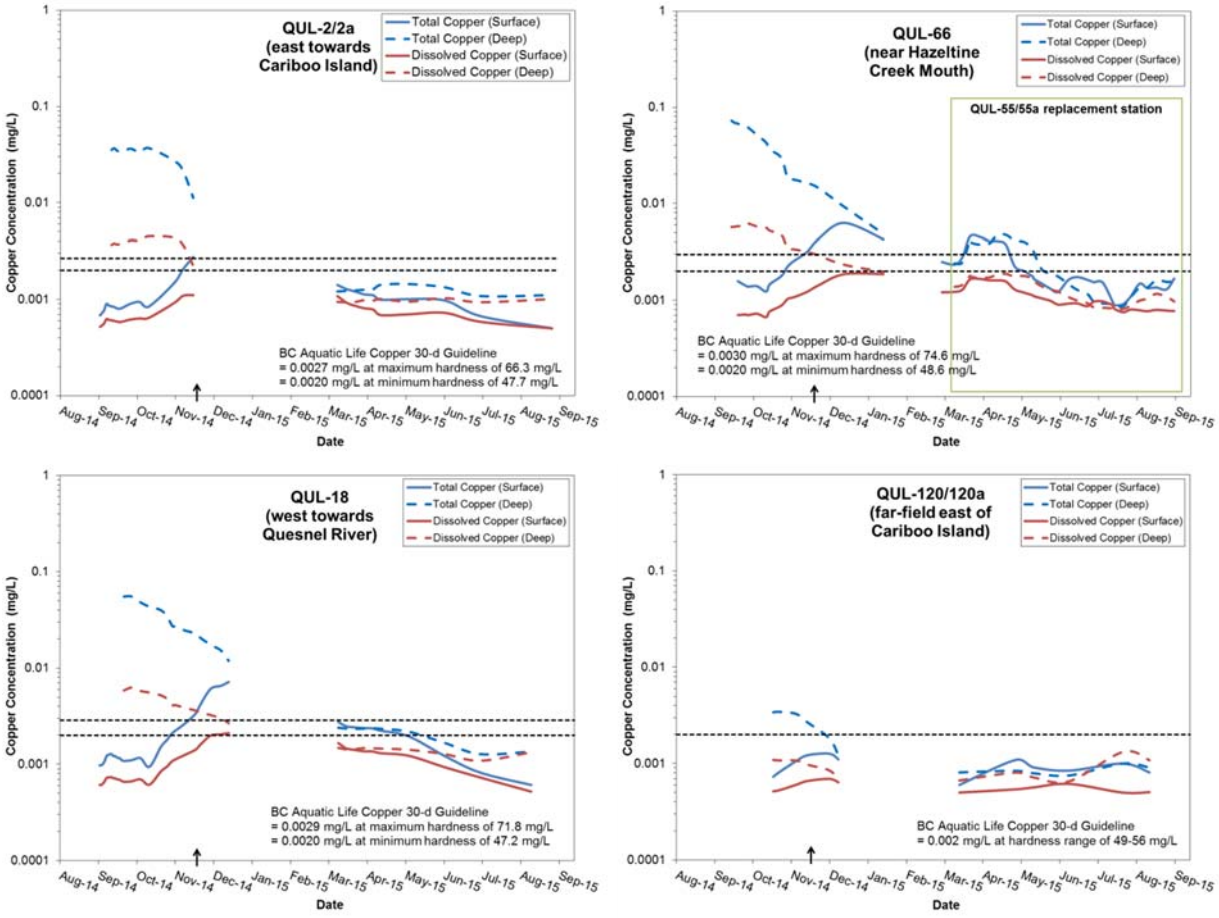


Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 10: Post-event Instantaneous Total and Dissolved Copper Concentrations at Stations QUL-2/2a, QUL-66/55/55a, QUL-18, and QUL-120/120a, Quesnel Lake.

Following the event, 30-d average concentrations of total and dissolved copper at depth were elevated above surface concentrations and the 30-d BC WQG for aquatic life at stations in the West Basin (Figure 11). At mid-field stations QUL-2/2a and QUL-18, 30-d average concentrations decreased below the BC WQG by March 2015 (Figure 11). At near-field Station QUL-66/55/55a, near the mouth of Hazeltine Creek, the 30-d average for total copper remained elevated above the BC WQG from March to May 2015, reflective of higher turbidity levels associated with Hazeltine Creek during this period and a concurrent increase in total and dissolved copper concentrations at HAC-01/a/b/c (see Section 3.2.2.4).

Total and dissolved concentrations of copper at each of the four Quesnel Lake stations remained at around 0.001 mg/L by June 2015.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake. Gaps represent >30 d between sampling.

Figure 11: Post-event Rolling 30-day Average Total and Dissolved Copper Concentrations at Stations QUL-2/2a, QUL-66/55/55a, QUL-18, and QUL-120/120a, Quesnel Lake.

3.2.2.3 Quesnel River

Copper

Total copper concentrations at Station QUR-1 in Quesnel River peaked in December, reflecting increased turbidity during this period, and exceeded the maximum BC WQG until January 2015 (Figure 12). Dissolved copper concentrations were substantially lower than the maximum BC WQG for aquatic life throughout the sampling period. By May 2015, total copper concentrations converged with dissolved concentrations, which would suggest that most of the copper associated with suspended particulate matter had settled out of the water column.

The 30-d average concentrations of total copper declined from a peak in January 2015 to below the 30-d BC WQG for aquatic life by mid-April and continued to decline through August (Figure 12). The 30-d average dissolved concentrations were slightly above the most conservative 30-d BC WQG between December and mid-January, but also declined through to August.

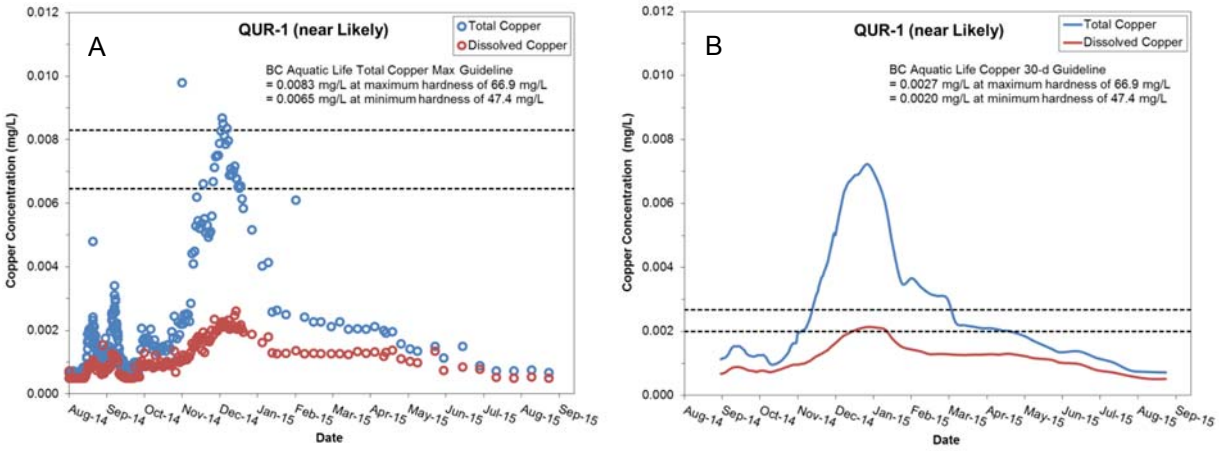


Figure 12: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Station QUR-1 near Likely, Quesnel River.

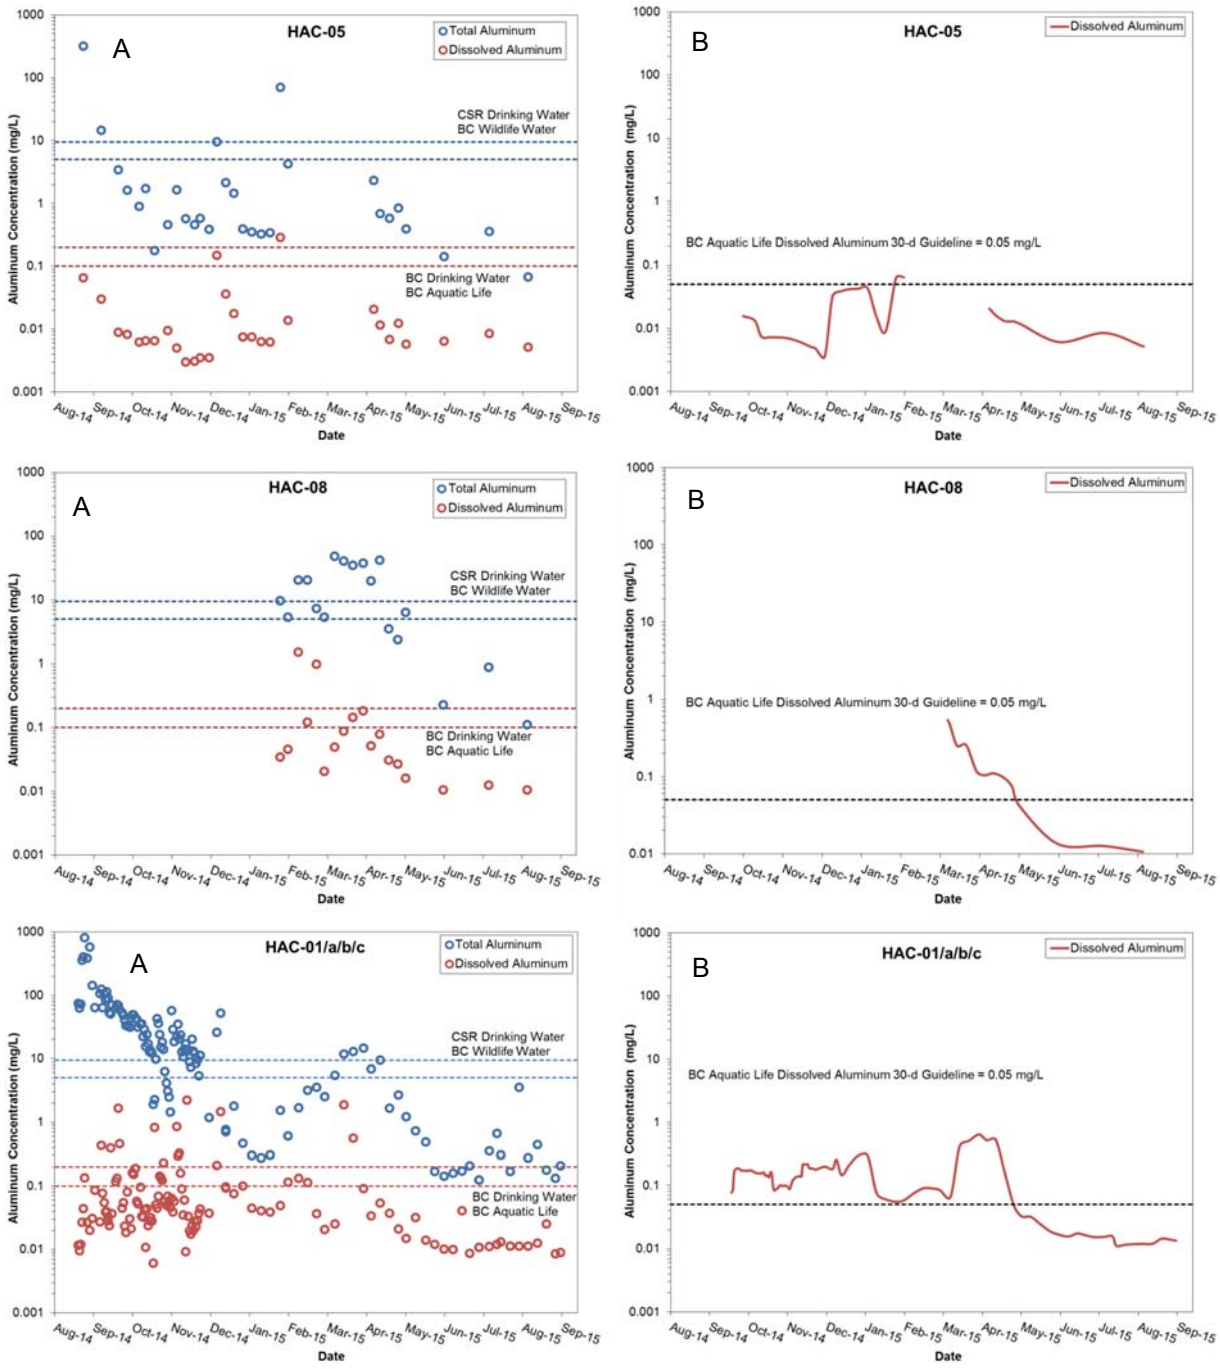
3.2.2.4 Hazeltine Creek

Hazeltine Creek was not defined as a receiving environment in the PEEIAR because the creek was not considered to be fish habitat during the period assessed based on rationale provided in Golder (2015a). For the purpose of the DSI, however, Hazeltine Creek is considered as part of the receiving environment. Spatial and temporal trends in creek water quality are presented graphically for the four metals identified as COPCs in Table 1 that had the largest magnitude of guideline exceedance (i.e., aluminum, copper, chromium, and iron). Trends are shown for Station HAC-05 in upper Hazeltine Creek, Station HAC-08 upstream of the sedimentation ponds, and Station HAC-01/a/b/c downstream of the sedimentation ponds in lower Hazeltine Creek.

Aluminum

In upper Hazeltine Creek (HAC-05), aluminum concentrations remained below BC WQGs or CSR standards for drinking water, wildlife water, and aquatic life following the event through August 2015, with a few exceptions (Figure 13). In the lower creek, total and dissolved aluminum concentrations at HAC-01/a/b/c were above corresponding maximum BC WQGs and CSR standards following the event until December 2014, and again from February to April 2015 (Figure 13). Aluminum concentrations were similarly elevated at HAC-08 during this period in 2015. From May through August 2015, concentrations in lower Hazeltine decreased below maximum guidelines.

The 30-d average dissolved concentrations at stations HAC-05, HAC-08, HAC-01/a/b/c were consistently above the 30-d dissolved aluminum BC WQG for aquatic life until late April 2015 and then decreased below guidelines through August 2015 (Figure 13). Elevated aluminum concentrations at stations in lower Hazeltine Creek reflected the increased turbidity during the same time period.



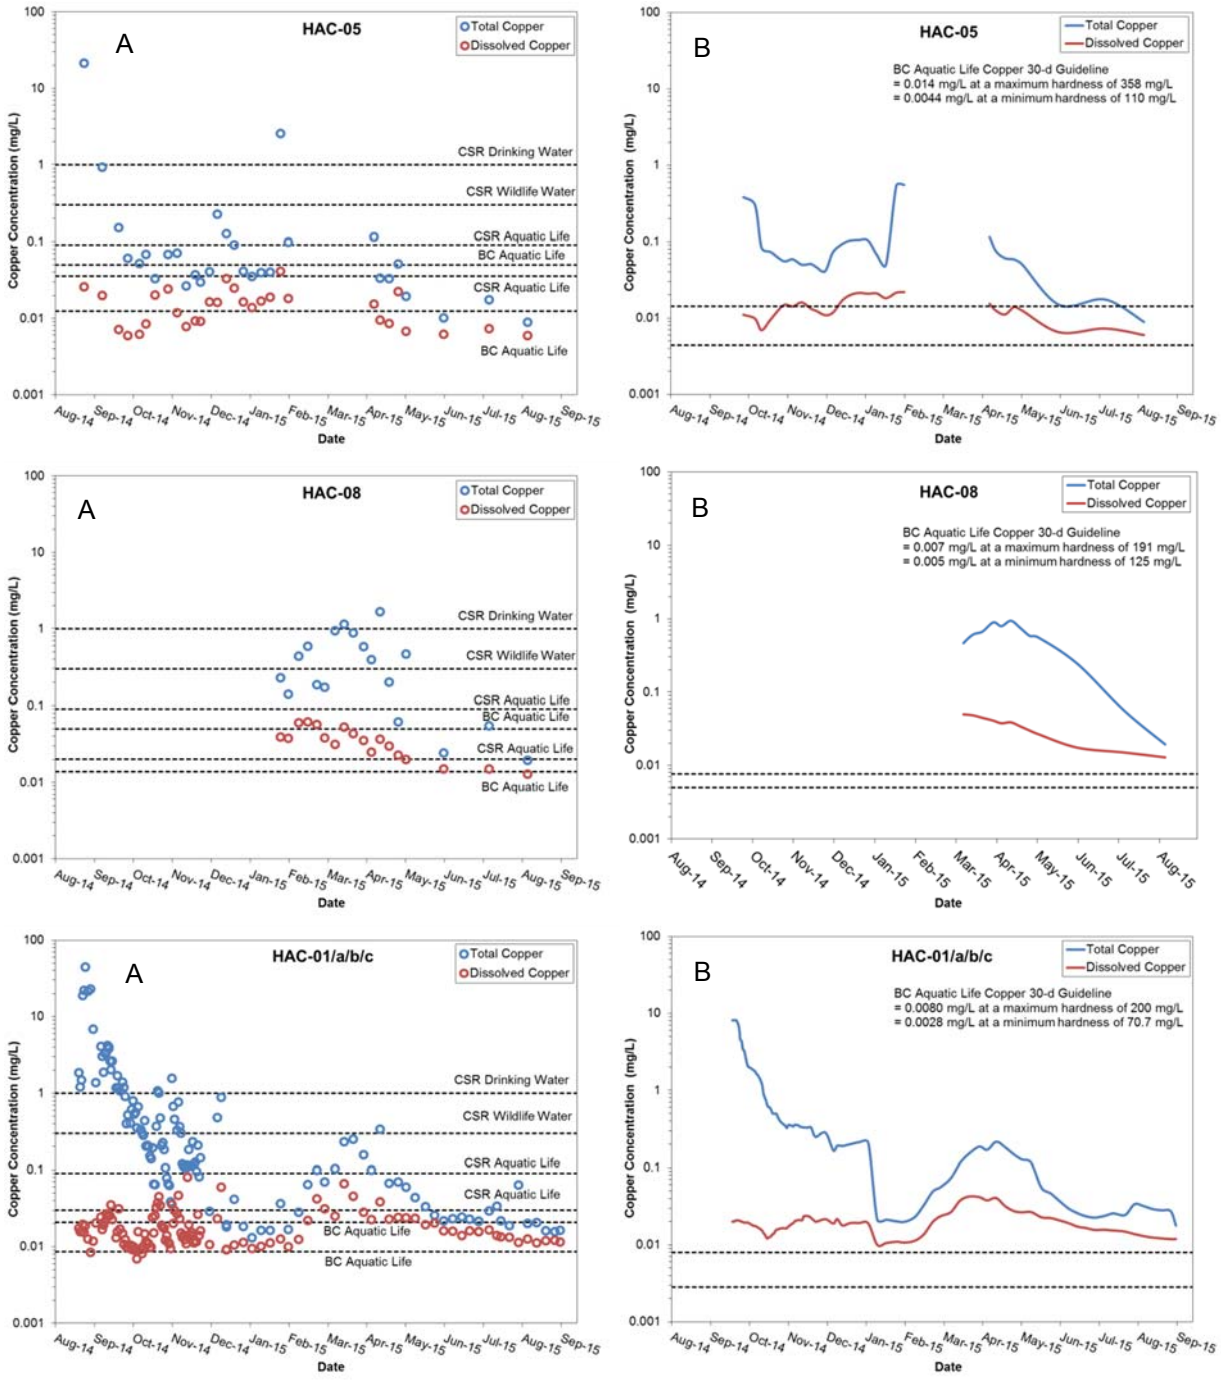
Note: CSR – Schedule 6 Drinking Water Total Aluminum Standard = 9.5 mg/L; BC Wildlife Water Total Aluminum Max Guideline = 5 mg/L; BC Drinking Water Dissolved Aluminum Max Guideline = 0.2 mg/L; BC Aquatic Life Dissolved Aluminum Max Guideline = 0.1 mg/L. Dashed line colour corresponds to total or dissolved values. Gaps represent >30 d between sampling.

Figure 13: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Aluminum Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

Copper

Following the event and until June 2015, total copper concentrations in Hazeltine Creek were typically above BC WQGs and CSR standards for aquatic life (Figure 14). From June to August 2015, total concentrations in the upper creek were mostly below the maximum BC WQG when minimum hardness conditions were considered. Total concentrations at HAC-08 and HAC-01/a/b/c decreased over time, but showed the same trend of peak concentrations in March 2015 that corresponded with increased turbidity and total forms of other metals during turbid flow episodes that occurred during the early freshet and ongoing rehabilitation work in the creek. Total concentrations decreased below CSR standards by May 2015 and remained within the range of BC WQGs based on the range of hardness observed at this station. Dissolved concentrations at HAC-05, HAC-08, and HAC-01/a/b/c were typically below the maximum BC WQG with the exception of several guideline exceedances that occurred between February and April 2015 (Figure 14).

In the upper creek, 30-d average concentrations of total and dissolved copper were mostly above the 30-d BC WQGs for aquatic life based on maximum and minimum hardness, respectively (Figure 14). Thirty-day average concentrations in the lower creek were consistently above the 30-d BC WQG calculated using the reported hardness range, but appear to continue to decline.



Note: CSR – Schedule 6 Drinking Water Total Copper Standard = 1 mg/L; CSR – Schedule 6 Wildlife Water Standard = 0.3 mg/L; CSR – Schedule 6 Aquatic Life Total Copper Standard = 0.03-0.09 mg/L; BC Aquatic Life Total Copper Max Guideline = 0.009-0.04 mg/L. Gaps represent >30 d between sampling.

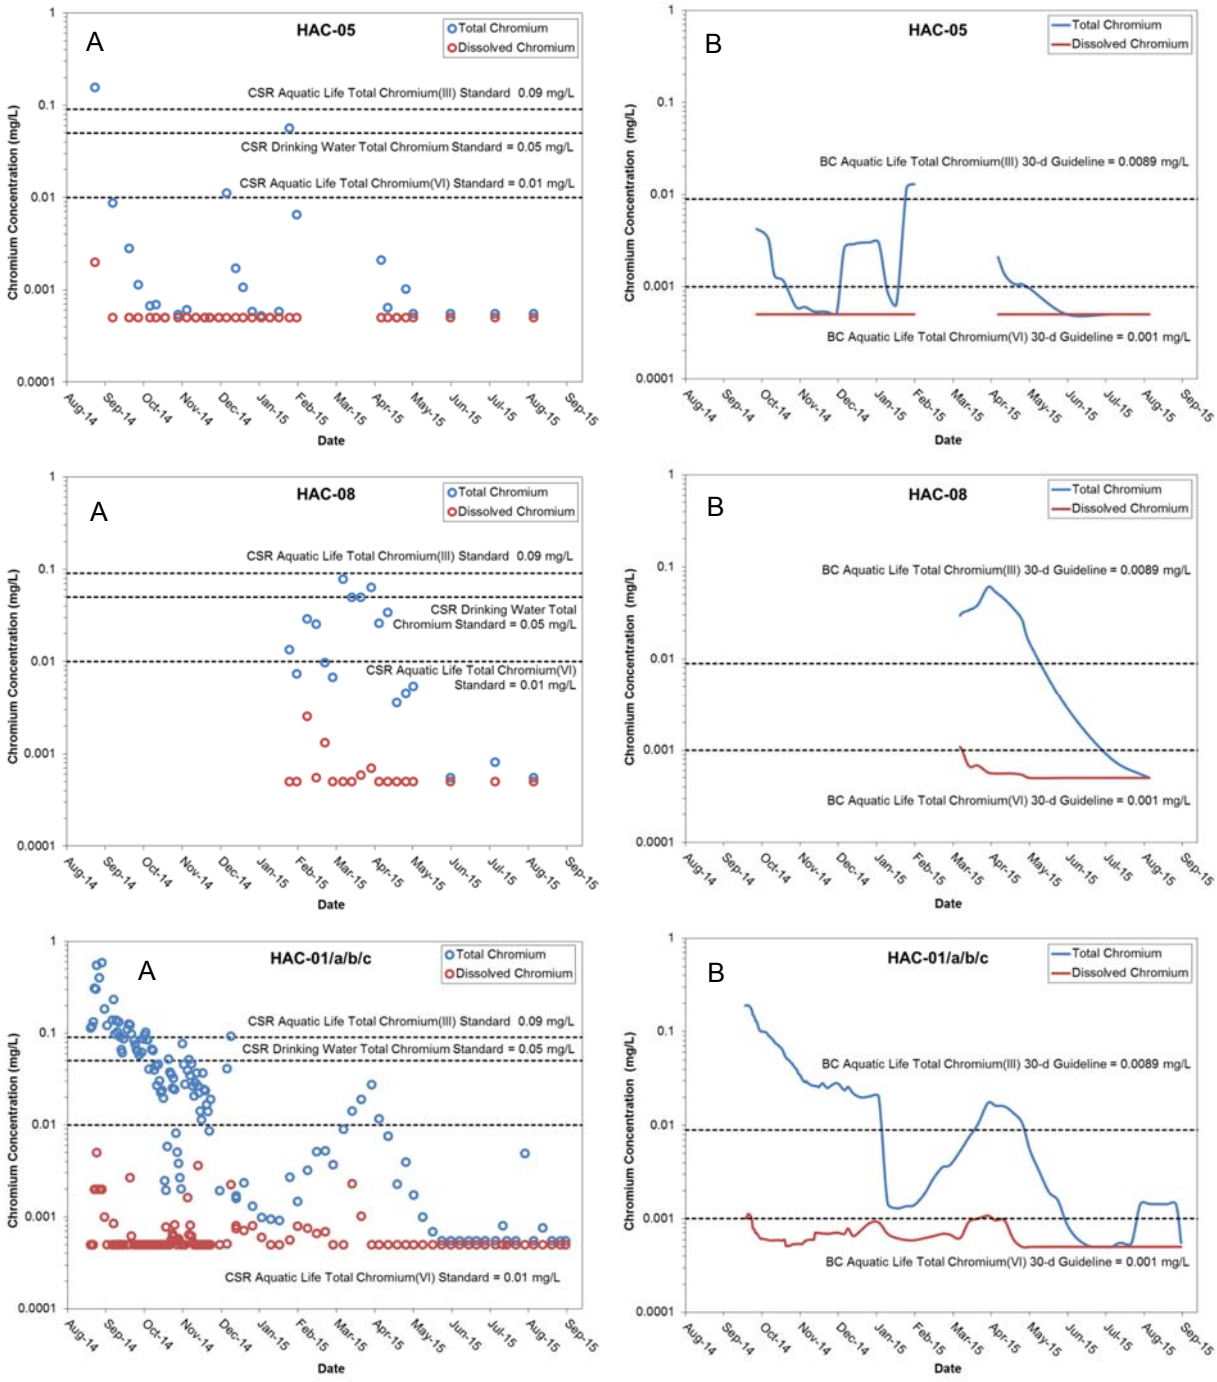
Figure 14: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Copper Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

Chromium

As discussed in Golder (2015a), the available speciation data for Hazeltine Creek indicates the dominant chromium species in Hazeltine Creek was chromium III, which is less toxic than the chromium VI form. However, as a conservative measure, guidelines and standards for both chromium species were considered in this assessment.

At the upper creek station, total concentrations were typically below the CSR Standards for drinking water and aquatic life; however, one sample collected immediately after the event exceeded the Cr-III CSR standard (Figure 15). Total concentrations fluctuated through December 2014 and January 2015, and 30-d average concentrations typically did not exceed the 30-d BC (Cr-III) WQG. In the lower creek, total concentrations at HAC-01/a/b/c were above CSR standards following the event and into early January 2015 and showed the same peak in concentration in March 2015 as was observed for total forms of other metals (Figure 15). The 30-d average concentration of total chromium also exceeded the 30-d BC (Cr-III) WQG during March (Figure 15). Total chromium concentrations were similarly elevated at HAC-08 during this period in 2015. Total concentrations had decreased below CSR standards and the 30-d BC (Cr-III) WQG by May and June 2015, respectively.

Dissolved concentrations in Hazeltine Creek were consistently below the BC WQGs and CSR standards.



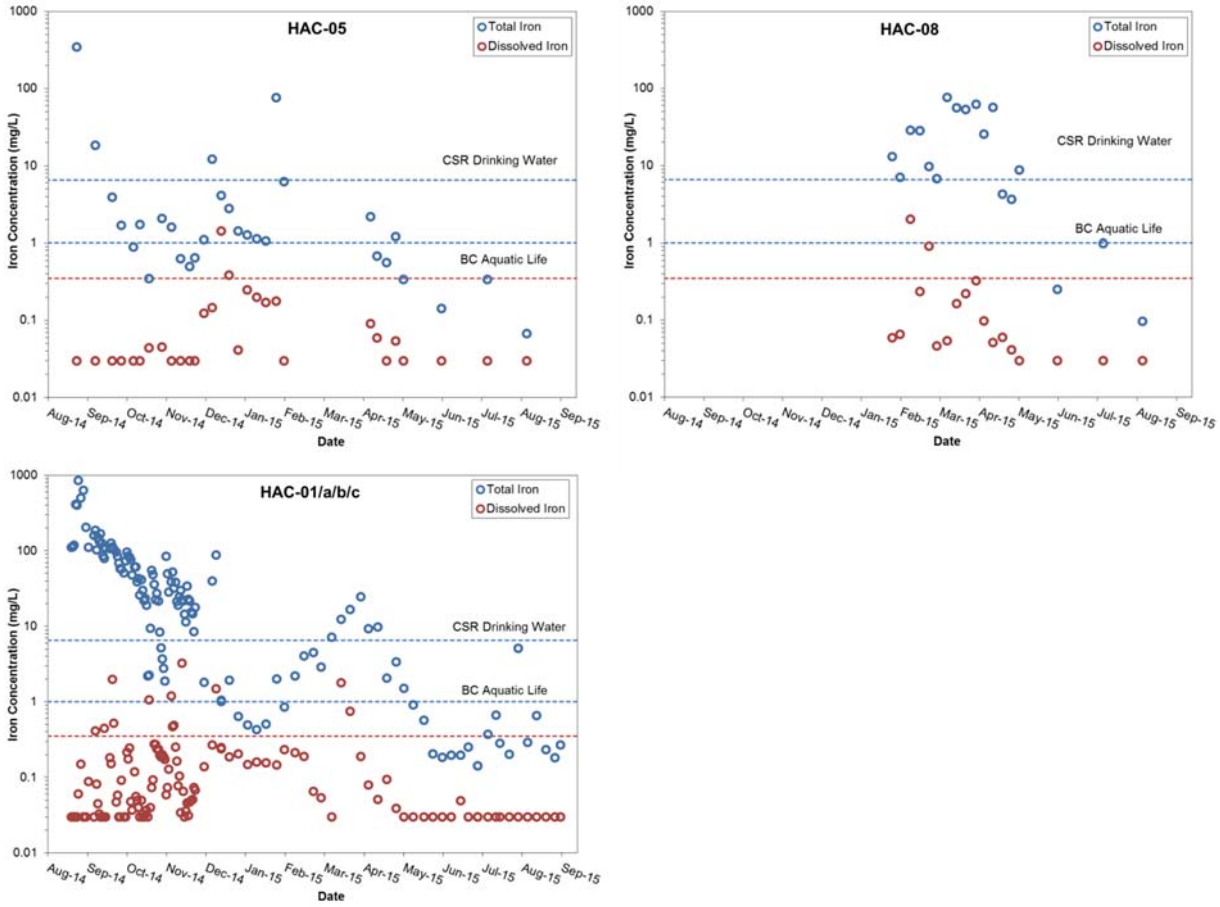
Note: Gaps represent >30 d between sampling.

Figure 15: Post-event Instantaneous (A) and Rolling 30-day Average (B) Total and Dissolved Chromium Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

Iron

Total iron concentrations at the upper station HAC-05 exceeded the CSR drinking water standard intermittently following the event and exceeded the BC WQG for aquatic life consistently until May 2015 (Figure 16). Dissolved iron concentrations were typically below the BC WQG for dissolved iron at this station.

In lower Hazeltine Creek, total iron concentrations at HAC-01/a/b/c were elevated immediately following the event and remained so into late November 2014, after which concentrations decreased below guidelines until they peaked again in March 2015. Total iron concentrations were similarly elevated at HAC-08 during this period in 2015. Total iron concentrations showed the same peaks observed for concentrations of total forms of other metals. Total concentrations exceeded the CSR standard and BC WQG during these periods, then decreased below CSR standard and BC WQG by mid-May (Figure 16). The exception was a single event in August in which total values at both lower stations were more than ten times the preceding and subsequent values taken in July and August. Dissolved concentrations were variable after the event through April 2015, but typically did not exceed the BC WQG and were close to the limit of detection after April 2015.



Note: CSR – Schedule 6 Drinking Water Total Iron Standard = 6.5 mg/L; BC Aquatic Life Total Iron Max Guideline = 1 mg/L; BC Aquatic Life Dissolved Iron Max Guideline = 0.35 mg/L. Dashed line colour corresponds to total or dissolved values.

Figure 16: Post-event Instantaneous Total and Dissolved Iron Concentrations at Stations HAC-05, HAC-08, and HAC-01/a/b/c, Hazeltine Creek.

Other Metals

Spatial and temporal trends for other metals identified as COPCs in Table 1 are presented graphically in Attachment 7 and described below. Note that the order of COPCS presented in Attachment 7 follows the order presented below.

Arsenic

Total arsenic concentrations at Station HAC-05 in upper Hazeltine Creek were initially elevated after the event, but were typically below BC WQGs and CSR standards for aquatic life, wildlife water, and drinking water from September 2014 through August 2015 (Attachment 7). Total and dissolved concentrations converged with time and likely resulted from erosion controls in the creek.

In lower Hazeltine Creek, total concentrations at HAC-08 exceeded maximum BC WQGs and CSR standards in January through April 2015 and remained below guidelines thereafter (Attachment 7). Thirty-day average concentrations of total arsenic were consistently above the 30-d BC WQG for aquatic life until June 2015. Total concentrations at HAC-01/a/b/c exceeded maximum BC WQGs and CSR standards following the event until December 2014 (Attachment 7). Total concentrations decreased over time and remained below guidelines from December 2014 through August 2015. Thirty-day average concentrations of total arsenic were consistently above the 30-d BC WQG for aquatic life until January 2015 and slightly exceeded the guideline in April 2015. Since May 2015, 30-d average concentrations have been below the 30-d BC WQG. Dissolved concentrations remained well below guidelines at all three stations and at all times since September 2014.

Molybdenum

Total and dissolved concentrations of molybdenum at stations HAC-05 and HAC-01/a/b/c were elevated above the BC WQG for wildlife water immediately following the event, but were consistently below maximum BC WQGs from September 2014 through August 2015 (Attachment 7). Molybdenum concentrations at HAC-08 were consistently below guidelines during the monitoring period in 2015. Total and dissolved concentrations were similar throughout the sampling period. Thirty-day average concentrations were well below the 30-d BC WQG for aquatic life and only slightly above the most conservative 30-d BC WQG for irrigation through August 2015, similar to that observed for Polley Lake (Section 3.2.2.1).

Cadmium and Titanium

Total forms of these metals were identified as COPCs in Table 1 based on the 95th percentile values exceeding CSR standards. Consequently, total cadmium and total titanium will be retained as COCs in the DSI (Section 5.0). Dissolved cadmium was not identified as a COPC based on comparison to the BC WQG which is a dissolved guideline. There is no BC WQG for titanium.

Beryllium, Cobalt, Lead, and Manganese

Total forms of these metals were identified as COPCs in Table 1 based on 95th percentile values exceeding the corresponding 30-d BC WQGs for aquatic life.

In upper Hazeltine Creek, 30-d average concentrations of these metals did not exceed the 30-d BC WQGs from March through August 2015 (Attachment 7). In lower Hazeltine Creek, peak concentrations of these metals were identified in March and April relative to other months in 2015 (Attachment 7). Thirty-day average concentrations of total beryllium and cobalt were above the 30-d BC WQGs from March to June at HAC-08 and March to May at HAC-01/a/b/c and decreased below guidelines thereafter. With respect to lead and manganese, 30-d average concentrations at HAC-08 exceeded the 30-d BC WQG under the most conservative site-specific hardness scenario (i.e., lowest hardness) from March to May, but did not exceed the 30-d BC WQGs at HAC-01/a/b/c from March through August 2015.

Zinc

Total zinc was identified as a COPC in Table 1 based on 95th percentile values exceeding the maximum and 30-d BC WQGs for aquatic life under the most conservative site-specific hardness scenario (i.e., lowest hardness).

In upper Hazeltine Creek, total zinc did not exceed BC WQGs from March through August 2015 (Attachment 5). In lower Hazeltine Creek, peak concentrations were identified in February and March relative to other months in 2015 (Attachment 7). At these lower creek stations, instantaneous concentrations only exceeded the most conservative maximum BC WQG in February and March at HAC-08 and in March at HAC-01/a/b/c, and then decreased below the guideline thereafter. The 30-d average concentrations at the lower creek stations exceeded the most conservative 30-d BC WQG from February to June 2015 and decreased below the guideline thereafter.

3.2.3 Selenium

Prior to the event, selenium concentration trends in water, sediment, and biota in Polley Lake were being monitored by MPMC in response to the identification of increasing selenium concentrations in the lake attributed to a mine-related source that was controlled through mitigation measures in 2009 (Minnow 2014). Between 2006 and 2009, selenium increased two-fold above baseline in Polley Lake to a maximum concentration of 0.0019 mg/L due to selenium inputs from North Bell Dump seepage and runoff from the eastern side of the mine site. Concentrations then decreased to approximately 0.0007 mg/L from 2009 to 2013 following construction of a runoff collection system (Minnow 2014).

After the event, total and dissolved concentrations of selenium were similar to each other throughout Polley Lake and did not reflect the trend of higher total concentrations at depth that was observed for copper (Attachment 7). Concentrations remained stable at around 0.0009 mg/L from November 2014 through August 2015. In Hazeltine Creek, selenium was measured above guidelines immediately after the event with total concentrations higher than dissolved. Concentrations decreased to below guidelines by October 2014. Total and dissolved concentrations converged by December 2014, and stabilized at around 0.001 mg/L through August 2015. At station QUL-66/55/55a close to the mouth of Hazeltine Creek, total and dissolved concentrations were measured at or near the detection limits from August 2014 through August 2015. Note that the analytical detection limit for selenium was improved in March 2015 (see Attachment 7, Figure 15), which led to an apparent decrease in concentrations in Quesnel Lake.

Overall, post-event selenium concentrations in Polley Lake, Hazeltine Creek, and the near-field environment of Quesnel Lake remained stable below guidelines or decreased to below guidelines shortly after the event and remained stable thereafter. Current BC water quality guidelines are protective of toxicity to aquatic life, including the potential for food chain accumulation. Since the concentrations are below these guidelines, concentrations of selenium in water as a result of the tailings dam failure are not considered to be a risk to aquatic life.

3.2.4 Nutrients: Phosphorus

Phosphorus was not identified as a COPC for Polley and Quesnel lakes based on screening of total phosphorus (TP) data collected in these lakes from March to August 2015 (Table 1). Concentrations of total and dissolved phosphorus and orthophosphate were, however, evaluated further over time to assess event-related changes at representative lake stations. Unlike some of the nitrogen forms (e.g., ammonia and nitrite), phosphorus is not toxic to aquatic biota, but rather phosphorus tends to limit primary productivity in freshwater lake environments (Environment Canada 2004). Instantaneous concentrations of TP at surface and depth in Polley and Quesnel lakes were compared to the BC WQG range for lakes (i.e., 0.005 to 0.015 mg/L; BC MoE 2015a) that is

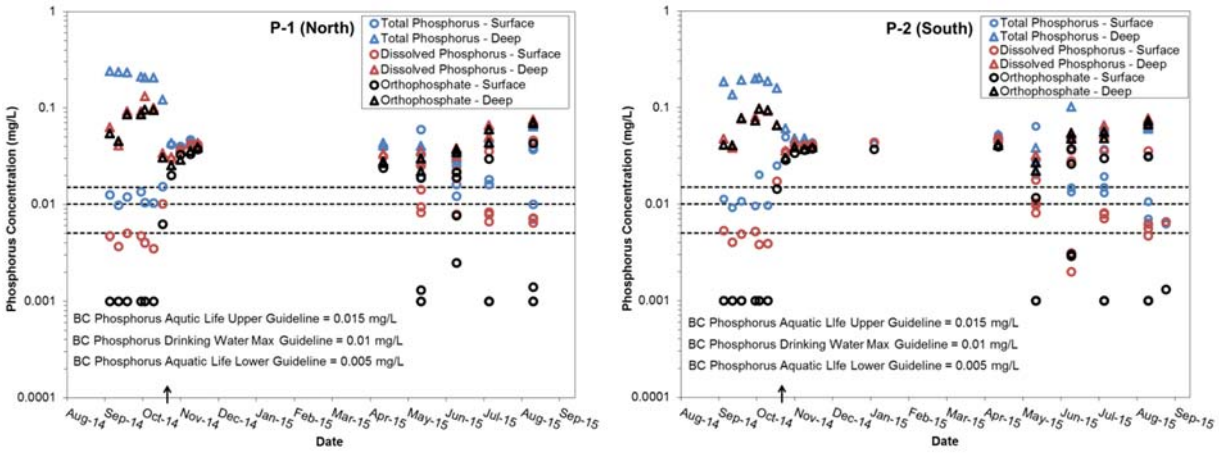
intended to be applied to the spring turnover concentration or the mean epilimnetic growing season concentration (May to September). An assessment of event-related changes in phosphorus and subsequent potential impacts on primary productivity based on this guideline comparison is therefore conservative, as reflected in the discussion of results for each lake. Consistent with the approach taken in the PEEIAR, the evaluation of event-related changes in waterborne phosphorus is intended to be integrated with biological information to assess potential impacts on lake productivity in the HHERA.

3.2.5 Polley Lake

Following the event and through August 2015, concentrations of TP at the surface in Polley Lake were within the pre-event range of concentrations reported in the PEEIAR for Polley Lake. Pre-event TP concentrations were defined as: mean = 0.041 mg/L; 95th percentile = 0.094 mg/L.; minimum = 0.0046 mg/L (Appendix A; Golder 2015a). Both pre-event mean and upper limit concentrations were above the BC WQG range of 0.005 to 0.015 mg/L. This is consistent with the observation by Minnow (2014) that the trophic status of the lake changed from oligotrophic/mesotrophic to mesotrophic/eutrophic in 2012, two years prior to the event. At depth, TP concentrations were elevated above pre-event concentrations prior to fall turnover (Figure 17).

Dissolved phosphorus and orthophosphate were also higher at depth compared to the surface. In deep samples, concentrations of dissolved phosphorus and orthophosphate were similar; but surface samples contained orthophosphate concentrations near or below the detection limit. Pre-event dissolved phosphorus concentrations were defined as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.002 mg/L; pre-event orthophosphate concentrations were defined as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.001 mg/L (Appendix A; Golder 2015a).

From April through August 2015, a number of total and dissolved phosphorus concentrations and deep orthophosphate concentrations were above the TP BC WQG range (Figure 17). Concentrations were, however, within or below the range of pre-event concentrations reported in the PEEIAR for Polley Lake and so no event-related changes to phosphorus concentrations in Polley Lake were identified from April through August.



Note: Arrow represents the approximate timing of late-October turnover in Polley Lake.

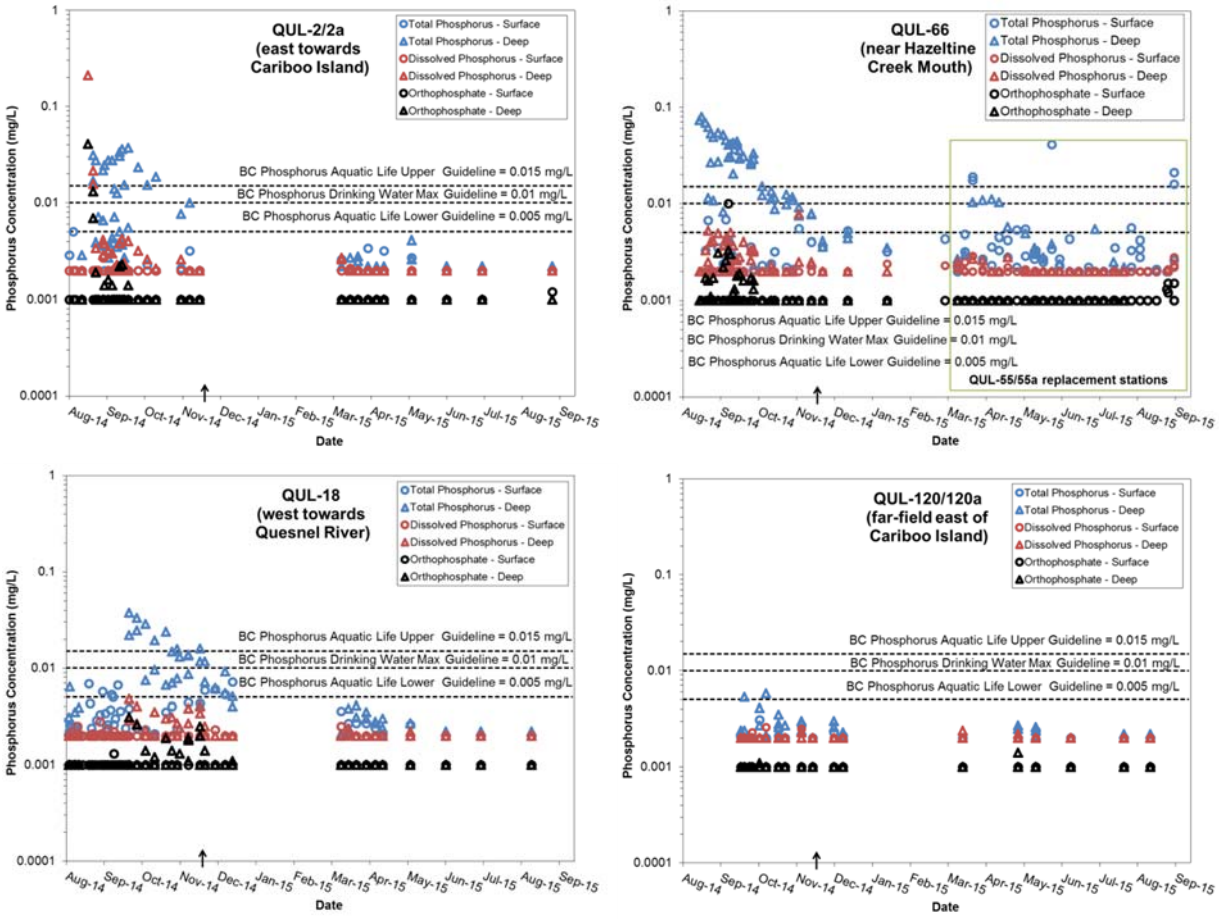
Figure 17: Post-event Instantaneous Total and Dissolved Phosphorus and Orthophosphate at Stations P1 and P2, Polley Lake.

3.2.5.1 Quesnel Lake

After the event, TP concentrations at depth exceeded the BC WQG range in the West Basin of Quesnel Lake, but were not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Figure 18). By fall turnover, TP concentrations had substantially decreased in the West Basin of Quesnel Lake. Through August 2015, TP concentrations were below the BC WQG range and resembled pre-event concentrations with the exception of a few intermittent exceedances at near-field station QUL-66/55/55a, near the mouth of Hazeltine Creek (Figure 18). Pre-event TP concentrations were defined as: median = 0.004 mg/L; 95th percentile = 0.008 mg/L.; minimum = <0.002 (Appendix A; Golder 2015a).

At the near-field, mid-field, and far-field stations, dissolved phosphorus and orthophosphate concentrations reported between March and August were below pre-event concentrations (Figure 18). Pre-event dissolved phosphorus concentrations were defined as: median = 0.003 mg/L; 95th percentile = 0.004mg/L; minimum= <0.002. Pre-event orthophosphate concentrations were defined as: median = 0.003 mg/L; 95th percentile = 0.005mg/L; minimum = <0.001 (Appendix A; Golder 2015a).

Collectively, an evaluation of the phosphorus data collected between March and August suggest that event-related changes of concern for phosphorus were not evident in Quesnel Lake.



Note: Arrow represents the approximate timing of mid-November turnover in Quesnel Lake.

Figure 18: Post-event Instantaneous Total and Dissolved Phosphorus and Orthophosphate at Stations QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a, Quesnel Lake.

4.0 DISCUSSION OF CONTAMINANTS OF POTENTIAL CONCERN

Following initial screening of water quality data using relevant BC WQGs and CSR standards, COPCs were identified for the receiving environment as described in Section 2.2. In this section, the results presented in Section 3 are discussed with reference to whether each COPC will be carried forward for further assessment as Contaminants of Concern (COCs) in the DSI.

Changes in concentrations of COPCs were evaluated for stations selected to be representative of Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River. Where appropriate, COPCs were assessed with respect to concentrations in the near-field (i.e., close to the Hazeltine Creek mouth), mid-field, and far-field areas of Quesnel Lake to provide a spatial representation of lake concentrations. COPCs in Hazeltine Creek were evaluated in the upper creek near the TSF and in the lower creek both upstream and downstream of the sedimentation ponds. Turbidity and copper were evaluated in Quesnel River near the community of Likely downstream of the outflow from Quesnel Lake.

Post-event changes in COPCs evaluated for the DSI are summarized in Tables 2 and 3, which indicate whether guideline exceedances occurred at surface or at depth during two consecutive time periods; between March and May 2015 and between June and August 2015. These time periods are generally reflective of turbid episodes in Hazeltine Creek (March to May) and clear-flow conditions (June to August) in Hazeltine Creek that influenced the nature of inputs to Quesnel Lake (i.e., higher suspended particulate matter and potentially metal inputs during turbid episodes). Consistent with the PEEIAR WQIA, the updated assessment for the DSI was based on comparison to BC WQGs for the protection of aquatic life, but consideration was also given to whether turbidity levels met the requirements specified in amended Pollution Abatement Order 107461. For comparative purposes, Tables 2 and 3 also shows post-event changes in COPCs documented in the PEEIAR WQIA for two consecutive time periods; between August and November 2014 and between November 2014 and April 2015.

Table 2: Summary of Post-Event Changes in Suspended Particulate Matter over Time in Polley Lake, Quesnel Lake, and Quesnel River in Relation to the PEEIAR WQIA and the WQIA Update for the DSI

Notes:
near-field: Near to the Hazeltine Creek Mouth; Stations QUL-66 and QUL-55/55a
mid-field: Stations QUL-18 (west) and QUL-2/2a (east)
far-field: Station QUL-120/120a (east)
Surface = 1-10 m depth in Polley Lake, 1-20 m depth in Quesnel Lake; Deep = >10 m depth in Polley Lake, >20 m depth in Quesnel Lake
n/a: Not applicable; only surface water samples were collected from Hazeltine Creek and Quesnel River

(a) Focus on the four metals identified as COPCs in Table 1 that had the largest magnitude of guideline exceedance (i.e., aluminum, copper, chromium, and iron). See Section 3.2.2.4 for an assessment of all identified COPCs
(b) Comparison to chromium (III) WQGs
(c) Total iron concentrations were below the total maximum BC WQG except one value recorded in August at HAC-01 (see further discussion in Section 3.2.2.4)
(d) Concentrations began to increase above the 30-d BC WQG range (based on the range of hardness) in October 2014

● = Concentrations are below applicable BC WQGs at representative stations or are below pre-event concentrations

● = Concentrations exceed applicable BC WQGs and are above pre-event concentrations in one or more samples from at least one representative station

4.1 Changes in Water Quality from March to August 2015

4.1.1 Hazeltine Creek

As described in Section 3.2.2.4 and shown in Tables 2 and 3, some COPC guideline exceedances occurred in Hazeltine Creek during February, March, April, and May 2015, when turbid flow periods were evident in the creek due to restoration activities that also coincided with the onset of an early freshet. Turbid flow periods were characterized by elevated concentrations of particulate matter and some metals (mainly total forms) that resulted in increased inputs of these parameters to the near-field environment in Quesnel Lake. Clear-flow conditions, which were defined by instantaneous measures of turbidity less than 9.5 NTU[7], prevailed in Hazeltine Creek during January, June, July, and August of 2015, with the exception of brief periods of turbidity at the end of July and the middle August. The brief turbid periods in late summer did not correspond with rainfall events (Attachment 6, Figure 5), but were likely a result of the change in discharge location of the creek at that time and maintenance activities in the sedimentation ponds (pers. comm. S. Litke). Photographs showing turbid and clear-flow conditions are shown in Attachment 6, Figures 1-4.

Under clear-flow conditions only total and dissolved copper exceeded BC WQGs for the protection of aquatic life (Attachment 4: Table 4-6). Copper therefore remains the primary substance of concern in Hazeltine Creek. When the creek is subject to erosion resulting in turbid flow events, turbidity and TSS and some other metals such as iron, aluminum, and chromium may also exceed BC WQGs.

4.1.2 Polley Lake

Levels of TSS, turbidity, and copper were low in Polley Lake and have remained below guidelines throughout 2015 for the period assessed. Molybdenum concentrations were below the wildlife water maximum guideline, but were near the most conservative chronic BC WQG (irrigation end use) expected to be protective of ruminant wildlife that might be particularly sensitive to dietary exposure. Molybdenum was not included in Table 3 because, as discussed in Section 3.2.2.1, adverse effects to wildlife are not expected due to a low potential for sustained dietary exposure and the low magnitude of exceedance of the most conservative chronic guideline for irrigation. Total phosphorus concentrations remained within the range previously observed in Polley Lake prior to the event.

4.1.3 Quesnel Lake

Levels of TSS and turbidity were low in the far-field area of Quesnel Lake and remained below guidelines throughout 2015 for the period assessed. In the West Basin of Quesnel Lake, TSS levels were also low and below guidelines, with the exception of some higher levels recorded in the near-field area at the mouth of Hazeltine Creek. Pollution Abatement Order requirements for the near-field and mid-field (west) stations were not always met between March and June 2015. In July and August 2015, turbidity levels were below long-term chronic guidelines in Quesnel Lake and Pollution Abatement Order requirements were met.

In the West Basin of Quesnel Lake, iron and chromium continued to be below BC WQGs. Within the West Basin, event-related changes in total copper were still identified close to the mouth of Hazeltine Creek and at the western mid-field station further away from the mouth, but not at the eastern mid-field station or at the far-field station east of Cariboo Island where concentrations were below guidelines.

[7] Equivalent to the 24-h BC WQG of +8 NTU above the median pre-event background of 1.5 NTU

Dissolved copper concentrations remained below the BC WQG for total copper at these stations. Observed trends in total copper concentrations at these lake stations were related to particulate copper inputs from Hazeltine Creek to the lake in March through May, when TSS and turbidity concentrations were higher relative to other months in 2015.

From March through August 2015, instantaneous TP concentrations were below the BC WQG range and resembled pre-event concentrations with the exception of a few higher concentrations recorded at near-field Station QUL-66/55/55a, near the mouth of Hazeltine Creek. At the near-field, mid-field and far-field stations, dissolved phosphorus and orthophosphate concentrations reported during the same time period were below pre-event concentrations. The evaluation of phosphorus water data collected between March and August 2015, suggested that event-related changes that might be of concern with respect to the potential for a change in lake trophic status, were not evident in Quesnel Lake.

The updated evaluation of changes in water quality for the DSI confirmed an overall decreasing trend in COPCs since the event. Guideline exceedances generally occurred within a localised area close to the Hazeltine Creek mouth and likely reflected periodically higher levels of sediment transported to the lake from Hazeltine Creek.

This guidelines-based assessment is reliant on BC WQGs that are conservative in their derivation and should not be used for remediation purposes. As discussed by Golder (2015a), two sedimentation ponds were commissioned in lower Hazeltine Creek in December 2014 to manage erosion from exposed banks in Hazeltine Creek, but peaks in TSS have periodically occurred with a localised influence on Quesnel Lake. Ideally, more direct measures of toxicity should be used that take into consideration the mixture of contaminants and other parameters in the water. The results of the follow-up toxicity testing program (March to August 2015) with water samples sampled throughout the post-event period provided a more realistic assessment of potential impact of changes in water quality to aquatic life. These results are presented and discussed in the problem formulation component of the aquatic risk assessment (Golder 2015b). The findings of the toxicity testing program indicate that, although there were still some localised changes in water quality in Quesnel Lake between March and August 2015, toxicological testing results do not show toxicity in the water column and confirm the interim findings of the PEEIAR WQIA.

4.1.4 Quesnel River

Similar to the eastern far-field area of Quesnel Lake, water quality in Quesnel River between March and August did not exhibit event-related changes that were identified to be of concern with respect to exceedance of water quality guidelines or a departure from pre-event conditions.

5.0 IDENTIFICATION OF CONTAMINANTS OF CONCERN FOR THE HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT

Based on the evaluation of water quality conditions from March through August 2015, COCs are identified below for consideration in the problem formulation components of the HHERA. The risk assessment will focus on water quality uses related to aquatic life, wildlife water, and drinking water for human consumption. Contaminants of concern are identified separately for each of these uses in Tables 4 through 6 based on the findings of the WQIA update and exceedances of BC WQGs or CSR standards specific to the use under consideration. Consistent with the WQIA update presented above, the influence of turbid flow versus clear-flow conditions in Hazeltine Creek on creek and lake water quality has been considered in the identification of COCs. Pre-event background conditions were also considered.

Table 4: Summary of Contaminants of Concern Identified for Aquatic Life Based on Data Collected from March to August 2015

Study Area	Parameters Identified as Contaminants of Concern for the HHERA[1]
Polley Lake[2]	*no substances*
Hazeltine Creek[2]: turbid episodes	• turbidity, total suspended solids • total metals: aluminum, arsenic, beryllium, cadmium, chromium, cobalt, copper, iron, titanium, zinc, • dissolved aluminum and copper
Hazeltine Creek[2]: clear-flow conditions	• total and dissolved copper
Quesnel Lake: clear-flow conditions in Hazeltine Creek	*no substances*
Quesnel Lake: turbid episodes in Hazeltine Creek	• Near-field: turbidity, total copper • Mid-field west: turbidity, and total copper • Mid-field east: no substances • Far-field: no substances
Quesnel River	*no substances*

Note:
1) Parameters were identified based on exceedance of BC WQGs for aquatic life or CSR aquatic life standards and were above pre-event concentrations in one or more samples from at least one representative station.
2) Molybdenum in Polley Lake and Hazeltine Creek exceeded the 30-d BC WQG for irrigation, but did not exceed the maximum BC WQG for aquatic life or the CSR aquatic life standard; therefore, molybdenum was not retained as a COC for aquatic life.

Table 5: Summary of Contaminants of Concern Identified for Wildlife Water Based on Data Collected from March to August 2015

Study Area	Parameters Identified as Contaminants of Concern for the HHERA[1]
Polley Lake	*no substances*
Hazeltine Creek[2]: turbid episodes	• turbidity, total suspended solids • total metals: aluminum, copper, iron
Hazeltine Creek[2]: clear-flow conditions	• total suspended solids
Quesnel Lake	*no substances*
Quesnel River	*no substances*

Note:
1) Parameters were identified based on exceedance of BC WQGs for wildlife water or CSR wildlife water standards and were above pre-event concentrations in one or more samples from at least one representative station.
2) Molybdenum in Polley Lake and Hazeltine Creek exceeded the 30-d BC WQG for irrigation, but did not exceed the maximum BC WQG for wildlife water or the CSR wildlife water standard; therefore, molybdenum was not retained as a COC for wildlife water.

Table 6: Summary of Contaminants of Concern Identified for Drinking Water Based on Data Collected from March to August 2015

Study Area	Parameters Identified as Contaminants of Concern for the HHERA[1]
Polley Lake	*no substances*
Hazeltine Creek: turbid episodes	• turbidity • total metals: aluminum, arsenic, iron, lead, manganese
Hazeltine Creek: clear-flow conditions	• turbidity – untreated water only
Quesnel Lake	• turbidity – untreated water only
Quesnel River	• turbidity – untreated water only

Note:
1) Parameters were identified based on exceedance of BC drinking WQGs or CSR drinking water standards and were above pre-event concentrations in one or more samples from at least one representative station.

6.0 STATEMENT OF LIMITATIONS

This technical memorandum was prepared for the exclusive use of MPMC. The inferences concerning the data, site and receiving environment conditions contained in this memorandum are based on information obtained during investigations conducted at the site by Golder Associates Ltd. (Golder), other consultants and MPMC, and are based solely on the condition of the site at the time of the site studies and subsequent investigations and remediation and other information obtained by Golder, as described in this memorandum. Soil, surface water and groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors.

In evaluating the subject site and water quality data, Golder has relied in good faith on information provided. The factual data, interpretations and recommendations pertain to a specific project as described in this memorandum, based on the information obtained during the assessment by Golder on the dates cited in the memorandum, and are not applicable to any other project or site location. Golder accepts no responsibility for any deficiency or inaccuracy contained in this memorandum as a result of reliance on the aforementioned information.

The findings and conclusions documented in this memorandum have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this memorandum at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this memorandum, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this memorandum. All third parties relying on this memorandum do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder's memorandum or other work product. Golder is not responsible for any unauthorized use or modifications of this memorandum.

MPMC may rely on the information contained in this memorandum subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this memorandum, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein.

If new information is discovered during future work, including excavations, sampling, soil boring, predictive geochemistry or other investigations, Golder should be requested to re-evaluate the conclusions of this memorandum and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this memorandum is affected by any change of site conditions, purpose, development plans or significant delay from the date of this memorandum in initiating or completing the project.

7.0 CLOSURE

We trust that this Technical Memorandum provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at (604) 296-4200.

Notes

Routine samples were taken throughout the period according to 2015 Post-Breach Environmental Monitoring Plar

Routine stations are consistently monitored; typically either weekly, bi-weekly (every 2 weeks), monthly, or bi-monthly (twice per month

Continuous logger measures field parameters (i.e., pH, temperature, specific conductivity, DO, and turbidity) every 15 minute:

a) All equipment blanks carried out on MPMC Kemmerer 1 (used for all Polley Lake and Quesnel Lake sampling)

b) Additional duplicate sample was taken as part of another MPMC water quality monitoring program

Table 3-2. Summary of Data Quality Objective Exceedances, March to August 2015

Date	Sample ID	Parameter(s) RPD > DQO	BC WQG Exceedance
5-Mar-2015	De-ionized Water Blank	Dissolved Organic Carbon	No
18-Mar-2015	QUL-55X-0m	Turbidity, Manganese-D	No (turbidity exceedance of chronic guideline in original sample, but not duplicate; no associated 30-d guideline exceedance)
24-Mar-2015	HAC-01bX	Turbidity	Turbidity exceedance in original and duplicate
24-Mar-2015	QUL-2aX-0m	Copper-T	No
1-Apr-2015	EDC-01X	Ammonia, Phosphorus-T, DOC, Aluminum-D, Iron-D	Aluminum-D exceedance in original and duplicate
21-Apr-2015	QUL-55X-0m	Nitrogen-T	No
28-Apr-2015	HAC-05X	Phosphorus-T, Aluminum-T, Cadmium-T, Cobalt-T, Iron-T, Lead-T, Titanium-T, Vanadium-T	Iron-T exceedance in original, but not duplicate

Notes

D - dissolved, T - total

RPD - relative percent difference, DQO - data quality objective

BC WQG - BC water quality guideline

ATTACHMENT 4

Post-event Water Quality in Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River, March to August 2015

Table 4-1: Post-event Water Quality in Polley Lake, Hazeltine Creek, Quesnel Lake, and Quesnel River, March to August 2015

A = approved guideline, W = working guideline, Min = Minimum concentration requirement based on life stage
nm = not measured
< = reported value is <MDL
CSR-Schedule 6 Generic Numerical Water Standards: Aquatic life standards assume minimum 1:10 dilution available, available at http://www.bclaws.ca/Recon/document/ID/freeside/375_96_08 accessed October 8 201
BC WQGs for total metals substituted where dissolved metal WQGs do not exist

a) BC Water Quality (BCWQ) guidelines for the protection of freshwater aquatic life, except where noted (WW = wildlife water, IR = irrigation), available at http://www2.gov.bc.ca/gov/content/environment/air-land-water/water/water-quality/water-quality-guidelines/approved-water-quality-guidelines, accessed October 8 2015
b) BC WQ guideline for the protection of drinking water, available at http://www2.gov.bc.ca/gov/content/environment/air-land-water/water/water-quality/water-quality-guidelines, accessed October 8 2015
c) CSR Generic Numerical Water Standards for the protection of aquatic life
d) CSR Generic Numerical Water Standards for the protection of drinking water
e) hardness dependent F guideline: BC Max WQG (mg/L) = 0.4 at hardness of 10 mg/L, otherwise = (-51.73 + (92.57 *log(hardness)))*0.01
f) hardness dependent sulphate guideline: BC 30-d WQG (mg/L) = 128 at hardness <30 mg/L, at hardness 31-75 mg/L = 218, at hardness 76-180 mg/L = 309, at hardness 181-250 mg/L = 429, at hardness >250 mg/L determine base on site wat
g) pH and temperature dependent ammonia guideline: values selected from Tables 3 and 4 in BC WQG based on maximum temperature of 20°C and pH 8.2
h) chloride dependent nitrite guideline: BC Max WQG (mg/L) = 0.06 at Cl <2 mg/L, at Cl 2-4 mg/L = 0.12, at Cl 4-6 mg/L = 0.18, at Cl 6-8 mg/L = 0.24, at Cl 8-10 = 0.30, at Cl >10 = 0.
BC 30-d WQG (mg/L) = 0.02 mg/L at Cl <2 mg/L, at Cl 2-4 mg/l = 0.04, at Cl 4-6 mg/L = 0.06, at Cl 6-8 mg/L = 0.08, at Cl 8-10 mg/L = 0.1, at Cl >10 = 0.
i) pH dependent dissolved Al guideline: BC Max WQG (mg/L) = 0.1 at pH ≥6.5, at pH <6.5 = EXP(1.209-2.426*(pH)+0.286*(pH^2)); BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, at pH <6.5 = EXP(1.6-3.327*(median pH)+0.402*(median pH^2); minimum baseline surface water pH = 5.57
j) hardness dependent dissolved Cd guideline: max BC WQG (mg/L) = (exp(1.03*ln(hardness)-5.274))/1000 BC 30-d WQG (mg/L) = (exp(0.736*ln(hardness)-4.943))/100
k) guideline is for Cr(VI)
l) hardness dependent Cu guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness≤50 mg/L , at hardness >50 mg/L = 0.04*hardness/1000
m) hardness dependent Pb
n) hardness dependent Mn guideline: BC Max WQG (mg/L) = 0.01102*(hardness)+0.54; BC 30-d WQG (mg/L) = 0.0044*hardness+0.60
o) BC 30-d WQG (mg/L) = 0.0001/(MeHg/THg), where MeHg is mass (or concentration) of methyl mercury and THg is total mass (or concentration) of mercury in a given water volume; assumed = 0.00001 at 1% MeH
p) hardness dependent Ni guideline: BC 30-d WQG = 0.025 at hardness <60 mg/L, at hardness 60-120 mg/L =0.065, at hardness 120-180 mg/L = 0.11, at hardness >180 mg/L = 0.15
q) hardness dependent Ag guideline: BC Max WQG (mg/L) = 0.0001 at hardness≤100 mg/L, at hardness >100 mg/L = 0.003; BC 30-d WQG (mg/L) = 0.00005 at hardness≤100 mg/L, at hardness > 100 mg/L = 0.0015
r) hardness dependent Zn guideline: BC Max WQG (mg/L) = (33+0.75(hardness-90))/1000; BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/100
s) up to 10 - highly sensitive to acid inputs; 10 to 20 - moderately sensitive; over 20 - low sensitivity. Refer to calcium regarding sensitivity to acid inputs, the more restrictive of calcium or alkalinity is applicable.
t) up to 4 - highly sensitive to acid inputs; 4 to 8 - moderately sensitive; over 8 - low sensitivity. Refer to alkalinity, the more restrictive of calcium or alkalinity applies.
u) CSR Standard may not protect all amphibians. Consult director for further advice.
v) CSR Standard varies with chloride concentration. Consult director for further advice.
w) value exceeds BC Drinking Water Quality Guidelines for turbidity only for untreated water
x) CSR Standard varies with pH and temperature. 10°C is assumed.
y) CSR Standard to protect freshwater aquatic life.
z) CSR Standard is hardness dependent.
aa) Wildlife Water values are the lowest of CSR Generic Numerical Water Standards for Livestock Water or the Canadian Water Quality Guidelines for the Protection of Agriculture Water Uses – Livestock. For parameters without these standards or guidelines, either the CSR Schedule 6 Generic Numerical Wate
Standards and Schedule 10 Generic Numerical Soil and Water Standards for Drinking Water were used.
bb) Background turbidity is 1.5 NTU for Hazeltine Creek and 1.0 NTU for Polley Lake, Quesnel Lake, and Quesnel River
cc) Background is equal to MDL of 3.0 mg/L for total suspended solids.

CSR-Schedule 6 Generic Numerical Water Standards: Aquatic life standards assume minimum 1:10 dilution available, available at http://www.bclaws.ca/Recon/document/ID/freeside/375_96_08 accessed October 8 201

BC WQGs for total metals substituted where dissolved metal WQGs do not exist

a) BC Water Quality (BCWQ) guidelines for the protection of freshwater aquatic life, except where noted (WW = wildlife water, IR = irrigation), available at http://www2.gov.bc.ca/gov/content/environment/air-land-water/water/water-quality/water-quality-guidelines/approved-water-quality-guidelines, accessed October 8 2015

b) BC WQ guideline for the protection of drinking water, available at http://www2.gov.bc.ca/gov/content/environment/air-land-water/water/water-quality/water-quality-guidelines, accessed October 8 201

c) pH dependent dissolved Al guideline: BC Max WQG (mg/L) = 0.1 at pH ≥6.5, at pH <6.5 = EXP(1.209-2.426*(pH)+0.286*(pH^2)); BC 30-d WQG (mg/L) = 0.05 at pH ≥6.5, at pH <6.5 = EXP(1.6-3.327*(median pH)+0.402*(median pH^2); minimum baseline surface water pH = 5.57

d) guideline is for Cr(VI)

e) hardness dependent Cu guideline: BC Max WQG (mg/L) = (0.094(hardness)+2)/1000; BC 30-d WQG (mg/L) = 0.002 at hardness≤50 mg/L , at hardness >50 mg/L = 0.04*hardness/100

f) hardness dependent Pb guideline: BC Max WQG (mg/L) = 0.003 at hardness ≤8 mg/L, at hardness >8 mg/L = (EXP((1.273*ln(hardness))-1.46))/1000; BC 30-d WQG (mg/L) = (3.31+EXP(1.273(ln(hardness))-4.704))/1000 at hardness >8 mg/L, no guideline at hardness ≤8 mg/

g) hardness dependent Mn guideline: BC Max WQG (mg/L) = 0.01102*(hardness)+0.54; BC 30-d WQG (mg/L) = 0.0044*hardness+0.60

h) BC 30-d WQG (mg/L) = 0.0001/(MeHg/THg), where MeHg is mass (or concentration) of methyl mercury and THg is total mass (or concentration) of mercury in a given water volume; assumed = 0.00001 at 1% MeH

i) hardness dependent Zn guideline: BC Max WQG (mg/L) = (33+0.75(hardness-90))/1000; BC 30-d WQG (mg/L) = (7.5+0.75(hardness-90))/100

j) CSR Generic Numerical Water Standards for the protection of aquatic life

k) CSR Generic Numerical Water Standards for the protection of drinking water

l) Wildlife Water values are the lowest of CSR Generic Numerical Water Standards for Livestock Water or the Canadian Water Quality Guidelines for the Protection of Agriculture Water Uses – Livestock. For parameters without these standards or guidelines, either the CSR Schedule 6 Generic Numerical Water Standards and Schedule 10 Generic Numerical Soil and Water Standards for Drinking Water were used

m) Background turbidity is 1.5 NTU and 3.0 mg/L for total suspended solids.

ADDENDUM TO MOUNT POLLEY SURFACE WATER QUALITY IMPACT ASSESSMENT UPDATE

Dear Ms. Hughes:

Golder Associates Ltd. (Golder) is pleased to provide Mount Polley Mining Corporation (MPMC) with the following addendum to the Surface Water Quality Impact Assessment (WQIA) update undertaken by Golder (2016). This addendum is intended to provide an update on post-event water quality conditions in Polley Lake, Hazeltine Creek, Lower Edney Creek, Quesnel Lake, and Quesnel River primarily based on water quality monitoring undertaken by MPMC from September to December 2015 and in consideration of 2015 data collected from January through August by MPMC and previously reported by Golder.

1.0 INTRODUCTION

This addendum represents the second update to the original water quality impact assessment (WQIA) for the Post-Event Environmental Impact Assessment Report (PEEIAR) (Golder 2015a). The 'event' refers to the tailings dam failure that occurred at the Mount Polley Mine on August 4, 2014, when the Tailings Storage Facility (TSF) Perimeter Embankment failed and there was a subsequent debris flow into the receiving environment.

A chronology of post-event water quality assessments submitted to MPMC by Golder is summarized below. The assessment approach has involved the progressive evaluation of data collected by MPMC during their post-breach monitoring program that was initiated following the event in August 2014.

- **Original WQIA for the PEEIAR** (Golder 2015a) was based on water quality data collected by MPMC just after the event from August to 2014 to April 2015.

- **Surface WQIA Update** undertaken by Golder (2016) to provide an update to the original PEEIAR WQIA and to inform the Detailed Site Investigation (DSI) for the forthcoming Human Health and Ecological Risk Assessment (HHERA). The HHERA is being completed in 2016 in response to the Pollution Abatement Order (BC MoE 2015a). The WQIA update primarily considered water quality data collected by MPMC from March to August 2015, with consideration of post-event data collected prior to March 2015 as needed to evaluate temporal trends.
- **Addendum to the Surface WQIA Update** presented here is intended to provide an update to the two preceding post-event assessments. The addendum includes previously unreported data collected by MPMC from September to December, 2015.

The objective of the addendum is to evaluate water quality data collected by MPMC in 2015 to assess temporal trends of contaminants of potential concern through to December 2015 in Polley Lake, Hazeltine Creek, Lower Edney Creek, Quesnel Lake and Quesnel River.

2.0 METHODS

Water quality data collected from receiving environments in Polley Lake, Hazeltine Creek (including lower Edney Creek), Quesnel Lake, and Quesnel River were screened using relevant BC water quality guidelines (BC WQGs) (BC MoE 2015b, BC MoE 2015c) and *Contaminated Sites Regulation* (CSR) standards (CSR 2014). For contaminants of potential concern (COPCs) identified for further evaluation as described in Section 2.2, temporal trends were evaluated within the context of applicable BC WQGs and CSR standards. Based on this evaluation contaminants that remained of concern in each receiving environment by the end of 2015 were identified.

2.1 Data Collection and Compilation

The addendum focussed on water quality data collected by MPMC in 2015, including data collected between September and December 2015 that had not previously been evaluated. Data collected from January to August 2015 were reported in the two previous assessments (Golder 2015a, 2016).

From September to December 2015, water quality samples were collected in accordance with the Post TSF-Breach 2015 Monitoring Plan (MPMC 2015); methods are described in Golder (2016). In general, the addendum focused on stations assessed in the WQIA (Golder 2016; Figure 1); however due to the continued evolution of the post-breach monitoring program, a small number of stations were moved, renamed, added, or discontinued. A summary of updated monitoring stations and sampling frequencies is provided in Table A1.

Following completion of quality assurance/quality control (QA/QC) and database entry procedures, MPMC provided Golder with updated electronic data files containing water quality data for September through December 2015 (Table A2). These data were used as received from MPMC with an additional check of transcription by Golder prior to being screened to identify COPCs.

2.2 COPC Identification

To confirm COPCs for the updated assessment, discrete water quality data collected from September through December 2015 were compiled and screened against BC WQGs and CSR standards. Data compiled for all stations sampled within a given area (i.e., Polley Lake, Hazeltine and Edney creeks, Quesnel Lake, and Quesnel River) were evaluated as one dataset per area, for screening purposes. Substances were classified as COPCs based on criteria described in the WQIA (Golder 2016); however, in this addendum maximum concentrations of each substance were used to conservatively identify COPCs.

2.3 COPC Evaluation

Changes in COPC concentrations in 2015 were evaluated qualitatively over time at representative stations previously assessed in the original PEEIAR WQIA (Golder 2015a) and the WQIA update (Golder 2016), as well as at additional representative stations identified during the post-event monitoring program. This updated 2015 assessment included 13 representative stations that are described below with additional details provided in Table A1.

- **Polley Lake**: Station P1 and P2 that have been routinely sampled since August 2014.
- **Hazeltine Creek**: Stations HAC-10, HAC-05/a, HAC-08/a, and HAC-01/a/b/c, listed in order from upstream to downstream.
  - Station HAC-10 is the furthest upstream station in Hazeltine Creek and is located downstream of the Polley Lake inflow. Data collected at this station from April through December 2015 were expected to contribute to a greater spatial representation of water quality conditions in the creek.
  - Station HAC-05 was moved upstream of the Gavin Lake Road bridge to avoid potential water quality impacts associated with the road. HAC-05 and HAC-05a (upstream of the bridge) have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-05/a).
  - Station HAC-08 was temporarily moved downstream of the Ditch Road bridge. HAC-08 and HAC-08a (downstream of the bridge) have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-08/a).
  - HAC-01/a/b/c is located immediately downstream of the sedimentation ponds close to the confluence with Quesnel Lake. This station represents water quality at the outflow of Hazeltine Creek and was the most frequently sampled station in the creek between August 2014 and October 2015. To adapt to changes in the creek channel due to rehabilitation activities and construction of sedimentation ponds HAC-01/a/b/c has been moved slightly over time (a change in location was indicated with a subsequent letter in the station code). Samples collected at HAC-01, HAC-01a, HAC-01b, and HAC 01c in lower Hazeltine Creek have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., HAC-01/a/b/c). This station was discontinued in October, 2015 due to lack of flow through the lower sedimentation pond and was replaced by monitoring at HAC-12 in the upper sedimentation pond.

- **Lower Edney Creek**: Stations EDC-01 and EDC-02 are located below the sedimentation ponds close to the confluence with Quesnel Lake.
  - Station EDC-01 was sampled before and after Hazeltine and Edney creeks were re-directed. Data collected at this station from February through December 2015 were expected to contribute to a greater spatial representation of water quality conditions.
  - Station EDC-02 is located downstream of the confluence with Hazeltine Creek. Data collected at this station from February through July 2015 were expected to contribute to a greater spatial representation of water quality conditions.
- **Quesnel Lake**: Stations QUL-2/2/a, QUL-66, QUL-18, and QUL-120/120a.
  - Station QUL-66 was replaced by QUL-55, QUL-55a, and then QUL-58 due to changes in the location of the Hazeltine Creek outflow into the lake. These stations have contiguous sampling periods and for the purposes of this assessment are considered to represent the same location (i.e., are collectively referred to as QUL-66 throughout this addendum).

Stations meeting the following criteria were not included in the COPC evaluation:

- stations not previously assessed as a representative station (Golder 2015a, 2016);
- stations do not contribute to a greater spatial representation of water quality conditions; and
- stations with all parameter concentrations below relevant BC WQGs or CSRs, based on the results of the initial screening step described in Section 2.2.

2.3.1 Changes in COPC Concentrations Over Time

Instantaneous measurements and/or rolling 30-day (d) average values for each COPC were assessed qualitatively and compared to BC WQGs and CSR standards. Data values, guidelines, and standards were plotted and compared based on the methods outline in Section 2.3.2 of the WQIA update (Golder 2016).

Concentrations reported as less than the method detection limit (MDL) were set equal to the MDL for purposes of plotting data and calculating 30-d averages. Typically, 30-d averages would be calculated using, at a minimum, data from at least five samples per 30-d period. If only monthly data were available, and reported concentrations were not stable from month-to-month, plotted 30-d rolling average concentrations were replaced with instantaneous data values (see appended figures 2 to 21). For the relevant figures, instantaneous data shown on the 30-d rolling average plots were identified by open circles connected by dashed lines.

As in the previous WQIA assessments (i.e., Golder 2015a, 2016), water quality trends for identified COPCs were evaluated against hardness-dependent WQGs calculated using hardness concentrations measured during the post-event period. Minimum and maximum hardness concentrations reported for each receiving environment area (i.e., Polley Lake, Hazeltine and Edney creeks, Quesnel Lake, and Quesnel River) during the post-event period were used, rather than station-specific minimums and maximums. With respect to Quesnel Lake and Quesnel River, exposure mean hardness values in 2015 were sufficiently similar to pre-event mean hardness values; for other waterbodies such as Hazeltine Creek and Polley Lake, exposure hardness in 2015 was higher than the pre-event mean hardness value reported prior to the event. Consequently, for Hazeltine Creek and Polley Lake, 2015

data were also compared to WQGs calculated based on mean pre-event hardness concentrations for these waterbodies as previously reported in the original PEEIAR WQIA (Golder 2015a). These guidelines provided conservative lower guideline boundaries for COPCs based on conditions not necessarily reflective of those present in these waterbodies in 2015. It should however be noted that for some receiving environments, such as Hazeltine Creek, the pre-event hardness value was higher than the minimum hardness value measured in 2015 and therefore did not represent the most conservative exposure condition.

3.0 RESULTS

3.1 COPC Identification

Table 1 contains a list of the COPCs identified for this assessment based on the COPCs examined in the PEEIAR (Golder 2015) and the WQIA update (Golder 2016) and confirmed by screening data from September to December 2015 against guidelines and standards. Dissolved aluminum and total and dissolved selenium were identified as COPCs for Hazeltine Creek and Edney Creek, based on elevated concentrations in the September to December 2015 dataset.

Table 1: Contaminants of Potential Concern (COPCs) Identified in the Receiving Environment Based on Water Quality Monitoring in 2015[1]

Waterbody	COPC: Physical[2]	COPC: Total Metals	COPC: Dissolved Metals	COPC: Non-Metal Substances
Polley Lake	*no substances*	**copper**	**copper**	**TP**
Hazeltine Creek and Edney Creek	**turbidity, TSS**	**aluminum**, **arsenic, beryllium**, **chromium, cobalt, copper**, **iron, lead, manganese, selenium, zinc**	**aluminum, copper, selenium**	*no substances*
Quesnel Lake	**turbidity (QUL-66 only)**	**copper**	*no substances*	**TP (QUL-66 only)**
Quesnel River	**turbidity[3]**	*no substances*	*no substances*	*no substances*

Notes: TP = total phosphorus; TSS = total suspended solids; QUL = Quesnel Lake
1. Refer to Golder (2015) (January to April 2015), Golder (2016) (March to August 2015) and Section 2.2 (September to December 2015)
2. Background turbidity concentrations are 1.5 NTU in Hazeltine Creek based on pre-event median value and 1 NTU in Quesnel Lake and Quesnel River.
3. Turbidity was identified as a COPC for Quesnel River based on in-situ data from a continuous logger.

To be conservative in the assessment for Polley Lake, copper was retained as a COPC because it was considered a primary COPC for the PEEIAR (Golder 2015a) and was assessed in the WQIA update (Golder 2016) even though the maximum copper concentration from September to December was below applicable guidelines. Total phosphorus was retained as a COPC for Polley Lake and Quesnel Lake because the maximum concentrations were above the BC WQG range and data are intended to be integrated with biological information to assess potential impacts on lake productivity.

3.2 Changes in COPC Concentrations Over Time

The following section describes post-event changes in receiving environment water quality with respect to COPCs listed in Table 1. Changes in COPC concentrations over time from January through December 2015 are discussed below in comparison to relevant BC WQGs and CSR standards. Results are presented according to each group of COPCs (i.e., suspended particulate matter, metals, nutrients), then within each COPC group. Changes in specific COPCs are discussed for each waterbody.

Data shown for Hazeltine Creek and Quesnel River represent discrete surface grab samples collected as described in the PEEIAR WQIA (Golder 2016), except where a continuous data logger measured turbidity. Quesnel Lake and Polley Lake data are from discrete grab samples taken at various depths and were categorized as either surface (1-20 m) or deep (greater than [>] 20 m) for the purpose of evaluating changes over time.

3.2.1 Suspended Particulate Matter (Turbidity/TSS)

3.2.1.1 Hazeltine Creek and Edney Creek

Turbidity levels in Hazeltine Creek showed a progressive decrease from peak levels in the first few months of 2015 to levels closer to applicable BC WQGs by the end of the year. However, levels in upper Hazeltine Creek (HAC-10 and HAC-05/a) and the lower creek above the sedimentation ponds (HAC-08/a) fluctuated during September-December 2015. During this time monthly concentrations at these stations were occasionally above the maximum and 30-d BC WQGs (Figure 2).

In lower Edney Creek at EDC-01 turbidity levels were typically below maximum and 30-d guideline values, except for a spike in October 2015. Turbidity levels at EDC-02 exhibited a general decrease over time until the station was discontinued in July 2015; however, concentrations were predominantly above the 30-d guideline. Elevated turbidity observed at HAC-01/a/b/c throughout July and August continued through September and October (Figure 2) with reported concentrations above the 24-h aquatic life and/or 30-d guidelines. Turbidity concentrations in Hazeltine Creek and Edney Creek were routinely above the BC WQG for untreated drinking water but were within the turbidity range reported for the creek prior to the event.

A similar progressive decline in TSS concentrations was also observed in Hazeltine Creek from peak concentrations in the first few months of 2015 to concentrations below BC WQGs by the end of the year (with the exception of HAC-08/a). Concentrations of TSS at HAC-10, HAC-05/a, and HAC-01/ab/c in Hazeltine Creek and at EDC-01 in Edney Creek were consistently below the 24-h aquatic life and 30-d guidelines throughout September-December 2015 (Figure 3). Before the station was discontinued in July 2015, TSS concentrations at EDC-02 exhibited a general decrease that was similar to the temporal trend observed at HAC-01/a/b/c (Golder 2016; Figure 3). Concentrations at HAC-08/a were variable throughout September-December 2015 and were intermittently above the 24-h aquatic life and 30-d guidelines.

3.2.1.2 Quesnel Lake

Turbidity concentrations measured at the surface and at depth in Quesnel Lake at stations QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a were below BC WQGs from approximately April through August 2015 (Golder 2016). At the surface at QUL-66, turbidity levels generally remained below guideline values with the exception of a single exceedance of the aesthetic drinking water guideline for untreated water and the 30-d aquatic life guideline in spring 2015. Turbidity at QUL-66 continued to decline through September and remained below guidelines into December 2015 with concentrations close to or below background (1 NTU) (Figure 4).

3.2.1.3 Quesnel River

Daily average and in-situ turbidity concentrations at station QUR-1 in Quesnel River showed a progressive decrease over time throughout 2015. Turbidity levels remained well below guidelines with the exception of a few intermittent spikes measured by the continuous data recorder (Figure 5). The elevated values measured by the

continuous recorder were not corroborated by the in-situ grab sample data and as discussed in Golder (2016) these measurements can be influenced by fouling associated with long-term deployment.

3.2.2 Copper

3.2.2.1 Polley Lake

Copper concentrations measured in Polley Lake were not elevated above BC WQGs during the March-August 2015 period, and so copper was no longer considered a COPC by the WQIA update (Golder 2016). However, as described in Section 3.1, copper was retained in this addendum because it is considered a primary COPC within the overall context of the PEEIAR. Both total and dissolved concentrations were below BC WQGs, with the exception of the total 30-d rolling average concentration associated with surface samples collected at P2 in early November 2015 that approximated the most conservative 30-d guideline based on pre-event hardness (Figure 6).

3.2.2.2 Quesnel Lake

Total and dissolved copper concentrations measured in Quesnel Lake were typically below maximum BC WQGs by the end of April 2015 (Golder 2016). By late August 2015, copper concentrations reported for QUL-66 near the mouth of Hazeltine Creek were similar or only slightly elevated relative to concentrations reported elsewhere in the lake, including the far field station (QUL-120/120a) east of Cariboo Island (Golder 2016). Total and dissolved copper concentrations at QUL-2/2a, QUL-66, QUL-18, and QUL-120/120a were below maximum and 30-d guidelines from September through December 2015, with the exception of a single monthly sample collected at near-field (QUL-66) and far-field (QUL-120/120a) stations in September (Figure 7). The corresponding monthly sample in September at the mid-field west station (QUL-18) approximated the most conservative 30-d guideline based on minimum measured hardness.

3.2.2.3 Quesnel River

No metals were identified as COPCs for the receiving environment in Quesnel River in the original WQIA and the WQIA update; this was also the case for data collected from September to December 2015.

3.2.2.4 Hazeltine Creek and Edney Creek

Discrete Grab Samples (Instantaneous values)

In upper Hazeltine Creek at HAC-05/a, total copper concentrations were above the maximum BC WQG (based on measured maximum hardness) from January to May 2015, after which concentrations decreased to concentrations below the maximum guideline (based on mean pre-event hardness) by the end of the year (Figure 8). From April to December 2015 total concentrations were below applicable CSR standards. Dissolved concentrations at HAC-05/a were within the WQG range based on measured hardness but were above the WQG based on pre-event hardness until May 2015. Dissolved concentrations decreased thereafter and were below the WQG based on pre-event hardness from May to December 2015. At the most upstream station (HAC-10) total and dissolved concentrations followed a similar trends to those described for HAC-05/a.

In lower Hazeltine Creek (HAC-08/a, EDC-01, EDC-02, HAC-01/a/b/c), total concentrations peaked above BC maximum WQGs and at least one CSR standard[1] from February through April (Figure 8). Total concentrations then decreased at all four stations to concentrations within the BC maximum guideline range (based on measured hardness values) by the end of the year and generally remained above the maximum guideline based on pre-event hardness. Dissolved concentrations at HAC-08/a and HAC-01/a/b/c peaked above the maximum guideline and were within the CSR aquatic life standard range based on measured hardness. Dissolved concentrations decreased thereafter at these stations and were below the maximum guideline based on pre-event hardness at both HAC-08/a and HAC-01/a/b/c by the end of the year. The same was true for EDC-01.

Thirty-Day Rolling Average Values

During the months prior to June, total copper concentrations in upper and lower Hazeltine Creek (HAC-05/a, HAC-08/a, EDC-02, HAC-01/a/b/c) peaked above the 30-d BC WQG range based on measured hardness (Figure 8). Concentrations then decreased to values within the 30-d guideline range based on measured hardness and remained above the guideline based on pre-event hardness. Dissolved concentrations in the lower creek (HAC-08/a, HAC-01/a/b/c) only peaked above the 30-d guideline range (based on measured hardness) from March to May, with a subsequent decrease to concentrations within this guideline range. Concentrations remained above the 30-d guideline based on pre-event hardness (Figure 8). Dissolved concentrations at the other Hazeltine Creek stations were within the 30-d guideline range based on measured hardness and either approximated or were above the guideline based on pre-event hardness.

3.2.3 Other Metals

3.2.3.1 Hazeltine Creek and Edney Creek

Aluminum

In upper Hazeltine Creek (HAC-10, HAC-05/a), total and dissolved concentrations remained below maximum guideline values in 2015, with the exception of a single sample in January at HAC-05/a. In lower Hazeltine Creek (HAC-08/a, EDC-01, EDC-02, HAC-01/a/b/c), concentrations peaked in February through April and were above or approximated maximum guideline values; concentrations then decreased below guidelines by May and remained stable until the end of the year. Concentrations at HAC-05/a in upper Hazeltine and HAC-08/a in lower Hazeltine showed slight increases in November and December, based on monthly sampling; in the case of HAC-08/a concentrations approximated maximum guidelines for the protection of aquatic life (Figure 9).

Dissolved concentrations were above the 30-d dissolved guideline in lower Hazeltine Creek until May and June, when they decreased below this guideline and remained relatively stable until November, when concentrations at HAC-05/a and HAC-08/a increased to approach but not exceed the 30-d guideline value (Figure 10).

Arsenic

Total arsenic was evaluated as a COPC in the WQIA update, based on guideline exceedances that occurred in Hazeltine Creek in spring 2015 (Golder 2016; Figure 11). During this time concentrations at HAC-08/a peaked

[1] The CSR standard for aquatic life at the Edney Creek stations; the CSR for wildlife at HAC-01/a/b/c, and the CSR for drinking water at HAC-08/a.

above the CSR drinking water and wildlife standards as well as the BC drinking water maximum guideline. Thirty-day rolling average total concentrations at HAC-08/a also peaked above the 30-d BC WQG during this time, before decreasing to concentrations more typical of the other stations on the creek by August. Total concentrations at the stations in Hazeltine and Edney creeks shown on Figure 11 were typically well below the maximum and 30-d guidelines from June through December, with the exception of two measurements at HAC-08/a upstream of the sediment ponds in September and December.

Beryllium

Thirty-day rolling average total concentrations were elevated above the 30-d WQG at HAC-08/a and HAC-01/a/b/c during spring 2015 (Figure 12). Concentrations at EDC-02 were also elevated during this time. From July through December 2015, total concentrations at the Hazeltine and Edney Creek stations were below guideline values and were at or near the MDL, with the exception of one sample collected at HAC-08/a in December 2015 that was detected above the WQG (Figure 12).

Chromium

As discussed in Golder (2015a), the available speciation data for Hazeltine Creek indicates the dominant chromium species in Hazeltine Creek was chromium (III), which is less toxic than the chromium (VI) form. However, as a conservative measure, guidelines and standards for both chromium species have been considered when assessing water quality in Hazeltine Creek.

Total chromium was evaluated as a COPC in the WQIA update, largely based on guideline exceedances recorded in spring 2015 in Hazeltine Creek at stations HAC-08/a, HAC-05/a, and HAC-01/a/b/c (Golder 2016; Figure 13). However, by June 2015, total concentrations in Hazeltine Creek had decreased below the most conservative guidelines shown on Figure 13. In 2015, concentrations at stations HAC-10 and EDC-01 and EDC-02 in Edney Creek exhibited temporal trends similar to those previously reported for other stations in Hazeltine Creek (Figure 13).

Total chromium concentrations measured at the Hazeltine and Edney creek stations were below applicable maximum guidelines from June to December 2015, and many were at or near the MDL. The same was true for total 30-d rolling average concentrations that were below the Cr(III) and Cr(VI) 30-day guidelines at all stations, with the exception of intermittent exceedances of the Cr(VI) guideline by total concentrations at HAC-08/a and HAC-01/a/b/c that were still below the more applicable Cr(III) 30-day guideline.

Cobalt

Instantaneous total concentrations reported in 2015 for the Hazeltine Creek stations shown on Figure 14 were below the maximum BC WQG. Thirty-day average total concentrations were above the 30-d BC WQG from March to June at HAC-08/a and March to May at HAC-01/a/b/c, then decreased below the 30-d guideline thereafter (Figure 14). Stations EDC-01 and EDC-02 exhibited a similar temporal trend over the time period leading up to the end of August 2015, but did not exceed the guideline. Total concentrations remained stable well below the 30-d guideline from September through December, with the exception of intermittent values in the monthly September and December samples at HAC-08/a that approached or approximated the guideline.

Iron

Total concentrations at stations in lower Hazeltine Creek were consistently above the BC maximum WQG for aquatic life and the CSR drinking water standard until May 2015 (Figure 15). The higher CSR standard was mostly exceeded at HAC-08/a and HAC-01/a/b/c, with only a few exceedances at other stations. From May to December, total concentrations remained below this guideline, with the exception of one sampling event in August, during which total values at HAC-08/a and HAC-01/a/b/c were more than ten times the preceding and subsequent values recorded in July and August (Golder 2016). Intermittent values measured in September and December at station HAC-08/a were above the BC maximum guideline. Concentrations at the other stations monitored in 2015 were below the BC maximum guideline.

Lead

Total lead was assessed as a COPC in the WQIA update (Golder 2016). In upper Hazeltine Creek, instantaneous concentrations were typically below guideline values in 2015 and 30-d average concentrations were below the long-term average guideline, with the exception of a concentration reported for HAC-05/a in January that was also above the CSR drinking water standard (Figure 16). In lower Hazeltine Creek, after peaking in March through April, rolling 30-d average concentrations declined below the 30-d BC WQG in May and remained relatively stable through the end of December. The exception was an intermittent increase at HAC-08/a in December that approached the 30-d guideline range shown on Figure 16.

Manganese

Total concentrations were below BC maximum WQGs and the CSR drinking water standard (Figure 17). The exceptions were total concentrations at HAC-05/a (January and February) and HAC-08/a (February to April) that were within the BC maximum guideline range, and concentrations at HAC-01/a/b/c (February to April) that were below the BC maximum guideline but above the CSR drinking water standard. Rolling-average 30-d manganese concentrations in Hazeltine Creek stations were below the 30-day guideline based on measured hardness and pre-event hardness, with the exception of HAC-08/a (March through May) and HAC-05/a (January and February) (Figure 17).

Selenium

The WQIA update indicated that post-event selenium concentrations in Hazeltine Creek remained stable below applicable guidelines/standards or decreased below these regulatory benchmarks shortly after the event, remaining stable thereafter (Golder 2016). In 2015, instantaneous and rolling 30-day average concentrations remained well below applicable BC WQGs and CSR standards with the exception of the monthly sampling event in December 2015 at HAC-05/a and HAC-08/a located below the authorized discharge of treated effluent that commenced in December 2015 (Figure 18). Continued monitoring of water quality in Hazeltine Creek through March 2016 confirmed that selenium concentrations at HAC-05/a and HAC-08/a are above the BC WQGs and CSR drinking water and aquatic life standards (MPMC, unpublished data). However, concentrations showed a progressive decrease from 0.024 mg/L in December to 0.014 mg/L in March at HAC-05/a and from 0.020 mg/L in December to 0.012 mg/L in March at HAC-08/a. Selenium concentrations reported at these stations between December 2015 and March 2016 are within the range predicted by Golder (2015b) that did not consider Hazeltine Creek to be a receiving environment in the short-term, but rather a conduit to Quesnel Lake, where fish were

present and potential breeding habitat for aquatic feeding birds is more prevalent. Water quality continues to be monitored in Hazeltine Creek, including stations downstream of the authorized discharge of treated effluent.

Zinc

Total and 30-d rolling average concentrations reported for HAC-05/a, HAC-08/a, EDC-02, and HAC-01/a/b/c between January and June were typically within the BC WQG range based on measured hardness and above BC WQGs calculated using mean pre-event hardness (Figure 19). Concentrations reported for the other stations shown on Figure 19 were below the BC maximum guideline range. Between June and December, total and 30-day rolling average concentrations for all stations shown on Figure 19 were below the most conservative BC WQG, with the exception of a few intermittent values for HAC-08/a.

3.2.4 Nutrients: Total Phosphorus

3.2.4.1 Polley Lake

Following the event and through August 2015, concentrations of total phosphorus (TP) at the surface in Polley Lake were within the pre-event range of concentrations reported in the PEEIAR for Polley Lake (Golder 2015a). Pre-event TP concentrations were defined as: mean = 0.041 mg/L; 95th percentile = 0.094 mg/L.; minimum = 0.0046 mg/L. Both pre-event mean and upper limit concentrations were above applicable BC WQGs (i.e., 0.005 to 0.015 mg/L). This is consistent with the observation by Minnow (2014) that the trophic status of the lake changed from oligotrophic/mesotrophic to mesotrophic/eutrophic by 2012, two years prior to the event.

Prior to fall turnover in 2014, concentrations of all three forms of phosphorus at depth were elevated above pre-event concentrations, unlike surface concentrations that were within pre-event concentration ranges (Golder 2016). Pre-event dissolved phosphorus concentrations were defined in Golder (2015) as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.002 mg/L; pre-event orthophosphate concentrations were defined as: mean = 0.03 mg/L; 95th percentile = 0.08mg/L; minimum = <0.001 mg/L (Appendix A; Golder 2015a). Several months after the 2014 fall turnover, in April 2015, total and dissolved phosphorus and orthophosphate concentrations measured at depth were within or below these pre-event concentration ranges reported in the PEEIAR (Figure 20).

From July to October, there was a greater degree of disparity in phosphorus concentrations between those measured at the surface and those measured at depth. Higher concentrations above the TP WQG range were reported at depth and these concentrations remained relatively stable over the summer months, whereas surface concentrations decreased to concentrations within or below the TP WQG range. The noted disparity was likely the result of lake stratification during the summer, such that after mixing during fall turnover, concentrations measured at the surface and at depth in November were similar. Sampling in Polley Lake was suspended in November due to the onset of winter conditions.

Golder (2016) concluded that in 2015 there were no event-related changes to phosphorus concentrations in Polley Lake based on an analysis of data collected from April through August 2015. This conclusion is supported by data collected from September through November shown on Figure 20.

3.2.4.2 Quesnel Lake

After the event, TP concentrations at depth exceeded the BC WQG range in the West Basin of Quesnel Lake, but were not elevated at the far-field station (QUL-120/120a) east of Cariboo Island (Golder 2015a). By fall turnover in 2014, TP concentrations had substantially decreased in the West Basin of Quesnel Lake. Through August 2015, TP concentrations were below the BC WQG range and resembled pre-event concentrations with the exception of a few intermittent exceedances at near-field station QUL-66, near the mouth of Hazeltine Creek (Golder 2016; Figure 21). At the near-field, mid-field, and far-field stations, dissolved phosphorus and orthophosphate concentrations reported between March and August were below pre-event concentrations (Golder 2016; Figure 21).

Collectively, an evaluation of the phosphorus data collected between March and August 2015 suggest that event-related changes of concern for phosphorus were not evident in Quesnel Lake (Golder 2016). After September 2015, total phosphorus concentrations were intermittently above the most conservative BC WQG at near-field station QUL-66, near the mouth of Hazeltine Creek, but did not exceed the drinking water BC WQG or the upper boundary of the aquatic life guideline. Dissolved and orthophosphate concentrations remained at or near the MDL through to the end of December 2015 (Figure 21).

4.0 SUMMARY OF CHANGES IN WATER QUALITY IN 2015

Based on the evaluation of water quality trends in this addendum, the following parameters remain as COPCs due to measured concentrations in December 2015 that remain above BC WQGs and CSR Standards (Table 2). A summary of water quality during 2015 in each receiving environment is provided below.

Table 2: Contaminants that Remain of Potential Concern in the Receiving Environment Based on Water Quality Monitoring as of December 2015

Waterbody	COPC: Physical[2]	COPC: Total Metals	COPC: Dissolved Metals	COPC: Non-Metal Substances
Polley Lake	*no substances*	*no substances*	*no substances*	*no substances*
Hazeltine Creek and Edney Creek	**turbidity, TSS**	**copper**, **selenium**	**copper, selenium**	*no substances*
Quesnel Lake	*no substances*	*no substances*	*no substances*	*no substances*
Quesnel River	*no substances*	*no substances*	*no substances*	*no substances*

Notes: TSS = total suspended solids

4.1.1 Hazeltine Creek

As described in Golder (2016), there were exceedances of total metal WQGs and CSR standards in Hazeltine Creek in the first half of 2015, mainly during turbid flow periods typically associated with elevated concentrations of particulate matter. Clear-flow conditions ensued upon the completion of channel stabilization activities that typically resulted in much lower concentrations of particulate matter and subsequently lower concentrations of total forms of various metals.

The majority of metals identified as COPCs by Golder (2016) had decreased to below guideline levels by mid-summer and remained stable through December 2015, with a few noted exceptions (e.g., beryllium, chromium, and cobalt at HAC-08/a). By December 2015, only total and dissolved copper consistently exceeded BC WQGs for the protection of aquatic life. Copper, turbidity and total suspended solids therefore remain the primary substances of concern in Hazeltine Creek.

Concomitant with the initiation of the authorized discharge of treated effluent in December 2015, selenium concentrations increased at HAC-05/a and HAC-08/a, located close to and downstream from the discharge location, respectively. Even though the most sensitive receptors to selenium (i.e., egg laying vertebrates) are either excluded (fish) or are limited in number (aquatic feeding birds), selenium is also conservatively flagged to be of concern in Hazeltine Creek. However, as discussed in Section 3.2.2.4, concentrations appear to have decreased in the first quarter of 2016 by 1- 2 times compared to the concentrations reported in December 2015.

Copper therefore remains the primary substance of concern in Hazeltine Creek based on the 2015 data. When the creek is subject to erosion resulting in turbid flow events, turbidity, TSS, and some other metals also exceed guidelines. Selenium is conservatively flagged to be of concern but concentrations appear to be decreasing following the initial discharge of treated effluent to the creek; and selenium will continue to be monitored as part of routine monitoring programs.

4.1.2 Polley Lake

Levels of TSS, turbidity, and copper were low in Polley Lake and remained below guidelines throughout 2015. With respect to nutrients, total phosphorus concentrations were within the range observed in Polley Lake prior to the event. Therefore no contaminants remained of concern by December 2015 in Polley Lake.

4.1.3 Quesnel Lake

Levels of TSS and turbidity were low in the far-field area of Quesnel Lake as well as in the West Basin and remained below guidelines throughout 2015, with the exception of some higher levels recorded in the near-field area at the mouth of Hazeltine Creek when turbid inflows from Hazeltine Creek were present from March to May 2015. Close to the mouth of Hazeltine Creek, turbidity progressively declined between June and December to levels close to or below background (1 NTU).

Within the West Basin, total copper was below applicable BC WQGs and CSR standards in the near-field, mid-field and far-field stations. Exceptions to this were instances where concentrations were above applicable BC WQGs between March and May in the near-field close to the mouth of Hazeltine Creek and to a lesser extent at the western mid-field station further away from the mouth. These higher total concentrations coincided with turbid flow periods in Hazeltine Creek and dissolved concentrations did not exceed BC WQGs. Other metals monitored at the Quesnel Lake stations in 2015 were below applicable BC WQGs and CSR standards.

In agreement with Golder (2016), phosphorus data collected throughout 2015 suggested that event-related changes of concern with respect to the potential for a change in lake trophic status were not evident in Quesnel Lake.

Based on the evaluation of the 2015 dataset, no contaminants remained of concern by December in Quesnel Lake.

4.1.4 Quesnel River

Similar to the eastern far-field area of Quesnel Lake, water quality in Quesnel River between March and August did not exhibit event-related changes that were identified to be of concern with respect to exceedance of water quality guidelines. Therefore no contaminants remained of concern by December 2015 in Quesnel River.

5.0 STATEMENT OF LIMITATIONS

This technical memorandum was prepared for the exclusive use of MPMC. The inferences concerning the data, site and receiving environment conditions contained in this memorandum are based on information obtained during investigations conducted at the site by Golder Associates Ltd. (Golder), other consultants and MPMC, and are based solely on the condition of the site at the time of the site studies and subsequent investigations and remediation and other information obtained by Golder, as described in this memorandum. Soil, surface water and groundwater conditions may vary with location, depth, time, sampling methodology, analytical techniques and other factors.

In evaluating the subject site and water quality data, Golder has relied in good faith on information provided. The factual data, interpretations and recommendations pertain to a specific project as described in this memorandum, based on the information obtained during the assessment by Golder on the dates cited in the memorandum, and are not applicable to any other project or site location. Golder accepts no responsibility for any deficiency or inaccuracy contained in this memorandum as a result of reliance on the aforementioned information.

The findings and conclusions documented in this memorandum have been prepared for the specific application to this project, and have been developed in a manner consistent with that level of care normally exercised by environmental professionals currently practising under similar conditions in the jurisdiction. Golder makes no other warranty, expressed or implied and assumes no liability with respect to the use of the information contained in this memorandum at the subject site, or any other site, for other than its intended purpose.

Any use which a third party makes of this memorandum, or any reliance on or decisions to be made based on it, are the responsibility of such third parties. Golder accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or action based on this memorandum. All third parties relying on this memorandum do so at their own risk. Electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore no party can rely upon the electronic media versions of Golder's memorandum or other work product. Golder is not responsible for any unauthorized use or modifications of this memorandum.

MPMC may rely on the information contained in this memorandum subject to the above limitations.

Golder makes no other representation whatsoever, including those concerning the legal significance of its findings, or as to other legal matters touched on in this memorandum, including, but not limited to, ownership of any property, or the application of any law to the facts set forth herein.

If new information is discovered during future work, including excavations, sampling, soil boring, predictive geochemistry or other investigations, Golder should be requested to re-evaluate the conclusions of this memorandum and to provide amendments, as required, prior to any reliance upon the information presented herein. The validity of this memorandum is affected by any change of site conditions, purpose, development plans or significant delay from the date of this memorandum in initiating or completing the project.

6.0 CLOSURE

We trust that this Addendum provides sufficient information for your present needs. If you have any questions, please do not hesitate to contact the undersigned at (604) 296-4200.

Table A1: Summary of Mount Polley TSF Breach Water Quality Monitoring Program, September to December 2015

Area	Station Name	Sample Location Type	Frequency	Comments
Polley Lake	P1	Routine	Monthly	
	P2	Routine	Monthly	
Upper Hazeltine	HAC-05	Routine	Weekly-Monthly	Weekly samples transitioned to monthly. Replaced by HAC-05a upstream of the bridge after 10/1/2015, except for one sample collected 12/22/2015.
	HAC-05a	Routine	Weekly	Established upstream of the Gavin Lake Road bridge to replace HAC-05 as of 11/2/2015.
	HAC-10	Routine	Weekly-Monthly	Weekly samples transitioned to monthly as of 5/4/2015.
Lower Hazeltine	HAC-01c	Routine	Weekly	Established at new outlet of HAC 7/31/2015. Discontinued 10/5/2015 due to lack of flow through lower sedimentation pond. Replaced by HAC-12.
	HAC-08	Routine	Weekly-Monthly	Temporarily replaced by HAC-08a downstream of the bridge between 8/6/2015 and 10/1/2015.
	HAC-08a	Routine	Weekly-Monthly	Temporarily sampled on 9/8/2015, in place of HAC-08.
	HAC-12	Routine	Weekly	Established 11/2/2015 to replace HAC-01/a/b/c. Located in the upper sedimentation pond.
	HAC-13	Routine	Weekly	Established in upper HAC, upstream of the discharge, on 12/3/2015.
Edney Creek	EDC-01	Routine	Weekly-Monthly	Weekly samples transitioned to monthly.
	EDC-02	Routine	Weekly	Downstream of confluence with HAC; discontinued after HAC/EDC redirected 7/25/2015.
Quesnel River	QUR-1	Routine	Weekly-Bi-weekly	Weekly samples transitioned to bi-weekly.
Quesnel Lake	QUL-2a	Routine	Weekly-Monthly	Weekly samples transitioned to monthly.
	QUL-18	Routine	Weekly-Monthly	Weekly samples transitioned to monthly.
	QUL-21a	Routine profile only	-	
	QUL-40a	Routine	Monthly	
	QUL-42	Routine	Monthly	In Mitchell Bay, east of HAC mouth and just before the sill. Established 9/17/2015.
	QUL-54	Routine profile only	-	Replaced by QUL-54a when HAC redirected 7/25/2015. However, was sampled weekly in October 2015.
	QUL-54a	Routine profile only	-	Established to replace QUL-54 when HAC redirected 7/25/2015. Discontinued after 10/5/2015 and replaced by QUL-57.
	QUL-55	Routine	Weekly	Discontinued and replaced by QUL-55a when HAC redirected 7/25/2015. However, was sampled weekly in October 2015.
	QUL-55a	Routine	Weekly	Established to replace QUL-55 when HAC redirected 7/25/2015. Discontinued 10/5/2015 and replaced with QUL-58.
	QUL-56	Routine profile only	-	Discontinued when HAC redirected 7/25/2015. Sampled weekly in October 2015.
	QUL-56a	Routine profile only	-	Established to replace QUL-56 when HAC redirected 7/25/2015. Sampled 7/28/2015, 10/1/2015, and 10/5/2015 only. Discontinued and replaced by QUL-59.
	QUL-57	Routine	Weekly	Located in the IDZ of the effluent discharge in QUL. Established 12/9/2015 as a replacement for QUL-54/54a.
	QUL-58	Routine	Monthly-Weekly	Located in the IDZ of the effluent discharge in QUL. Established 11/5/2015 to replace QUL-55/55a; transitioned to weekly sampling 12/2/2015.
	QUL-59	Routine	Weekly	Located in the IDZ of the effluent discharge in QUL. Established 12/2/2015 to replace QUL-56/56a.
	QUL-66a	Routine profile only	-	2015 sampling limited to October and November only.
	QUL-79	Routine profile only	-	2015 sampling limited to October and November only.
	QUL-120a	Routine	Monthly	
	QUL-ZOO-1	Profile only for zooplankton	-	Profiled 7/8/2015, 8/20/2015, and 9/10/2015.
	QUL-ZOO-7	Profile only for zooplankton	-	Profiled 7/8/2015, 8/20/2015, and 9/10/2015.
	QUL-ZOO-8	Profile only for zooplankton	-	Profiled 7/8/2015, 8/20/2015, and 9/10/2015.

Notes

Routine samples were taken throughout the period according to 2015 Post-Breach Environmental Monitoring Plan

Routine stations are consistently monitored; typically either weekly, bi-weekly (every 2 weeks), monthly, or bi-monthly (twice per month)

HAC = Hazeltine Creek; EDC = Edney Creek; QUR = Quesnel River; QUL = Quesnel Lake; IDZ = initial dilution zone; ZOO = zooplankton station.

'Lyn Anglin, Imperial Metals Corporation
Trish Miller, Golder Associates

Re: Sediment Quality Data Report - August 2015 Collections

This memorandum provides a brief summary of sediment quality data collected by Minnow Environmental Inc. on behalf of the Mount Polley Mining Corporation (MPMC) in the vicinity of the Mount Polley Mine (Figure 1). Sediment samples were collected in August 2015 from three waterbodies (Polley Lake, Hazeltine Creek and Quesnel Lake) affected by the August 4th 2014 failure of the Mount Polley Tailings Dam and from corresponding reference areas. The purpose of this memorandum is to provide data to be used by Golder Associates in a Detailed Site Investigation Report required under the British Columbia Contaminated Sites Regulation (Government of British Columbia 1996).

Methods

Sediment samples were collected between August 13th and 26th 2015 at stations in Polley Lake, Bootjack Lake, the Hazeltine Creek Sedimentation Pond and Quesnel Lake (Figure 1; Appendix Table A.1). Where possible, samples were collected from the same locations and using the same methods as in 2014 (Minnow 2015).

Sampling

Briefly, in Polley and Bootjack lakes, sediments for the analysis of metals and total organic carbon (TOC) were collected using a Kajak-Brinkhurst (KB) corer in accordance with technical guidance for gravity coring outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for Environmental Effects Monitoring (EEM; Environment Canada 2012). Sediment samples for particle size distribution were collected using a petite ponar grab sampler (15.24 cm x 15.24 cm; 0.023 m^2 sampling area). Five replicate stations were sampled to represent each area (Appendix Table A.1). All core samples were extruded into a core collar and then cut using a core knife to collect the top 3 cm of sediment, which was then transferred into a

minnow environmental inc.
A Trinity Consultants Company

250 mL glass sampling jar labeled with the project number, sample location and collection date. The procedure was then repeated to provide a composite sample of sufficient volume for the required analyses. All sampling equipment was rinsed between stations using site water

In Quesnel Lake, sediment samples from littoral habitats were collected using a stainless steel petite ponar grab sampler and sediment samples from profundal habitats were collected using a stainless steel petite or standard ponar grab sampler (22.86 cm x 22.86 cm; 0.052 m^2 sampling area) in accordance with technical guidance outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for EEM (Environment Canada 2012). Profundal grab samples (mean depth approximately 100 meters) were collected with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). Three to five replicate stations were sampled to represent each sampling area (Appendix Table A.1). At each station, composite samples of the top three centimeters of surficial sediment of three to ten acceptable grabs (i.e., full to each edge of the sampler) were collected. Each grab was collected into a plastic tote and observed for completeness and any unusual characteristics. If the sample was deemed acceptable, surficial material to a depth of 3 centimeters was transferred to a second tote using a stainless steel spoon. Remaining sediment was discarded. The procedure was then repeated for all subsequent grabs. The material within the tote was homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars labeled with the project number, sample location and collection date. All sampling equipment was rinsed between stations using site water.

In the Hazeltine Creek Sedimentation Pond, sediment samples were collected using a stainless steel spoon. Five replicate stations were sampled to represent each sampling area (Appendix Table A.1). At each sampling station, a composite sediment sample was prepared from ten spoons of sediment. Surficial sediment was carefully collected to ensure the capture of a uniform depth (top 3 cm) and to limit disturbance that could result in loss of fines. Each spoonful was placed into a plastic tote. After ten scoops were collected, the material within the tote was homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars labeled with the project number, sample location and collection date. All sampling equipment was rinsed between stations using site water.

Field duplicate (split) sediment samples were collected at a frequency of 10% for quality assurance/quality control (QA/QC) purposes. Supporting information collected at each

sampling site included GPS (Geographic Positioning System) coordinates, sampling depth, Secchi depth (lakes only), field meter measurements of temperature, specific conductance, dissolved oxygen and pH (using a YSI EXO™ handheld portable field meter equipped with YSI EXO2™ Sonde), site photographs (including photographs of sediment samples), and notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). Immediately after collection, samples were placed into a cooler with ice packs, where they were maintained cool prior to transport to the field laboratory where they were placed in a refrigerator and held until shipment to the analytical laboratory. Sediment samples were shipped to the analytical laboratory (ALS Environmental, Burnaby BC) at minimum frequency of weekly. Prior to shipment, samples were placed in a cooler with frozen ice packs and a chain-of custody form was prepared and packed with the samples. Coolers were shipped overnight for next day delivery to ALS Environmental.

Laboratory Analysis

Upon receipt, ALS Environmental opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and assigned each sample a unique sample identification code. A sample receipt confirmation was then sent to MPMC and Minnow for verification.

Laboratory analysis included moisture content, pH, particle size distribution, total organic carbon content, total nitrogen concentration, and metal concentrations. Total organic carbon content and metal concentrations were determined in the silt/clay fraction (<63 µm diameter) in accordance with recent recommendations by the British Columbia Ministry of Environment (BCMoE 2012) and because sediment quality characterization conducted in 2014 indicated similar results in <63 µm and <2 mm sediments (Minnow 2015). Upon completion of the analyses, data reports were provided by ALS Environmental to MPMC and Minnow electronically in Adobe Acrobat Portable Document Format (PDF) and as MSExcel files.

Data Analysis

Upon receipt of the analytical data, a Data Quality Assessment (DQA) was completed, including an examination of data completeness, method detection limits achieved, laboratory precision, laboratory accuracy, and field precision. Following the completion of DQA, sediment quality data were summarized by area, by calculating mean, median, standard deviation, standard error, 95% confidence limits, minimum and maximum. Data

were then evaluated in comparison to Contaminated Sites Regulation (CSR) criteria (Government of British Columbia 1996) and reference concentrations.

Environmental matters pertaining to contaminated sites in British Columbia generally fall under the jurisdiction of the BC Ministry of the Environment pursuant to the *Environmental Management Act* (*EMA*; Government of British Columbia 2003). The key regulations under the *EMA* relating to the assessment and remediation of contaminated sites are the Contaminated Sites Regulation (Government of British Columbia 1996) and the Hazardous Waste Regulation (HWR; Government of British Columbia 1988). Within the CSR, numeric criteria for sediment listed in Schedule 9 (Government of British Columbia 1996) are used to determine if sediments are contaminated. CSR criteria have been defined for a limited number of analytes for sensitive and typical sediment environments. Sensitive sediment is defined as sediment at a site with sensitive aquatic habitat (e.g., spawning habitat) and for which sensitive management objectives apply, and typically apply to the ecologically active zone (top one meter) of sediments in an aquatic receiving environment (BCMoE 2013). Typical sediment is defined as any sediment that is not sensitive sediment (BCMoE 2013).

Reference values contained within this memorandum fall into two categories - pre-event data and data collected at reference sites in 2014 and 2015. Pre-event and reference data were compiled and used to calculate reference screening values. For each pre-event or reference dataset, 95th percentile values were calculated and compared. The highest pre-event or reference 95th percentile value was then used to screen the data from the exposed areas to identify analytes present at impacted areas at concentrations greater than pre-event and/or reference.

Results

Data Quality Assessment indicated good sediment data quality, meaning that data can be used with a high level of confidence for interpretation and the derivation of conclusions (Appendix C).

Polley Lake

Sediment collected from Polley Lake in 2015 (from the south side of the lake at Station POL-P2; Figure 1) was predominantly silt and clay, and was similar in particle size distribution to sediments collected in 2014 and from the reference lake (Bootjack Lake; Table 1; Appendix Table D.1). As observed in 2014, total organic carbon (TOC) content was lower in Polley Lake than reference (Table 1).

Table 1: Summary sediment quality data for Polley Lake and Bootjack Lake sampling areas, Mount Polley Mine, 2014 and 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

[1] Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] Reference 95th percentiles for 2015 data were calculated using data displayed in Appendix Table D.1. For calculation of 2014 and Historical Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

[4] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

Sediment metal and nitrogen concentrations at Polley Lake (sampling area POL-P2) in 2015 were also very similar to those observed in 2014. Arsenic and copper were the only analytes with concentrations greater than the CSR "sensitive" criteria and reference (Table 1; Appendix Table D.1).

Copper was the only analyte with concentrations greater than the CSR "typical" criterion and reference (Table 1; Appendix Table D.1). However, copper in reference Bootjack Lake and in Polley Lake prior to the dam failure also exceeded the CSR "typical" criterion (Table 1). In 2015, the mean copper concentration in Polley Lake sediment exceeded reference by approximately 2.2-times and the CSR "typical" criterion by approximately 3.4-times (Table 1).

Hazeltine Creek Sedimentation Pond

Sediment collected from the upper Hazeltine Creek Sedimentation Pond in 2015 (Figure 1) was primarily silt and clay (92.5%), and had lower sand content than sediment collected from lower Hazeltine Creek in 2014 (Table 2; Appendix Table D.2). The high fines (silt and clay) content of this sediment was noted during 2015 field collections. Similar to 2014, the TOC content of sediment collected in 2015 was lower than observed in Hazeltine Creek pre-event (Table 2).

Metal concentrations in sediments collected in 2015 were similar to those observed in 2014, as was the nitrogen content. Arsenic and copper were the only analytes to exceed the CSR "sensitive" criteria and pre-event concentrations in Hazeltine Creek in 2015 (Table 2; Appendix Table D.2). In 2014, concentrations of both arsenic and copper exceeded the CSR "sensitive" criteria, but arsenic did not exceed pre-event concentrations (Table 2). The higher arsenic concentrations observed in 2015 are likely due to the finer particle sizes encountered in 2015.

As observed in 2014, concentrations of copper exceeded the CSR "typical" criterion as well as pre-event concentrations (Table 2; Appendix Table D.2). Copper was the only analyte to exceed the "typical" CSR criterion, with the 2015 mean copper concentration exceeding this criterion by approximately 2.0 times on average, and exceeding pre-event concentrations (in lower Hazeltine Creek) by 11.2 times on average (Table 2).

Quesnel Lake Littoral

Sediment collected from the littoral near-field area of Quesnel Lake in 2015 (LNF; Figure 1) was predominantly sand (82.4%), and had a higher sand content than sediment

Table 2: Summary sediment quality data for samples collected in lower Hazeltine Creek in 2014 and collected in the Hazeltine Creek Sedimentation Pond in 2015, Mount Polley Mine. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] For calculation of Historic Hazeltine Creek 95th percentiles see Minnow (2015).

[4] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

collected from this location in 2014 (49.2%; Table 3; Appendix Table D.3). This difference in sediment composition was evident during sample collection in the field, and the decrease in the fines (silt and clay) content of sediment (49.7% in 2014, and 15.6% in 2015) may be a result of washing of fine sediment from these locations between August 2014 and August 2015. The particle size distribution of sediment collected in the littoral far-field area (Figure 1) was similar in 2014 and 2015, and was also similar to sediment collected in the Quesnel littoral reference area. As observed in 2014, the TOC content of sediment in 2015 was lower in the near-field area than in the far-field or reference areas (Table 3; Appendix Table D.3).

Concentrations of nitrogen and metals in the <63 µm (silt and clay) fraction of sediment collected from the near-field area were similar in 2014 and 2015 despite the differences in particle size distribution (Table 3). This similarity in sediment chemistry suggests that fines remaining in the near-field area were event-affected. However, aquatic organisms inhabiting this sediment would be exposed to the whole sediment, not solely the fines (<63 µm) fraction. In the far-field area, sediment concentrations of nitrogen and metals were also similar in 2014 and 2015.

As in 2014, arsenic and copper were the only analytes to exceed the CSR “sensitive” criteria as well as reference concentrations in the near-field area (Table 3; Appendix Table D.3). Copper was the only analyte in the near-field area with concentrations exceeding the CSR “typical” criterion and reference concentrations, as was also observed in 2014. The mean copper concentration of Quesnel Lake near-field area sediment exceeded the CSR “typical” criterion by approximately 2.7 times on average, and exceeded reference by approximately 13.2 times on average (Table 3). The concentrations of metals in sediment from the far-field area did not exceed CSR criteria or reference concentrations, and were generally lower than those observed in the near-field area. For instance, mean sediment arsenic and copper concentrations observed in the far-field area were approximately 3.7 and 9.8 times lower, respectively, than in the near-field area in 2015 (Table 3).

Quesnel Lake Profundal

Sediment collected from the Quesnel Lake profundal near-field area (Figure 1) was composed primarily of silt and clay (93%), with a particle size distribution similar to that observed in 2014, but which had a higher clay content (35.5%) and lower sand content (7.0%) than observed in the Quesnel Lake profundal reference area (Table 4; Appendix Table D.4). The TOC content of sediment from the near-field area was lower than that observed at the reference area, as was also observed in 2014 (Table 4).

Table 3: Summary of sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2014 and 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

[1] Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] Reference 95th percentiles for 2015 data were calculated using data displayed in Appendix Table D.3. For calculation of 2014 Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

[4] Summary statistics for reference area LRef2 are based only on data from replicates LRef2-01 to LRef2-03 due to high sand content in replicates LRef2-04 and LRef2-52-05 (> 90%).

[5] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

Table 4: Summary of sediment quality for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2014 and 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values shown in bold text also exceed all Reference 95th Percentile values.

[1] Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] Reference 95th percentiles for 2015 data were calculated using data displayed in Appendix Table D.4. For calculation of 2014 Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

[4] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

Sediment concentrations of nitrogen and metals observed in the profundal near-field area in 2015 were very similar to those observed in 2014, with arsenic and copper being the only analytes with concentrations whose concentrations exceeded the CSR “sensitive” criteria (Table 4; Appendix Table D.4). Sediment arsenic concentrations exceeded one of the two reference area concentrations (PRef1), but not both, the greater of which exceeded the CSR “typical” criterion (reference area PRef2).

Copper was the only analyte observed in the profundal near-field area to exceed the CSR “typical” criterion, as was also observed in 2014 (Table 4; Appendix Table D.4). In 2015, the mean copper sediment concentration exceeded the CSR “typical” criterion by approximately 3.6 times on average, and exceeded reference concentrations by approximately 14.5 times on average (Table 4).

Summary

Copper was the only analyte observed to exceed the CSR “typical” criterion in sediment from the three waterbodies affected by the Mount Polley Tailings Dam failure (Polley Lake, Hazeltine Creek and Quesnel Lake). Copper also exceeded reference or pre-event concentrations within all three of these waterbodies. Sediment arsenic concentrations exceeded the CSR “sensitive” (but not “typical”) criterion in all 2015 sampling areas except the Quesnel Lake littoral far-field area. These “sensitive” criteria apply to the top one meter of sediments in aquatic receiving environments (BCMoE 2013). Overall, there was little difference in the chemistry of sediment from the three waterbodies affected by the Mount Polley Tailings Dam failure between the 2014 and 2015 sampling events.

APPENDIX B

ANALYTICAL REPORTS

MOUNT POLLEY MINING CORP.
ATTN: Colleen Hughes
PO Box 12
Likely BC V0L 1N0

Date Received: 21-AUG-15
Report Date: 02-OCT-15 12:45 (MT)
Version: FINAL REV. 3

Client Phone: 250-790-2215

Certificate of Analysis

Lab Work Order #: L1661656

Project P.O. #: NOT SUBMITTED
Job Reference:
C of C Numbers:
Legal Site Desc:

Comments:

Tessier sequential extraction and AVS/SEM analyses are not included in this report.

23-SEP-2015 Revision 2: The report to company has been modified.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AVS-COL-VA	Soil	Acid volatile sulphide by colourimetric	EPA 821/R-91-100

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The evolved hydrogen sulphide (H2S) is carried into a basic zinc acetate (ZnAc) solution by argon gas. The acid volatile sulfide is then determined colourimetrically.

C-TOT-63UM-LECO-SK	Soil	Total Carbon by combustion method (63um)	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

C-TOT-ORG-63UM-SK	Soil	Organic Carbon by combustion method(63um	SSSA (1996) p. 973

Total Organic Carbon (C-TOT-ORG-LECO-SK, C-TOT-ORG-SK)

Total C and inorganic C are determined on separate samples. The total C is determined by combustion and thermal conductivity detection, while inorganic C is determined by weight lass after addition of hydrochloric acid. Organic C is calculated by the difference between these two determinations.

Reference for Total C:
Nelson, D.W. and Sommers, L.E. 1996. Total Carbon, organic carbon and organic matter. P. 961-1010 In: J.M. Bartels et al. (ed.) Methods of soil analysis: Part 3 Chemical methods. (3rd ed.) ASA and SSSA, Madison, WI. Book series no. 5

Reference for Inorganic C:

HG-63UM-CVAF-VA	Soil	Hg in Soil by CVAFS	EPA 200.2/245.7

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).

HG-SEM-CVAFS-VA	Soil	Simultaneously Extracted Metals in Soil	EPA 821/R-91-100; EPA245.7

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system.
The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA 245.7).

MET-63UM-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modifed from EPA Method 6020A).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

MET-SEM-ICP-VA	Soil	Simultaneously Extracted Metals (ICPOES)	EPA 821/R-91-100; EPA 6010B

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-TESS-CM-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #2)	Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #2, the extraction solution is 1M Sodium Acetate adjusted to pH 5 and is intended to extract the "Carbonate" metals.

MET-TESS-EA-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #1)	Tessier Extraction 1979/EPA 6020A

Reference Information

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #1, the extraction solution is 1M Magnesium Chloride and is intended to extract the "Exchangeable and Adsorbed" metals.

MET-TESS-FEO-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #3) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #3, the extraction solution is 0.1 M Hydroxylamine Hydro› Chloride in 25% v/v Acetic Acid and is intended to extract the Easily Reducible Metals and Iron Oxides .

MET-TESS-OB-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #4) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #4, the extraction solution is 0.02 M Nitric Acid followed by 3.2M Ammonium Acetate and is intended to extract the Organic Bound metals.

MET-TESS-RM-CCMS-VA Soil METALS BY CCMS (TESSIER RM EXTRACTION) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with up to 6 different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For the Tessier "RM" Extraction, the extraction solution is 50/50 mix of 1:1 Nitric Acid along with 1:1 Hydrochloric Acid, and is hot block digested as per the BC SALM procedure. This is intended to extract the Residual metals.

MOISTURE-VA Soil Moisture content ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

N-TOT-LECO-SK Soil Total Nitrogen by combustion method SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

PH-1:2-VA Soil pH in Soil (1:2 Soil:Water Extraction) BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PSA-PIPET+GRAVEL-SK Soil Particle size - Sieve and Pipette SSIR-51 METHOD 3.2.1

Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

Reference:

Burt, R. (2009). Soil Survey Field and Laboratory Methods Manual. Soil Survey Investigations Report No. 5. Method 3.2.1.2.2. United States Department of Agriculture Natural Resources Conservation Service.

S-TOT-LECO-SK Soil Total Sulphur by combustion method ISO 15178:2000

The sample is ignited in a combustion analyzer where sulfur in the reduced SO2 gas is determined using a thermal conductivity detector.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Reference Information

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AVS-COL-VA	Soil	Acid volatile sulphide by colourimetric	EPA 821/R-91-100

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The evolved hydrogen sulphide (H2S) is carried into a basic zinc acetate (ZnAc) solution by argon gas. The acid volatile sulfide is then determined colourimetrically.

C-TOT-63UM-LECO-SK	Soil	Total Carbon by combustion method (63um)	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

C-TOT-ORG-63UM-SK	Soil	Organic Carbon by combustion method(63um	SSSA (1996) p. 973

Total Organic Carbon (C-TOT-ORG-LECO-SK, C-TOT-ORG-SK)

Total C and inorganic C are determined on separate samples. The total C is determined by combustion and thermal conductivity detection, while inorganic C is determined by weight lass after addition of hydrochloric acid. Organic C is calculated by the difference between these two determinations.

HG-63UM-CVAF-VA	Soil	Hg in Soil by CVAFS	EPA 200.2/245.7

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).

HG-SEM-CVAFS-VA	Soil	Simultaneously Extracted Metals in Soil	EPA 821/R-91-100; EPA245.7

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system.
The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA 245.7).

MET-63UM-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modifed from EPA Method 6020A).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

MET-SEM-ICP-VA	Soil	Simultaneously Extracted Metals (ICPOES)	EPA 821/R-91-100; EPA 6010B

This analysis was carried out in accordance with the method described in EPA 821/R-91-100. In summary, hydrochloric acid is added to the sediment samples within a purge and trap system. The extract produced from the addition of the acid is then analyzed for simultaneously extracted metals (SEM) using inductively coupled plasma - optical emission spectrophotometry (EPA Method 6010B).

MET-TESS-CM-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #2)	Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #2, the extraction solution is 1M Sodium Acetate adjusted to pH 5 and is intended to extract the "Carbonate" metals.

MET-TESS-EA-CCMS-VA	Soil	METALS BY CCMS (TESSIER EXTRACTION #1)	Tessier Extraction 1979/EPA 6020A

Reference Information

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #1, the extraction solution is 1M Magnesium Chloride and is intended to extract the "Exchangeable and Adsorbed" metals.

MET-TESS-FEO-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #3) Tessier Extraction 1979/EPA 6020A

This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #3, the extraction solution is 0.1 M Hydroxylamine Hydro› Chloride in 25% v/v Acetic Acid and is intended to extract the Easily Reducible Metals and Iron Oxides .

MET-TESS-OB-CCMS-VA Soil METALS BY CCMS (TESSIER EXTRACTION #4) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with 5 or 6 (if a pre-liminary water extraction is included) different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For Extraction #4, the extraction solution is 0.02 M Nitric Acid followed by 3.2M Ammonium Acetate and is intended to extract the Organic Bound metals.

MET-TESS-RM-CCMS-VA Soil METALS BY CCMS (TESSIER RM EXTRACTION) Tessier Extraction 1979/EPA 6020A

"This analysis is modified from the extraction procedure outlined in the "Sequential Extraction Procedure for the Speciation of Particulate Trace Metals" Analytical Chemistry, (A. Tessier, P.G.C. Campbell, and M. Bisson, June 1979). Initially, the sample is manually homogenized, dried at <60 degrees Celsius, sieved through a 2 mm (10 mesh) sieve (this sieve step is omitted for international soil samples), and a representative subsample of the dry material is weighed for extraction. In summary, the sample is sequentially extracted with up to 6 different extraction solutions. The extract is then centrifuged for 30 minutes and the supernatant is subsequently removed and analysed. Instrumental analysis of the digested extract is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Note: For the Tessier "RM" Extraction, the extraction solution is 50/50 mix of 1:1 Nitric Acid along with 1:1 Hydrochloric Acid, and is hot block digested as per the BC SALM procedure. This is intended to extract the Residual metals.

MOISTURE-VA Soil Moisture content ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

N-TOT-LECO-SK Soil Total Nitrogen by combustion method SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

PH-1:2-VA Soil pH in Soil (1:2 Soil:Water Extraction) BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PSA-PIPET+GRAVEL-SK Soil Particle size - Sieve and Pipette SSIR-51 METHOD 3.2.1

Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

Reference:

Burt, R. (2009). Soil Survey Field and Laboratory Methods Manual. Soil Survey Investigations Report No. 5. Method 3.2.1.2.2. United States Department of Agriculture Natural Resources Conservation Service.

S-TOT-LECO-SK Soil Total Sulphur by combustion method ISO 15178:2000

The sample is ignited in a combustion analyzer where sulfur in the reduced SO2 gas is determined using a thermal conductivity detector.

Reference Information

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

1 2

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

C1.0 INTRODUCTION

Data Quality Assessment (DQA) was conducted on data collected as part of the Mount Polley Mining Corporation (MPMC) Sediment Quality Data Report. The objective of DQA is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

C1.1 Background

A variety of factors can influence the physical, chemical and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Depending on the magnitude of the problem, inaccuracy or imprecision have the potential to affect the reliability of any conclusions made from the data. Therefore, it is important to ensure that programs incorporate appropriate steps to control the non-natural sources of data variability (i.e., minimize the variability that does not reflect natural spatial and temporal variability in the environment) and thus assure the quality of the data.

Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. DQA involves comparison of actual field and laboratory measurement performance to data quality objectives (DQOs) established for a particular study, such as evaluation of method detection limits, blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). A trusted analytical laboratory certified by Canadian Association for Laboratory Accreditation (CALA) with a rigorous internal quality assurance program was selected to ensure the highest possible quality.

DQOs were established a-priori to reflect reasonable and achievable performance expectations. Programs involving a large number of samples and analytes usually yield some results that exceed the DQOs. This is particularly so for multi-element scans since the analytical conditions are not necessarily optimal for every element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the parameters fail to meet the DQOs. Overall, the intent of DQA is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of this project.

C1.2 Types of Quality Control Samples

Several types of quality control (QC) samples were assessed based on samples collected (or prepared) in the field and laboratory. These samples include the following:

- **Blanks** are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed the same way as regular samples. These samples will reflect any contamination that occurred in the field (in the case of field or trip blanks) or the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be non-detectable, although a data quality objective of twice the method detection limit allows for slight "noise" around the detection limit.

- **Field Duplicates** are sub-sample pairs collected from a randomly selected field station using identical collection and handling methods that are then analyzed separately in the laboratory. The duplicate samples are handled and analyzed in an identical manner in the laboratory. The data from field duplicate samples reflect natural variability, as well as the variability associated with sample collection methods, and therefore provide a measure of field precision.

- **Laboratory Duplicates** are sub-sample pairs created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.

- **Certified Reference Materials and QC Standards** are samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to target results to provide a measure of analytical accuracy. The results are reported as the percent of the known amount that was recovered in the analysis.

C2.0 SEDIMENT SAMPLES

C2.1 Holding Time and General Laboratory Flags

All sediment analyses were conducted within ALS Environmental's recommended hold times. There were no general laboratory flags associated with either analytical report (i.e., ALS Environmental Report L1661656 and L1664712; Appendix B).

C2.2 Method Detection Limits

Analytical laboratory reports (Appendix B) were examined to provide an inventory of analytes for which sample results were less than the method detection limit (MDL). Only seven analytes – percent gravel, percent sand, total organic carbon, bismuth, boron, total sulphur and thallium - had results reported as less than MDL. None of these analytes have applicable CSR criteria (Table C.1), and therefore the achieved MDLs were appropriate for the study and the rare instances of results reported as <MDL did not adversely affect data interpretability.

C2.3 Laboratory Blank Sample Analysis

All of the reported method blank results were non-detectable (Appendix B). Thus, the method blank results for this study suggest no inadvertent sample contamination within the laboratory.

C2.4 Data Precision

Field Duplicate Samples

Four field duplicate samples were collected for quality assurance (Table C.2). Evaluation of precision associated with sediment physical and chemical characteristics indicated excellent precision. The only occurrence of a relative percent difference (RPD) between duplicates of greater than the DQO of 40% was for percent clay in a sample from the littoral reference area (Table C.2). These duplicate samples had a low proportion of clay sized particles (6.3% and 3.5%). Consequently, although the absolute difference was small (2.8%), the relative percent difference was 57.4% (Table C.2). Overall, the precision associated with sediment quality analyses is suitable.

Laboratory Duplicate Samples

Two laboratory duplicate samples were evaluated for metals; and another ten laboratory duplicate samples were evaluated for a combination of moisture, pH, particle size, total

Table C.1: Laboratory method detection limit (MDL) evaluation for basic sediment chemistry analyses relative to generic numerical sediment criteria. Only analytes with <MDL values are reported.

Analyte		Units	BC CSR Criteria [1, 2]		Maximum Method Detection Limit Achieved
			Sensitive	Typical

nitrogen, total organic carbon, and total sulfur (Appendix B). All laboratory duplicate results (97 in total) met ALS Environmental's data quality objective of <30% RPD (Appendix B) and thus laboratory precision achieved in this study is considered good.

C2.5 Data Accuracy

Data accuracy was evaluated based on results of certified reference materials (CRM), internal reference materials (IRM) and laboratory control samples (LCS; Appendix B). Specifically, six CRM and two LCS samples were used to evaluate the accuracy of metal analyses, three IRM samples were used to evaluate the accuracy of particle size, total nitrogen, total organic carbon and Sulphur, and another eight LCS samples were evaluated for moisture and pH (Appendix B). All CRM, IRM and LCS results (274 in total) met ALS Environmental's data quality objectives for accuracy (Appendix B) and thus laboratory accuracy achieved in this study is considered good.

C3.0 DATA QUALITY STATEMENT

Data collected for the August 2015 sediment quality survey at the Mount Polley Mine was of good quality as characterized by good detectability, negligible analyte concentrations in method blanks, good field and laboratory precision, and good laboratory accuracy. Therefore, associated data can be used with a high level of confidence in the derivation of conclusions.

APPENDIX D

SEDIMENT QUALITY DATA

Table D.1: Raw sediment quality data for Polley Lake and Bootjack Lake sampling areas, Mount Polley Mine, 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

[1] Reported moisture, pH, and total nitrogen data are based on bulk sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996)

[3] The maximum historic reference 95th percentile value from among upper and lower Hazeltine Creek is displayed for each parameter. For calculation of Historic Reference 95th percentiles see Minnow (2015).

Table D.3: Raw sediment quality data for Quesnel Lake littoral sampling areas, Mount Polley Mine, 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion. Values for exposed sites shown in bold text also exceed all Reference 95th Percentile values.

[1] Reported moisture, pH, and total nitrogen data are based on bulk sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Summary statistics are reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996)

[3] 2015 Reference 95th percentiles were calculated using displayed data, for calculation of 2014 Reference 95th percentiles see Minnow (2015). The 5th percentile is reported for pH.

[4] The maximum reference 95th percentile value from among reference areas sampled in 2014 (PREF1 and PREF2) is displayed for each parameter. Refer to Minnow (2015) for raw data.

Table D.4: Raw sediment quality data for Quesnel Lake profundal sampling areas, Mount Polley Mine, 2015. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Re: Sediment and Sediment Porewater Quality Data Report - August 2016 Collections

Sediment quality monitoring is a key component of the ongoing impact assessment of the Mount Polley Mine Tailings Storage Facility (TSF) breach of August 4th 2014. Sediment quality of lakes and creeks affected by the breach was characterized in 2014 and again in 2015, and documented a chemical impact within the debris flow path, particularly at deep (settling) areas of Polley Lake and Quesnel Lake (Minnow 2015a,b). Beyond basic sediment chemistry (i.e., total concentrations of metals in sediment), a number of chemical and biological techniques have been applied to gain understanding of the mobility, bioavailability and potential toxicity of sediment-associated metals (e.g., selective extractions, metal to sulphide ratios, sediment porewater concentrations, labile metal concentrations, sediment toxicity testing, benthic invertebrate community assessment). This memorandum summarizes the results of sediment quality monitoring undertaken in 2016, and includes sediment quality data and sediment porewater quality data.

Methods

Sediment samples were collected between August 4th and 29th 2016 from lakes in the vicinity of the Mount Polley Mine (Polley Lake, Bootjack Lake, and Quesnel Lake) and from the Hazeltine Creek Sedimentation Pond (Figures 1 and 2) for three purposes (Table 1): 1) to characterize/verify sediment and porewater chemistry at locations sampled in 2014 and/or 2015; 2) to provide additional data for mapping the spatial extent of the influence of the TSF breach on sediment quality; and 3) to provide supporting data for a sediment toxicity investigation which will be reported separately.

To address the first purpose, sediment samples were collected from the same stations monitored in 2014 and 2015 (Table 1; Figure 1; Minnow 2015a, 2015b), using the same

Table 1: Overview of sediment and porewater quality sampling in the vicinity of the Mount Polley Mine, August 2016.

Program Component	Objective	Waterbody Area	Area Type	Area Codes	Analyses
Monitoring	Characterize sediment and porewater quality at locations sampled in 2014 and/or 2015, and provide temporal comparisons of sediment quality among years.	Polley Lake - Deep	Exposed	POL-P1 POL-P2	Sediment Quality (n=5 per area) [1] Porewater Quality (n=3 per area) [2]

methods, where possible [1] (Appendix Table A.1). Data were then used to assess current sediment and porewater quality, and to provide temporal comparisons of sediment quality to previous sampling events (2014 and 2015). Data from impacted areas was compared to reference, but there are no pre-event data from Quesnel Lake representing background. To address the second purpose, a total of 17 new stations (or "in-fill" stations) were sampled to provide greater spatial coverage and resolution within the impacted area (Table 1; Figure 2). The entire sediment quality dataset, including the infill stations, will then be used, working in collaboration with Golder Associates, to produce sediment concentration maps for key parameters in order to depict the spatial extent of sediment quality impact from the TSF breach. The third purpose will be addressed using data for the sediments collected under purpose 1 and with additional data from a total of 10 new stations (or "intermediate" stations; Table 1; Figure 2). Based on previous data, intermediate stations were selected to provide samples with sediment physical and chemical characteristics (particularly in terms of texture, organic content and metal concentrations) that were not well represented in previous monitoring. These samples will be used to strengthen an evaluation of the influence of sediment characteristics on sediment toxicity.

Sampling

In Polley and Bootjack lakes, sediments for the analysis of total metals, moisture, pH, total organic carbon (TOC), total nitrogen, and total sulphur were collected using a Tech Ops corer or Kajak-Brinkhurst (KB) corer, with the exception of two sampling stations where samples were collected using a petite ponar (Appendix Tables A.1 - A.2). All core samples were collected in accordance with technical guidance for gravity coring outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for Environmental Effects Monitoring (EEM; Environment Canada 2012). Briefly, upon collection, core samples were inspected and if deemed acceptable, were extruded into a core collar, cut using a core knife to collect the top 3 cm of sediment, and transferred into a 250 mL glass sampling jar labeled with the project number, sample location and collection date. The procedure was then repeated to provide a composite sample of sufficient volume for the required analyses (Appendix Table A.1). Sediments for the analysis of particle size distribution and porewater were collected using a petite (15.24 cm x 15.24 cm; 0.023 m^2 sampling area) or standard (22.86 cm x 22.86 cm; 0.052 m^2 sampling area) ponar grab sampler in accordance with technical guidance outlined in the British

[1] Four sampling stations were relocated to better match the dominant sediment physical characteristics within respective sampling areas (stations PNF-4 and PNF-5 in the Quesnel Lake deep area, and stations LNF1-1 and LFF-1 in the Quesnel Lake shallow area).

Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for Environmental Effects Monitoring (EEM; Environment Canada 2012). In Polley Lake (mean depth approximately 30 meters), grab samples were collected with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). At each station, composite samples of the top three centimeters of surficial sediment of two to ten acceptable grabs (i.e., full to each edge of the sampler) were collected (Appendix Table A.1). Each grab was collected into a plastic tote and observed for completeness and any unusual characteristics. If the sample was deemed acceptable, surficial material to a depth of 3 centimeters was transferred to a second tote using a stainless steel spoon. Remaining sediment was discarded. The procedure was then repeated for all subsequent grabs. The material within the tote was homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars for particle size analysis or into large sealable bags (double-bagged) for porewater extraction and analysis, with each container labeled with the project number, sample location and collection date. All sampling equipment was rinsed between stations using site water. Replicate stations within each area were sampled as outlined in Table 1.

In Quesnel Lake, sediment samples from deep habitats (mean depth approximately 100 meters) were collected using either a petite or standard ponar grab sampler with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). Samples collected from shallow habitats were collected using a petite ponar only (Appendix Table A.1). All grab samples were collected in accordance with technical guidance outlined in the British Columbia Field Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for EEM (Environment Canada 2012). At each station, composite samples of the top three centimeters of surficial sediment of five to twelve acceptable grab samples (i.e., full to each edge of the sampler) were collected as described above for grab sampling in Polley and Bootjack lakes (Appendix Table A.1). Upon collection, the surficial material was homogenized using a stainless steel spoon and transferred into 250 mL glass sampling jars for sediment quality parameters (total metals, particle size, moisture, pH, TOC, total nitrogen, and total sulphur) or into large sealable bags (double-bagged) for porewater extraction and analysis, each labeled with the project number, sample location and collection date. All sampling equipment was rinsed between stations using site water. Replicate stations were sampled to represent each monitoring area (Table 1).

Sediment samples from the upper Sedimentation Pond were collected using a petite ponar grab sampler in accordance with technical guidance outlined in the British Columbia Field

Sampling Manual (BCWLAP 2003) and the federal Technical Guidance Manual for EEM (Environment Canada 2012). Sampling was conducted as described above for Quesnel Lake, with a composite sample of the top three centimeters of surficial sediment of ten to fifteen acceptable grabs collected from each station (Appendix Table A.1). Samples were then transferred into 250 mL glass sampling jars for sediment quality analyses or into large sealable bags (double-bagged) for porewater extraction and analysis, each labeled with the project number, sample location and collection date. As outlined in the Mount Polley Mine Comprehensive Environmental Monitoring Plan (CEMP; MPMC 2016), sediment quality parameters for the Hazeltine Creek Sedimentation Pond included oil & grease and polycyclic aromatic hydrocarbon (PAH) analyses (Table 1). Five replicate stations were sampled to represent the area (Table 1).

Spatial extent “in-fill” samples were collected from locations selected to increase spatial coverage in Quesnel Lake and Polley Lake (Appendix Table A.2) for the purposes of concentration mapping. Samples were collected using the same methods described above for sampling within each of these waterbodies, with the exception that samples from Quesnel Lake consisted of one to two acceptable grabs per composite (Appendix Table A.2). Four of the twenty-one selected locations could not be sampled due to inappropriate substrate type, despite multiple sampling attempts at the sampling location, and in the area immediately surrounding it (Appendix Table A.2). Lastly, sediment toxicity “intermediate” samples were collected as described above from ten deep locations in Quesnel Lake (Table 1) using a petite ponar with the assistance of a commercial line hauler (Ace Line Hauler - Brutus Plus 40). Samples collected for this purpose consisted of five to nine acceptable grabs (Appendix Table A.2).

Field duplicate (split) sediment samples were collected at a frequency of 10% for quality assurance/quality control (QA/QC) purposes. Supporting information collected at each of the monitoring stations (Appendix Tables A.1 to A.3) included GPS (Geographic Positioning System) coordinates, sampling depth, Secchi depth (lakes only), field meter measurements of temperature, specific conductance, dissolved oxygen and pH (using a YSI EXO™ handheld portable field meter equipped with YSI EXO2™ Sonde), site photographs (including photographs of sediment samples), notes of the presence or absence of aquatic vegetation, and other physical observations (sediment texture, colour, density, etc.). Immediately after collection, all sediment samples were placed into a cooler with ice packs, where they were maintained cool prior to transport to the field laboratory, where they were placed in a refrigerator and held until shipment to the analytical laboratory. All sediment

samples were shipped to the analytical laboratory (ALS Environmental, Burnaby BC) at a minimum frequency of bi-weekly. Prior to shipment, samples were placed in a cooler with frozen ice packs and a chain-of custody form was prepared and packed with the samples. Coolers were shipped overnight for next day delivery to ALS Environmental.

Laboratory Analysis

Upon receipt, ALS Environmental opened the coolers, measured temperature to verify the maintenance of cold samples, removed each sample from the coolers, logged the sample, and assigned each sample a unique sample identification code. A sample receipt confirmation was then sent to Mount Polley and Minnow for verification.

Laboratory analysis for sediment quality included moisture content, pH, particle size distribution, TOC, total nitrogen, total sulphur, and total metal concentrations. For sediment samples collected from the upper Hazeltine Creek Sedimentation Pond, laboratory analyses also included oil and grease, and PAHs. Total organic carbon content and total metal concentrations were determined in the silt/clay fraction (<63 µm diameter) in accordance with recent recommendations by the British Columbia Ministry of Environment (BCMoE 2012) and because sediment quality characterization conducted in 2014 indicated similar results in <63 µm and <2 mm sediments (Minnow 2015a).

Sediment samples for porewater extraction and analysis were homogenized and centrifuged (using a ThermoFisher Scientific Sorvall™ ST 40 centrifuge) at 2500 rpm for 10 minutes to separate water and solids. The supernatant (water) was then removed by pipette and subjected to chemical analysis for hardness, dissolved organic carbon, alkalinity, anions (including nitrate, nitrite, and sulphate), and dissolved metals. Supernatant collected for all analytes except alkalinity was filtered using a 0.45µm membrane filter.

Upon completion of the analyses, data reports were provided by ALS Environmental to MPMC and Minnow electronically in Adobe Acrobat Portable Document Format (PDF) and as MSExcel files (Appendix B).

Data Analysis

Upon receipt of the analytical data, a Data Quality Assessment (DQA) was completed, including an examination of data completeness, method detection limits achieved, laboratory precision, laboratory accuracy, and field precision. Following the completion of the DQA, sediment and porewater quality data were summarized by area, by calculating mean, median, standard deviation, standard error, 95% confidence limits, minimum, and

maximum. Sediment quality data from exposed areas were then evaluated in comparison to Contaminated Sites Regulation (CSR) criteria (Government of British Columbia 1996) and reference concentrations, while porewater quality data from exposed areas were evaluated relative to reference concentrations.

CSR criteria have been defined for a limited number of analytes (including seven metals) for sensitive and typical sediment environments (Schedule 9; Government of British Columbia 1996) and are used to determine if sediments are contaminated. Sensitive sediment is defined as sediment at a site with sensitive aquatic habitat (e.g., spawning habitat) and for which sensitive management objectives apply, and typically apply to the ecologically active zone (top one meter) of sediments in an aquatic receiving environment (BCMoE 2013). Typical sediment is defined as any sediment that is not sensitive sediment (BCMoE 2013). For the purposes of this memorandum, sediment from all waterbodies (with the exception of the Hazeltine Creek Sedimentation Pond) were evaluated in comparison to CSR criteria for both sensitive and typical sediments. The Hazeltine Creek Sedimentation Pond is a man-made, regularly maintained waterbody or "maintained watercourse" (BCMoE 2013), therefore sediments from this area were evaluated relative to CSR "typical" criteria.

Reference values for sediment quality data contained within this memorandum fall into two categories - pre-event data (i.e., those collected between 1989 and 2013; available for Polley Lake and Hazeltine Creek) and data collected at reference sites between 2014 and 2016. Pre-event and reference data were compiled separately and used to calculate reference screening values. For each pre-event dataset (for each area; Table 1), 95th percentile values were calculated based on all compiled data from prior to 2014 (Minnow 2015a) [2]. For each reference dataset (i.e., 2014, 2015, or 2016), 95th percentile values were calculated for each reference area. These 95th percentile pre-event values (where available) and reference values were then compared within each area (Table 1), and the highest value for each analyte among them was used to screen data from exposed areas to identify analytes present at concentrations greater than pre-event and/or reference. For porewater samples, reference 95th percentile values were calculated for each area using 2016 data (Table 1). For the majority of areas, porewater samples were collected for the first time in 2016, therefore pre-event data and prior reference data is not available. The calculated reference values were then used to screen data from exposed areas to identify

[2] One pre-event 95th percentile value was calculated for each sampling area type (i.e., Polley Lake mid-depth and deep, and upper and lower Hazeltine Creek) from all compiled pre-event data (i.e. prior to 2014). See Minnow (2015a) for raw data and calculations.

analytes present at concentrations greater than reference, with the exception of the upper Hazeltine Creek Sedimentation Pond for which there is no associated reference area.

Principal component analysis (PCA) was also used to assist with the interpretation of general trends and patterns of variability in sediment and porewater quality data between exposed-reference area pairs, and was completed for all areas with the exception of the Hazeltine Creek Sedimentation Pond. Prior to analysis, data were screened to ensure that any variables with no variation (e.g., those that were not detectable) were removed from the data matrix, and data were log transformed ($log_{10}[x+1]$). Principal component axes were then generated from the correlation matrix of the sediment quality or porewater quality variables using the program PC-ORD© version 6 (McCune and Mefford 2011). Scores for each station were subsequently plotted for inspection.

As a means of evaluating the relative enrichment of metals in sediment and porewater, ratios of mean metal concentrations in each exposed area relative to the associated reference were calculated for both of these media (enrichment factors) and then compared. The relative enrichment factors were considered in light of potential redox changes caused during sampling, sample homogenization, porewater extraction, filtering and analysis.

Results

Data Quality Assessment indicated acceptable sediment and sediment porewater data quality, meaning that data can be used with a high level of confidence for interpretation and the derivation of conclusions (Appendix C).

Polley Lake

Sediment collected from deep monitoring areas of Polley Lake in 2016 (POL-P1 and POL-P2; Figure 1) was almost entirely silt and clay (99.5%). The particle size distribution of these sediments was very similar to those collected in 2014 and 2015, as well as to sediments from deep areas of the reference lake (Bootjack Lake; Table 2; Appendix Table D.1). Sediment collected from mid-depth areas of Polley Lake (POL-1 and POL-2; Figure 1) was also predominantly silt and clay (> 93.0%), with a similar particle size distribution to samples collected in 2014, as well as to associated reference sediments (BOL-1; Figure 1; Table 2; Appendix Table D.2). As observed in previous years, TOC and total nitrogen content were lower in sediments from Polley Lake than in associated reference sediments (Table 2; Appendix Tables D.1 - D.2).

Table 2: Summary sediment quality data for Polley Lake and Bootjack Lake sampling areas, Mount Polley Mine, 2014 - 2016. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion.

Bolded: Value for exposed site exceeds all Reference 95th Percentile values (< 5th percentile for pH).

[1] Reported moisture, pH, total sulphur and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Means were reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] The maximum reference 95th percentile value of those presented in Tables D.1 and D.2 is displayed for each parameter. For raw 2016 reference data see Appendix Tables D.1 and D.2, for all others see Minnow (2015a) and Minnow (2015b). The 5th percentile is reported for pH.

[4] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

Mean metal concentrations in sediment from the deep areas of Polley Lake were very similar to those observed in previous sampling years (2014 for POL-P1; 2014 and 2015 for POL-P2; Table 2). Manganese concentrations increased between 2014 and 2016 at the south deep sampling area (POL-P2), but were lower than reference (Table 2). Metals identified by the sediment PCA as explaining separation of exposed and reference sediments from deep areas and mid-depth areas (separation primarily along PCA Axis 1; 66.3% and 61.6% variance, respectively) agreed well with the POIs and IPs previously identified for this area (arsenic, copper, iron and zinc; calcium, molybdenum, sodium, strontium tin and titanium; Minnow 2015a), with the exception that iron, molybdenum, and zinc were not identified in the PCA of 2016 data (Appendix Tables D.3 – D.6; Appendix Figures D.1 - D.2).

Arsenic and copper were the only analytes in sediment collected from deep and mid-depth areas of Polley Lake in 2016 with concentrations greater than the CSR “sensitive” criteria (Table 2; Appendix Tables D.1 - D.2). Mean arsenic concentrations exceeded the CSR “sensitive” criterion at all deep sampling areas, and at the south mid-depth area (POL-2; Figure 1), as well as reference concentrations at the deep areas only (Table 2; Figure 3; Appendix Table D.2). Copper was the only analyte with concentrations greater than the CSR “typical” criterion and reference in all Polley Lake areas (deep and mid-depth), except at the mid-depth area POL-1 where it exceeded the CSR “typical” criterion, but not reference (Table 2). It is of note that copper in reference sediment, and in Polley Lake sediment prior to the dam failure (mid-depth and deep areas), naturally exceeded the CSR “typical” criterion (Appendix Tables D.1 - D.2). Mean copper concentrations in sediment collected from Polley Lake in 2016 exceeded the CSR “typical” criterion by up to approximately 2.9 times in deep areas, and up to approximately 2.3 times in mid-depth areas, while associated reference values were exceeded by up to approximately 1.7 and 1.1 times, respectively (Table 2).

Arsenic and copper were also the only analytes to exceed the CSR “sensitive” criterion in sediment collected for the purposes of spatial extent “in-fill” in Polley Lake (3 samples; Figure 2), with exceedances of these criteria occurring in two of the three collected samples (Appendix Table D.7). Copper concentrations also exceeded the CSR “typical” criterion in these two samples by up to approximately 3 times (Appendix Table D.7).

Mean porewater concentrations of arsenic and copper in Polley Lake deep and mid-depth areas also exceeded reference values (Table 3; Appendix Tables E.1 - E.2). Porewater copper concentrations were higher in mid-depth areas than in deep areas (Table 3), which

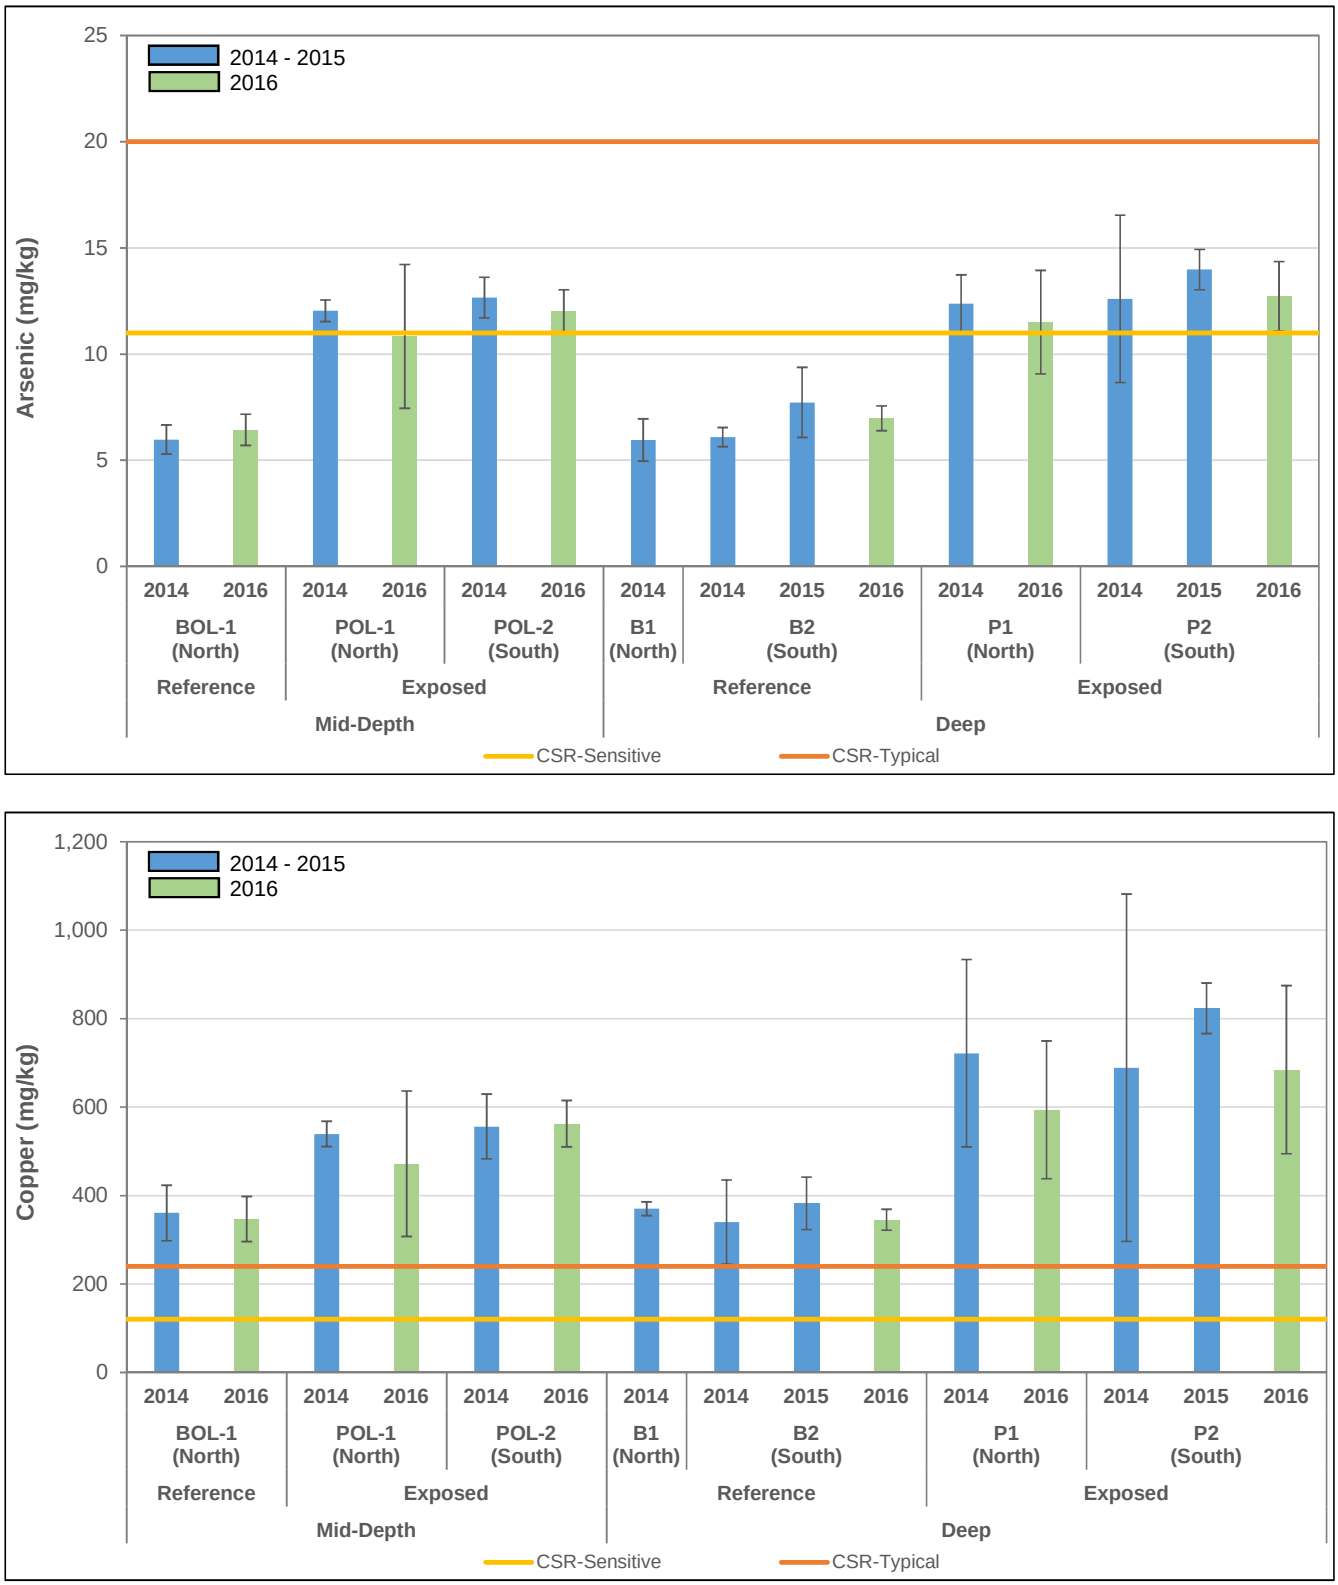

Figure 3: Mean arsenic and copper concentrations (± t*SE) in sediment (< 63µm fraction) from mid-depth and deep sampling areas in Polley Lake and an associated reference area (Bootjack Lake), Mount Polley Mine, 2014 - 2016.

CSR = Contaminated Sites Regulation (Government of British Columbia 1996).

Table 3: Summary porewater quality data for Polley Lake and Bootjack Lake sampling areas, Mount Polley Mine, 2016 [1].

Bolded: Exceeds 95th percentile of reference data.

[1] Summary statistics were calculated using method detection limit (MDL) values if data were below the MDL. Means were reported as < MDL if all data used in their calculation were < MDL. If MDLs were variable, the mean was reported as < the maximum MDL.

[2] Calculated from 2016 reference data; for raw data see Appendix Tables E.1 and E.2.

[3] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

is the opposite of sediment copper concentrations in these areas (Table 2). Metals identified by PCA as important in explaining the separation of exposed and reference porewater results from deep Polley Lake areas included the nickel, selenium, uranium, vanadium and zinc (Appendix Tables E.3 - E.4; Appendix Figure E.1). In the mid-depth areas, key metals identified by PCA of porewater included arsenic, calcium, cobalt, molybdenum, strontium, and zinc (Appendix Tables E.5 - E.6; Appendix Figure E.2). Results of these two PCAs agreed moderately well with the POIs and IPs identified for these areas in 2014 (Minnow 2015a), as well as with associated sediment PCA results (Appendix Tables D.3 - D.6; Appendix Figures D.1 - D.2). Of the metals that were common in best explaining exposed-reference area variability in porewater (nickel, selenium, uranium, and zinc), zinc was previously identified as a POI for Polley Lake, and both nickel and selenium were identified as POIs or IPs for other sampling areas (Minnow 2015a). Comparison of enrichment factors (exposed concentrations versus reference concentrations) in porewater and sediment indicated that arsenic and copper enrichment in porewater from deep and mid-depth areas of Polley Lake was either lower or similar to enrichment of these metals in sediment (Appendix Table F.1). Higher enrichment factors in porewater than in sediment were observed for a number of POIs, IPs, and parameters identified by porewater PCA (i.e., calcium, iron, molybdenum, nickel, selenium, strontium, uranium, and zinc; Appendix Table F.1). Lower enrichment in porewater (than in sediment) suggests limited mobility, whereas higher enrichment in porewater suggests potential mobility. However, due to the critical importance of changes in redox in influencing porewater chemistry/metal mobility, these findings must be verified by the results of porewater studies that were completed in August 2016 under redox-controlled conditions (to be reported separately).

Quesnel Lake Deep

Sediment was collected from five stations in the Quesnel Lake deep near-field area in 2016 (Figure 1; Table 1). The placement of these stations was supported by previous characterization of the spatial impact of the TSF breach (Minnow 2015a), and further confirmed by a sediment distribution study undertaken in support of the Mount Polley Mine Phase 1 Environmental Effects Monitoring conducted in April, 2016 (Minnow 2016a). The latter confirmed the appropriate placement of the deep near-field area stations, as the success and fullness of grab samples increased with depth. Specifically, fine grained sediment samples could be consistently collected by grab sampling only at lake depths of 70 ± 17 m or more, while sampling attempts at shallower depths returned cobble, woody

debris, coarse sand, and/or only a very small amount of sediment (Appendix Figure A.1 and Appendix Table A.4).

Sediment collected from the Quesnel Lake deep near-field area in 2016 was composed almost entirely of silt and clay (98.2%). Samples collected in 2016 from this area had higher average clay content (51.1%) than those collected in 2014 and 2015 (22.6 and 35.5%, respectively) due to the relocation of two stations in an effort to achieve more uniformity in sediment texture within the area (see Methods section). Sediment collected from the deep far-field area had higher clay content (32.6%) relative to samples from 2014 at this location (15.5%), and higher clay and lower sand (0.39%) content than observed at the reference area (10.9% clay; 19.8% sand). As observed in previous years, the TOC content of sediment from both the deep near-field (0.35%) and far-field (0.15%) sampling areas was lower than in the reference area (1.92%). Total nitrogen was similarly low in the exposed areas (0.039% in near-field, 0.024% in far-field) relative to reference (0.16%; Table 4; Appendix Table D.8).

Mean concentrations of the majority of metals in sediment were higher in 2016 than in 2014 and 2015 in the deep near-field area (Table 4; Figure 4). This difference is due to the relocation of two stations in 2016, which resulted in higher metal concentrations for these stations and higher mean values for the area. In the far-field deep area, sediment metal concentrations were very similar in 2016 and 2014, with the exception of potassium and sodium whose concentrations were approximately 2.0 and 2.1 times those reported in 2014, and more similar to those reported for the deep near-field area (Table 4). These apparent increases may be due to the higher clay content of sediment collected in this area in 2016 relative to 2014, with clay content of these sediments in 2016 being more similar to the near-field area. Metals identified by the sediment PCA as explaining separation of exposed and reference sediments from deep areas of Quesnel Lake (separation primarily along PCA Axis 1; 69.0% variance) agreed well with the POIs and IPs previously identified for this area (copper, calcium, sodium, strontium and tin; Minnow 2015a; Appendix Tables D.9 - D.10; Appendix Figure D.3).

As observed in Polley Lake, arsenic and copper were the only analytes in 2016 to exceed the CSR “sensitive” criteria in sediment from the deep near-field and far-field areas of Quesnel Lake (Table 4; Figure 4; Appendix Table D.8). Mean arsenic concentrations in both areas exceeded results from Reference Area 1 (PREF1; Figure 4); however were similar to results from Reference Area 2 in 2014 (PREF2; Figure 4). The elevated arsenic concentrations at Reference Area 2 suggest that arsenic concentrations may be naturally

Table 4: Summary of sediment quality for Quesnel Lake deep sampling areas, Mount Polley Mine, 2014 - 2016. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion.

Bolded: Value for exposed site exceeds all Reference 95th Percentile values (< 5th percentile for pH).

[1] Reported moisture, pH, total nitrogen, and total sulphur data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Means were reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] The maximum reference 95th percentile value of those presented in Appendix Table D.8 is displayed for each parameter. For raw 2016 reference data see Appendix Table D.8, for all others see Minnow (2015a) and Minnow (2015b). The 5th percentile is reported for pH.

[4] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

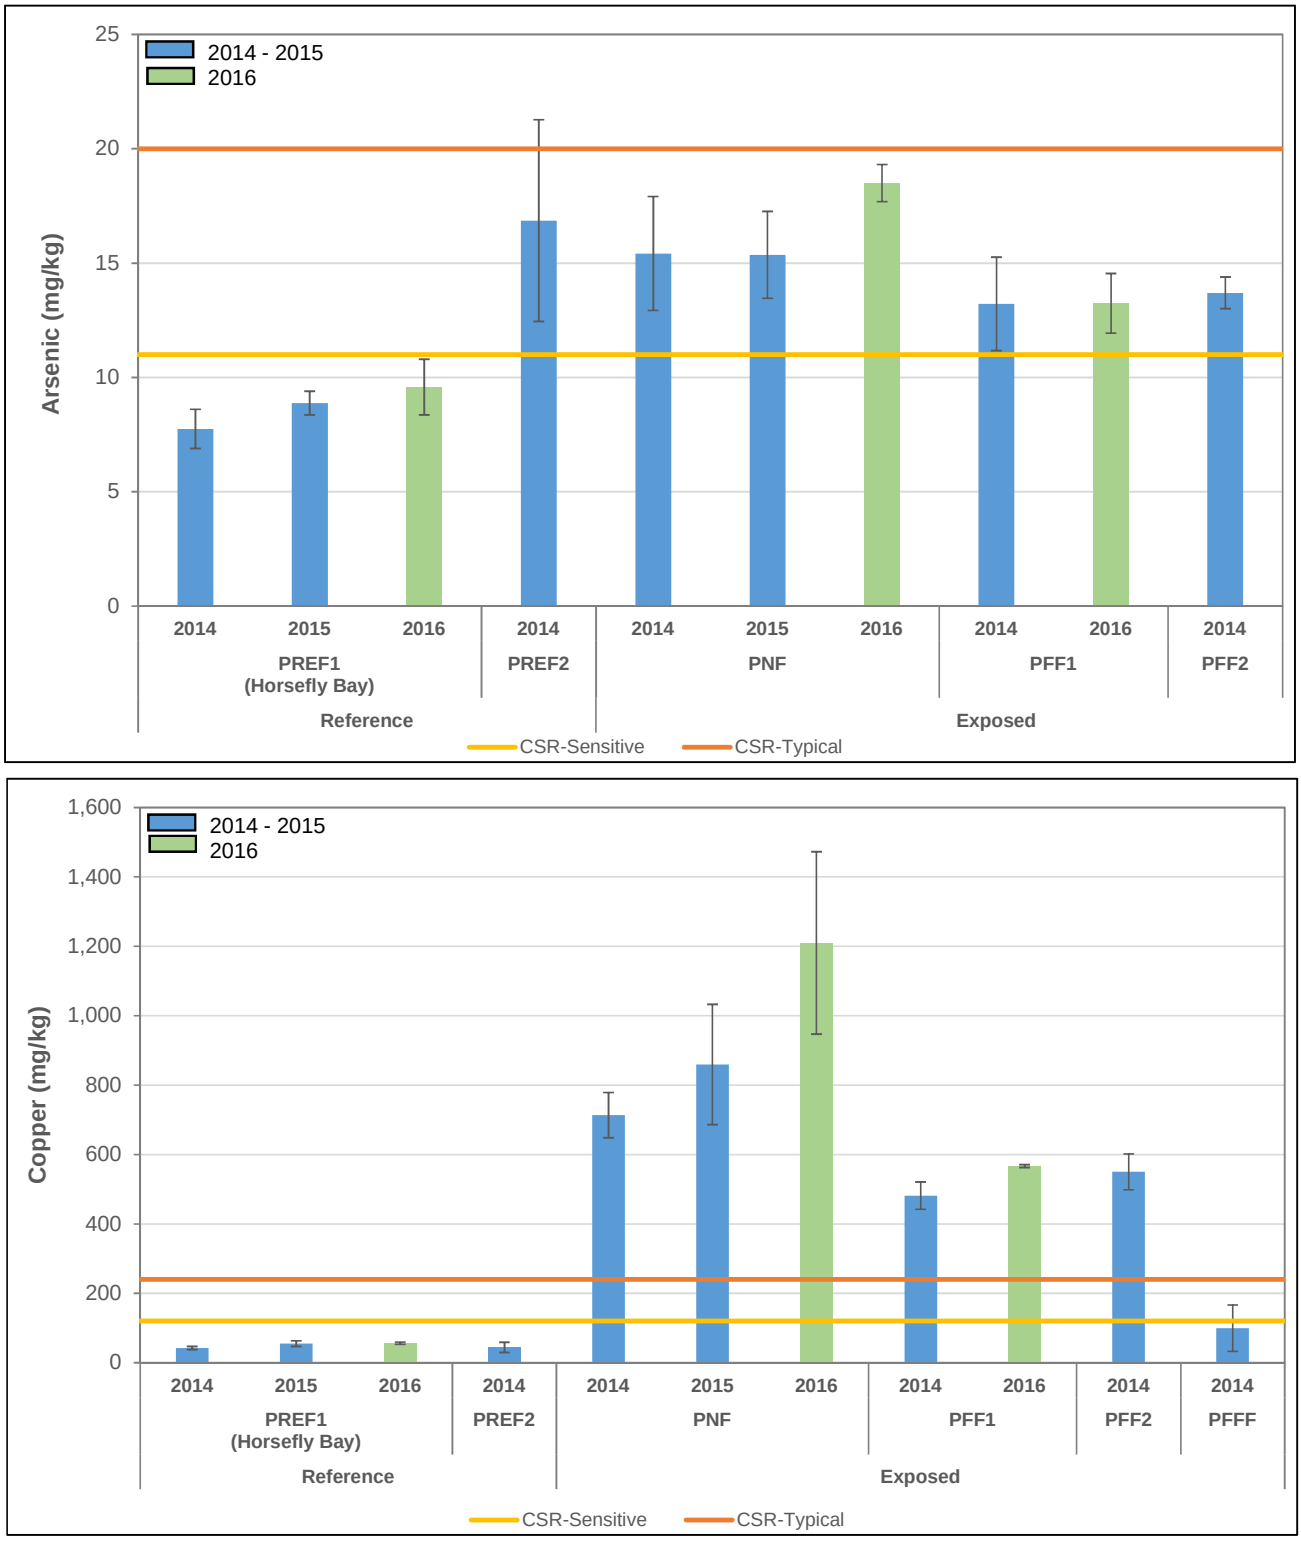

Figure 4: Mean arsenic and copper concentrations (± t*SE) in sediment (< 63µm fraction) from deep sampling areas in Quesnel Lake, Mount Polley Mine, 2014 - 2016.

CSR = Contaminated Sites Regulation (Government of British Columbia 1996).

Note: For ease of display, results from the PFFF area (2014; mean arsenic concentration = 89.2 ± 61.6 mg/kg) have been omitted from the arsenic plot.

elevated at some areas of Quesnel Lake, which is consistent with elevated arsenic concentrations noted in regional stream sediments (MPMC 2015). Similar to 2014, copper exceeded the CSR "typical" criterion and reference in sediment from both the deep near-field and far-field areas; by approximately 5.0 and 2.4 times, and 19.9 and 9.3 times on average, respectively (Table 4). Mean sediment concentrations of most metals in the far-field area were lower than in the near-field area in 2016. In particular, copper was approximately 2.1 times lower in sediment from the far-field than the near-field area, on average, and mean arsenic concentrations were similar between the areas (Table 4; Figure 4).

Arsenic, chromium, and copper were the only analytes in sediment collected for the purposes of spatial extent "in-fill" or sediment toxicity "intermediates" to exceed the CSR criteria (Appendix Tables D.11 - D.12). Specifically, twenty one, five, and fourteen of the twenty four collected samples exceeded the "sensitive" criteria for arsenic, chromium, and copper, respectively. A further nine, one, and ten of these samples also exceeded the "typical" criteria for arsenic, chromium, and copper, by up to 2.4, 1.2, and 5.1 times, respectively (Appendix Tables D.11 - D.12). In all instances except one, if chromium concentrations exceeded either CSR criterion, copper concentrations exceeded neither, suggesting that sediment from locations with elevated chromium concentrations are not substantially affected by the TSF breach.

Porewater copper concentrations in the deep near-field and far-field areas exceeded reference, however arsenic concentrations did not, suggesting low mobility (Table 5; Appendix Table E.7). Despite the approximately 2-fold difference in copper sediment concentrations between the near-field and far-field areas, mean porewater copper concentrations at these two areas were very similar (Table 5). Metals identified by PCA as important in explaining the separation of exposed and reference porewater results from Quesnel Lake deep areas included magnesium, potassium, and uranium (not previously identified as POIs or IPs), and the IPs calcium, sodium and strontium (Appendix Tables E.8 - E.9; Appendix Figure E.3). Porewater enrichment of POIs, IPs and parameters identified by porewater PCA in the deep near-field and far-field areas was generally lower than in sediment (with the exception of sodium; Appendix Table F.2). Of the POIs, IPs, and parameters identified by porewater PCA, higher enrichment factors in porewater than in sediment were only observed for sodium and uranium (Appendix Table F.2). Lower enrichment in porewater (than in sediment) suggests limited mobility, whereas higher enrichment in porewater suggests potential mobility. Limited mobility of POIs and IPs is

Table 5: Summary porewater quality data for Quesnel Lake deep sampling areas, Mount Polley Mine, 2016 [1].

Bolded: Exceeds 95th percentile of reference data.

[1] Summary statistics were calculated using method detection limit (MDL) values if data were below the MDL. Means were reported as < MDL if all data used in their calculation were < MDL. If MDLs were variable, the mean was reported as < the maximum MDL.

[2] Calculated from 2016 reference data; for raw data see Appendix Table E.7.

[3] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

consistent with the findings of a number of previous evaluations indicating low mobility of metals in tailings and tailings-influenced sediment (e.g., SRK 2015a; SRK 2015b; Minnow 2015a; Minnow 2016b). However, as noted above, due to the critical importance of changes in redox in influencing porewater chemistry/metal mobility, these findings must be verified by the results of porewater studies that were completed in August 2016 under redox-controlled conditions (to be reported separately).

Quesnel Lake Shallow

Sediment collected from the shallow near-field area of Quesnel Lake in 2016 (LNF1; Figure 1) was predominantly sand (89.2%), which, while similar to the sand content of samples collected from this location in 2015, remains higher than observed in 2014 (49.2%), or at the associated reference area in 2016 (64.0%; Table 6; Appendix Table D.13). The high sand content of substrate from this area was visually evident during sample collection in both 2015 and 2016, and is likely a result of continued washing of fine substrates from these shallow sampling locations [3]. The particle size distribution of sediment collected in the littoral far-field area (LFF; Figure 1) was similar in 2016 to the two previous years, and to sediment collected in the shallow reference area. Sediment TOC and total nitrogen content were lower in the near-field area than in the far-field or reference areas, which is consistent with the larger mean particle size in this area, and was also observed during previous sampling years (Table 6; Appendix Table D.13).

Mean sediment metal concentrations in the near-field area were generally similar among the three sampling years (2014-2016) despite the differences in particle size distribution (Table 6). This similarity is likely due to the analysis of metals in the fines fraction (<63 µm) rather than bulk sediment, suggesting that fines remaining in the near-field area were affected by the TSF breach. It is important to note, however, that aquatic organisms inhabiting this sediment would be exposed to the whole sediment, not solely the fines (<63 µm fraction). Mean concentrations of chromium, iron, and vanadium were higher in the near-field area in 2016 relative to 2014 (2.3 times higher, on average), with iron and vanadium concentrations (previously identified as IPs) also exceeding reference values by approximately 2.9 and 9.1 times, respectively (Table 6). Conversely, sediment concentrations of barium, potassium, sodium, and strontium were lower in 2016 relative to

[3] Near-field locations for sediment sampling in 2016 were the same as those sampled in 2014 and 2015, with the exception of station LNF1-1. Whereas sand had been the dominant substrate during 2015 sediment sampling at this location, cobble was the predominant substrate in 2016. Therefore, this station was relocated due to the absence of appropriate substrate for sediment sampling.

Table 6: Summary of sediment quality data for Quesnel Lake shallow sampling areas, Mount Polley Mine, 2014 - 2016. Metals and total organic carbon data are based on the < 63µm fraction of sediment[1].

Value is > Contaminated Sites Regulation (CSR) Sensitive Criterion.

Value is > Contaminated Sites Regulation (CSR) Typical Criterion.

Bolded: Value for exposed site exceeds all Reference 95th Percentile values (< 5th percentile for pH).

[1] Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Means were reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] The maximum reference 95th percentile value of those presented in Appendix Table D.13 is displayed for each parameter. For raw 2016 reference data see Appendix Table D.13, for all others see Minnow (2015a) and Minnow (2015b). The 5th percentile is reported for pH.

[4] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

2014 (2.0 - 2.6 times lower). These differences may be indicative of the continued movement of fines from the shallow near-field area as discussed above. In the shallow far-field area, mean metal concentrations were generally similar among sampling years, with the exception of increases in copper, calcium, molybdenum, and strontium relative to 2014 (approximately 2.1 to 3.3 times higher than 2014 concentrations), all of which were identified either as POIs or IPs in 2014 (Minnow 2015a). Concentrations of these four analytes exceeded reference in 2016, but did not exceed reference in 2014 or 2015 (Table 6; Appendix Table D.13). Metals identified by the sediment PCA as explaining separation of exposed and reference sediments from shallow areas of Quesnel Lake (separation primarily along PCA Axis 1; 47.2% variance) generally agreed with the POIs (arsenic, copper, iron and manganese) and moderately well with the IPs identified for this area (barium, calcium, mercury, molybdenum, selenium, silver, sodium, strontium, tin and vanadium; Minnow 2015a; Appendix Tables D.14 - D.15; Appendix Figure D.4).

As observed in both Polley Lake and in the Quesnel Lake deep exposed areas, mean arsenic and copper concentrations in sediment from the shallow near-field area of Quesnel Lake exceeded CSR “sensitive” criteria and reference. Copper concentrations also exceeded the CSR “typical” criterion (by approximately 2.7 times on average; Table 6). Results from 2016 for arsenic and copper are consistent with those from both 2014 and 2015 in the near-field sampling area (Table 6; Figure 5; Appendix Table D.13). Mean sediment metal concentrations in the shallow far-field area in 2016 did not exceed CSR criteria, although copper concentrations were higher than reference, as also observed in 2015 (Table 6). Sediment metal concentrations were generally lower in the far-field area in 2016 than in the near-field, with mean arsenic and copper concentrations being approximately 3.4 and 9.5 times lower, respectively (Table 6; Figure 5).

Similar to the Quesnel Lake deep areas, porewater copper concentrations from the shallow near-field area exceeded reference, but arsenic concentrations did not, suggesting low arsenic mobility in this area. In the far-field area, porewater concentrations of both copper and arsenic exceeded reference (Table 7; Appendix Table E.11). Metals identified by PCA as important in explaining separation of exposed and reference porewater results from shallow Quesnel Lake areas included the copper, silver, selenium, and tin (Appendix Tables E.12 - E.13; Appendix Figure E.4), which agreed well with the POIs and IPs identified for this area in 2014 (Minnow 2015a) and with sediment PCA results for the same areas (Appendix Tables D.14 - D.15; Appendix Figure D.4). Despite elevation of porewater copper concentrations above reference in both shallow exposed areas of Quesnel Lake

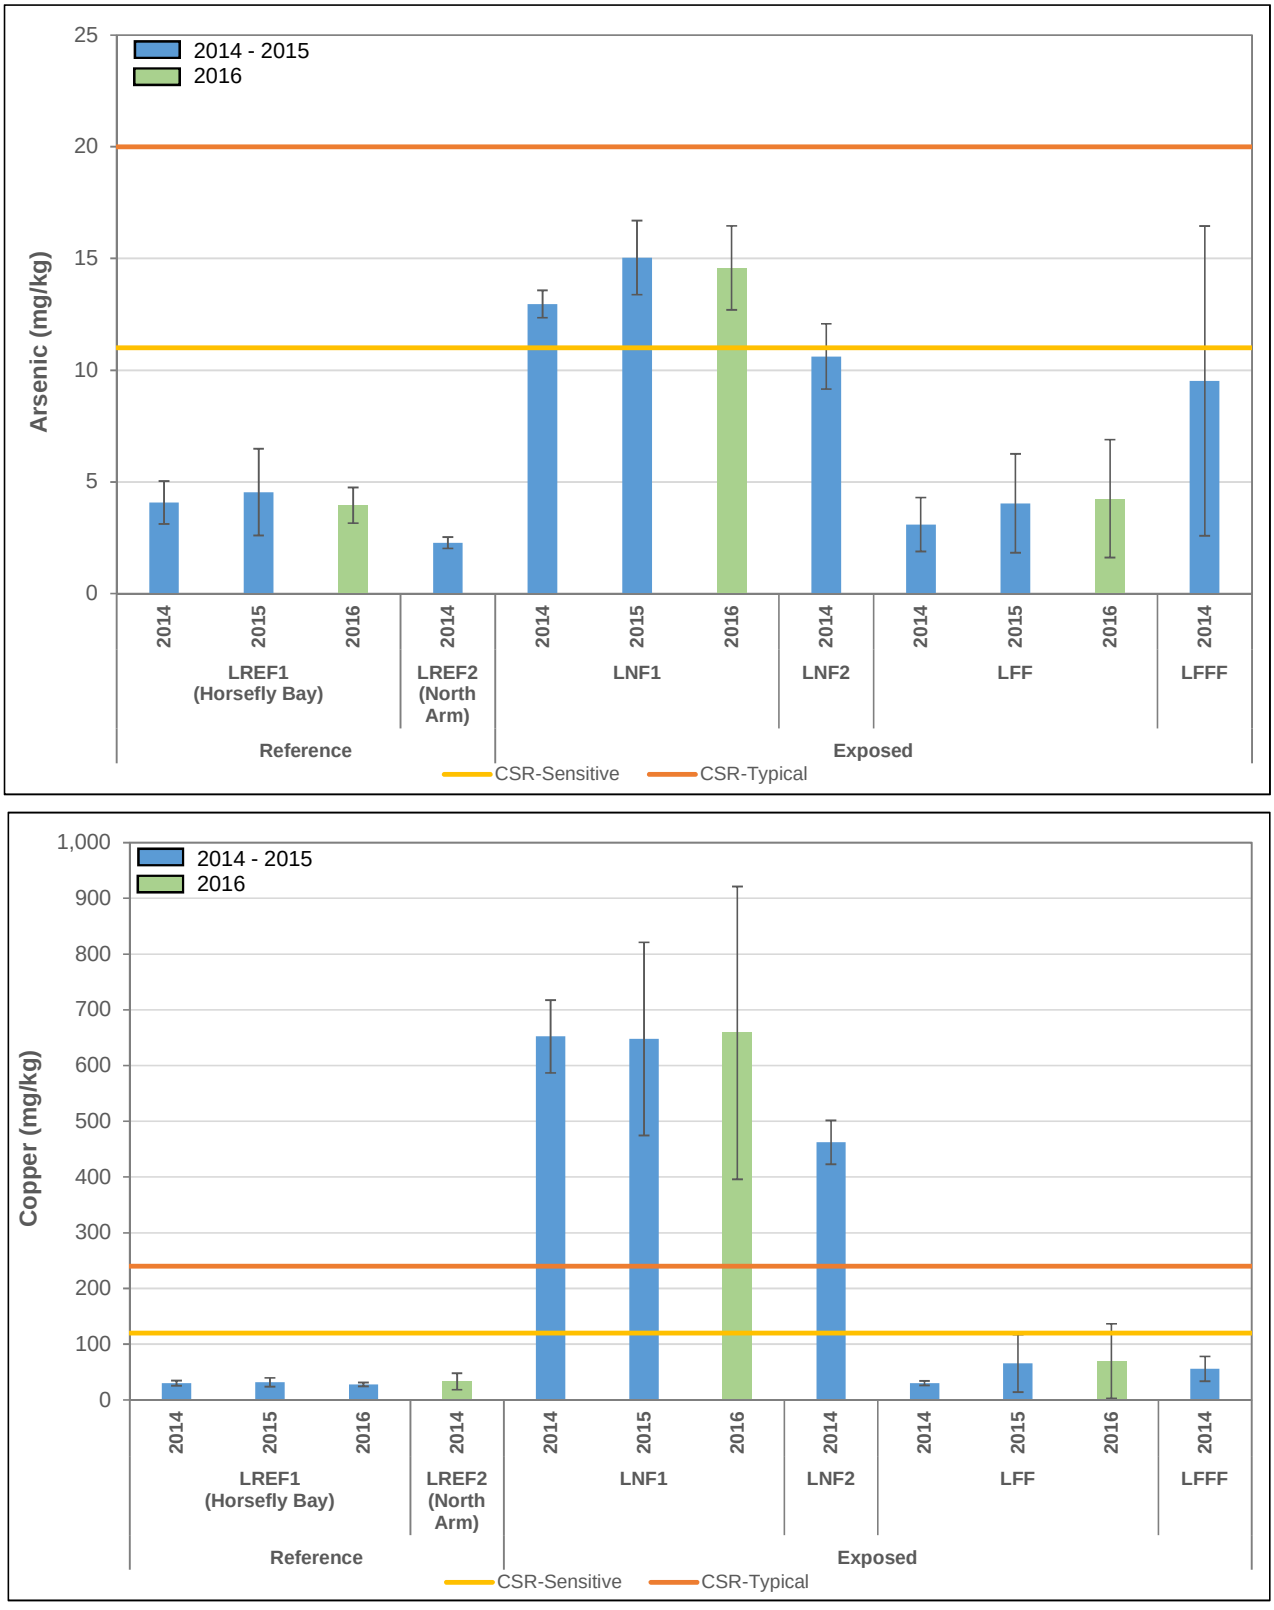

Figure 5: Mean arsenic and copper concentrations (± t*SE) in sediment (< 63µm fraction) from shallow sampling areas in Quesnel Lake, Mount Polley Mine, 2014 - 2016.

CSR = Contaminated Sites Regulation (Government of British Columbia 1996).

Table 7: Summary porewater quality data for Quesnel Lake shallow sampling areas, Mount Polley Mine, 2016 [1].

Bolded: Exceeds 95th percentile of reference data.

[1] Summary statistics were calculated using method detection limit (MDL) values if data were below the MDL. Means were reported as < MDL if all data used in their calculation were < MDL. If MDLs were variable, the mean was reported as < the maximum MDL.

[2] Calculated from 2016 reference data; for raw data see Appendix Table E.11.

[3] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

(near-field and far-field), copper enrichment in porewater (exposed / reference) was similar to that in sediment, as was porewater enrichment of most of the remaining POIs, IPs and parameters identified by porewater PCA in the near-field area (Appendix Table F.3). Of the POIs, IPs, and parameters identified by porewater PCA, higher enrichment factors in porewater than in sediment were observed at the far-field area for arsenic, barium, and molybdenum (Appendix Table F.3), but the absence of similar enrichments in the shallow near-field area suggest that the far-field enrichment may not be related to the TSF breach.

Hazeltine Creek Sedimentation Pond

Sediment collected from the Hazeltine Creek Sedimentation Pond in 2016 (Figure 1) was primarily silt and clay (93.2%), with particle size distribution similar to sediment collected from this monitoring area in 2015 (Table 8; Appendix Table D.16). TOC content was slightly higher than in previous sampling years (2014 and 2015), but remained much lower than observed in Hazeltine Creek prior to the TSF breach (Table 8; Appendix Table D.16)

Sediment metal concentrations in 2016 were generally similar to those observed in 2014 (Hazeltine Creek shortly after the TSF breach) and 2015 (sedimentation pond), while total nitrogen was slightly higher than in the two previous sampling years. Concentrations of selenium and thallium were higher in 2016 than in 2014 and 2015 by approximately 2.5 to 2.6 times (Table 8). Slight temporal increases in three additional analytes were also observed (aluminum, chromium, and nickel), with concentrations of these metals exceeding pre-event concentrations in 2016 only (Table 8).

The Hazeltine Creek Sedimentation Pond is a man-made, regularly maintained waterbody or “maintained watercourse” (BCMoE 2013), and is not currently fish habitat. Therefore, sediments from this area were evaluated only relative to CSR “typical” criteria. Copper was the only analyte in 2016 to exceed the CSR “typical” criterion and reference (pre-event) concentrations, by approximately 1.6 and 4.1 times, respectively, on average (Table 8; Appendix Table D.16).

Porewater chemistry of the Hazeltine Creek Sedimentation Pond in 2016 differed from that of Lower Hazeltine Creek in 2014 (Table 9; Appendix Table E.14). Porewater concentrations of some analytes (i.e. aluminum, arsenic, copper, molybdenum, potassium, and selenium) were higher than in 2014. However, sediment present in the Hazeltine Creek Sedimentation Pond in 2016 differed substantially from sediment that was present in Lower Hazeltine Creek in 2014. Specifically, samples collected in 2014 represented freshly

Table 8: Summary sediment quality data for samples collected in lower Hazeltine Creek (2014) and Hazeltine Creek Sedimentation Pond (2015-2016), Mount Polley Mine. Metals and total organic carbon data are based on the < 63µm fraction of sediment [1].

Value is > Contaminated Sites Regulation (CSR) Typical Criterion.

Bolded: Value for exposed site exceeds all Reference 95th Percentile values (< 5th percentile for pH).

[1] Reported 2015 moisture, pH, and total nitrogen data are based on bulk sediment. Reported 2014 pH data are based on < 63 µm sediment. Data reported as less than the method detection limit (MDL) were used at the MDL for the calculation of summary statistics. Means were reported as < MDL if all the data used in their calculation were < MDL.

[2] Contaminated Sites Regulation (Government of British Columbia 1996).

[3] The maximum reference 95th percentile value of those presented in Table D.16 is displayed for each parameter. For raw 2016 reference data see Appendix Table D.16, for all others see Minnow (2015a) and Minnow (2016b). The 5th percentile is reported for pH.

[4] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

[1] Summary statistics were calculated using method detection limit (MDL) values if data were below the MDL. Means were reported as < MDL if all data used in their calculation were < MDL. If MDLs were variable, the mean was reported as < the maximum MDL.

[2] t*SE = [T distribution critical value]*[Standard error]. The t*SE value, when added or subtracted from the mean, results in the upper and lower 95% confidence limits of the mean, respectively.

deposited tailings-influenced material, and had higher sand content than those collected in 2016 which represented depositing fines from the Hazeltine Creek drainage (Table 8).

Sediment collected from the Hazeltine Creek Sedimentation Pond was evaluated for content of oil and grease as well as PAHs as a requirement of the MPMC 2016 CEMP (MPMC 2016). In all cases, concentrations of both oil and grease and PAHs were well below the CSR "typical" criteria, as well as below the method detection limits established by the analytical laboratory (Appendix Table D.17).

Summary

Sediment quality monitoring undertaken in 2016 at lake areas affected by the Mount Polley Mine TSF breach, and at the Hazeltine Creek Sedimentation Pond verified the results of two previous sampling events (2014 and 2015). Overall, only minor differences in sediment quality were observed relative to 2014 and/or 2015 results. Copper remained the only analyte to exceed the CSR "typical" criterion in sediment of exposed sampling areas in Polley Lake, Quesnel Lake (with the exception of the shallow far-field area), and the Sedimentation Pond, and also exceeded reference or pre-event concentrations in the majority of areas. Sediment arsenic concentrations exceeded the CSR "sensitive" (but not "typical") criterion in all 2016 sampling areas except the shallow far-field area of Quesnel Lake, but were lower than reference in more than half of the areas, and did not exceed the CSR "typical" criterion in the Sedimentation Pond. Elevated arsenic concentrations at reference areas suggest naturally elevated background concentrations, which is consistent with regional elevations noted previously (e.g., MPMC 2015). At locations where sediment copper (and/or arsenic) were observed to be greater than reference, enrichment in porewater (exposed concentrations / reference concentrations) was generally lower than or similar to sediment enrichment, suggesting low mobility to be confirmed by the results of sediment porewater studies that were completed in August 2016 under redox controlled conditions.

Reference Information

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLR	Detection Limit Raised due to required dilution, limited sample amount, and/or high moisture content (soil samples)

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

IC-CACO3-CALC-SK	Soil	Inorganic Carbon as CaCO3 Equivalent	Calculation
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.

Reference:
Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

F0205

Reference Information

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Titanium (Ti)	DUP-H	L1826516-18

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
DLR	Detection Limit Raised due to required dilution, limited sample amount, and/or high moisture content (soil samples)
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

IC-CACO3-CALC-SK	Soil	Inorganic Carbon as CaCO3 Equivalent	Calculation
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.

Reference:
Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

RUSH

Priority processing

please log all highlighted soils for:

- CSR + Full Metals
- TOC/TIC
- Avail N, P, K

"Group A" soils are due Sept 15 with 'P' codes

"Group B" soils are due Sept 21, no priority code

SK sublets should go out Monday.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Lithium (Li)	DUP-H,J	L1826551-21, -22, -23, -24, -25, -26, -27, -28, -29, -30, -31

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DLR	Detection Limit Raised due to required dilution, limited sample amount, and/or high moisture content (soil samples)
DUP-H,J	Duplicate results outside ALS DQO, due to sample heterogeneity. Duplicate results and limits are expressed in terms of absolute difference.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	SSSA (1996) P. 973-974

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.

MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CRC ICPMS.

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. This method does not dissolve all silicate materials and may result in a partial extraction. depending on the sample matrix, for some metals, including, but not limited to Al, Ba, Be, Cr, Sr, Ti, Tl, and V.

NO3-AVAIL-SK	Soil	Available Nitrate-N	Method = Alberta Ag (1988)

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm.

Reference:
Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

G0148

Reference Information

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

RUSH

Priority processing

Please log all highlighted soils for:

- CSR + Full Metals
- TOC/TIC
- Avail N, P, K

"Group A" soils are due Sept 16 with 'P' codes

"Group B" soils are due Sept 21, no priority code.

SK sublets should go out Monday.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Method Blank	Magnesium (Mg)-Total	MB-LOR	L1826684-15, -16
Method Blank	Magnesium (Mg)-Total	MB-LOR	L1826684-15, -16

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-DRY-MICR-HRMS-VA	Tissue	Metals in Tissue by HR-ICPMS Micro (DRY)	EPA 200.3/200.8

Trace metals in tissue are analyzed by high resolution inductively coupled plasma mass spectrometry (HR-ICPMS) modified from US EPA Method 200.8, (Revision 5.5). The sample preparation procedure is modified from US EPA 200.3. Analytical results are reported on dry weight basis.

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-MICR-HRMS-VA	Tissue	Metals in Tissue by HR-ICPMS Micro (WET)	EPA 200.3/200.8

Trace metals in tissue are analyzed by high resolution inductively coupled plasma mass spectrometry (HR-ICPMS) modified from US EPA Method 200.8, (Revision 5.5). The sample preparation procedure is modified from US EPA 200.3. Analytical results are reported on wet weight basis.

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MOISTURE-TISS-VA	Tissue	% Moisture in Tissues	ASTM D2974-00 Method A

This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

F0205

Reference Information

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

APPENDIX B

Human Health Risk Assessment Supporting Information

APPENDIX B-1

Data Screening for the Human Health Risk Assessment

1.0 INTRODUCTION

In British Columbia (BC), environmental matters pertaining to contaminated sites generally fall under the jurisdiction of the BC Ministry of Environment (MoE), pursuant to the *Environmental Management Act* (EMA, SBC 2003, Chapter 53 assessed 23 October 2003, including BC Reg. 179/2016 amendments effective 19 July 2016). Exceptions include federal lands and waters with migratory fish that fall under the jurisdiction of Environment Canada. The two key regulations under the EMA relating to the assessment and remediation of contaminated sites are the *Contaminated Sites Regulation* (CSR; BC Reg. 375/96, O.C. 1480/96 and M271/2004 including amendments up to BC Reg. 184/2016, effective 19 July 2016), and the *Hazardous Waste Regulation* (BC Reg. 63/88, O.C. 268/88 including amendments up to BC Reg. 179/2016 App 1 amendments effective 19 July 2016).

The CSR provides numerical standards for the evaluation of soil, groundwater, soil vapour and sediment quality that were selected as assessment criteria for the Study Area. Under the CSR, the contaminants of concern evaluated in the risk assessment are those substances that are found to exceed a regulatory standard in the detailed site investigation (DSI) (CSR Section 11[1]).

Substances are identified as contaminants of concern in the DSI based on an exceedance of a standard for protection of either ecological or human health. One of the first steps in the risk assessment is to identify which contaminants are a concern for the ecological receptors and which contaminants are a concern for human health. In the human health risk assessment (HHRA), the contaminants of concern identified in the DSI are compared to standards derived specifically for the protection of human health. If substances are present in concentrations less than the human health-specific standard, then the concentrations are concluded to be acceptable, and risks associated with that substance and that media are concluded to be acceptable.

The contaminant of potential concern (COPC) screening approach is discussed in more detail below in Section 2.0. This appendix presents the data, screening criteria and screening results for soil, groundwater, sediment, surface water, air, vegetation and fish tissue for the HHRA.

2.0 APPROACH FOR FURTHER EVALUATION OF CONTAMINANTS OF POTENTIAL CONCERN FOR HUMAN HEALTH

The starting point for identifying contaminants on a Study Area is the DSI. In the DSI, possible contaminants are tested in relevant environmental media based on their physical/chemical properties and fate when introduced to the environment. Contaminants identified in the DSI (see Table 1 below) were passed along to the risk assessment to determine the significance of the concentrations measured in the environment. In the problem formulation step of the HHRA, contaminants are evaluated in terms of their hazard with respect to human health. The CSR standards for the protection of human health were used as the primary screening criteria for determining if COPCs require assessment in the HHRA in each of the media. Note that under the CSR, only those parameters that exceed a CSR standard are required to be further evaluated in the risk assessment. The CSR does not provide screening criteria protective of human health for sediment, air, vegetation or fish tissue; therefore, COPCs in these media were identified using a slightly different approach (see Sections 5.0 [sediment], 7.0 [air], 8.0 [vegetation] and 9.0 [fish tissue]).

The CSR standards are the first line of assessment in a CSR risk assessment. For many potential contaminants, there are different standards for human health protection and environmental protection. The screening process in the risk assessment sorts the contaminants identified in the DSI into those that are a potential concern for humans, those that are a potential concern for the environment and those that may be a concern for both humans and the environment.

The CSR standards are intended to be protective of all situations for both human and ecological receptors, and incorporate multiple conservative assumptions such as safety factors and conservative exposure conditions. Therefore, comparison to standards represents a conservative evaluation of the potential for the contaminant concentrations to cause adverse effects. Comparison to background concentrations was also included in the screening process. Since the Study Area is located in a highly mineralized area with rich ore deposits, this was considered a reasonable approach to identify and retain the substances that are present at concentrations exceeding what is normal for this area of BC.

The following general approach was used to identify COPCs for the HHRA:

- **Step 1** – Compare the maximum concentrations to the applicable human health-based screening criteria. If the maximum concentration of a parameter exceeds the screening criterion, the substance was retained for further evaluation. A substance was concluded to be present in non-hazardous concentrations and eliminated from further evaluation if the maximum observed concentration was lower than the human health-based screening criteria or the 95th percentile regional background concentration.
- **Step 2** – For the substances retained at the completion of Step 1, calculate the 95% upper confidence limit of the mean (UCLM) concentration as an upper bound estimate of mean exposure and compare to the human health-based screening criteria. A substance was retained for further evaluation in the HHRA if the 95% UCLM was greater than the screening criteria.

The results of the above screening methodology are presented in the sections below. The local reference concentrations are presented for information purposes. The methods for establishing the local background concentrations, where applicable, are also presented below. Aluminum is not regulated in soil under the CSR; however, aluminum was retained for evaluation as a COPC at the request of project reviewers.

Table 1: Contaminants of Concern Identified in the Detailed Site Investigation

Remediation Area	Contaminant	Medium	CSR Schedule
Area 2 – Polley Plug/Polley Flats and Area 4, 5, and 6 – Hazeltine Channel	Copper	Soil	5 – Toxicity to soil invertebrates and plants
	Vanadium	Soil	4 – Parkland and Agricultural
	Sulphur	Soil	4 – Agricultural
	Molybdenum	Soil	4 – Agricultural
	Iron	Groundwater	6 – Irrigation
			6 – Drinking Water
	Manganese	Groundwater	6 – Irrigation
			6 – Drinking Water
	Arsenic	Groundwater	6 – Drinking Water
			6 – Livestock
	Molybdenum	Groundwater	6 – Irrigation
			6 – Livestock
	Sulphate	Groundwater	6 – Drinking Water
	Total and dissolved copper	Surface Water	BC Water Quality Guideline – Aquatic Life
	Copper	Sediment	9 – Typical
Area 3 – Polley Lake	Arsenic	Sediment	9 – Sensitive
	Copper	Sediment	9 – Sensitive
			9 – Typical
Area 7 – Edney Creek Mouth	Total and dissolved copper	Surface Water	BC Water Quality Guideline – Aquatic Life
Area 8 – Quesnel Lake	Copper	Sediment – Littoral and Profundal	9 – Sensitive
			9 – Typical
	Arsenic	Sediment – Littoral and Profundal	9 – Sensitive

3.0 SOIL

3.1 Soil Data

The surficial (less than 1 metres below ground surface) soil samples collected after tailings storage facility (TSF) embankment breach were compiled in the DSI Update (Appendix A). As described in the DSI Update, the term “soil” refers to the following material types that were sampled as part of the investigation:

- tailings
- native soils underlying deposited tailings (native)
- native background soils (local background)

Native soil was further split into native organic soil and native mineral soil. Local background concentrations were developed for both organic and mineral soils. Therefore, native under tailings soil samples were also categorized as organic or mineral in order to screen against the appropriate background concentrations. These datasets were used to identify human health COPCs in soil.

The local background concentrations for native soil were developed in accordance with Protocol 4 (BC MoE 2010) and Technical Guidance 16 (BC MoE 2005). The methods for determining local background soil concentrations, including sample locations and calculation of the 95th percentile local background concentrations, are provided in Appendix A-1 of the DSI Update. The local background data were used to establish which parameters had changed in soil following the breach.

3.2 Soil Screening Criteria

The applicable land use is urban parkland (PL) and agricultural land (AL). The PL and AL standards are considered to be protective of people on a site 24 hours per day, 7 days per week, 52 weeks per year. Soil data were compared to the following CSR PL and AL standards (BC MoE 2016a):

- CSR Schedule 5 – Matrix Numerical Soil Standards, intake of contaminated soil
- CSR Schedule 4 – Generic Numerical Soil Standards
- CSR Schedule 10 – Generic Numerical Soil and Water Standards

The CSR Schedule 5 standards were derived based on a soil allocation factor of 20%, chemical-specific tolerable daily intake, child body weight of 13 kilogram, gut absorption factor of 100%, child ingestion rate of 80 milligrams per day and a land use-specific exposure term (BC MoE 1996). The parkland and agricultural land uses have the same exposure terms (1.0). The CSR Schedule 4 generic soil standards are equivalent to the generic Canadian Council of Ministers of the Environment (CCME) guidelines for most of the parameters. In instances where the CCME have derived a pathway-specific direct contact guideline and the CSR has derived a generic standard, the CSR standard is lower (i.e., more conservative). The CSR Schedule 10 generic soil standards are based on the United States Environmental Protection Agency (US EPA) preliminary remediation goals for residential soils.

3.3 Soil Screening Results

3.3.1 Contaminants of Concern Identified in the Detailed Site Investigation Update

The DSI Update identified the following metals with concentrations greater than the CSR PL or AL standard in soil:

- **Tailings Soil**: copper, molybdenum, sulphur and vanadium
- **Native Organic Soil**: copper, sulphur
- **Native Mineral Soil**: copper, sulphur

If land is used to grow produce for human consumption, the CSR standard for cadmium is 3 mg/kg, if not, the standard is 35 mg/kg. The DSI Update did not identify cadmium as a contaminant of concern based on a comparison to 35 mg/kg. Based on stakeholder feedback that crops may be grown in the Study Area in the future and that people may consume berries and plants from the Study Area, cadmium was carried forward for further evaluation in the HHRA, in addition to the contaminants listed above.

3.3.2 Contaminants of Concern Identified for the Human Health Risk Assessment

The screening results are presented in Table 2 below.

Table 2: Contaminants of Potential Concern in Tailings Soil, Native Organic Soil and Mineral Soil

Parameter	n	Screening Criteria[1] (basis)	95th Percentile Local Background	Maximum	95% UCLM[2]	Retain as a Soil COPC for Human Health?
Tailings						
Aluminum	130	n/a	21,815	24,600	14,984	**Yes**
Cadmium	182	3 (I)	0.3	3.4	0.25	No
Copper	182	15,000 (I)	39	1,560	-	No
Molybdenum	182	5 (G)	0.72	7.34	3.98	No
Sulphur	26	500 (G)	500	3500	1615	No (see text)
Vanadium	182	200 (G)	88.1	289	177	No
Native Organic						
Aluminum	7	n/a	22,075	25,700	17,136	**Yes**
Cadmium	24	3 (I)	1	3.37	0.84	No
Copper	24	11,500 (I)	79	352	-	No
Sulphur	2	500 (G)	nc	7000	nc	No (see text)
Native Mineral						
Aluminum	32	n/a	21,815	26,000	15,634	**Yes**
Cadmium	51	3 (I)	0.3	0.66	-	No
Copper	52	15,000 (I)	39	366	-	No
Sulphur	12	500 (G)	500	1100	855	No (see text)

Notes:

Concentrations are in milligrams per kilogram (mg/kg), unless otherwise noted.

"-" = 95% UCLM not calculated because maximum was below screening criterion; % = percent; COPC = contaminant of potential concern; G = generic standard; I = intake of contaminated soil; n = number of samples; n/a = not available; nc = not calculated, there were insufficient samples to calculate the statistic; UCLM = upper confidence limit of the mean.

[1] If both a CSR AL and PL standard was available, the lower of the two is shown.

[2] The 95% UCLM was calculated using ProUCL (US EPA 2016a). For non-detect values, the full detection limit was assumed for calculating the 95% UCLM.

Aluminum is not regulated in soil under the CSR, but was retained as a COPC at the request of project reviewers.

Maximum concentrations of copper were below the human health screening criterion in all three soil types; therefore, copper was not retained as a soil COPC. Maximum concentrations of cadmium, molybdenum, sulphur, and vanadium exceeded their respective screening criterion and/or 95th percentile background concentration in at least one soil type; therefore, the 95% UCLM concentrations were calculated for these parameters as part of the secondary screening.

With the exception of sulphur, the 95% UCLM concentrations were below their respective screening criteria and/or 95th percentile local background concentration. The 95% UCLM concentration of sulphur in tailings and native mineral soils exceeded the CSR AL standard and the 95th percentile local background concentration. Only two soil samples were collected and analyzed for sulphur in native organic soils. A CSR PL standard is not available for sulphur.

Toxicity data via chronic oral exposure is lacking for sulphur. Supporting information is not available for the derivation of the generic CSR AL standard for sulphur. There is no sulphur CSR standard for other land uses, including residential land use, suggesting that it is not a human health concern. The CSR standard is based on elemental sulphur present in a sample. Soil samples analyzed for sulphur as part of the 2014 and 2015 investigation work were analyzed for total sulphur, and are, therefore, considered to be a conservative estimate of available elemental sulphur in the soil at the Study Area. As discussed in Section 3.2, the generic CSR standards were generally equivalent to the CCME soil quality guidelines for the protection of human and environmental health. Sulphur is considered an essential mineral that is critical for biological function, as it is a component of amino acids, vitamins and insulin. Elemental sulphur is naturally present in the environment and poses low toxicity in humans (US EPA 1991). The BC MoE, Health Canada, the Agency for Toxic Substances and Disease Registry (ATSDR) and the US EPA have not derived toxicity reference values for sulphur. Therefore, based on the lack of toxicity information, sulphur was not evaluated further in this assessment.

4.0 GROUNDWATER
